Original Papers

Comparing Self-Reported Running Distance and Pace With a Commercial Fitness Watch Data: Reliability Study (e39211)
Garrett Bullock, Joanne Stocks, Benjamin Feakins, Zahra Alizadeh, Amelia Arundale, Stefan Kluzek. ................................................................. 13

Prevalence of Body Dysmorphic Disorder in the Spanish Population: Cross-Sectional Web-Based Questionnaire Study (e46515)
Álvaro Loewen, Hilario Blasco-Fontecilla, Chao Li, Marcos Bella-Fernández, Belén Ruiz-Antorán. ................................................................. 22

Methodological Insights on Recruitment and Retention From a Remote Randomized Controlled Trial Examining the Effectiveness of an Alcohol Reduction App: Descriptive Analysis Study (e51839)
Melissa Oldham, Larisa Dinu, Gemma Loebenberg, Matt Field, Matthew Hickman, Susan Michie, Jamie Brown, Claire Garnett. .......................... 37

Remote Delivery of the Cuidándome Telehealth Intervention for Self-Management of Depression and Anxiety Among Latin migrant Women: Randomized Controlled Trial (e52969)
Carmen Alvarez, Subhash Aryal, Elizabeth Vrany, Maria Sanchez R, Rosalpíe Quiles, Lia Escobar-Acosta, Felicia Hill-Briggs. ......................... 50

Feasibility and Acceptability of a Mobile Technology Intervention to Support Postabortion Care After Surgical Abortion (the FACTS Study Phase 3): Mixed Methods Prospective Pilot Study (e46284)
Roopan Gill, Gina Ogilvie, Wendy Norman, Brian Fitzsimmons, Ciana Maher, Regina Renner. ................................................................. 66

The Sukaribit Smartphone App for Better Self-Management of Type 2 Diabetes: Randomized Controlled Feasibility Study (e46222)
Cecilia Josefsson, Thea Liljeroos, Margareta Hellgren, Ulrika Pöder, Mariann Hedström, Erik Olsson. ................................................................. 80

Office Workers’ Views About the Uses, Concerns, and Acceptance of Hand Hygiene Data Collected From Smart Sanitizers: Exploratory Qualitative Interview Study (e47308)
Sophie Rutter, Sally Sanger, Andrew Madden, Sukaina Ehdeed, Catherine Stones. ................................................................. 95

Population-Level Portal-Based Anxiety and Depression Screening Perspectives in HIV Care Clinicians: Qualitative Study Using the Consolidated Framework for Implementation Research (e48935)
Daniela Zimmer, Erin Staab, Jessica Ridgway, Jessica Schmitt, Melissa Franco, Scott Hunter, Darnell Motley, Neda Laioterapong. ......................... 108

Dentists’ Information Needs and Opinions on Accessing Patient Information via Health Information Exchange: Survey Study (e51200)
Shuning Li, Grace Felix Gomez, Huiping Xu, Anushri Rajapuri, Brian Dixon, Thankam Thyvalikakath. ................................................................. 120
Promoting Self-Efficacy of Individuals With Autism in Practicing Social Skills in the Workplace Using Virtual Reality and Physiological Sensors: Mixed Methods Study (e52157)
Sung-In Kim, So-youn Jang, Taeowan Kim, Bogoan Kim, Dayoung Jeong, Taehyung Noh, Mingon Jeong, Kaely Hall, Meelim Kim, Hee Yoo, Kyungsik Han, Hwajung Hong, Jennifer Kim. 132

Mapping the Cardiometabolic Patient Experience and Self-Care Behaviors to Inform Design, Implementation, and Persistent Use of Digital Health Care Solutions: Mixed Methods Study (e43683)
Jan Liska, Marie Mical, Christophe Mailiard, Cécile Dessapt, Europa Bendig, Daniel Mai, John Piette, Sabina De Geest, Guillaume Fontaine. 146

Linguistic Variables and Gender Differences Within a Messenger-Based Psychosocial Chat Counseling Service for Children and Adolescents: Cross-Sectional Study (e51795)
Zeki Efe, Sabrina Baldofski, Elisabeth Kohls, Melanie Eckert, Shadi Saee, Julia Thomas, Richard Wundrack, Christine Rummel-Kluge. 157

Rosie, a Health Education Question-and-Answer Chatbot for New Mothers: Randomized Pilot Study (e51361)
Quynh Nguyen, Elizabeth Aparicio, Michelle Jasczynski, Amara Channell Doig, Xiaohe Yue, Heran Mane, Neha Srikanth, Francis Gutierrez, Nataly Delcid, Xin He, Jordan Boyd-Graber. 172

Clinical Needs Assessment of a Machine Learning–Based Asthma Management Tool: User-Centered Design Approach (e45391)
Lu Zheng, Joshua Ohde, Shauna Overgaard, Tracey Brereton, Kristelle Jose, Chung-Il Wi, Kevin Peterson, Young Juhn. 185

Exploring Adolescents’ Attitudes Toward Mental Health Apps: Concurrent Mixed Methods Study (e50222)
Helene Høgsdal, Henriette Kyrrstad, Marte Rye, Sabine Kaiser. 196

The Impact of Social Media Use on Mental Health and Family Functioning Within Web-Based Communities in Saudi Arabia: Ethnographic Correlational Study (e44923)
Bdour Alwuqaysi, Allie Abdul-Rahman, Rita Borgo. 206

Enabling Personalization for Digital Cognitive Stimulation to Support Communication With People With Dementia: Pilot Intervention Study as a Prelude to AI Development (e51732)
Nick Hird, Tohmi Osaki, Samik Ghosh, Sucheendra Pataniappan, Kiyoshi Maeda. 221

Designing and Developing a Mobile App for Management and Treatment of Gestational Diabetes in Nepal: User-Centered Design Study (e50823)
Aarthi Shanmugavel, Prabin Shakya, Archana Shrestha, Jyoti Nepal, Abha Shrestha, Jean-Francois Daneault, Shristi Rawal. 239

Preoperative Virtual Reality to Expose Patients With Breast Cancer to the Operating Room Environment: Feasibility and Pilot Case Series Study (e46367)
Jordana Sommer, Kristin Reynolds, Pamela Hebbard, Michael Smith, Natalie Mota, W Mutch, Jessica Maples-Keller, Leslie Roos, Renée El-Gabalawy. 256

Educational Video Intervention to Improve Health Misinformation Identification on WhatsApp Among Saudi Arabian Population: Pre-Post Intervention Study (e50211)
Ebtihal Alsaad, Sharifah AlDossary. 273

A Blended Intervention Targeting Emotion Dysregulation in Adults With Attention-Deficit/Hyperactivity Disorder: Development and Feasibility Study (e53931)
Emilie Nordby, Frode Guribye, Viktor Schønning, Sander Andersen, Jonna Kuntsi, Astri Lundervold. 288

Designing a Web-Based Navigation Tool to Support Access to Youth Mental Health Services: Qualitative Study (e48945)
Alison Calear, Philip Batterham, Sonia McCallum, Michelle Banfield, Elizabeth Moore, Natalie Johnson, Alyssa Morse. 304
Development and Usability Testing of an mHealth Tool for Trauma-Informed Prevention of Substance Use, HIV Acquisition, and Risky Sexual Behaviors Among Adolescents: Mixed Methods Study (e52835)
Carla Danielson, Angela Moreland, Austin Hahn, Devin Banks, Kenneth Ruggiero. 315

Virtual Exercise in Medicine: A Proof of Concept in a Healthy Population (e45637)
Barbara Le Roy, Charles Martin-Krumm, Charlotte Poupon, Raphaëlle Richieri, Eric Malbos, Fanny Barthélémy, Eric Guedj, Marion Trousselard. 331

Experiences Among Patients With Cystic Fibrosis in the MucoExocet Study of Using Connected Devices for the Management of Pulmonary Exacerbations: Grounded Theory Qualitative Research (e38064)
Maxime Morsa, Amélie Perrin, Valérie David, Gilles Rault, Enora Le Roux, Corinne Alberti, Rémi Gagnayre, Dominique Pougeon Bertrand. 347

Culturally Adapting the World Health Organization Digital Intervention for Family Caregivers of People With Dementia (iSupport): Community-Based Participatory Approach (e46941)
Anna Messina, Rebecca Amati, Anna Annoni, Beatrice Bano, Emiliano Albanese, Maddalena Fiordelli. 365

A Bluetooth-Enabled Device for Real-Time Detection of Sitting, Standing, and Walking: Cross-Sectional Validation Study (e47157)
Reza Daryabegi-Khotbehsara, Jonathan Rawstorn, David Dunstan, Sheikh Shariful Islam, Mohamed Abdelrazek, Abbas Kouzani, Poojith Thummala, Jenna McVicar, Ralph Maddison. 380

Demographics and Social Factors Associated With Persistent Nonuse of Video Appointments at a Multisite Health Care Institution: Cross-Sectional Study (e50572)
Pravesh Sharma, Celia Kamath, Tabetha Brockman, Anne Roche, Pamela Sinicrope, Ruoxiang Jiang, Paul Decker, Vanessa Pazdernik, Christi Patten. 394

Transfer of Knowledge on Pneumoconiosis Care Among Rural-Based Members of a Digital Community of Practice: Cross-Sectional Study (e52414)
Brian Soller, Orrin Myers, Akshay Sood. 409

Improving Medical Photography in a Level 1 Trauma Center by Implementing a Specialized Smartphone-Based App in Comparison to the Usage of Digital Cameras: Prospective Panel Study (e47572)
Jan El Barbari, Maxim Fikuart, Nils Beisemann, Michael Müller, Hannah Syrek, Paul Grützner, Jochen Franke, Sven Vetter. 420

Machine Learning and Symptom Patterns in Degenerative Cervical Myelopathy: Web-Based Survey Study (e54747)
Alvaro Touzet, Tanzil Rujeedawa, Colin Munro, Konstantinos Margetis, Benjamin Davies. 430

Testing a Behavioral Activation Gaming App for Depression During Pregnancy: Multimethod Pilot Study (e44029)
Rachel Vanderkruik, Craig Ferguson, Lauren Kobylish, Joseph Locascio, Gabriella Hamlett, Parker Killenberg, Robert Lewis, Noah Jones, Ella Rossa, Hannah Dineen, Rosalind Picard, Lee Cohen. 438

Telephone-Based Training Intervention for Using Digital Communication Technologies for Social Housing Residents During the COVID-19 Pandemic: Mixed Methods Feasibility and Acceptability Evaluation (e45506)
Tim Walker, Sarah Buckingham, Ria Poole, Lewis Elliott, Tamaryn Menneer, Gengyang Tu, Karyn Morrissey. 457

Acceptance of a Web-Based Intervention in Individuals Who Committed Sexual Offenses Against Children: Cross-Sectional Study (e48880)
Sonja Schröder, Claudia Buntrock, Louisa Neumann, Jürgen Müller, Peter Fromberger. 474

Development and Implementation of Digital Diagnostic Algorithms for Neonatal Units in Zimbabwe and Malawi: Development and Usability Study (e54274)
Hannah Gannon, Leyla Larsson, Simbarashe Chimhuya, Marcia Mangiza, Emma Wilson, Erin Kessler, Gwendoline Chimhini, Felicity Fitzgerald, Gloria Zailani, Caroline Crehan, Nushrat Khan, Tim Hull-Bailey, Yali Sassoon, Morris Baradza, Michelle Heya, Msandeni Chiume. 486
Patient Phenotyping for Atopic Dermatitis With Transformers and Machine Learning: Algorithm Development and Validation Study (e52200)
Andrew Wang, Rachel Fulton, Sy Hwang, David Margolis, Danielle Mowery ................................. 501

Examining a Remote Group-Based Type 2 Diabetes Self-Management Education Program in the COVID-19 Era Using the ORBIT Model: Small 6-Week Feasibility Study (e46418)
Madison Hiemstra, Sonja Reichert, Marc Mitchell ................................................................. 516

Home Blood Pressure Telemonitoring Technology for Patients With Asymptomatic Elevated Blood Pressure Discharged From the Emergency Department: Pilot Study (e49592)
Karen Tran, Meagan Mak, Laura Kyper, Jesse Bittman, Birinder Mangat, Heather Lindsay, Chad Kim Sing, Liang Xu, Hubert Wong, Martin Dawes, Nadia Khan, Kendall Ho .................................................. 524

Acceptability of a Self-Led Mindfulness-Based Intervention for Teens with Type 1 Diabetes: Pilot Randomized Controlled Trial (e45659)
Tori Humiston, Caroline Cummings, Stephen Suss, Laura Cohen, Holly Hazlett-Stevens, Amy Hughes Lansing .................................................... 538

“I Just Wanted a Dentist in My Phone”—Designing Evidence-Based mHealth Prototype to Improve Preschool Children’s Oral and Dental Health: Multimethod Study of the Codevelopment of an App for Children’s Teeth (e49561)
Waraf Al-yaseen, Daniela Raggio, Mariana Araujo, Nicola Innes ................................................. 547

Administrative Dashboard for Monitoring Use of a Web-Based Parent Training Intervention: Usability Study (e53439)
Susan Breitenstein, Julia Berteletti, Shea Smoske, Charles Barger, Kyrie Tipps, Nathan Helsabeck ......................................................... 564

Web-Based Mindfulness Meditation as an Adjunct to Internet-Delivered Cognitive Behavioral Therapy for Public Safety Personnel: Mixed Methods Feasibility Evaluation Study (e54132)
Caeleigh Landry, Hugh McCall, Janine Beaehm, Nickolai Titov, Blake Dear, R Carleton, Heather Hadjistavropoulos .................................................. 574

Formative Evaluation of a Comprehensive Self-Management Intervention for Irritable Bowel Syndrome, Comorbid Anxiety, and Depression: Mixed Methods Study (e43286)
Kendra Kamp, Pei-Lin Yang, Emily Friedman, Alejandra Lopez, Sarah Iribaren, Pamela Barney, Sean Munson, Margaret Heitkemper, Rona Levy ......................................................... 592

Investigating the Potential of a Conversational Agent (Phyllis) to Support Adolescent Health and Overcome Barriers to Physical Activity: Co-Design Study (e51571)
Richard Moore, Abdel-Karim Al-Tamimi, Elizabeth Freeman .................................................. 604

Improvements in Adolescents’ Disordered Eating Behaviors in a Collaborative Care Digital Mental Health Intervention: Retrospective Observational Study (e54253)
Landry Huffman, Darian Lawrence-Sidebottom, Aislinn Beam, Amit Parikh, Rachael Guerra, Monika Roots, Jennifer Huberty .................................................. 623

Data Representation Structure to Support Clinical Decision-Making in the Pediatric Intensive Care Unit: Interview Study and Preliminary Decision Support Interface Design (e49497)
Naja Yakob, Sandrine Laliberté, Philippe Doyon-Poulin, Philippe Jouvet, Rita Noumeir ......................................................... 635

Comparison of Blended Learning With Traditional Dermatology Learning for Medical Students: Prospective Evaluation Study (e49616)
Cristiana Silva, Cidia Vasconcellos, Murilo Souza, Juliana Fernandes, Vitoria Rego ......................................................... 656

Abstract

Background: There is substantial evidence exploring the reliability of running distance self-reporting and GPS wearable technology, but there are currently no studies investigating the reliability of participant self-reporting in comparison to GPS wearable technology. There is also a critical sports science and medical research gap due to a paucity of reliability studies assessing self-reported running pace.

Objective: The purpose of this study was to assess the reliability of weekly self-reported running distance and pace compared to a commercial GPS fitness watch, stratified by sex and age. These data will give clinicians and sports researchers insights into the reliability of runners’ self-reported pace, which may improve training designs and rehabilitation prescriptions.

Methods: A prospective study of recreational runners was performed. Weekly running distance and average running pace were captured through self-report and a fitness watch. Baseline characteristics collected included age and sex. Intraclass correlational coefficients were calculated for weekly running distance and running pace for self-report and watch data. Bland-Altman plots assessed any systemic measurement error. Analyses were then stratified by sex and age.

Results: Younger runners reported improved weekly distance reliability (median 0.93, IQR 0.92-0.94). All ages demonstrated similar running pace reliability. Results exhibited no discernable systematic bias.

Conclusions: Weekly self-report demonstrated good reliability for running distance and moderate reliability for running pace in comparison to the watch data. Similar reliability was observed for male and female participants. Younger runners demonstrated improved running distance reliability, but all age groups exhibited similar pace reliability. Running pace potentially should be monitored through technological means to increase precision.

Introduction

Physical activity is an essential component of a healthy lifestyle [1]. There is a substantial body of evidence highlighting the physical, social, and psychological health benefits of regular physical activity [1-3]. Sustainable physical activity interventions are needed, given that 31% of the global population is sedentary [4]. The World Health Organization’s physical activity action plan [5] identifies sport as an underused yet significant contributor to physical activity.
One widely popular sport globally is running [6]. Over the past 40 years, running has become one of the most popular physical leisure activities [7,8]. An estimated 50 million people in Europe participate in running as a way to stay healthy [9]. Due to high running participation prevalence [9], researchers have attempted to quantify running habits and training load, most notably through self-report [10]. Running load or workload is the distance run in 1 session. A training session is 1 running bout. Running speed is the intensity at which one runs for 1 running session [9,10]. However, there are potential inaccuracies from over–self-reporting due to recall bias [11] and social desirability of higher levels of physical activity [12], with potential differences by sex and age groups [13]. Further, the reliability of self-reported running pace has not been investigated, which is an important factor in quantifying running training intensity [14]. Due to these issues, research has investigated the reliability of wearables in quantifying running load [15]. Wearables, such as accelerometers, have demonstrated excellent reliability in assessing gait patterns, acceleration, and velocity [15].

Although wearable accelerometers are ubiquitously used in the general population [16] and are reliably used in research to measure physical activity levels [17], they are rarely used by running populations to track running load and training [18]. Runners opt for wearable GPS watches to track running training [19], with up to 90% of regular runners using some form of GPS monitoring when running [18]. GPS wearable technology quantifies running workload and speed [20]. A systematic review determined that there is excellent reliability for step counting and moderate validity for energy expenditure and distance run [21]. The most popular GPS wearable technology used by runners is the Garmin watch, as indicated by a previous survey where 44% of GPS and sports watches were Garmin, compared to 27% for Polar and 7% for Nike watches [22].

There has been previous related work in evaluating the reliability of running self-reports in large samples. In a sample of 92 endurance runners, followed for a 52-week (ie, 1 year) period, 93% of the runners participated in the entire follow-up period [10]. In a study of 53 running participants over 18 weeks, the response rate was 73% over the reporting period [23]. Another study surveyed 228 runners for at least 6 months, with a 2.2% attrition rate [24].

Although there is substantial evidence investigating the reliability of running distance self-reporting [10] and GPS wearable technology [20], there are currently no studies investigating the reliability of participant self-reporting in comparison to GPS wearable technology in running populations. There is a critical sports science and medical research gap due to a paucity of reliability studies assessing self-report running pace. Further, as GPS wearable technology is expensive [25], there may be a barrier for some recreational runners, decreasing the efficacy of using GPS monitoring alone to assess running workload [22]. Therefore, this study aimed to assess the reliability of weekly self-reported running distance and pace compared to a commercial GPS fitness watch, stratified by sex and age. These data will give clinicians and sports researchers insights into the reliability of runners’ self-reported pace, which may improve training designs and rehabilitation prescriptions.

**Methods**

**Study Design**

A prospective cohort study was conducted using a mobile-based app. Participants accessed a dynamic digital consent form through the app or the recruitment website during the spring of 2021 over a 4-month period. During consent, participants could select different levels of study engagement. All levels of engagement involved the following: (1) an acknowledgement, understanding, and consent to participate in the study; (2) a baseline questionnaire collecting information on demographics, previous and current injury and illness history, footwear and foot posture, knee symptoms, lifestyle, and previous year’s training load; and (3) weekly reports on training load and each participant’s perceptions of cardiorespiratory symptoms, mood, and incidence of illness and injury in the last week. More advanced participation involved connecting participants’ Garmin Connect (Garmin Ltd) data, which included sharing data on running distance, running speed, and heart rate during each training or racing session. Participants added their Garmin Connect information at study recruitment. Garmin data were then automatically uploaded every week when the participant was within the study. Once the participant reaches the end of the study data collection or voluntarily leaves the study, the Garmin data collection link is terminated, ending data upload (Figure 1). Participants could opt out of the study at any time.
**Ethical Considerations**

This study received a favorable ethical review from the University of Nottingham (FMHS 113-1120). All methods were performed following the relevant guidelines and regulations of the Declaration of Helsinki. Before study inclusion, all participants were detailed about the risks and benefits of participation. All participants provided informed consent to participate.

**Population and Recruitment Strategy**

This study aimed to examine recreational runners. The inclusion criteria of this subgroup of the larger “Running Through” [26] study consisted of the following: (1) age ≥18 years; (2) performing running activities; and (3) connecting their Garmin Connect data to the weekly reports. Exclusion criteria consisted of individuals meeting the following conditions: (1) not able or willing to use the internet regularly; (2) diagnosed with an immunocompromised disorder; (3) diagnosed with memory impairment; (4) diagnosed with a neurodegenerative disorder; (5) diagnosed with inflammatory osteoarthritis; and (6) undergone trunk or lower extremity orthopedic surgery in the last 6 months. The larger “Running Through” study consisted of both Garmin and self-report data. Participants were recruited through email, the study website, social media, and word of mouth. Participants resided in the United Kingdom or Europe. All recruitment was performed in English. Participants did not receive compensation for participating in this study. Watch ownership was not known by the research team.

**Weekly Survey**

Participants were sent an encrypted text message or email weekly to report weekly running distance, pace, and incidence of illness and injury [10]. Garmin Connect data also monitored running distance and pace. Garmin monitoring has demonstrated excellent reliability and validity [20].

**Data Storage**

The University of Nottingham’s secure server hosted the research survey tool through the RedCap (Research Electronic Data Capture) service [27]. Data were queried from the secure database using a unique randomized and encrypted identification number.

**Data Reduction**

Watch data were downloaded to an encrypted SQL database using Garmin Connect software (Garmin Ltd). For convenience, these data were combined with the RedCap survey data and tables containing key variables that could be used to link these data. Custom functions were written in R using the DBI and MariaDB packages to interface with the database. The rjson and bit64 packages were additionally used to facilitate the extraction of JavaScript Object Notation format activity data and provide necessary extensions to R’s base data classes. Once data were downloaded, they were aggregated, cleaned, and checked for quality assurance. Data checks were performed through automation and manually.

**Statistical Analyses**

Participant statistics were described using mean (SD) or median (IQR) for continuous variables and frequencies (percentages).
for categorical variables. Overall running exposure was calculated in person kilometers.

To assess reliability, intraclass correlational coefficients (ICC$_{2,1}$) were calculated for weekly running distance and running pace between self-reports and weekly reports generated by the Garmin Connect data. Reliability was rated as poor (<0.50), moderate (0.50-0.75), good (0.75-0.90), and excellent (0.90) [28]. Correlation and Bland-Altman plots were also calculated to assess any systemic measurement error. Analyses were then stratified by sex and age strata (18-40, 41-60, and ≥61 years). All analyses were performed in R 4.1.2 (R Foundation for Statistical Computing) [29], with the psych package for ICC calculations and BlandAltmanLeh for Bland-Altman plots.

</table>

A total of 485 participants linked their Garmin Connect data to the study, with 475 participants included for a total of 3602 participant weeks. Of these, 3 participants were excluded due to lack of follow-up, and another 7 did not run during the collection period (Table 1; the flow chart is available in Multimedia Appendix 1). Participants self-reported running a weekly median of 26.2 (IQR 12.8-39.7) km at a median pace of 6.0 (IQR 5.4-6.7) min/km compared to 25.9 (IQR 4.7-41.8) km running distance at a median pace of 6.1 (IQR 5.2-7.0) min/km (Table 2) recorded by the Garmin watch.

**Results**

Weekly and pace reliability were rated as good and moderate, respectively, for both sexes and for runners aged 18-40, 41-60, and ≥61 years. Furthermore, weekly distance reliability was rated as excellent and moderate in runners aged 18-40 years. All results exhibited no discernable systematic bias (Figure 2; Table 3; Multimedia Appendix 1).

**Discussion**

**Principal Findings**

The overall findings of this study indicate that the weekly self-report of running distance by runners wearing a Garmin watch demonstrated good reliability compared to the Garmin watch data. Distance reliability was similar between female and male participants and across age strata, except for participants aged 18-40 years, who demonstrated excellent reliability. Weekly self-report of running pace demonstrated moderate reliability compared to Garmin watch data, with similar reliability observed between sex and age strata. There were no discernable patterns or systematic biases concerning self-reported running distance or pace.

**Comparison to Previous Work**

Self-reported running distance exhibited good reliability compared to Garmin data. The reliability is higher in this study compared to a previous study on physical activity (ICC 0.67-0.81) [30]. However, the previous study examined multiple countries and recorded all physical activity beyond running. The homogenous country sample and the focus on running in our study may affect the comparison of these results [31]. Younger adults (aged 18-40 years) demonstrated increased running distance reliability reporting compared to the older age strata (aged 41-60 and ≥61 years). This is comparable with previous research, in which younger adults displayed improved self-report reliability [30]. Younger adults may have a greater aptitude to monitor their running through technology [32]. However, this is only speculative, and further research is required.

Self-reported running pace demonstrated moderate reliability compared to Garmin Connect data. There are currently no studies investigating the reliability of self-reported running pace. However, recreational runners usually train at one pace, with little change at different distances [33]. The moderate reliability observed in this sample may be due to these runners reporting their perceived running pace, with little fluctuation between sessions or weeks. However, specific variances may have occurred in the actual running pace, decreasing the reliability of these data. Previous literature has suggested that instant feedback through the use of heart rate or step cadence can increase a recreational runner’s ability to self-report running pace [33]. However, further work is needed to investigate the efficacy of this approach.

These findings necessitate future research. Participants were recreational runners, and most of them were older than 40 years. Future work is needed to assess the reliability of self-report in comparison to GPS monitoring data in elite runners of all ages and younger populations across different skill or competition levels. All runners in this study already owned a Garmin watch before the study enrollment. Understanding how self-reporting changes among new GPS activity monitor users is needed. Running pace demonstrated moderate reliability in this recreational runner sample. Future research is required to investigate the effectiveness of running pace training on self-report reliability.
Limitations

As with all studies, there are limitations to this study. First, there is the risk of recall bias due to the weekly intervals for self-reporting, which decreases the precision of these findings. Participants may have not worn or activated their Garmin watch for specific runs, decreasing the reliability of these data. GPS monitoring devices are expensive, causing a high barrier to entry. Such a barrier may add selection bias to this reliability study, decreasing the generalizability of these results to all running populations. Further, the sample in this study comprised recreational runners; therefore, the results are not generalizable to elite runners or populations that solely engage in walking for exercise. Finally, participants used different versions of the Garmin watch. As different watch versions may exhibit different reliability, there is a potential for decreased data precision.

Practical Applications

Physical activity monitors have effectively enhanced physical activity levels by providing user feedback, facilitating behavior change—following prescribed training—and preventing injuries [34]. The good to excellent reliability of self-reported weekly running distance observed in this cohort of recreational runners across all adult age groups supports previous research indicating that runners can effectively report running loads [30]. These findings strengthen the notion that self-report can be used to reliably monitor runners as they begin or maintain an exercise regimen or return to running following an injury. However, the moderate reliability exhibited for running pace suggests that recreational runners of all ages are not as adept at monitoring their running pace. Incorporating technological monitoring for running pace may be pertinent to maintain prescribed running paces either for specific training regimens (ie, preparing for a race) or when returning to running following an injury.

Conclusions

Weekly self-report demonstrated good reliability for running distance compared to the Garmin watch data, with similar reliability between sex and age groups. However, the weekly self-report demonstrated only moderate reliability for running pace compared to the Garmin data, with similar reliability between sex and age groups. Sports researchers and scientists can use weekly self-reported running distance in conjunction with Garmin data when quantifying weekly training load. However, caution should be exercised when relying on self-reported running pace to evaluate running intensity in recreational runners. Running pace potentially should be monitored through technological means to increase precision.

Data Availability

Data and corresponding codes are available within the Open Science Framework [35].

Acknowledgments

Abstract

Background: Body dysmorphic disorder (BDD) is defined as excessive concern with mild or nonexistent defects in personal physical appearance, which are not perceived by others. The worldwide prevalence of BDD ranges between 0.5% and 3.2%, with no differences across genders. The mean age of onset of BDD is 16.9 years. BDD is typically associated with young age, psychiatric disorders, and dermatological procedures. Patients with BDD typically display poorer mental health status than patients diagnosed with other mental disorders.

Objective: The aim of this study was to estimate the prevalence of BDD in Spain and to identify the variables associated with BDD.

Methods: We performed a cross-sectional descriptive study by collecting data through an anonymous web-based survey targeting the Spanish population aged 18 years or older. The measures in this study were (1) sociodemographic variables, (2) variables associated with dermatological and psychiatric disorders and cosmetic procedures, (3) scales measuring quality of life (12-item Short Form health survey, version 2) and (4) BDD (BDD Questionnaire). Statistical analysis was performed with SPSS software version 21. P values less than .05 were considered significant.

Results: Of the 2091 participants who took the survey, 322 (15.2%) met the criteria of having BDD. The mean age of the participants with BDD was 23.5 (SD 9.6) years. In terms of BDD prevalence, women accounted for 19.9% (284/1421), men accounted for 5.2% (34/653), and students accounted for 25.2% (263/1043). Approximately 46.6% (150/322) of the participants with BDD reported a history of psychiatric comorbidities, including anxiety disorders, depressive disorders, and eating disorders. BDD was significantly associated with female gender, younger age (18-24 years), students, monthly income of less than €500 (€1=US $1.11), and the presence of dermatological and some psychiatric disorders such as depression, anxiety, and eating disorders (P<.05). The number of body parts of concern in participants with BDD was significantly higher than that in those without BDD (4.6 vs 2.2, respectively; P<.001). Regarding the body parts of concern, body fat was the most common concern for both groups with BDD and without BDD, followed by thighs, face, hips, and skin in the BDD group and thighs, teeth, and hair in the non-BDD group. Participants with BDD showed a significantly poorer self-perception of their mental health, irrespective of the presence of any mental disorder (P<.001).
Conclusions: Our findings showed that the prevalence of BDD in Spain was higher than expected. Further, BDD is frequently associated with other psychiatric disorders, particularly depressive disorder, anxiety disorder, and eating disorder. Participants with BDD had a poorer perception of quality of life associated with mental but not physical health problems. Finally, the perception of quality of mental health life in participants with BDD was independent of diagnosis of any mental disorder.

body dysmorphic disorder; prevalence; adults; Spain; comorbidities; mental health; depression; anxiety; OCD; obsessive-compulsive disorder

Introduction

Body dysmorphic disorder (BDD) is a common psychiatric disorder affecting 0.5%-3.2% of the general population worldwide [1]. A multicentric study in Spain showed that the prevalence of BDD was higher among patients with acne (10.6%) [2]. The prevalence of BDD across genders is debatable. One study showed similar prevalence of BDD across both genders (49% females and 51% males) [3]. Another study reported higher prevalence among females (68.5%) [4]. The average age of onset of BDD is 16.9 years [5]. One study reported an inverse relationship between the prevalence of BDD and age: 78.6% of participants with BDD were aged 18-27 years, 14.3% were aged 28-37 years, and 7.1% were aged 38 years or older [6]. Furthermore, BDD is closely associated with other mental disorders. A recent systematic review [1] showed that the highest prevalence of BDD was among psychiatric inpatients (5.8%-37.78%). The psychiatric disorders most frequently associated with BDD are depressive disorder (47%-56.3%), borderline personality disorder (54.3%), and eating disorders (12%-45%), whereas obsessive-compulsive disorder (3%-15.3%) and schizophrenia are less closely associated with BDD. Participants who had cosmetic procedures (2.9%-57%) slightly overlap with BDD prevalence in the general population. The prevalence of BDD in both psychiatric outpatients (0.3%-2%) and students (1.3%-5.8%) partially overlaps with that observed in the general population. Among dermatologic patients, the prevalence of BDD was reported to be 2.1%-36% [1].

The etiology of BDD is multifactorial, encompassing biological, psychological, and sociocultural factors. BDD has been associated with parental rejection, as well as physical, emotional, or sexual abuse during adolescence [7]. Studies have shown a possible genetic association in first-degree relatives, with affected patients being up to 3-8 times more likely to develop BDD than the general population [7]. Shy, anxious, and perfectionistic individuals may also have a greater predisposition to develop this disorder [8].

The most important symptom of BDD is distortion of body perception, which leads to low self-esteem, anxiety, depression, social isolation, and obsessive-compulsive behaviors [9]. The clinical profile of BDD is characterized by repetitive actions such as constant checking in mirrors, applying excessive makeup to cover defects, dermatillomania, comparing one's appearance with that of others, and excessive exercise, taking up an average of 3-8 hours daily [10]. Patients with BDD are usually preoccupied with 5-7 different parts of their body [11], the most common being skin (53.8%), nose (38.5%), and hair (34.6%). The other body parts that are of frequent concern are weight and muscle mass (30.8%), face (30.8%), chest and trunk (19.2%), and teeth (19.2%) [1]. The mental and physical health status perceived by patients with BDD are lower than that perceived by the general population [12].

Given that the primary concern of patients with BDD revolves around their external appearance, it is common for people with BDD to predominantly seek dermatological and cosmetic procedures over seeking professional help for the treatment of their underlying psychiatric pathology [13]. Moreover, patients diagnosed with BDD often do not seek help for various reasons: they feel ashamed or lack insight [14]. Furthermore, BDD is likely to be underdiagnosed, given the large number of barriers to diagnosis such as the absence of appropriate tools, lack of information and awareness among health care professionals, and professionals' refusal to lose a patient or inability to diagnose it properly [15]. In addition, not all health care professionals are familiar with this disorder [9]. This leads to poor identification in psychiatric and cosmetic settings where BDD cases are notoriously prevalent [14]. If professionals do not perform a detailed anamnesis, it is difficult for patients to disclose their concerns, given the shyness underlying this disorder [16]. To overcome this shortcoming, clinicians may use the BDD Questionnaire (BDDQ), a validated diagnostic tool for BDD, with sensitivity of 100% [17-19], specificity of 89%-93% for psychiatric inpatients [18], and 93% for dermatologic patients [19]. The BDDQ is a brief questionnaire that assesses different items of the patient’s body perception [16]. Finally, treatment is based on pharmacological and nonpharmacological measures. The former includes the use of fluoxetine, a serotonin reuptake inhibitor antidepressant. The latter is based on psychotherapy—most notably cognitive behavioral therapy [20]. Randomized clinical trials have shown a rate of 50%-80% improvement in patients as well as a lower relapse rate following pharmacological treatment [21].

In summary, BDD is a poorly studied and underdiagnosed psychiatric disorder. This may be because BDD is not perceived as a disorder by aesthetic practitioners, who may think that they are merely offering a “service” [22-24]. The main objective of our study was to estimate the prevalence of BDD in Spain. Additionally, we explored the association of BDD with sociodemographic variables, presence of dermatological or psychiatric disorders and cosmetic procedures, and quality of life.
Methods

Design and Scope of This Study
A cross-sectional descriptive study was conducted. The general population aged 18 years and older in Spain was invited to access the study protocol via a link to Google Forms. The security and lawful use of personal data collected on the website is guaranteed by accepting the data privacy policy included in the survey. The measures in the protocol consisted of (1) sociodemographic variables, (2) variables associated with dermatological and psychiatric disorders and cosmetic procedures, and (3) perception of health and quality of life, measured using the 12-item Short Form version 2 (SF-12v2) health survey, and (4) a validated scale for the diagnosis of BDD, using the BDD questionnaire screening test [17].

Study Sample Population
Participants 18 years and older from the general population residing and registered in Spain at the time the survey was performed and who voluntarily completed the study's web-based questionnaire were included. The sample size was calculated using Epidat 4.0 (Dirección Xeral de Saúde Pública da Consellería de Sanidade da Xunta de Galicia) based on the following estimate: population size, 40,000,000; expected proportion, 5%; accuracy, 1%; confidence level, 95%; and design effect, 1.0. The minimum total number of responses required for 1% precision with 95% confidence level was 1825 participants.

Variables
The following variables were collected: sociodemographic variables such as gender (female, male, or other, ie, participants who do not identify themselves as male or female), year of birth, region of residence, race, educational level, employment status, and range of monthly income. Variables related to other comorbidities associated with BDD were comorbidity with dermatologic and psychiatric disorders and cosmetic procedures. Regarding the year of birth, the participants were classified into 4 age groups: 18-24 years, 25-44 years, 45-64 years, and 65 years or older. This classification was based on previous studies related to mental health and the use of these services according to age group [25].

Quality of Life Assessment
Data on quality of life and perception of their state of health were collected through the SF-12v2 health survey, which is validated as a psychometric instrument for numerous diseases and conditions, including mental illness. It assesses the participant's physical and mental state through 8 health domains: 4 related to physical health, that is, general health, physical function, role-physical, and bodily pain; and 4 related to mental health, that is, vitality, social function, role-emotional, and mental health [26].

BDD Assessment
BDD assessment was performed using the BDDQ [17]. A version adapted and validated in Spanish was used [27]. The BDDQ is a brief (7-item) self-report measure derived from the Diagnostic and Statistical Manual of Mental Disorders, fourth edition diagnostic criteria. The first 6 items require a dichotomous answer (yes/no) and the last one is multiple choice. The test will be positive if the patient answers “yes” to questions 1 and 2, “yes” to question 3, 4, 5, or 6, and if in question 7, the time indicated is more than 1 hour per day [17].

Data Handling
The Google Forms platform was used for the web-based survey. The questionnaire was distributed telematically, both through a link via mobile phone and a printed QR code. The data obtained were extracted and sorted in Microsoft Excel. Subsequently, we used SPSS to create the database and perform the corresponding analyses. A license was obtained for the SF-12v2 health survey, which together with the use of the QualityMetric program provided, allowed for its correct interpretation. The database was generated in an anonymized form guaranteeing exclusive access by the principal investigator, thereby allowing respect, privacy, and confidentiality of the data.

Statistical Analysis
Statistical analysis was performed with SPSS software (version 21; IBM Corp). All statistical analyses were performed at .05 level of significance. A descriptive study was conducted for all the variables included in this study. Quantitative variables were expressed as mean and standard deviation (SD). Qualitative variables were expressed as absolute value (n) and percentage with an estimated 95% CI. Comparison of means was performed using 2-sided Student t test or Mann-Whitney U test as appropriate after checking normality with the Kolmogorov-Smirnov test. The association of the qualitative variables was estimated by means of the chi-square statistic. Multiple logistic regression models were used to determine the association of different variables with each other. A univariate analysis was performed where a significantly higher risk ratio for BDD diagnosis was obtained for some of the variables studied. The significant variables obtained in the univariate model were subsequently included in the multivariate analysis. Thereafter, given the heterogeneous conditions of the population, a subgroup analysis was performed with a multivariate model considering the gender and age variables.

Ethics Approval
This study was conducted in accordance with the requirements expressed in the Declaration of Helsinki 2013. Participants were invited to participate online by clicking on the link to the survey. Information about the purpose of the survey and its anonymous and voluntary nature was included in the survey header. Participants were identified by a numerical code in order to respect the confidentiality of the participants' personal data. The automatic code is assigned directly by Google Forms at the time of download through a time stamp. This project was approved by the ethics committee of the Hospital Universitario Puerta de Hierro Majadahonda in Madrid (promoter protocol code PI 206/21, December 20, 2021).
Results

A total of 2091 participants were included in this study. The sociodemographic and clinical characteristics of the participants are described in Table 1.

The prevalence of BDD in the population assessed in this study was 15.2% (284/1421, 19.9% in females vs 34/653, 5.2% in males). Regarding age, the prevalence of BDD was higher in the youngest age group (18-24 years; 267/1091, 24.5%), followed by the 25-44 years age group (30/279, 10.8%) (Figure 1). The number of body parts of concern in participants with BDD was significantly higher than that in participants without BDD (4.6 vs 2.2, respectively; \( P < .001 \)). Regarding the body parts of concern, body fat was the most common concern in both groups, followed by thighs, face, hips, and skin in the BDD group and thighs, teeth, and hair in the non-BDD group (Figure 2). Regarding the sociodemographic characteristics of the BDD population (n=322), the majority were females (284/322, 88.2%), with a mean age of 23.5 (SD 9.6) years, and Caucasians (243/722, 75.5%). Approximately 81.7% (1533/2091) were students, and 76.6% (247/322) of them had a university education level. Among the participants diagnosed with BDD, 63.4% (204/322) had a history of dermatologic disease, the most frequent being acne (115/204, 56.5%) and dermatitis (99/204, 48.5%). Approximately 46.6% (150/322) of the participants with BDD reported a history of psychiatric comorbidities, and the most frequent were anxiety disorders (108/150, 72%), depressive disorders (84/150, 56%), eating disorders (72/150, 48%), and attention-deficit/hyperactivity disorder (18/150, 12%). Approximately 17.7% (57/322) of the population with BDD had previously undergone a cosmetic procedure, the most frequent being laser treatment for acne, blemishes, and other skin lesions (17/57, 29.8%); mesotherapy (9/57, 15.8%); and rhinoplasty (7/57, 12.3%). The factors related to BDD are reported in univariate and multivariate analyses in Table 2. BDD diagnosis was significantly associated with female gender, other genders, age 18-24 years, students, monthly income level of less than €500 (€1=US $1.11), and participants with dermatologic and psychiatric comorbidities (\( P < .001 \)). All these variables were included in the multivariate model, with gender (female and other), age, student occupation, depressive disorder, eating disorders, and anxiety disorders remaining at \(< .05\) significance as diagnostic predictors of BDD.

Given the heterogeneity of the population, most of whom were women aged 18-24 years, we performed a multivariate analysis considering gender and age (Table 3). On the one hand, after multivariate analysis by gender in the group of women, students, eating disorder, and anxiety disorder remained with a significance at <.05 as diagnostic predictors of BDD (Table 3). In the male group after multivariate analysis, none of the factors analyzed showed statistical significance. On the other hand, in the multivariate analysis by age (Table 3), the following factors remained with significance at <.05 as diagnostic predictors of BDD. In the 18-24 years analysis, the diagnostic predictors were female gender and other gender, students, depressive disorder, eating disorder, and anxiety disorder. In the 25-44 years analysis, the diagnostic predictor was income level between €2000 and €2999. In the 45-64 years analysis, the diagnostic predictor was female gender, and the >64 years analysis was not performed due to the small sample size.

Notes:
- BDD<sup>a</sup>: Body Dysmorphic Disorder
- Ref: Reference category
- P values are adjusted for age group.
Regarding quality of life, BDD was not statistically associated with physical health status. However, those diagnosed with BDD showed significantly lower levels of mental health than those without BDD (Figure 3). Additionally, quality of life analysis was performed considering psychiatric comorbidity as a factor affecting quality of life. Differences regarding mental health status remained statistically significant ($P<.05$) for patients with BDD, irrespective of the presence of psychiatric pathology (Figure 4).

Figure 3. Association of body dysmorphic disorder with (A) physical and (B) mental health status. BDD: body dysmorphic disorder.
Discussion

Principal Findings

Our study reveals many interesting aspects of BDD. Most of our findings are consistent with those reported previously [1,4,6,12,13]. For example, BDD is particularly prevalent in the young adult population [5], and patients with BDD are particularly concerned about an average of 4.6 different body parts. However, some findings are novel in our study. For instance, the prevalence of BDD in our sample population (15.2%) was higher than expected (0.5%-3.2%) [1]. Further, in addition to the described association between BDD and eating and depressive disorders, we report that BDD is closely associated with anxiety disorders. The most relevant finding of our study is the perception of quality of life: participants with BDD had a poorer perception of quality of life associated with mental but not physical health problems. Moreover, the perception of quality of mental health in patients with BDD was independent of diagnosis of any mental disorder.

Our study reports that the prevalence of BDD in adults is 15.2% in Spain, which is higher than that reported in the general population (0.5%-3.2%) in another study [1] and higher than that reported in a Spanish multicentric study in patients with acne (10.6%) [2]. Our findings may be explained by 2 factors. First, our sample population was particularly young, with more than half of the participants being in the age group of 18-24 years. As shown in a previous study [6], the younger the age of the patient, the greater is the possibility of BDD diagnosis. Second, our data reflect more of a screening diagnosis as compared with a definitive diagnosis established with BDDQ via an interview by a health professional, which is more demanding [17].

Our study shows that the sociodemographic characteristics most associated with the diagnosis of BDD are gender (female and other), age group of 18-24 years, students, income level of less than €500/month, and a diagnosis of previous dermatologic or psychiatric disease. Regarding gender, females showed a statistically significant ($P<.001$) higher prevalence of BDD than males (284/1421, 19.9% vs 34/653, 5.2%, respectively). Previous studies have reported similar prevalence between men and women [3] or increased prevalence in women (68.5%) compared to that in men [4]. In our study, almost 67.9% (1421/2091) of the participants were women, which may suggest the need for future studies controlled by sex to clarify the differences. Regarding age, the mean age at diagnosis of BDD in the participants in our study was 23.5 years, which is higher than the mean age of 16.9 years described elsewhere [5]. This is probably because our study only included populations 18
years and older, resulting in an increase in the mean age at diagnosis. Furthermore, we found a higher prevalence of BDD among students (263/1043, 25.2%), which was also higher than 1.3%-5.8% reported in another study [1]. Again, this could be because almost half our sample was comprised of students. Moreover, this can be attributed to the influence of social media in the current age, increasing young people's concern about their body image [1]. It would be appropriate to conduct a more specific study including this young population group.

Participants with BDD in our study were concerned about an average of 4.6 different body parts, which is in line with that reported by previous studies (5-7 body parts) [13]. The body parts that were of the most concern were body fat (248/322, 77%), thighs (191/322, 59.3%), face (166/322, 51.6%), hip (144/322, 44.7%), and skin (126/322, 39.1%). Skin (14/26, 54%) and face (8/26, 31%) were the body parts of the greatest concern in previous studies [1]. The prevalence of BDD in participants with dermatologic conditions (204/1072, 19%) in our study falls within the range (4.9%-21.1%) reported in the literature [1]. However, it is necessary to emphasize that previous studies did not distinguish between dermatologic patients per se and those undergoing aesthetic procedures [1].

Regarding the association between previous dermatologic disease and BDD, we found no significant relationships. The association between BDD and acne (115/532, 21.6%) in our study was slightly higher than that previously described (8.8%-21.1%) [1]. The association of BDD with having undergone rhinoplasty was 12.1% (39/322), which was lower than that previously documented (20.1%) [1]. However, the sample size limited our capability to extract meaningful conclusions on this issue. Among participants with previous psychiatric pathology and BDD, there was a significant association with eating disorders (72/136, 52.9%) and depressive disorders (84/244, 34.4%), similar to the findings of 12%-45% and 47%-56.3%, respectively, reported in a previous systematic review [1]. In addition, our study showed a significant comorbidity with anxiety disorders (108/292, 36.9%), making it necessary to conduct future studies in this subgroup.

Regarding quality of life, participants diagnosed with BDD had a perception of having a poorer mental health status than those without BDD. In contrast, there were no significant differences in the physical status between participants with and without BDD [12]. Ultimately, the diagnosis of BDD was associated with a perception of reduced quality of life that is not subsidiary to the presence of mental health disorders. In other words, our study suggests that BDD could be used as a marker or predictor of an individual’s perception of quality of life, which is independent of the presence of mental health problems.

**Limitations and Strengths**

Our study was based on the use of a questionnaire that was disseminated telematically, which is why we obtained a heterogeneous participant base, being represented mostly by female students in an age range of 18-24 years. The higher percentage of prevalence obtained may be linked to the specific population in this study. However, we must bear in mind that, despite obtaining the first diagnostic approximation with BDDQ, its confirmation must subsequently be backed up by an interview with a health professional [17]. Furthermore, the mean age at BDD diagnosis (23.5 years) in our study was higher than that (16.9 years) described previously [5] because this study was limited to participants aged 18 years and older. Additionally, the number of participants in our study who had undergone previous plastic surgeries was too less to achieve a proper statistical power.

With regard to the strengths of this study, we increased the number of variables related to BDD compared to the number of variables used in previous studies [2-6,12,13], which, together with the total number of participants, resulted in a large database. Further, we introduced the quality of life indicators through the SF-12v2 health survey.

**Conclusion**

Patients with BDD experience serious biopsychosocial repercussions. This study provides the first approximation of the prevalence of BDD in the Spanish population, which was found to be higher than expected, although our results should be interpreted cautiously. BDD was particularly prevalent in participants aged 18-24 years, students, and women. BDD is associated with psychiatric conditions such as eating disorder, anxiety disorder, and depressive disorder, and with dermatologic conditions such as acne and dermatitis. No significant associations were found between BDD and the performance of previous aesthetic procedures, which could be due to our small sample size. Finally, BDD could be a marker of an individual’s perception of quality of health, irrespective of psychiatric diagnoses. Future studies should confirm our preliminary findings.

**Acknowledgments**

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

**Authors’ Contributions**

HBF and BRA conceptualized this study, contributed to the methodology, supervised this study, and contributed to the resources. AL and CL curated the data and contributed to visualization. CL and MBF performed a formal analysis of this study. AL, HBF, and BRA contributed to the investigations. HBF contributed to project administration. AL and MBF wrote the original draft. HBF performed reviewing and editing.
Conflicts of Interest

In the last 24 months, HBF has received lecture fees from Takeda, BIAL, laboratorios Rubio, and laboratorios Rovi. He has also been granted 3 prizes for the development of a serious videogame for treating attention-deficit/hyperactivity disorder (The Secret Trail of Moon) called as the Shibuya Prize by Takeda, first prize of the College of Psychologists of Madrid, and a prize for the Best Innovative Health Initiative within Healthstart. He is the Principal Investigator of an iPfIS research contract (accessed on August 12, 2022; IF16/00039), Coprincipal Investigator of a MINECO research grant (RTI2018-101857-B-I00), and Principal Investigator of a research of the Sincronia project, funded by the start-up Bitsphi; recipient of a Fund for the Improvement of Postsecondary Education grant and an IDIPHIPSA intensification grant; involved in 2 clinical trials (Mensia Koala, Newrofeed Study; ESKETSU12002); and a cofounder of Hagaia Solutions. He is also an employee and member of the advisory board of Ita Salud Mental (Korian).

Abstract

Background: Randomized controlled trials (RCTs) with no in-person contact (ie, remote) between researchers and participants offer savings in terms of cost and time but present unique challenges.

Objective: The goal of this study is to examine the differences between different forms of remote recruitment (eg, National Health Service [NHS] website, social media, and radio advertising) in the proportion of participants recruited, demographic diversity, follow-up rates, and cost. We also examine the cost per participant of sequential methods of follow-up (emails, phone calls, postal surveys, and postcards). Finally, our experience with broader issues around study advertising and participant deception is discussed.

Methods: We conducted a descriptive analysis of 5602 increasing-and-higher-risk drinkers (Alcohol Use Disorders Identification Test score ≥8), taking part in a 2-arm, parallel group, remote RCT with a 1:1 allocation, comparing the intervention (Drink Less app) with usual digital care (NHS alcohol advice web page). Participants were recruited between July 2020 and March 2022 and compensated with gift vouchers of up to £36 (a currency exchange rate of £1=US $1.26988 is applicable) for completing follow-up surveys, with 4 stages of follow-up: email reminders, phone calls, postal survey, and postcard.

Results: The three main recruitment methods were advertisements on (1) social media (2483/5602, 44.32%), (2) the NHS website (1961/5602, 35.01%), and (3) radio and newspapers (745/5602, 13.3%), with the remaining methods of recruitment accounting 7.37% (413/5602) of the sample. The overall recruitment cost per participant varied from £0 to £11.01. Costs were greater when recruiting participants who were men (£0-£28.85), from an ethnic minority group (£0-£303.81), and more disadvantaged (£0-£49.12). Targeted approaches were useful for recruiting more men but less useful in achieving diversity in ethnicity and socioeconomic status. Follow-up at 6 months was 79.58% (4458/5602). Of those who responded, 92.4% (4119/4458) responded by email. Each additional stage of follow-up resulted in an additional 2-3 percentage points of the overall sample being followed up, although phone calls, postal surveys, and postcards were more resource intensive than email reminders.

Conclusions: For remote RCTs, researchers could benefit from using a range of recruitment methods and cost-targeted approaches to achieve demographic diversity. Automated emails with substantial financial incentives for prompt completion can achieve good follow-up rates, and sequential, offline follow-up options, such as phone calls and postal surveys, can further increase follow-up rates but are comparatively expensive. We also make broader recommendations focused on striking the right balance when designing remote RCTs. Careful planning, ongoing maintenance, and dynamic decision-making are required throughout a trial to balance the competing demands of participation among those eligible, deceptive participation among those who are not eligible, and ensuring no postrandomization bias is introduced by data-checking protocols.

Introduction

Randomized controlled trials (RCTs) are used to examine the efficacy of interventions on a wide range of health-related behaviors and outcomes [1-4]. RCTs examining the efficacy of digital interventions are increasingly taking place on the web or remotely. Web-based trials feature no in-person contact between researchers and participants, with the administration of the intervention and all measures completed on the web. Remote trials also have no in-person contact between researcher and participant but may involve some offline follow-up options, such as completing surveys over the phone or by post. Web-based and remote trials can be cheaper and less labor-intensive than in-person trials, although they present some unique challenges around recruitment, retention, and participant deception. Here, we present methodological insights from a large-scale (n=5602) remote RCT examining the effectiveness of a digital intervention, the “Drink Less” app [5], in helping increasing-and-higher-risk drinkers (Alcohol Use Disorders Identification Test [AUDIT] score ≥8) to reduce their alcohol consumption.

Digital interventions, such as websites and apps, are increasingly being used for a wide range of health behaviors [6] and can offer benefits over in-person interventions in terms of cost, convenience, and anonymity [7]. RCTs aiming to evaluate digital interventions can be conducted on the web or remotely and may have several advantages relative to trials requiring in-person contact. First, web-based and remote settings could increase the external validity of the trial, as having to travel to in-person appointments for baseline or follow-up assessments does not reflect real-world implementation or how users access digital interventions [8]. Second, in theory, participants can be recruited from throughout nations or even globally, giving a larger and potentially more generalizable sampling frame [9]. Third, the cost of web-based or remote trials is likely to be much less as they can be partly automated, reducing demands on researcher time, and could potentially reduce researcher bias through double blinding [9].

However, there are also significant challenges with web-based or remote RCTs beyond those conducted in person. First, it may be harder to recruit participants or to recruit a broadly representative sample [10,11], as some groups, such as older adults and people from less advantaged communities, may be less likely to engage with research conducted remotely [12]. Second, researchers have less control over who signs up, and it is possible that motivated individuals may sign up multiple times for financial incentives [8,13]. Third, once recruited, researchers may have less control over how participants engage with the intervention [14] or respond to follow-ups [8]. This could be particularly problematic with groups who may have low digital literacy and may not understand how to use the intervention, although this may be reflective of how people would engage with digital interventions in real-world settings. There are other challenges that are present in both remote and in-person trials. Contamination occurs when the comparator group finds the intervention being tested outside of the trial [9]. This could be particularly likely if the comparator group receives an intervention they do not deem acceptable and seeks out alternatives. These biases could introduce bias into RCTs, which could obscure the effect of the intervention.

Here, we draw on data from a large-scale remote RCT, evaluating the effectiveness of the Drink Less app [5] compared with usual digital care (the National Health Service [NHS] alcohol advice web page). Drink Less is a theory- and evidence-informed, app-based intervention designed by researchers [15,16] to help increasing-and-higher-risk drinkers reduce their alcohol consumption. To mitigate some of the potential challenges outlined above, the trial used a multipronged recruitment strategy, including an advertisement on the NHS website and social media advertising [5]. In line with previous research [11], and to maximize follow-up rates, we offered substantial financial incentives to complete follow-up surveys, including an additional amount for completing the primary outcome within the first 24 hours, and undertook a comprehensive follow-up approach by sequentially sending follow-up reminders through email, SMS text messages, and telephone and by post. These strategies and broader methodological issues will be discussed ahead.

This study aims to:
1. Compare different remote recruitment methods in terms of cost per recruited participant, retention rates, participant deception, and sociodemographic diversity.
2. Compare the proportion of returned responses using different strategies for follow-up at each time point, and compare the cost and time associated with each follow-up stage.
3. Consider broader methodological issues pertaining to recruitment, retention, and participant deception, and discuss the success of strategies to mitigate these issues throughout the trial.

Methods

The protocol and analysis plan were preregistered on the Open Science Framework [17]. The trial was registered (ISRCTN64052601). The main trial findings are reported elsewhere [18].

Design

Participants

A total of 5602 participants were randomized in the RCT evaluating Drink Less. Participants were eligible if they were aged 18 years or older, lived in the United Kingdom, were increasing-and-higher-risk drinkers (AUDIT score ≥8) [19], had access to an iOS device (iPhone, iPod touch, or iPad), and wanted to drink less alcohol. Recruitment ran from July 2020 to March 2022 and included an advertisement on the NHS website, a mail-out to a database of UK-based users of the smoking cessation app “Smoke Free”, radio and social media advertising, press releases, and local advertising through health care providers. Advertisements were codeveloped with public representatives.

Informed consent was sought at baseline to participate in 3 web-based follow-up surveys at 1, 3, and 6 months. Surveys were completed on the web through Qualtrics (Silver Lake), although at the 6-month follow-up, offline options (eg, phone and post) were available. The 6-month follow-up survey assessed primary and secondary outcomes relating to alcohol use and a range of related measures. The 1- and 3-month follow-up surveys only assessed secondary outcome measures relating to alcohol use. We attempted to contact participants within 30 days of their first invitation to complete each follow-up survey. To maximize data retention and to allow for time taken for answers to be posted at 6-month follow-up, data provided up to 2 weeks after the 30-day period were accepted.

Initially, as well as through 3 emails (days 0, 5, and 9) and (from January 15, 2022) a total of 2 SMS text messages (days 5 and 9), we had planned that at the 1-, 3-, and 6-month follow-up, all participants would also be sequentially offered opportunities to complete follow-up through phone (called twice from days 10 to 17), a mailed survey (from day 18), and a mailed postcard (from day 30). However, due to resource constraints, from November 2020 on, we only used automated emails on days 0, 5, 9, and 11 to contact participants at the 1- and 3-month follow-up; we no longer called or sent postal surveys. With the aim of improving these follow-up rates with less resource, we added SMS text messaging follow-ups. Phone calls, mailed surveys, and postcard follow-ups were retained for the 6-month follow-up survey (when the primary outcome was measured).

Measures

Recruitment Method

At baseline, participants were asked to specify where they saw the study advertised, with the following response options: NHS website, social media (eg, Facebook and Twitter [subsequently rebranded X]), other media (eg, radio and newspapers), emailed by the Smoke Free app, local health care provider, word of mouth, Google, general practitioner (GP) surgery, or other. If they selected “other,” free-text responses that fell within one of the response options were recoded (eg, Facebook would be social media). The response options “local health care provider” and “GP surgery” were collapsed. Throughout the study, both untargeted and targeted (eg, at men) social media advertisements were used. These were analyzed separately.

Participant Deception

We experienced 3 distinct subgroups of participant deception throughout the trial: duplicates, manual fraud, and bots. Duplicate responses, where individuals signed up more than once with identical names and phone numbers, were the least prevalent (n=49) and easiest to detect. Data checks were undertaken each month to search for duplicate values. Manual fraud was a more prevalent form of participant deception (n=297), defined as individuals who signed up multiple times with false information, such as phone numbers linked to businesses where they were not known or addresses that did not exist. To identify manual fraud, monthly checks were made on all addresses and telephone numbers provided to ensure street names matched the postcode and that numbers were mobile phone numbers. Any suspicious responses were flagged, and the participants were contacted and asked to confirm their details over the phone. Where individuals were not known at the phone number provided, they were removed from the study. To make it easier to automatically screen out those engaging in manual fraud, we added attention checks, whereby individuals were asked to select a certain response option. Participants were also asked to confirm their age at 2 different points in the baseline survey to ensure they were consistent. Individuals failing either of these attention checks were screened out of the survey before randomization. The most prevalent type of fraud were “bot” responses (n=863). These were fraudulent responses similar to manual fraud, but they occurred in batches of 20-30 at a time when contact information was given in noticeably similar formats (eg, firstname123@emailaddress.com), often with American street addresses (being UK-based was an inclusion criteria of the trial). These responses seemed to be automated and were identified using the same process of address checking as above (individuals not known at the phone number provided were removed from the study). Adding a CAPTCHA (Completely Automated Public Turing test to tell Computers and Humans Apart) to the survey eliminated this issue. A more detailed discussion on participant deception is described elsewhere [20].

Sociodemographic Characteristics

Sociodemographic measures were assessed at baseline. This study focuses on gender, ethnicity, and occupation (to derive socioeconomic status [SES]: ABC1 [managerial, professional, and intermediate occupations] versus C2DE [skilled, semiskilled, unskilled manual, and lowest-grade worked or unemployed]).

Analysis

Aim 1: Methods of Recruitment

Each recruitment method is compared in terms of the proportion of enrolled participants, the proportion of participants who were men, from a minority ethnic group, or from a more disadvantaged background (C2DE), and the proportion of participant deception. Cost-per-recruited participant citing each recruitment method (eg, total spend on recruitment method divided by the number of participants citing recruitment method) is reported. As well as the overall cost per participant, we also present the cost per participant stratified by gender (eg, for each
man recruited), ethnicity (eg, for those from ethnic minority individuals), and SES (eg, for those from more disadvantaged backgrounds). Finally, we present follow-up rates at 1-, 3-, and 6-months for each method of recruitment.

**Aim 2: Follow-Up**

The proportion of the sample responding at each sequential stage of follow-up (ie, emails, phone calls, postal surveys, and postcards) is reported. The cost of each follow-up stage per participant responding at each stage is also reported. This was derived by dividing the estimated researcher time and other relevant costs by the number of follow-ups completed at each stage.

**Aim 3: Broader Methodological Issues**

Broader methodological issues such as advertising, participant deception, technical support, contamination, and boosting retention are discussed. We describe and briefly discuss the strategies we used throughout the trial to mitigate issues.

**Ethical Considerations**

Ethical approval for the iDEAS (iOS Drink Less, Evaluating the Effectiveness of an Alcohol Smartphone app) trial was granted by the University College London (UCL) Ethics Committee (16799/001). Participants provided informed consent before participating in the trial. Study data were pseudonymized and stored on a secure university drive. Participants were compensated with gift vouchers of up to £36 (a currency exchange rate of £1=US $1.26988 is applicable) for completing the 3 surveys: £6 for the survey at 1 and 3 months and £12 at 6 months, with an additional £12 if the 6-month survey was completed within 24 hours.

**Results**

**Sample Characteristics**

A total of 5602 participants completed the baseline survey between July 2020 and March 2022: 65.78% (3685/5602) responded at 1-month follow-up, 63.80% (3574/5602) at 3-month follow-up, and 79.58% (4458/5602) at 6-month follow-up. Over half (3207/5602, 57.25%) of the sample were women, 42.22% (2365/5602) were men, 0.46% (26/5602) were “other,” and 0.07% (4/5602) preferred not to say. Most of the sample were White (5296/5602, 94.54%) and earned above-average income (4151/5602, 74.01%) and earned above-average income (4151/5602, 74.01%). The sample characteristics were similar at each follow-up. Table 1 reports the sociodemographic characteristics of the sample at baseline and those responding at each stage of follow-up.

**Table 1.** Sample characteristics at baseline and among those who responded at 1-month, 3-month, and 6-month follow-up for increasing-and-higher-risk drinkers participating in the iDEAS (iOS Drink Less, Evaluating the Effectiveness of an Alcohol Smartphone) randomized controlled trial (RCT).

Aim 1: Recruitment Methods, Demographic Diversity, and Cost Per Participant

Most participants recruited for this trial reported seeing it advertised on social media (2483/5602, 44.32%), the NHS website (1961/5602, 35.01%), or through radio or newspapers (745/5602, 13.3%), with all other recruitment methods accounting for 7.37% (413/5602) of the sample (Table 2).

a The percentage of participants recruited from each method (ie, N=included sample value).
b The percentage of the overall sample from each recruitment method including those removed after participant deception checks.

Ongoing sociodemographic tracking throughout the study revealed that women, White, and advantaged participants were being overrecruited. In response, strategies targeted at a more diverse sample in terms of gender, SES, and ethnicity were introduced with mixed success. This included targeted social media advertisements aimed at men and radio advertisements on Talk Radio, Asian Sounds (in English and Urdu), and Punjabi Radio (in English and Punjabi).

Recruitment methods differed in the proportion of men (range 17%-97%), with targeted approaches including social media advertising (353/364, 97% men) and radio advertising (591/745, 79.3%) being the most successful in recruiting a sample of men. Word of mouth was most effective in terms of recruiting a balanced sample in terms of gender (74/142, 52.1% men) but recruited a small proportion (142/5602, 2.53%) of the sample overall.

Recruiting through GP surgeries and local health care providers resulted in the highest proportion of participants from minority ethnic groups (3/15, 20%) but recruited a small proportion of participants in total (15/5602, 0.27%). Untargeted social media advertisements and word of mouth were the next best, with 6.94% (147/2119) and 6.3% (9/142) of the sample coming from ethnic minority individuals, respectively.

The NHS website, word of mouth, and Google all recruited around a third of participants who were more disadvantaged. However, both Google (159/5602, 2.84%) and word of mouth (142/5602, 2.53%) recruited a small proportion of participants in total.

The final column of Table 2 refers to the proportion (and number) of participants who were removed from the study due to participant deception, citing each recruitment method. A total of 84.54% (1028/1216) of participants identified as fraudulent cited social media as the place they saw the advertisement. It should be noted here that these participants may not have been honest in terms of where they saw the study advertisement and may have been deliberately misreporting where they found the study or responding at random.

Money spent on each of the recruitment methods varied from £0 for the NHS advertisement and word of mouth to £8203 for radio or newspaper advertisements (Table 3; a currency exchange rate of £1=US $1.26988 is applicable). Of the paid forms of recruitment, social media advertising and advertising through health care providers were the cheapest ways of recruiting participants who were men, ethnic minorities, or from more disadvantaged backgrounds.

Although the overall number of participants recruited from health care settings was low, this was impeded by the COVID-19 pandemic. The initial recruitment plan was to have posters in primary care surgeries throughout the United Kingdom; however, due to the pandemic and associated lockdowns for most of the recruitment period, many people received health care on the web and were not visiting GP surgeries. We only started advertising in GP surgeries for the last 5 months of trial recruitment (in November 2021).

Those recruited from health care providers (15/15, 100%), Smoke Free email (51/55, 93%), and word of mouth (126/142, 88.7%) appeared to have the highest response rates and those recruited through advertisements on Google (109/159, 69%), and the NHS website (1513/1961, 77%) appeared among the lowest. Table 4 presents the follow-up rates at 1-, 3-, and 6-month follow-up.

Aim 2: Retention During Sequential Follow-Up

At 6-month follow-up, 92.4% (4119/4458) of those who responded did so in response to 1 of the 3 email notifications. An additional 2.02% (90/4458) responded following 2 phone calls from the research team, and 3.25% (145/4458) responded following a postal survey. The final stage of recruitment, a postcard sent through mail to participants featuring just the key outcome measure for the trial (AUDIT-C), yielded a further 2.33% (104/4458) of the followed-up sample. The estimated costs of each sequential stage of follow-up are presented in Tables 5 and 6.
Table 5. A summary of time spent and cost on different stages of contacting participants of the iDEAS (iOS Drink Less, Evaluating the Effectiveness of an Alcohol Smartphone) randomized controlled trials at 1- and 3-month follow-up. A currency exchange rate of £1=US $1.26988 is applicable.

\(^a\)Time spent sending manual reminders and SMS text messages. On average, an email and SMS text message reminder took 2 minutes and 5 seconds to send, and a voucher email took 1 minute and 8 seconds to send.

\(^b\)The cost here is the average of 2 research staff salaries (£19.77) × research hours.

\(^c\)For the first 3 months of follow-up, we contacted participants twice manually by email, followed sequentially by phone calls, a written survey, and a postcard with the primary outcomes. However, this was not sustainable, so the subsequent follow-up stages were dropped at 1 and 3 months and are not presented below but are included in this total. 1-month phone completions=22, and 1-month postcard completions=16. 3-month phone completions=4, and 3-month postcard completions=1. SMS text messages were added 18 months into recruitment and sent at the same time as the first and second emails, so individual effects cannot be differentiated. SMS text messages did not add significantly to the time spent sending them, as they were also sent through mail merge at the same time.

\(^d\)Based on 10 pence (US $0.12) per SMS text message.

Aim 3: Broader Methodological Insights

**Retention**

Each SMS text message cost 10 pence (US $0.12) to send and required minimal researcher time as texts were sent to participants through mail merge at the same time as email reminders were sent. This was relatively low cost and low effort, and there was an increase in the average follow-up rate at 1- and 3-month follow-up in the 3 months before and after the introduction of the SMS text messages (from 58.0% (221/381) to 71.43% (830/1162) at 1 month and 58.5% (223/381) to 64.80% (753/1162) at 3 months).

**Recruitment**

Remote trials may unintentionally exclude participants with less experience using web-based surveys and digital interventions or with lower digital literacy. To mitigate this risk, in the recommendation email and at the end of the baseline survey, we included a link to a pictorial step-by-step guide to downloading and using the app [21] and encouraged participants to contact the research team if they needed technical support. Less than 10 participants contacted the research team for technical support throughout the trial.

Advertisement Development

Advertising any research study involves balancing incentivizing the target audience to participate while avoiding incentivizing those outside of the target market to falsify information to gain reimbursement. This is particularly true of remote research, where there is no face-to-face contact with researchers and therefore fewer barriers to participant deception. Below, we outline the process of developing the study advertisement, involving feedback from public and patient involvement (PPI) groups and dynamic changes throughout the trial in response to higher rates of participant deception.

**PPI Feedback on Advertising**

To improve the clarity and appeal of the advertisement, we attended meetings with 2 PPI groups (the Sheffield Addiction Recovery Research Panel and the Alcohol and Food Discussion Group at the University of Stirling) and asked for feedback on an advertisement we had designed (Figure 1). The PPI group highlighted language (eg, “Researchers at UCL” and “trial”) that they felt was too formal and would make the study sound frightening or labor-intensive. Furthermore, they did not like the phrase “digital support tools,” which they felt was unclear, and instead suggested we use the phrase “online support tools.” The group also suggested that to make the advertisement more appealing, we should make it clear that people would get support...

Textbox 1. Methodological recommendations for remote randomized controlled trials (RCTs).

**Recruitment**
- Use a range of recruitment methods.
- Monitor the demographic composition of the sample during trials and have targeted methods for underrecruited groups.
- Targeted advertising on social media or radio can be successful in recruiting men and can yield large numbers of responses. Having advertisements run consecutively for weeks seemed to result in cumulative benefits.
- General practitioner (GP) surgeries and word of mouth were good for recruiting a more balanced sample in terms of gender, ethnicity, and socioeconomic status (SES) but overall yielded lower numbers of participants. However, these methods were likely impacted by the COVID-19 pandemic and may be more effective with an increased investment of time or money in future trials.
- Offer technical support for online surveys and intervention use, ideally in different forms such as through pictorial step-by-step guides or through phone or email to ensure recruitment and engagement are inclusive.

**Follow-up**
- Offline follow-up options, such as phone calls and postal surveys, are more resource intensive but can increase follow-up rates.
- SMS text messaging services can be a relatively low-cost and low-effort way of boosting follow-up rates.

**Advertising and incentives**
- Avoid overly formal language, which may alienate participants, and use pictures.
- Highlight benefits to participants other than financial incentives (eg, support for alcohol reduction).
- Tailor advertising strategies to ensure the right balance of incentivization across different platforms. For example, if advertising on social media or where barriers to sign up are low, mentioning incentives could result in motivated individuals falsifying information. However, where there are more barriers to sign up, for example, through a radio advertisement where participants must find the study link independently, it may be necessary to highlight incentives more explicitly.

**Participant deception**
- Be aware of different types of fraud and the best ways to detect them, and continuously monitor data as strategies are likely to evolve in response to checks and barriers introduced. These may include address checks, phone calls, or requiring participants to submit ID.
- When creating online surveys, researchers should use fraud detection software if it is offered (eg, CAPTCHAS [Completely Automated Public Turing test to tell Computers and Humans Apart]) and check licenses to see if additional fraud detection software is available.
- Include attention-check questions where participants are asked to give stable information at different points in a survey or where participants are asked to select a particular response option.
- Ensure costing is included for the data monitoring resources required.

**Contamination**
- Consider the inclusion of sensitivity analyses, such as instrumental variable analysis, to capture the extent of contamination in remote randomized controlled trials.

**Discussion**

**Summary of Findings**
In this remote RCT, the 3 main participant recruitment methods were through advertisements on social media (2483/5602, 44.32%), the NHS website (1961/5602, 35.01%), and through radio or newspapers (745/5602, 13.3%), with all other methods of recruitment accounting for 7.37% (413/5602) of the sample. More participants who were women, White, and from more advantaged backgrounds responded to the initial recruitment. Targeted approaches through social media and radio advertising were successful in recruiting men but less successful in appealing to a more diverse demographic in terms of ethnicity and SES. The most effective methods for recruiting more balanced samples (health care providers and word of mouth) were often responsible for a relatively small proportion of the overall sample, suggesting greater investment in these methods could be a positive strategy in future trials. The costs associated with different recruitment methods varied. There was an increase in cost per participant when recruiting participants who were men, from ethnic minorities, and from more disadvantaged backgrounds across all recruitment methods.

There was evidence that the sequential approach taken to 6-month follow-up was successful, with 79.58% (4458/5602) follow-up rates at 6-months. Most participants responded following automated emails and substantial financial incentives, including an additional incentive to respond to the primary outcome within the first 24 hours, but each additional stage of follow-up resulted in an additional 2% to 3% of the sample following up. The advantage of the sequential approach is also evidenced by the greater follow-up rate (4458/5602, 79.58%) at 6-month follow-up when this process was followed, relative to the follow-up rates at 1- and 3-months (3685/5602, 65.78% and 3574/5602, 63.8%, respectively), where only email or SMS
text reminders were sent and less financial incentive was offered. However, each of the offline stages of follow-up was considerably more resource intensive than email reminders, so this is a practical consideration to be made at the costing stage. It would be of great interest to compare, across trials, the sociodemographic characteristics associated with the sample captured at each stage of follow-up. For example, it may be possible that offline stages of follow-up may be effective in retaining less digitally literate or less engaged participants.

Implications
When making methodological decisions about remote RCTs, there is rarely a right answer that is applicable to every study or circumstance. It is important to be aware of balancing forces, which often pull in different directions. For example, when considering advertising, it is important to balance making the study appealing to the target market with not making the study so appealing that it yields a high rate of participants who sign up with false information or who respond multiple times to gain financial reimbursement. There is a similar trade-off when considering processes aimed at reducing participant deception in the data. It is important that processes that aim to ensure participants are real and eligible do not add postrandomization bias to remote RCTs by removing “real” participants in potentially nonrandom ways. Part of navigating this balance is to plan carefully and tailor decisions to individual circumstances, as well as to monitor and learn from decisions made throughout a trial.

Previous Research
The findings of this study are in line with other studies that have focused on methodological issues in remote studies and RCTs [11,13]. The recruitment strategy undertaken was informed by a previous smoking cessation trial, which recommended using a range of sources but also monitoring the success of strategies throughout to recruit a large, diverse sample [11]. We have reported on the success of each strategy here to inform the planning of future trials. An additional potential strategy that we did not use here to improve ethnic diversity in trial participation is geotargeting of social media advertisements in geographic areas with an ethnically diverse population [22]. The multistage follow-up strategy and stepped approach to incentives (eg, an additional £12 if completed within 24 hours at 6 months) undertaken throughout the iDEAS trial were also informed by previous research [11]. The need to have ongoing strategies to detect participant deception in web-based studies and trials is also supported in other studies, and other strategies recommended beyond those we used are to check participant IDs during onboarding and undertake IP address checks [13].

Limitations
This study offers valuable insights for researchers conducting web-based or remote RCTs, but it is not without limitations. The cost per participant is calculated for different sociodemographic groups to demonstrate the relative increase in costs required to recruit a balanced sample. However, this stepped increase in costs is conflated by narrowing the focus to smaller groups in the population. For example, we would expect that each participant from ethnic minority groups would cost more than each participant overall when simply dividing the cost by the number of participants, because there are proportionately fewer of them. Regardless, our estimates of comparative costs for different demographic groups across different recruitment methods may help other researchers who are planning future trials. Furthermore, this study does not consider costs related to setting up the trial, developing automation, designing materials for data collection and recruitment, and engaging with stakeholders to promote recruitment. These are additional upfront and ongoing costs that should be considered when costing RCTs. There are also 2 limitations related to the generalizability of these findings. Due to the very small numbers of some ethnic minorities, ethnicity was treated as White versus ethnic minority. Grouping all ethnic minority participants together in this way does not allow examination of different methods of recruitment for attracting different ethnic minorities. Furthermore, the Drink Less app is currently only available to those with an iOS device, and as such, iOS device ownership was an entry requirement for the trial. There are some sociodemographic differences in iPhone ownership: relative to Android devices, iPhone owners are younger, more likely to be women [23], and have higher average incomes [24].

Conclusion
Most participants in this remote RCT were recruited through advertisements on social media (2483/5602, 44.32%), the NHS website (1961/5602, 35.01%), and through radio or newspapers (745/5602, 13.3%). Most recruitment methods oversampled participants who were more advantaged, women, and White. Targeted approaches through social media and radio advertising were successful in recruiting men but less successful in appealing to a more diverse demographic in terms of ethnicity and SES. There was evidence that the sequential approach taken to 6-month follow-up was successful, with 79.58% (4458/5602) follow-up rates at 6 months. This study offers recommendations for achieving balance in methodological challenges when conducting remote RCTs. Recruitment methods should be broad and targeted to achieve sociodemographic diversity. Automated emails with substantial financial incentives can achieve excellent follow-up rates of approximately 70%, but sequential offline follow-up can further boost retention by nearly 10% overall. SMS text messages can be a low-cost, low-effort way to improve follow-up rates. An important and broader takeaway is the importance of continuously monitoring, identifying, reacting to, and documenting new methodological challenges as they appear over the course of a trial. This is necessary not only to improve individual trials but also because pooling shared experiential learning can help research teams who are planning future trials.

Abstract

Background: Growing evidence suggests that Latina immigrant survivors of adverse childhood experiences (ACEs) are at increased risk for developing and remaining with either depression or anxiety or both symptoms. This study examined the feasibility and acceptability of a telehealth intervention—Cuidánde (quee-DAN-doh-meh, “taking care of myself”). Cuidánde is a 10-week, patient-centered, trauma-informed intervention delivered by a trained facilitator that promotes self-management of depression and anxiety symptoms through improved problem-solving skills and strategies.

Objective: The aim of this study was to examine the feasibility and acceptability of Cuidánde delivered remotely (via Zoom) with Latina immigrant ACE survivors with either depression or anxiety or both symptoms. We also estimated the effect sizes associated with the intervention on decreasing depression and anxiety symptoms and improving social problem-solving styles.

Methods: We evaluated Cuidánde using a randomized controlled trial design. Latina immigrants (N=47) who had experienced at least 1 ACE and had at least mild depression or anxiety symptoms were randomized to Cuidánde or a comparison group delivered by trained facilitators. We assessed for changes in depression and anxiety symptoms as well as social problem-solving styles at baseline, post intervention, and 3- and 6-month follow-up.

Results: Analyses indicated significant decreases over time within both Cuidánde and comparison groups for depression and anxiety symptoms and maladaptive problem-solving. The intervention effect was largest for anxiety; at 6-month follow-up, Cuidánde participants had significantly lower anxiety scores than the comparison group. In addition, we observed a greater average point reduction in depression symptoms at 6 months among Cuidánde participants (5.7 points) than in the comparison group (3.7 points).

Conclusions: A mental health program delivered via Zoom by a trained facilitator was feasible and acceptable to Latina immigrant women and can be beneficial for reducing anxiety and depression symptoms. More research is needed to assess the effectiveness of Cuidánde among a powered sample size of Latina immigrants.

Introduction

Background

Latina immigrant survivors of adverse childhood experiences (ACEs) are at increased risk of poor long-term health outcomes, as mental health disorders often go untreated in this population [1]. ACEs are a spectrum of adversities that occur in 18 years and younger of age and include physical and sexual abuse, family dysfunction such as living with an adult with mental illness, experiencing or witnessing community violence (eg, stabbing and shooting), and experiencing or witnessing violence perpetrated by an organized group (eg, gang violence and police or military brutality) [2]. These types of experiences are established risk factors for anxiety and depressive disorders in adulthood [1,3]. The United States has seen historic levels of immigrants from Central America—many fleeing from different types of adversity, trauma (eg, natural disasters, pervasive community, and political violence), and limited opportunity for socioeconomic advancement. Growing evidence suggests that foreign-born Latinos, particularly those from countries with high risks of community and political violence, experience high rates of early childhood adversity that are associated with poorer mental health outcomes [3]. When compared to the general US population and Latino immigrant men, Latina immigrants report significantly higher rates of multiple types of ACEs [1].

Despite the high burden of adversity and depression and anxiety symptoms, multiple barriers impede Latina immigrants’ access to mental health services. System-level barriers such as lack of health insurance and lack of language-concordant services are common barriers to accessing mental health services [4]. Despite the growth of the Latino population in the United States, there has been a decline in mental health services offered in Spanish [5]. In addition, while evidence-based psychological treatments are the recommended first-line treatment for mild to moderate depression [6], they are becoming less available in primary care settings [7]. Implementation of evidence-based psychological treatment services in Latino-servicing health care settings also remains a challenge. These limitations make it difficult for Latino immigrants who prefer psychotherapy to pharmacotherapy to access the mental health care they need [8,9]. Studies targeting Latinos in primary care settings have often used licensed personnel as interventionists; however, the sustainability of providing such services in low-resource settings is questionable. To address these barriers, mental health experts recommend expanding access to behavioral health services by providing them outside of specialized settings, using telehealth services [10], and rigorously training and supervising unlicensed personnel (such as community health workers) to deliver high-quality services [11].

Teletherapy and the use of paraprofessionals both show promise in increasing acceptability and engagement in the treatment of Latino immigrants experiencing depression. Among Latinos, adherence to teletherapy sessions was higher (>80%) compared to in-person sessions (42%-80%) [12,13]. Despite the methodological limitations, paraprofessional-led interventions have demonstrated improvements in depression symptoms among Latinos [14,15]. Given the shortage of behavioral health professionals, delivering mental health care through paraprofessionals or community health workers is a promising strategy for increasing access for underserved populations [11,16].

Community health workers are also attuned to the needs of the communities they serve and have feasible solutions. Community health workers who serve Latino populations acknowledge (1) the need for more mental health services, (2) the training for community health workers to better meet this need, and (3) the use of teleservices to make care more accessible [17]. Community health workers have also proposed group support for addressing mental health needs. Indeed, the group format helps to reduce feelings of isolation and shame as participants hear from others who have similar life experiences with trauma and depression and anxiety symptoms [18]. Further, group support maximizes the community health workers’ reach as multiple individuals can be served and supported by each other.

Problem-solving is an established evidence-based approach for managing depression and anxiety symptoms. Social problem-solving refers to the cognitive behavioral process used to cope with life stressors [19]. According to problem-solving theory, coping with stressors involves two independent components: (1) problem orientation and (2) problem-solving style [20]. Problem orientation refers to one’s general cognition and attitudes when faced with a problem; this process is also framed by past experiences and self-appraisal about problem-solving ability. Problem-solving style refers to cognitive behavioral activities people use to cope with or manage stressful situations and include rational problem-solving (RPS; systematic and deliberate application of problem-solving skills), impulsive-careless style (ICS; impulsive approaches to problems), and avoidance style (AS; procrastination and avoiding addressing the problem) [21,22]. Effective social problem-solving involves identifying barriers to practicing recommended behaviors and brainstorming strategies to overcome barriers [23].

Among Latina immigrant women, ACE survivors had lower self-confidence in stress management compared to women who did not report ACEs [3]. In addition, experiencing more types of adversity was negatively associated with overall social problem-solving skills and positively associated with negative problem orientation (NPO) and AS [3]. Understanding and overcoming barriers through problem-solving underscores the importance of trauma-informed care, in which trauma survivors are supported in understanding how childhood adversities
Contribute to mental and physical health and reducing negative self-evaluations that impact problem-solving styles [24]. To date, the most widely used and evaluated psychological intervention among Latino immigrants is cognitive behavioral therapy, and the established benefit to Latina immigrants is based on 3 randomized controlled trials with limited generalizability [25]. Randomized controlled trials testing problem-solving therapy for decreasing depression symptoms among Latina immigrants showed clinically significant reductions in symptoms up to a year postintervention when compared to pharmacotherapy [26,27]. In summary, there remains a need to expand the portfolio of effective mental health interventions to maximize reach and enhance responsiveness to diverse needs among Latina immigrants.

**This Study**

Given the lack of mental health services for Latina immigrants and the evidence for problem-solving and trauma-informed care, we developed Cuidándome (quee-DAN-doh-meh, “taking care of myself”). Cuidándome is a 10-week, culturally appropriate, trauma-informed, group-based intervention delivered once a week by a trained facilitator that promotes self-management of depression and anxiety symptoms through improved problem-solving skills and strategies. Multiple strategies were used to provide a trauma-informed intervention, including training the research team in therapeutic communication, screening and education about ACEs and their impact on health, and creating a safe and trusting environment for participants to work through their barriers for implementing useful strategies for depression and anxiety symptom management. Details of the adaptation and development process for Cuidándome are documented elsewhere [28]. The aims of this study were to (1) examine the feasibility and acceptability of Cuidándome delivered remotely (via Zoom; Zoom Video Communications) with Latina immigrant ACE survivors with either depression or anxiety or both symptoms and (2) estimate the effect sizes associated with the Cuidándome intervention on decreasing depression and anxiety symptoms and improving social problem-solving styles. We hypothesized that compared to the comparison group, the intervention group would report lower depression and anxiety symptoms, higher positive problem orientation (PPO) and RPS, and lower NPO, AS, and ICS at postintervention and at 3- and 6-month follow-up.

**Methods**

**Recruitment**

We recruited participants over 2 weeks in July 2021. Both active and passive strategies were used to recruit participants. Actively, we developed a database of Latina immigrants with a prior study [3] and contacted these women to assess for eligibility and participate in this study if interested. We also shared the study flyer with community health workers in the area, who distributed the flyer within their networks, including placing study flyers inside bags of food that were being donated during a food drive. Our passive strategies included posting flyers at laundromats and grocery stores in Latino-concentrated neighborhoods. Women who were interested in participating in the study texted or called the research phone. A bilingual research assistant obtained informed consent and established eligibility over the phone for all women verbalizing interest in participating in the study.

Establishing eligibility included the completion of a baseline study questionnaire (including demographic information and assessments for depression and anxiety symptoms) to verify eligibility for the study. Eligibility criteria included (1) being ≥18 years, (2) foreign-born (or born on the island of Puerto Rico), (3) self-identify as a Latina, (4) self-report of ≥1 ACE, (5) ability to understand and speak Spanish, and (6) have a score of ≥5 on the Patient Health Questionnaire-8 (PHQ-8)—an assessment for depression symptoms [29] or ≥5 on the Generalized Anxiety Disorder-7 (GAD-7)—an assessment for anxiety symptoms [30]. We excluded women currently enrolled in another study about mental health (to limit potential confounding or carryover effects), and we excluded women who reported being pregnant (given that pregnancy can contribute to depression symptoms). Figure 1 displays the CONSORT (Consolidated Standards of Reporting Trials) diagram, participant enrollment, and retention (Multimedia Appendix 1).
Ethical Considerations

All study procedures were approved by the Johns Hopkins University Ethics Review Board (IRB00287200). Oral consent was obtained from all participants in Spanish over the phone by the bilingual research assistants (native proficiency). To secure and protect all participant information, all data were collected and directly entered into REDCap (Research Electronic Data Capture) hosted at Johns Hopkins University. Only select research team members could access these data. All data were deidentified prior to export to SPSS (version 28; IBM Corp) for data analysis. Given the cost associated with data use, we compensated our participants up to US $190 for study participation (US $15 per session attended) and completion of all follow-up study questionnaires.

Procedures

Women who provided consent were found eligible for the study (based on the baseline study questionnaire), and women who agreed to enroll in the study were randomized to receive either Cuidándome or educational content from a health promotion manual designed in Mexico [31]. Randomization was stratified based on ACE score so that one group would not have more people with higher average ACEs than the other. After completion of the baseline questionnaire and randomization, participants were told when their group sessions would begin, and participants were mailed the corresponding workbook for

Figure 1. CONSORT flowchart of participant enrollment, allocation, and adherence. CONSORT: Consolidated Standards of Reporting Trials; GAD-7: Generalized Anxiety Disorder-7; PHQ-8: Patient Health Questionnaire-8.
their group assignment. Based on input from community partners and the significant use of mobile phones and apps in the study population, we did not make computer or internet access a requirement for participation. For those who were not familiar with Zoom, a brief orientation was scheduled to explain how to use Zoom. All participants were encouraged to join the group sessions when they were scheduled; if a participant could not attend the group session, a make-up session would be scheduled with the participant where the facilitator would review content from the missed week prior to the next group session. This progression was particularly important because the sessions were designed to build on each other.

Study questionnaires were completed at baseline (T0) as part of the eligibility assessment and enrollment process, within 1 month post intervention (T1), and again at 3 months (T2) and 6 months (T3) post intervention. Trained bilingual research assistants who were not involved in the intervention delivery administered the study questionnaire (see “Study Questionnaire” section for descriptions of items and measures) to participants via phone and entered responses into a secure REDCap database. Based on our experience and prior evidence, many low-income Latino immigrants rely on their smartphones for internet access, particularly if they do not subscribe to broadband services [32]. Our retention efforts included 3 weekly reminders via SMS text message for joining the Zoom sessions, mailing participants a Cuidándome bookmark and a booklet of poems.

**Intervention**

Table 1 provides the content overview for the intervention and comparison groups. To summarize, Cuidándome facilitates the learning and practice of systematic problem-solving through identification of the problem, generation of potential solutions, selection of the best solution, and implementation of the identified plan. Given participants’ history of trauma, the intervention sessions start with content about mental health and how ACEs, as well as other types of adversity, can contribute to mental health symptoms and conditions in adulthood. The remainder of the sessions guides participants through 5 evidence-based self-management strategies for managing depression and anxiety symptoms and identifying solutions for the barriers (life activities and stressors) that get in the way of practicing the recommended strategies. The weekly sessions lasted approximately 1 hour. In addition to the facilitator, all participants had the Cuidándome workbook that provided structured templates for guiding participants through the session activities. The first session included a discussion about ground rules, including the importance of confidentiality and not sharing comments made within the group with people outside of the group. During each session, the facilitator encouraged group discussion and shared reflections and strategies for overcoming challenges. The first 2 modules focus on psychoeducation and allow for discussion throughout. In the remaining modules, group learning through participant discussion is the priority; therefore, the facilitator presents the activity, guides participants through the exercises, and encourages discussion using vignettes and the workbook.
Comparison

Given our focus on Latina immigrant women with either depressive or anxiety or both symptoms, we opted to offer the comparison group some generic health education content rather than be waitlisted. The content for the comparison group came from a family health promotion manual from Instituto Mexicano del Seguro Social—the Mexican Institute for Social Security [31]. We selected this manual given our focus on a Spanish-speaking, immigrant Latina population. The content from Instituto Mexicano del Seguro Social was already in Spanish and culturally appropriate—particularly the nutrition

content that referenced traditional foods and diets common to our participants. The comparison content included 1 session about mental health conditions in general, which did not overlap with the more detailed Cuidándome training. Delivery of the comparison content mirrored the format of the intervention group: 1-hour weekly sessions delivered via Zoom.

Group Facilitators and Intervention Fidelity
The intervention facilitator is a bilingual, Latina immigrant with a bachelor degree, who was trained in problem-solving therapy by our expert clinical psychologist and who received ongoing support and guidance. The facilitator of the comparison group was an experienced registered nurse with a master in health education and expertise (over 15 years of experience) in facilitating health promotion groups for Latina immigrant women. Aside from training on human participants, the nurse for the comparison group did not receive any specific training but was oriented to the purpose of the comparison group and provided with the corresponding workbook content. All Zoom sessions were audio recorded and reviewed after the sessions by the principal investigator to assess for client-centeredness (eg, showing empathy and encouraging autonomy) in both groups and to determine if the Cuidándome facilitator followed the facilitator script and demonstrated a problem-solving approach (eg, guiding participants to targets for change and focusing on positive action).

Study Questionnaire

Demographic Characteristics
The study questionnaire included questions about demographic characteristics: age, relationship status, children, nativity, length of time in the United States, educational attainment, and employment status. Items about demographic characteristics were only administered at baseline.

Adverse Childhood Experiences
The Adverse Childhood Experiences-International Questionnaire was used, at baseline only, to assess for occurrence (eg, “Did you live with a household member who was a problem drinker or alcoholic, or misused street or prescription drugs?,” “Yes” or “No”) and frequency (eg, “Did a parent, guardian or other household member hit or cut you with an object, such as a stick (or cane), bottle, club, knife, whip etc.” “Many times,” “A few times,” “Once,” or “Never”) of different types of adversities that occurred in the age of 18 years and younger [33]. In addition to items that inquired about the traditional ACEs (eg, physical and emotional neglect), the Adverse Childhood Experiences-International Questionnaire also assesses for the types of adversity such as bullying and experiencing or witnessing community violence. Items about child marriage were not included in our assessment because we have not identified this experience as a significant part of our population’s history. We dichotomized item responses based on the presence or nonzero frequency of an experience (yes=1 and no=0) and summed all dichotomized item responses for a total score; higher scores indicated experiencing more types of adversity. This tool has been validated with Latina immigrants [3,34].

Primary Outcome Variables

Depression
We used the PHQ-8 to assess the frequency (0=not at all to 3=nearly every day) of depression symptoms during the last 2 weeks [29]. Item responses are summed for a total score (range 0-24), with higher scores indicating greater severity of symptoms. The PHQ-8 has been validated among Latina immigrants and demonstrated good reliability with our sample (α=.83).

Anxiety
We used the GAD-7 to assess the frequency (0=not at all to 3=nearly every day) of anxiety symptoms during the last 2 weeks [30]. Item responses are summed for a total score (range 0-21), with higher scores indicating greater severity of symptoms. The GAD-7 has also been validated among Latina immigrants and demonstrated good reliability with our sample (α=.76).

Social Problem-Solving
We assessed social problem-solving styles using the Social Problem-Solving Inventory-Revised (SPSI-R) [20]. The items assess attitude toward challenges as well as one’s tendencies and approach for managing stressors in everyday life. Items present different styles of thinking and reactions to scenarios to which participants report how accurately the statement reflects their attitudes or behaviors to challenges (0=not at all true of me to 4=extremely true of me). The SPSI-R assesses for (1) problem orientation and (2) problem-solving style. Problem orientation refers to one’s disposition and attitude toward a problem. People with a PPO perceive problems as solvable challenges and are optimistic and confident in their ability to manage the problem; higher scores on the PPO subscale indicate greater confidence and optimism for solving problems. People with an NPO tend to perceive problems as a threat and are less confident in their ability to address the problem; higher scores on the NPO indicate less confidence in their ability to address problems.

Three problem-solving styles are assessed with the SPSI-R: RPS, ICS, and AS. When faced with challenges, people who practice RPS tend to think through multiple solutions and intentionally implement the optimal approach; higher scores on the RPS subscale indicate higher levels of RPS. The ICS is used to describe the tendency to act on the first option that comes to mind rather than consider multiple solutions; higher scores on the ICS subscale indicate greater impulsivity when addressing problems. The AS describes the practice of procrastination or avoiding addressing a problem; higher scores on the AS subscale indicate greater tendency for practicing avoidance for addressing problems. Each subscale was added for a sum score. To obtain a total social problem-solving score, the subscales are calculated (maladaptive styles negatively impact the total score social problem-solving score) using the prescribed formula [20]. These assessments have been used among Latina immigrants and demonstrated good reliability (α=.74).
Statistical Analysis

Descriptive statistics (frequencies, means, and SDs) for all participant demographics and outcome variables were calculated. We tracked the number of sessions completed for each participant as an indicator of acceptability and asked participants if and how the intervention helped them at the end of the 10 weeks. The proportion of interested participants who consented and were screened as eligible to be in the study was also computed to help inform feasibility. We conducted independent \( t \) tests to assess differences in outcome variables (depression, anxiety, and social problem-solving styles) between the intervention and comparison groups at baseline and the follow-up time points (data not shown). In addition, paired \( t \) tests were used to compare the differences in means for the outcome variables from postintervention to 3- and 6-month follow-up time points (data not shown). For our primary analyses, mixed between-within participants’ ANOVA was used to examine differences in outcome variables between the intervention and comparison group, over time, from baseline to 6-month postintervention. We calculated effect sizes (Cohen \( d \): small <0.50, medium \( \geq 0.50 \) to <0.80, and large \( \geq 0.80 \)) using the difference in outcome means for the different groups divided by the pooled SDs.

Results

Participant Demographics, ACEs, and Retention

Our sample included 47 Latina immigrants at baseline (Table 2) and 41 participants at all follow-up assessments. There were no significant differences between the intervention and comparison group at baseline.

<sup>a</sup>Baseline sample.

<sup>b</sup>N/A: not applicable.
The most common ACEs included community violence (n=39, 83%), witnessing violence in the home (n=39, 83%), emotional abuse (n=36, 77%), physical abuse (n=36, 77%), and being bullied (n=35, 75%). In addition, 55% (n=26) of the sample reported some form of sexual abuse (unwanted sex, fondling, and attempted sex).

Figure 1 displays participant enrollment, retention, and adherence to the group sessions. Of the participants we assessed for eligibility, most (n=38, 63%) were women who contacted the research team indicating their interest to participate. The other participants were selected from the database for a previous study. Attrition was low, with 6 women discontinuing participation primarily due to work schedules. All Cuidánde participants (n=20, 100%) completed at least 9 of the 10 total sessions, and 76% (n=16) of the comparison group completed 9 of the total 10 sessions.

Depression and Anxiety and Social Problem-Solving

Overview

In Tables 3 and 4, we present the mean scores for depression, anxiety, and social problem–solving styles by study group (intervention and comparison) and time (baseline, postintervention, and 3- and 6-month follow-up). In Table 5, we compared for differences of change in scores between the intervention and comparison groups for depression, anxiety, and social problem–solving styles (interaction effect); compared the change in depression, anxiety, and social problem–solving styles over time within the groups (time main effect); and compared the 2 programs for changing depression, anxiety, and social problem–solving styles (intervention main effect).

Depression
Based on the PHQ-8, depression levels decreased from baseline to postintervention for both groups and remained below baseline at 3 and 6 months (Table 3). There were small effect sizes (Cohen d) at each time point (postintervention (T1): d=0.48; 3-month follow-up (T2): d=0.31; and 6-month follow-up (T3): d=0.37; Table 3). Depression symptoms significantly decreased over time (main time effect) for both intervention and comparison groups (Wilks Λ=0.53; F1,37=11.1; P<.001; Table 5). However, when comparing the 2 groups, the change in depression symptoms over time was not significant (interaction by time interaction in Table 5). There was also no significant difference between the 2 programs in reducing depression symptoms (intervention main effect in Table 5); specifically, at each time point, there was no significant difference in depression symptoms between the groups.

Anxiety
Based on the GAD-7, anxiety levels also decreased from baseline to post intervention and remained below baseline through 6 months for both groups (Table 3). We estimated small effect sizes (Cohen d) at each time point (T1: d=0.30 and T2: d=0.36) and medium (T3: d=0.65) effect sizes for reduced anxiety symptoms (Table 3). The reduction in anxiety symptoms over time was significant, with both groups showing a reduction in symptoms across the follow-up time points (Wilks Λ=0.51; F3,37=11.9; P<.001; Table 5). There was also a significant difference in the reduction of symptoms between the 2 groups, where Cuidándome was demonstrated to be more effective than the comparison program for reducing anxiety symptoms (F1,39=4.3; P<.001).

Social Problem-Solving Styles
Overall social problem-solving increased from baseline to all 3 time points. Similar to depression and anxiety symptoms, the increase in social problem-solving over time was significant with both groups showing improvement (Wilks Λ=0.51; F3,37=11.9; P<.001). When comparing the 2 groups, the increase in social problem-solving scores over time was not significant (intervention by time interaction in Table 5). There was also no significant difference between the 2 programs for increasing social problem-solving scores (intervention main effect in Table 5). The ANOVA analyses indicated that neither program had a significant effect on PPO or RPS (data not shown).

Negative Problem Orientation
NPO decreased from baseline to all 3 time points (Table 4). The reduction in NPO over time was significant for both groups (Wilks Λ=0.44; F3,37=16; P<.001; Table 5). Although there was change over time for both groups, this change did not differ by group (intervention by time interaction), and there was no significant difference in the effect of the 2 programs for reducing NPO (intervention main effect). However, the difference in NPO at 3-month follow-up between the 2 groups almost reached significance (Cuidándome: mean 5.45, SD 3.15 vs comparison: mean 7.66, SD 4.82; P=.09), and we estimated small (T1: d=0.10) and medium (T2: d=0.54 and T3: d=0.38) effect sizes (Table 4).

Avoidance Style
ASs decreased from baseline to all 3 time points (Table 4). Similar to NPO, the reduction in AS over time was significant for both groups (Wilks Λ=0.68; F3,37=5.8; P<.005; Table 5). There was no difference in change over time between the 2 groups, and there was no significant difference in the effect of the 2 programs for reducing ASs. However, the difference in mean scores postintervention (Cuidándome: mean 2.1, SD 2.17 vs comparison: mean 4.42, SD 4.81; P=.06) and at 6-month follow-up (Cuidándome: mean 1.65, SD 2.5 vs comparison: mean 4.0, SD 4.80; P=.06) approached significance, where Cuidándome participants reported lower AS at these time points (Table 4). We estimated medium effect sizes (T1: d=0.62, T3: d=0.61) for the intervention.

Impulsive-Careless Style
ICS decreased from baseline to all follow-up time points (Table 4). ICS decreased over time for both groups (Wilks Λ=0.75; F3,37=4.2; P=.02); however, the change in scores did not differ significantly between the groups, and neither program was more effective at reducing ICS scores (Table 5). Nonetheless, we
observed lower mean scores for Cuidándome participants compared to the comparison group that approached significance at 3-month follow-up (Cuidándome: mean 4.55, SD 4.08 vs comparison: mean 7.1, SD 4.54; \( P=0.07 \); Table 4). We calculated small (T1: \( d=0.14 \)) and medium (T2: \( d=0.59 \) and T3: \( d=0.40 \)) effect sizes for the intervention.

Discussion

Principal Findings

This study is one of the first to assess the feasibility and acceptability of a trauma-informed, problem-solving–based, self-management program delivered remotely for Latina immigrant ACE survivors with at least mild depression and anxiety symptoms. Our rapid recruitment (completed in 2 weeks), high attendance, and retention indicated that participants desired the program and found it acceptable. Based on the PHQ-8 means, participants in both groups were experiencing moderate levels of depression symptoms at baseline. Depression symptoms significantly decreased for both groups, with no significance in change between the intervention and comparison group. However, we observed lower depression scores among Cuidándome participants compared to the comparison group suggesting Cuidándome participants experienced fewer days with depression symptoms. Although both groups experienced improvements, Cuidándome participants on average reported a greater reduction in depression symptoms (5.7 points) compared to the comparison group (3.7-point reduction). For anxiety symptoms, Cuidándome was significantly more effective at reducing anxiety symptoms. On average, Cuidándome participants reported minimal to no anxiety symptoms at all follow-up time points compared to comparison group participants who on average reported mild symptoms. The effect sizes for depression and anxiety were small to medium, further supporting the beneficial impact of Cuidándome for these symptoms. Further study with a powered sample is needed to rigorously test the effectiveness of Cuidándome in this Latina immigrant population.

Contrary to our hypothesis, we did not see improvements in PPO or RPS—the components of social problem-solving that we anticipated Cuidándome would increase. Instead, we found that among Cuidándome participants, we observed lower scores for NPO and maladaptive problem-solving styles (avoidance and impulsive-careless). The goal setting and learning the problem-solving steps may have helped Cuidándome participants feel more inspired and empowered to address daily life challenges in order to pursue their goals. When discussing the benefits of Cuidándome, our participants shared that Cuidándome provided them with the steps for “how” to achieve their goals; this may have helped women have a more positive outlook on addressing challenges [28]. Women also shared that they felt a greater sense of confidence managing daily challenges and thinking through options before reacting to a situation. Regarding the lack of findings with the positive subscales, although we did not include assessments of social desirability, social desirability may have influenced participant responses and minimized the scales’ sensitivity to change. Further, we were not powered to identify statistically significant changes with any of our outcomes.

Other studies that have examined the effectiveness of problem-solving therapy for depression among Latinos have also identified improvements in depression symptoms [27,35]. However, this study is the first to show promising findings on anxiety as well as social problem-solving styles, which are the potential mechanisms of action for improving mental health outcomes.

We unexpectedly observed significant reductions in depression and anxiety symptoms in both groups. On review of the session recordings, we learned that the nurse facilitator for this group used both goal-setting and problem-solving (particularly brainstorming solutions) strategies in her sessions—particularly for the nutrition and physical activity sessions. At the end of these sessions, participants were encouraged to set a goal based on the session topic, and they discussed strategies for achieving those goals. Participants also exchanged contact information with fellow participants in the chat feature of Zoom. We did not assess social support, but it is possible that through these sessions, participants were able to expand their social network and increase social support, which is associated with lower depression and anxiety symptoms [36]. In addition, given that there were 2 sessions about physical activity and nutrition, comparison group participants may have increased their physical activity; indeed, increased physical activity is associated with a reduction in depression symptoms among Latina women [37] and other populations [38]. Finally, for all participants, we made ourselves available to connect them with community resources. Participants often called for information about where they could find health care services, work, and food. In our future work, we will assess whether change in social needs is associated with improved mental health.

Based on prior work, we surmise that the trauma-informed content and care from our research team were important contributors to retention. During the development phase of Cuidándome, the review of ACEs and their association with mental health conditions were the most time-consuming sessions because of participant engagement. Similar to findings by Kaltman et al [39] who also examined the feasibility and acceptability of an in-person, trauma-informed intervention, Cuidándome participants had positive reviews about the discussions on trauma, and they found it validating to learn that their current depression and anxiety symptoms could be related to early life adversities. Participants who were mothers felt inspired to engage with their children in a more positive way to not perpetuate the cycle of ACEs. Qualitative analysis of participant discussions during these sessions may provide more insight into participant responses to the trauma-informed content.

The success of this feasibility study may also be attributed to the intervention being offered remotely. Multiple structural (eg, documentation status) [40] and system-level barriers (eg, accessibility, health insurance, and language concordant services) make mental health services and care inaccessible for Latina immigrant women [41]. Cuidándome eliminated several of these macrolevel barriers—there was no need for participants...
to present themselves in any establishment with government-issued identification in order to obtain services, participants did not have to travel to a physical location, health insurance was not required, and the program was offered in Spanish. Using telehealth and trained personnel eliminated barriers that prevent marginalized groups from accessing a program that may be beneficial for mental health. More research with stakeholders is needed to determine how programs such as Cuidándome can be made more accessible and sustainable in community-based settings.

**Limitations**

We acknowledge several limitations with this study. First, we sought to establish acceptability and feasibility and did not calculate a sample size a priori. Our relatively small sample size may explain the few statistically significant findings between Cuidándome and the comparison program. In addition, our sample represented women primarily in urban and suburban settings with access to broadband services. A larger sample size that includes some geographic diversity may yield more generalizable findings.

Despite the limitations, this work contributes to the body of literature highlighting specific useful strategies (telehealth and nonlicensed personnel) that can be used to expand access to mental health services for populations socially at risk and underserved populations. Nonlicensed personnel such as community health workers have successfully delivered mental health services in low-resource settings [16]. This work aligns with other studies demonstrating the acceptability and effectiveness of training nonlicensed personnel to deliver mental health interventions [39,42] as well as the use of a web-based platform for administering these programs.

**Conclusions**

Our findings indicate that the Cuidándome intervention can improve depression and anxiety symptoms among Latina immigrant ACE survivors. Further, Cuidándome may also be beneficial for decreasing maladaptive behaviors (avoidance and impulsivity) associated with depression and anxiety symptoms. As the Latina immigrant population continues to grow, so should community-based mental health resources. More methodologically rigorous study of Cuidándome is needed; however, this study shows the promise of an intervention that leverages nonlicensed personnel and uses a web-based platform to increase the availability of a beneficial mental health program.

Abstract

Background: In Canada, 1 in 3 women and people of gestational age undergo an abortion in their lifetime. Despite the liberal legal context, barriers continue to exist for women and people who can become pregnant to access this service.

Objective: This study aims to (1) conduct a pilot study to demonstrate the feasibility and acceptability of myPostCare to support follow-up care after a procedural abortion; (2) use the findings to understand whether myPostCare has the potential to improve contraceptive behavior and knowledge, emotional well-being, and sexual health knowledge; and (3) develop a better understanding of how innovative mobile solutions can support integrative health programs in British Columbia with the goal of expanding to other sites across Canada.

Methods: People of gestational age (aged 14–45 y) who underwent a procedural abortion were recruited from 2 urban abortion facilities in British Columbia. The participants completed a baseline quantitative survey and were provided access to myPostCare for up to 30 days. A follow-up quantitative survey was sent via email on day 30. Qualitative interviews were conducted to explore user satisfaction and usability of myPostCare. Responses to the survey questions were summarized using descriptive statistics, and the system usability scale (SUS) was scored according to the instructions. A secure analytics platform was implemented to obtain data on the overall use of the website by users. Qualitative analysis was conducted with NVivo using a thematic analysis approach. This study was approved by the Women’s and Children’s Research Ethics Board.

Results: Overall, 62 participants were recruited (average age 30 y); 40% (25/62) of the participants completed the exit surveys, and 24% (6/25) consented to participate in the semistructured interviews; 40 participants had undergone an immediate postabortion intrauterine device (IUD) insertion, and 22 did not have an IUD inserted. Participants were satisfied with myPostCare. The SUS average score was 81.5 (SD 9.7; median 82.5, IQR 77.5-87.5), indicating high usability of the tool. Overall, 88% (22/25) of the participants changed their contraceptive method to an IUD. Web-based analytics demonstrated that there were 61 unique visitors to the site, and the top pages visited were Postprocedure Care, Emotional Well-Being, and Contraception Explorer. The longest time spent on the website was 56 minutes. The overall email open rate was 80%, with a click rate of 36%.

Conclusions: This study demonstrates that communities and individuals are important collaborators in developing a mobile innovation that facilitates access to high-quality patient-centered abortion care. Through the cocreation process, a digital platform such as myPostCare highlighted a gap in abortion care in Canada, particularly around follow-up support after a procedural abortion.
Introduction

More than 30% of women and people who can become pregnant in Canada undergo an abortion. To support access to this essential service, Canadian federal legislation requires that abortion services be provided by each provincial and territorial health system [1,2]. Recent literature suggests that despite the prevalence of the procedure, stigma surrounding abortion in Canada leads to barriers for women and people who can become pregnant to access postabortion support and share their abortion experiences [3]. The provision of information is an essential part of good-quality abortion services, which include follow-up care after a procedural abortion [4,5]. According to the National Abortion Federation Clinical Policy Guidelines, “appropriate and accessible post-procedure and follow-up care is essential to patients’ wellbeing” [4]. There is little evidence to suggest that “mandatory” follow-up visits will detect conditions that women and people who can become pregnant cannot detect themselves; however, there is evidence to suggest that more novel methods of offering “follow-up” visits for postabortion support are desired [6]. This includes the use of innovative mobile health (mHealth) solutions defined by the World Health Organization as “the use of mobile and wireless technologies to support the achievement of health objectives” [6,7]. More importantly, given the potential reach of mHealth, evidence has pointed to its potential to provide remote support and follow-up, particularly for women and people who can become pregnant and live in rural and remote areas [8].

In Canada, geographic barriers impact abortion access, leading women and people who can become pregnant to travel long distances for services. Upon returning to their communities, they may face challenges in accessing minimal, ineffective, or nonexistent follow-up care [8,9]. A qualitative study further explored women’s abortion experiences in the Yukon territory, a remote Canadian service area, highlighting that “fragmented services left women unsatisfied, stressed, and upset about lack of information, multiple appointments, and lengthy wait times” [10]. Women further expressed frustration with lack of follow-up counseling and recommended that it be routinely offered as they feel contact with health care providers is cut off after the procedure [10]. In addition to access issues, barriers of cost, knowledge among the general public, and health care provider competence and attitudes have also been highlighted in the literature [9]. Another study explored women’s expressed desire for postabortion support services, highlighting the stigma surrounding abortion that exists in political and social contexts, preventing women from sharing their experiences [3]. This study specifically highlighted that although women may not necessarily need mandatory physical follow-up, they desire access to postabortion support for emotional well-being [3]. Furthermore, there is a great deal of inconsistency in the type of support and information available to women and people who can become pregnant after an abortion.

The New England Journal of Medicine published a special report on Telehealth in the United States, highlighting its utility and future. In 2016, Kaiser Permanente of Northern California reported that its virtual (email, telephone, and video) communications had exceeded in-person visits [11]. Similarly, research supports the safe and effective use of telehealth for the provision of medication abortion care globally [12-14].

Three trials of mHealth interventions have aimed to study the role of mobile interventions in increasing the use of contraception [15-18]. Mobile for Reproductive Health and Mobile Alliance for Maternal Action have used best practices from health communication programs to systematically develop family planning text messages [18]. Furthermore, Smith et al [13,14] explored women’s needs in Cambodia to develop a mobile phone–based intervention to support postabortion family planning, specifically contraceptive adherence. In the United States, research on the acceptability and feasibility of remote technologies for follow-up after medication abortion suggested that women prefer either a telephone call or a text message over a clinic visit [19]. Most recently, researchers from University of San Francisco’s Program in Women-Centered Contraception developed a tablet-based contraceptive decision support tool for women [20]. This study used a multiphase approach that incorporated the end user throughout the entire design of the project. The tool has been designed in collaboration with key stakeholders and designers from Bedsider [21]. Using an iterative process informed by patient and provider input throughout, this family planning innovation demonstrated that including users in development led to a more patient-centered innovation [22]. Despite the development and implementation of these mHealth innovations for family planning, research is limited in understanding the follow-up needs of women and people who can become pregnant and undergo an abortion, and how they would perceive a tool to support them and to engage them as active participants in the design process.

Given the existing evidence in support of mHealth for family planning innovations, we aimed to determine whether a mobile technology intervention would be acceptable and feasible for women and people who can become pregnant to support follow-up care after first or second trimester procedural abortion. We developed a 3-phase study based on human-centered design and the “Development-evaluation-implementation” process from the Medical Research Council Frameworks for Complex Interventions [23] rooted in 2 theories: Technology Acceptance Model and Theory of Reasoned Action [24,25] phases 1 and 2 have been published previously [26,27]. This study was a prospective pilot that aimed to determine whether the intervention was satisfactory, acceptable, and usable for women and people who can become pregnant to support them in follow-up after a procedural abortion. Ultimately, this study is
the first to use mHealth and human-centered design in Canada as a novel approach to support follow-up care for women and people who can become pregnant and undergo procedural abortion.

**Methods**

**Participants**

Participants were recruited from 2 publicly funded abortion clinics in British Columbia, Canada. The eligibility criteria were as follows: (1) consent to undergo a first or second trimester procedural abortion, (2) ability to read and write English, (3) ability to participate in study procedures, and (4) aged ≥14 years. Participants were excluded if they were (1) attending the clinics because of fetal anomaly or miscarriage, (2) undergoing medication abortion, (3) in a situation where it may be dangerous to use a mobile intervention, and (4) unable to provide consent to participate. To elicit whether a woman was in a dangerous situation, counselors asked the patients as part of routine care if they felt safe in their current relationships. In cases where a risk is identified, counselors provided resources and would refer to the appropriate provider or service.

**Study Design**

The overall study design is a mixed methods user-centered design approach with 3 phases based on the “Development-evaluation-implementation” process from the Medical Research Council Frameworks for Complex Medical Interventions [28]. This is the final phase of the 3-phase study, with the findings from phases 1 and 2 already published [26,27].

Phase 3 is a prospective pilot mixed methods study conducted in 2 urban clinics in Vancouver, British Columbia, between March and June 2018 to test the acceptability and feasibility of myPostCare when implemented as part of clinical care. This study was approved by the Children’s and Women’s Research Ethics Board (H18-00036).

Eligible participants were screened by a primary investigator. They were then introduced to the study and consented under the supervision of the research coordinator. Participants consented to be contacted for a qualitative interview at 4 weeks. A baseline questionnaire that was adapted from validated survey tools was filled out to collect demographic information, contraception history, and levels of perceived well-being and distress in the past 2 months before the abortion [29-31]. The Arizona Integrative Outcomes Score was used and is a validated 1-item visual analog tool that allows self-rated global assessment of spiritual, social, mental, emotional, and physical well-being over the past 24 hours and 1 month [32].

The participants were registered on the website at the end of each recruitment day. Participants received 7 automatic email notifications that were timed with what would be expected after the procedure and prompted them to the website over the course of 30 days. At the end of 30 days, participants received a link to their email to complete a questionnaire adapted from the validated questionnaires [29-31,33,34]. This questionnaire specifically included questions about satisfaction with myPostCare, a system usability scale (SUS) comprising 10 questions, and an evaluation of the impact of various aspects of myPostCare including emotional well-being, contraceptive behavior, immediate postprocedural care, and sexual health. Data analytics were collected using a secure data analytic platform housed at the BC Children’s Hospital. Participants were compensated for their participation.

Participants who consented to the qualitative part of the study were contacted and invited to participate in semistructured interviews to explore their engagement with the mobile tool. This included system usability, experience of receiving email notifications, emotional well-being, contraceptive decision-making, immediate postprocedural concerns, and questions about sexual health. Questions explored experience with receiving timed email messages, feedback on the content of the notifications themselves, if they found the notifications helpful and why, did they follow the recommendations of the notifications, and did they visit the website after being prompted by the notifications. Participants received additional compensation for their participation in the interview.

**Data Analysis**

Descriptive analysis of each variable from the quantitative surveys and secure data analytic platforms was reported as mean (SD) or median for continuous variables and count (percentage) for categorical variables. All statistical analyses were performed in R (R Foundation for Statistical Computing). Using Piwik, a secure web analytics through the BC Children’s Hospital Research Institute, specific user engagement data were gathered from February 20 to May 2, 2018. The semistructured interview transcripts were uploaded to NVivo 11 (Lumivero) and read by 2 researchers. Inductive analysis was performed to identify emerging themes that were further refined through collaborative analysis with the first author and coinvestigator [35]. The highlighted text was coded into nodes representing similar or repeated ideas. Some text was coded to >1 node, reflecting the number of ideas presented. The nodes were categorized into specific themes, forming a thematic map that was later discussed with the research team. To enhance the validity of the findings, a triangulation approach was used. This involved cross-referencing data from the quantitative survey and the subsequent 2 phases of this study.

**Ethical Considerations**

This study received ethics approval by the Children’s and Women’s Research Ethics Board (H18-00036). Informed consent was obtained from all the participants included in this study. The study data were anonymized and deidentified. All data were stored in an encrypted file only accessible to the research team involved in the analysis of the study. Compensation was not provided to those who had completed the survey. A CAD $25 (US $18.38) honorarium was provided to those who completed an interview.

**Results**

**Participant Characteristics**

Participants were recruited from 2 abortion clinics in Vancouver, British Columbia. A total of 62 participants were recruited and completed the baseline survey. Of the 62 participants recruited, 25 (40%) women and people who can become pregnant...
responded to the follow-up survey. We investigated whether systematic differences existed between women who responded and those who did not. Table S1 in Multimedia Appendix 1 provides a summary of the demographic information from the baseline survey and a comparison between responders and nonresponders. There were no substantial differences between these 2 groups for any of the variables listed, although there was a nonsignificant trend for the responders to have a lower Arizona Integrative Outcomes Score. These results were not statistically significant ($P<.05$). All the participants identified as ciswomen.

For the qualitative interviews, of the 25 participants who completed the exit survey, 6 (24%) consented to participate in semistructured individual interviews. These were conducted via telephone.

**Quantitative**

**Change in Contraceptive Method**
Most of the respondents (22/25, 88%) indicated that they had changed their contraceptive method to an intrauterine device (IUD) at the time of their abortion, and 21 (95%) of the 25 respondents indicated that they had changed to a Mirena, whereas 1 (4%) of the 25 respondents indicated changing from a copper to Mirena. The contraceptive method of choice was not influenced by the website; however, the website and email notifications helped reassure participants about the signs, symptoms, and effectiveness of the IUD.

**System Usability Scale**
The SUS comprised 10 questions [36]. The average SUS was 81.5 (SD 9.7), and the median was 82.5 (IQR 77.5-87.5), which revealed that 75% (19/25) of the respondents indicated an SUS score >77, which is a very high score.

**Satisfaction**
Most of the respondents were satisfied with the website. Figure 1 graphically displays these results as percentages.

**Qualitative**

**Overview**
Qualitative analysis of the interviews was completed using thematic analysis including both inductive and deductive themes. Nine key themes were identified and are listed in Textbox 1.
Textbox 1. Key themes.

**Ease of Use**

Overall, there was unanimous agreement that myPostCare was easy to use with an organized and easy-to-navigate design. One participant highlighted the following:

> I thought it was very easy to use, which I really liked. I felt the information was well laid out with the menu sidebar on the side. The writing was easy to interpret and was not overly scientific. It was easy to navigate throughout the whole website. It didn’t feel like I was reading a research article. It was nicely spaced out and got to the point very quickly. [participant 3]

Furthermore, the language was accessible and user friendly. The participants felt that the drop-down features were very effective. We added this feature after the usability testing from phase 2, and therefore, it was consistent among our participants to hear that they appreciated this feature. The participants were highly satisfied with the ease of use of myPostCare. When asked about ease of use as it pertained to the information, 1 participant shared the following:

> The information there was superb. It was very user-friendly. Anyone could use that and get what they were looking for, no problem. [participant 5]

**Usefulness of myPostCare**

We asked about the overall usefulness of myPostCare by asking separately about the website and email notifications. Participants were satisfied with the overall frequency and timing of the email notifications:

> I like there was one email per week, it was not overwhelming. It gave you time to go back to the website in increments, not getting overwhelmed and not having it constantly on your mind, but it was a good refresher every week. This is what I needed. [participant 3]

> The timing was impeccable when you would get these e-mails and what you would be feeling. When they would come, they were right on point. I always felt like someone was at my fingertips if I needed help. [participant 5]

They found that the emails helped to navigate the recovery process from immediate signs and symptoms, emotional well-being, and contraception decision-making to general sexual health, such as a better understanding of their menstrual cycle. They also found that the emails helped them feel supported and not alone. This was an important point that resonated with all participants interviewed. A few participants stated the following:

> When I would get the email it would say, “Okay, now you might be going through this and this and this,” it gave me a moment to be like, “Right, I am. I might be going through this. I’m still having some symptoms. How am I actually feeling?” It was a reminder to check in with myself and also to think about how I may be experiencing symptoms at that time. [participant 1]

> It was nice to feel as though there was “someone” checking up on you even though it wasn’t a person. There was new content with each e-mail and helped to direct you to different stages of recovery process. I found that helpful. [participant 1]

The participants unanimously stated that myPostCare provided them the support that was needed at the right time. It was helpful for the resource to provide support over time and that it allowed them to navigate various aspects of their postcare journey. A few participants shared the following:

> I felt like I was cared for. It was amazing to get, “Hey, I hope you’re doing okay. Take care.” It just felt that someone was there for me and saying if you need to call or anything, you can at any time. [participant 2]

> I think this is a great resource. It was a really beneficial thing for me to have, for sure. [participant 6]

**Website**

Overall, all participants stated that they did not have a favorite page but that each category was helpful depending on the stage at which they were in the recovery process. Each participant mentioned that the Postprocedure care page and the Emotional Well-Being Support tool were the most effective:

> I think this is a great resource. It was a really beneficial thing for me to have, for sure. [participant 6]
The emotional well-being tool was helpful. I liked how each emotion had a little blurb about it. I liked the meditation. [participant 2]

Talking about various emotions that occur was important because I found that one week I felt one way but then all of a sudden I would feel different. It was nice to go back to the website, have those feelings identified and made me feel normal. [participant 3]

Most found that the emails were well timed with the website, and providing links embedded within the emails to direct participants to the website was appreciated. Participants stated that they did not click on the emotion “Good” but did use the suggestions provided such as the meditation, journaling, and going for a walk:

I wrote an entire journal entry one day, and that was really good and definitely got some crying out while I was doing that, so I think the website prompted me to do that that day, yes. [participant 3]

Just going through and trying to be at one with this, checking in, using the tools. There was good days, bad days. I have a wonderful program at work as well but I didn’t have to reach out to it because there was stuff here about meditation and making sure that I am looking after myself and doing something nice for myself. [participant 5]

In addition, a participant commented that the website had credible information, which helped to answer questions that she would have seen her physician about and, therefore, kept her out of the office or emergency room. When further asked if the website helped her understand when to seek hospital care, she mentioned that it was very clear. She specifically found the website helpful in preventing women from misunderstanding the website as a substitute for clinical care:

It [myPostCare] kept my husband and I out of emergency rooms...Here we are, two weeks and three days, and all of a sudden there’s an email about IUDs being that you could have spotting for three to six months. I am like, “Okay, We are good.” Then the bleeding stopped. It was just very empowering to have that information. [participant 5]

Finally, some participants found the website useful to support them as they did not have anyone else to talk to about their abortion, and the website helped them not feel isolated:

I went every time I got an e-mail and then there were two times that I went on it by myself when I was feeling pretty emotional and the emotional support tool helped. [participant 2]

It was good for me because I didn’t tell anybody. I didn’t have anyone to talk to. [participant 4]

It [myPostCare] is so critical, and I hope it never goes away and that it’s there for as long as women need this procedure. I hope that this site is always there. It was truly instrumental to my whole well-being through this whole procedure, so I thank you. [participant 5]

Frequency of Use

Participants used the website on its own but also clicked on the links within the emails. Some participants saved all the emails so that they could return to them. Using the website for 1 month seemed to be sufficient for all participants. One participant stated that she had visited the website 10 to 15 times:

I went every time I got an e-mail and then there were two times that I went on it by myself when I was feeling pretty emotional and the emotional support tool helped. [participant 2]

Time Spent on Website

The time spent on the website, as expressed in the qualitative interviews, was consistent with the results from the web-based analytics presented in the Web-Based Secure Analytics section. Most participants stated that they were on the website for anywhere from 2 minutes to 1 hour:

I’d probably went all together 10 to 15 times. There was one time I was on it for probably an hour, but the other times, it was probably anywhere between two to five minutes. [participant 2]

I’d say around half an hour: [participant 3]

Maybe the first couple of weeks, I kind of looked at it. I looked through it for half an hour at dinner, 20 minutes, 15, half an hour. [participant 4]

...going to guess at least an hour going back through, making sure I didn’t miss anything going to the link, so at least an hour. [participant 5]

Suggestions for Improvement of myPostCare

There was a strong sentiment to include blogs and stories shared by women and people who can become pregnant and have undergone an abortion. This was available on the website, but these were found under the “Good” emotion. Many did not necessarily explore this section and mentioned that if they were feeling good, they did not necessarily explore the emotional support tool and would be keener on using the Contraception Explorer or Sexual Health pages. Furthermore, suggestions to add these on the main landing page or to have rotating articles that are specific to women and people who can become pregnant telling their stories would be very useful. This was highlighted by participants as a means of further enhancing the community feeling and not feeling alone in their experience. When further explored, this also highlighted that sharing stories was also a way to help destigmatize the experience that many women and people who can become pregnant and who participated in our interviews had internalized. The following excerpts highlight this theme:

I really wanted to hear someone’s story that was positive. I would have liked to listen to just having a couple of people’s stories and how it affected them just to compare myself to them. I don’t know. [participant 2]

Putting up videos or even having articles on different stories. [participant 2]
For me personally, if I’m feeling good or when I was starting to feel good about myself again, I wouldn’t have gone on the website to check that. [participant 2]

I think more testimonials and more quotes that you can use on that website from people who have been through the experience, the better because it gives validation for what women are going through and kind of makes us feel less alone. [participant 6]

The more testimonials and the more feedback you can get from women of all ages, all experiences, all the better. [participant 6]

**Recommend to a Friend**

All participants who were interviewed would recommend myPostCare to a friend. Some also suggested that this would be specifically good for friends who did not necessarily feel comfortable going to their physician or who did not have a family physician with whom they had a trusting relationship:

Yes, I think it totally would. I think it’d be very helpful to have. I don’t think it’s going to solve a friend’s problems or anything, but for me, it was helpful to have. [participant 2]

Yes, and it’s definitely one that I want to, like, if I ever know somebody that is going through that, I’m definitely going to recommend that to them. [participant 3]

I really would. This is a great resource for the person that doesn’t think that their issues always warrant a call to their doctor. [participant 6]

**Privacy and Security**

Our participants were satisfied with the level of privacy and security afforded by the emails and website. In particular, they noted that the emails were separate from the website, and some participants suggested that it would be essential to keep it this way when myPostCare would be made live. One participant stated the following:

It’s very discrete, and I liked that. The login is required to get on the website, so to me, it was certainty sufficient. My name is not all over the website, so even if I left it open, it is what it is, who knows what I was in. It’s not too specific so I was never worried if I had it open in public. [participant 5]

**Design Features**

All participants stated that the design was professional and the language was unbiased. Many participants commented that the design of the website and emails was calming and supportive. They also enjoyed the consistency between the website and email notifications. Words such as “clearly thought out,” “pleasant and cool pictures,” “nice blues and greys,” and “positive and well-crafted” came up frequently among our interview participants. One participant commented the following:

Overall, I don’t know if this is weird to say, but it was very calming. Approachable in a sense. It doesn’t hurt your eyes to stay on the website for a while. I really liked the colours. The layout was easy. [participant 6]

Other participants noted that the site was structurally thought through and that the design was relatable to them. One participant highlighted the following:

I thought it was clearly thought out and structurally too. The language is nicely worded and was very unbiased. [participant 2]

It was very nice and pleasant, the pictures were very cool. I liked the ranges of things that were on there, the whole thing about meditating and then also just needing actual straight up information was really helpful too. [participant 2]

Very soothing colours. The nice blues and then greys, yes. [participant 2]

I thought it was very easy to use. I felt that the information was well laid out with the menu sidebar. The images were quite big and spaced out so had to scroll quite a bit and not get through a lot of information. [participant 3]

There was no harsh colours. There was no in-your-face type of things that popped into the website. I liked there were no advertisements. I think the peacefull colourings, the “click this if you feel called to.” It’s nice to have that sense of well-being with positivity on a sensitive topic, it was well crafted. [participant 3]

**Recommend to a Friend**

All participants who were interviewed would recommend myPostCare to a friend. Some also suggested that this would be specifically good for friends who did not necessarily feel comfortable going to their physician or who did not have a family physician with whom they had a trusting relationship:

Yes, I think it totally would. I think it’d be very helpful to have. I don’t think it’s going to solve a friend’s problems or anything, but for me, it was helpful to have. [participant 2]

Yes, and it’s definitely one that I want to, like, if I ever know somebody that is going through that, I’m definitely going to recommend that to them. [participant 3]

I really would. This is a great resource for the person that doesn’t think that their issues always warrant a call to their doctor. [participant 6]

**Privacy and Security**

Our participants were satisfied with the level of privacy and security afforded by the emails and website. In particular, they noted that the emails were separate from the website, and some participants suggested that it would be essential to keep it this way when myPostCare would be made live. One participant stated the following:

It’s very discrete, and I liked that. The login is required to get on the website, so to me, it was certainty sufficient. My name is not all over the website, so even if I left it open, it is what it is, who knows what I was in. It’s not too specific so I was never worried if I had it open in public. [participant 5]

**Design Features**

They also enjoyed the consistency between the website and email notifications. Words such as “clearly thought out,” “pleasant and cool pictures,” “nice blues and greys,” and “positive and well-crafted” came up frequently among our interview participants. One participant commented the following:

Overall, I don’t know if this is weird to say, but it was very calming. Approachable in a sense. It doesn’t hurt your eyes to stay on the website for a while. I really liked the colours. The layout was easy. [participant 6]

Other participants noted that the site was structurally thought through and that the design was relatable to them. One participant highlighted the following:

I thought it was clearly thought out and structurally too. The language is nicely worded and was very unbiased. [participant 2]

It was very nice and pleasant, the pictures were very cool. I liked the ranges of things that were on there, the whole thing about meditating and then also just needing actual straight up information was really helpful too. [participant 2]

Very soothing colours. The nice blues and then greys, yes. [participant 2]

I thought it was very easy to use. I felt that the information was well laid out with the menu sidebar. The images were quite big and spaced out so had to scroll quite a bit and not get through a lot of information. [participant 3]

There was no harsh colours. There was no in-your-face type of things that popped into the website. I liked there were no advertisements. I think the peacefull colourings, the “click this if you feel called to.” It’s nice to have that sense of well-being with positivity on a sensitive topic, it was well crafted. [participant 3]
there were some things that I felt like it was only me or it wasn’t normal, and then it would say something on the website that would make me feel better, more calm. [participant 2]

I would just grab my phone and then just go, look at the thing and, “Okay, this is normal to feel like this.” I don’t know if I had a favourite part, but I just found that everything was useful. [participant 4]

It was my other rock. My husband was my one rock, and the other one was this. It knew when things were going to happen, and when I was panicking about things, all of the sudden, there will be an e-mail. It was just perfect timing, and it was amazing. It truly was. I felt like I wasn’t alone. I went through every link. Even the links that were outside the website, I checked out every one of them. I read stories. It brought a sense of calm to me, I guess. It was truly, I never had such a good experience off of a website like this one. It was amazing. My husband went through everything. You would be panicking, I don’t know how many times we went back to this website to make sure that something that was going on wasn’t out of the ordinary, and of course, there would be, that it wasn’t out of the ordinary, so it was amazing. It truly was. [participant 5]

No, I think overall it was pretty straightforward. There wasn’t anything that I was surprised to see, and there wasn’t anything that I can remember that didn’t kind of fit in with what was expected through the e-mails. It all kind of made sense. [participant 6]

I think it was just a great experience to trial the website. I have my own personal reasons for my procedure and how I came about doing so, but I think it’s a great source for people that want to have that sense of community. I think it works really well for the specific areas that you’re trying to find more clarity. [participant 6]

Web-Based Secure Analytics

Table 1 presents the analytics results. Specifically, of the 62 participants, the number of unique visitors on the website was 61 (98%). Although only 25 participants completed the exit survey, all participants except 1 (98%) visited the website at least once. The number of returning visitors was 42. The average daily page views were 5; the total number of page views through the study period was 432; the highest number of hits at a single visit was 35; and the top 3 pages were Postprocedure Care, Emotional Well-Being, and Contraception Explorer. In total, 75% (47/62) of the participants were mobile users and 25% (16/62) were desktop visitors. The most popular contraceptive page visited was the IUD. The details of the number of page views throughout myPostCare are presented in Table 2.

Email Notifications Analytics

Among the 62 participants enrolled, 2 (3%) unsubscribed from email notifications after the “Welcome Message” on day 0, and 2 (3%) participants’ email address was not valid. The average open rate was 80%, and the click rate was 36%. The highest open and click rates were for Welcome Message at 73.1% and 31.3%, respectively. Interestingly, the desktop device was 57.4% and mobile was 42.6%, which is different from the device from which the website was viewed. The email open rates were higher than the click rates throughout. The open rates declined for both IUD and no IUD over time; however, they remained stable at an average of 53.7% and 53.8%, respectively. Figure 2 graphically represents data of the IUD versus no IUD streams open and click rates for given days.

Figure 2. Comparison of email open and click rates for intrauterine device (IUD) versus no IUD stream in percentage.

Discussion

Principal Findings

myPostCare is the first comprehensive web-based postabortion tool in Canada and has the potential to be integrated as part of family planning services. Integration of myPostCare into clinical practice provides an opportunity to consider a new approach to supplement follow-up care for abortion care specifically but women’s health generally. This study demonstrates the design and development of a comprehensive mobile intervention to facilitate care for women and people who can become pregnant and undergo a procedural abortion to support and normalize the emotional and physical aspects after abortion. We used a human-centered design methodology, an iterative development process that was informed by input from key stakeholders such as patients, family planning experts, and administrators involved in abortion care [22,37,38]. The results from the pilot evaluation of myPostCare demonstrated that it was feasible, acceptable, and satisfactory for women and people who can become pregnant.

Specifically, this 3-phase study demonstrates the importance of including the end users and key stakeholders in the design, development, and evaluation of a mobile intervention that services a population and health care issue that continue to be stigmatized. Formative research has provided important information regarding women’s interactions with technology, their needs and desires around follow-up and access to information, and feedback on design, which is essential for the success of myPostCare. A unique finding of this study that was
supported in the literature was the importance of including a component of emotional support as part of follow-up abortion care [39]. Furthermore, we learned that the success of myPostCare was not only owing to the interactive tools and information provided by the website but that the appropriately timed automatic email notifications that women received was an important aspect of their care throughout the 30 days after the procedure. An iterative design process was important to ensure that the research team was continually evaluating that myPostCare realized the needs of the target users.

We adopted a few theoretical frameworks, all of which use a comprehensive participatory approach to developing eHealth technologies. This was similarly performed by Gilbert et al [38] in the development of Get Checked Online, a web-based sexually transmitted infection testing resource. More specifically, integrating the Technology Acceptance Model and Theory of Reasoned action with the human-centered design methodology, we used a holistic approach to developing myPostCare. According to the Technology Acceptance Model, perceived ease of use and perceived usefulness of a system are the 2 predominant indicators of system adoption [27,32]. Participants in our study were accustomed to using some form of technology, either mobile phones or computers; did not require acquisition of new skills; and were keen on developing a technology-based tool to support follow-up care after an abortion. Importantly, myPostCare will not eliminate structural barriers to comprehensive abortion care, and although it may not directly affect health behavior and decision-making, it may assist in making the delivery of abortion care more efficient, convenient, patient centered, and accessible.

myPostCare is a unique addition to the literature because of its methodology and outcome. There is evidence to support eHealth technologies to improve health care; however, currently there is limited research on mobile interventions specifically to address postabortion care, although there are various interventions for contraception use. A randomized trial in Cambodia demonstrated that involving women in the design and testing of a mobile intervention to support postabortion contraception led to more women in the intervention group reporting use of effective contraception at 4 months; specifically, the use of long-acting contraceptives was higher in the intervention group at 4 and 12 months after the procedure [40].

Previous feasibility trials focused on usability and acceptability have highlighted the importance of conducting a pilot study first, which can then assist with the design of a larger randomized trial to measure effectiveness [41]. Finally, similar to studies on the development and testing of contraception tools, the integration of evaluation in real-time clinical care is essential to ascertain the barriers and challenges to implementation in the future [22].

The limitations of this study include overall generalizability to other populations, small convenience sample sizes for all 3 phases, loss to follow-up and low response rates in this challenging population, and recruitment bias. The sample size of 6 participants in the qualitative interviews was small, ideally requiring 20 participants to achieve meaningful saturation. Given that this study is an extension of 2 previous phases, researchers felt confident in the analysis being generalizable compared with the findings of the 2 previous phases and from previous studies highlighting the type of gaps that myPostCare fills as per the participants’ reflections. As it pertains to recruitment bias, those who consented to participate were likely individuals who are more engaged with technology, have higher socioeconomic demographics, and are more likely to be early adopters of a digital health intervention to support abortion care. In previous studies, this is referred to as a Digital Divide, which suggests that although many developers of technology-based health interventions are optimistic about their impact; this needs to be balanced by the fact that the pattern of adoption is along social gradients [38]. New technologies such as myPostCare may further reinforce these social divides. Furthermore, abortion continues to be a stigmatized issue, which can be a limitation for research, as this can be a sensitive topic for most and posed difficulties with recruitment and loss to follow-up in our study.

We evolved throughout each phase of the study to consider the challenges faced with patient engagement. For instance, recruitment took longer than expected for the qualitative interviews. We assumed that lack of participant engagement may be associated with stigma about abortion. In addition, we recognized that conducting research immediately after the procedure might be a sensitive time for individuals. This will need to be taken into consideration for future studies, particularly when thinking about diversifying the participants recruited and obtaining robust response rates for analysis.

Balancing these limitations are the strengths of our study, including the successful development of human-centered design elements, wide stakeholder engagement, diverse expertise on the research team, a large proportion of our sample size that was from rural locations, rigorous research methodologies, iterative design process, and development of the first web-based postabortion tool in Canada.

Further research could involve evaluating the effectiveness of myPostCare.ca and the overall patient experience through a randomized controlled trial. In addition, as suggested in other web-based literature [38], a health equity impact assessment with expert consultation and literature review may also help identify ways in which myPostCare reinforces or alleviates health inequities in sexual health services.

**Conclusions**

myPostCare was found to be feasible and acceptable to women and people who can become pregnant to support follow-up care after a procedural abortion. There are obvious digital divides in health care specifically, as there are limited digital tools for women’s health in Canada. Thus, there is great potential for expansion of myPostCare. More specifically, since the introduction of Mifepristone in Canada, the first area of expansion will be for medication abortion. Generally, the expansion may then involve other aspects of women’s reproductive health.

We learned that key stakeholder engagement and understanding the organizational context are important. These factors are important for ongoing research initiatives and their implementation in clinical practice. Engaging stakeholders and potential users in a participatory process throughout the entire design and development of myPostCare was crucial to its
success. Applying an iterative design and evaluation process that was flexible and dynamic, considering the factors of implementation at the outset, keeping in mind how myPostCare could change health care delivery, and the use of a multidisciplinary team were all unique and important aspects.

This study demonstrated that a technology-based intervention for postabortion care is feasible and acceptable. The success of myPostCare was based on the incorporation of a multidisciplinary team; participatory user-centered design process; robust stakeholder engagement; and the provision of nonjudgmental, nondirective, and medically accurate information. This study provides an example of the ongoing development of technology-based family planning services and is aligned with a larger gender-equitable, evidence-based programmatic agenda in Canada.

Abstract

Background: A new app, Sukaribit, was designed to enable contact between the caregiver and the patient with the intent to improve self-care and glycemic control (hemoglobin A1c [HbA1c]).

Objective: This study investigated the feasibility of the study methodology and the intervention in preparation for a larger effectiveness study.

Methods: Adults with type 2 diabetes were recruited in this randomized controlled feasibility study with a mixed methods design. The intervention group (n=28) tried Sukaribit for 2 months. They were encouraged to report blood glucose levels and medications, and they received feedback from a physician. The control group (n=31) received standard care. Both groups were evaluated with pre and postmeasurements of glycemic control (HbA1c), diabetes distress, physical activity, and self-care. Feasibility was evaluated against 5 progression criteria regarding recruitment, study methods, and active participation.

Results: Of the 5 progression criteria, only 2 were met or partially met. The recruitment process exceeded expectations, and data collection worked well for self-reported data but not for HbA1c measured with a home testing kit. The participants were less active than anticipated, and the effect sizes were small. Only the number of blood glucose tests per day was positively affected by the intervention, with 0.6 more tests per day in the intervention group.

Conclusions: Recruitment of participants to a future fully powered study may work with minor adjustments. The collection of HbA1c using home testing constituted a major problem, and an alternative strategy is warranted. Finally, the app was not used as intended. In order to proceed with a larger study, the app and study procedures need improvement.

Introduction

Background

Type 2 diabetes is a serious disease affecting the prognosis of many other diseases, including cardiovascular disease. Diabetes increases the risk of acute myocardial infarction, stroke, and heart failure [1,2]. To reduce the risk of both microvascular and macrovascular complications, it is important to control blood glucose levels [3] (ie, glycemic control), blood pressure, and lipid levels [4]. For people with type 2 diabetes, a prerequisite for good glycemic control is regular and frequent self-monitoring and knowledge of how blood glucose levels respond to food and physical activity. Many patients have
elevated levels of blood glucose, which suggests that self-management is often suboptimal [5].

Diabetes and Mobile Apps

Even if technical solutions to support diabetes self-management, such as smartphone apps, have become more common, they are used by a minority of patients [6]. It is not clear how many people use diabetes apps in Sweden, but in Australia, only 8% of people reportedly use diabetes mobile apps [6], despite almost unlimited availability with thousands of apps on the market. Reasons for people with diabetes to not use apps can be unawareness of their existence, technical literacy barriers, no need (the disease is not that bad or self-management is sufficient anyway), no recommendation from a health care professional, the resulting increased accountability for one’s own behaviors, or the time-consuming nature of some apps [7,8]. However, studies have shown that people with type 2 diabetes want to use smartphone apps, to reduce not only the practical burden but also the cognitive and emotional burden of diabetes self-management [9]. Studies also have shown that patients want to have more contact with their nurse or physician through digital media than is the case today [9,10]. The most effective app-based technical solutions, in terms of the potential to reduce hemoglobin A1c (HbA1c), are interactive and include components such as patient-generated health data, individualized feedback, 2-way communication, and tailored education [11,12]. These components are in line with the 2 behavior change techniques of “feedback on behavior” and “self-monitoring of behavior” that are associated with better glycemic control [13].

Figure 1. How the diabetes app is intended to improve glycemic control.

Sukaribit Smartphone App

The smartphone app Sukaribit (Beta version 1.1, Maishabit AB) was developed with a special focus on the interaction between the patient and caregiver. It has an intentionally basic design to be usable with more basic mobile phones, as it needs less capacity. The app stores and displays blood glucose measurements (patient-generated health data), enables digital 2-way patient-physician or nurse communication, provides individualized feedback, and delivers tailored education. For example, if the person with diabetes enters blood glucose measurements or steps (self-monitoring of behavior), the clinician can provide individualized feedback via the 2-way communication mechanism. The physician can give advice about medications or empower health-related behaviors (feedback on behaviors). The app aims to result in more frequent measurements, better blood glucose control, and better self-efficacy, which could be reflected in more optimal HbA1c (see Figure 1). Sukaribit aims to complement standard care by enabling feedback from the caregiver when patients are not at the clinic. There are several diabetes apps on the market. However, the American Diabetes Association requests longer-term clinical evidence, and clinical outcomes have been published in peer-reviewed literature for only a few diabetes smartphone apps [14]. In line with the British Medical Research Council guidelines for developing and evaluating complex interventions [15], this is the first scientific evaluation of the feasibility of the diabetes app Sukaribit.

Aim

The purpose of this study was to investigate the feasibility of the study methodology and the intervention before conducting a larger effectiveness study. Our research questions were as follows: (1) Are the study procedures feasible and effective? (2) Is the Sukaribit smartphone app (version 1.1) usable and accepted by people with type 2 diabetes? (3) How large are the effect sizes for the use of the Sukaribit smartphone app on HbA1c and other potential outcomes? In line with recommendations for feasibility evaluations, we developed predetermined progression criteria to decide whether to proceed to a full-scale randomized trial [16].

Methods

Research Design

The study was a randomized feasibility study with pre and postmeasurements from an intervention group and a control group. The control group received standard care. The report follows the Consolidated Standards of Reporting Trials (CONSORT) guidelines [17].

Ethical Considerations

The trial protocol was approved by the Swedish ethical review authority (diary number 2020-04894), and the participants provided written informed consent.

Progression Criteria

The aim was to study (1) the feasibility of study procedures and (2) the usability and acceptability of the intervention. This follows general recommendations for pilot studies by Avery et al [16]. In addition, we also studied (3) preliminary effect sizes (see the Preliminary Effect Sizes section). Aims (1) and (2) were evaluated against predetermined progression criteria (see Textbox 1) [16]. These progression criteria were set prospectively by the authors considering the possibility of finalizing recruitment of participants for a fully powered randomized controlled trial (RCT) within approximately 2 years and having an activity level in the intervention high enough to draw conclusions about its use. If the progression criteria were met, this indicated that a larger study is feasible using the procedure evaluated; otherwise, revisions should be considered.
Feasibility data were collected in a log by the research assistant, and the automated activity log from the Sukaribit app was shared with the researchers by Maishabit AB. To further explore if the app is usable and accepted by people with type 2 diabetes, an additional qualitative evaluation was conducted. Participants were asked open-ended questions in the portal about opinions and possible improvement of the app. The intervention group also participated in semistructured telephone interviews for further input about the acceptability of the intervention. The interview guide contained questions about the participant’s diabetes, self-care, and study participation, as well as about the mobile app. The interviews were audio-recorded (average length: 25 minutes) and transcribed. The physician was also interviewed about participation with a separate but similar interview guide.

Participants and Procedures

The study included 59 adults (age >18 years) with type 2 diabetes. Exclusion criteria were other serious illnesses, HbA1c >70 mmol/mol, BMI <25 kg/m², no regular access to the internet, and not owning a blood glucose monitor. The following 2 initial exclusion criteria were abandoned as they were not that important and not feasible for effective recruitment: people with HbA1c <50 mmol/mol (4 were initially excluded) and an age >65 years.

Participants were recruited (between February 2021 and April 2021) at health care centers in Uppsala, through nationwide adverts in 3 major Swedish newspapers, and via advertising on the national Swedish Diabetes Federation’s web page and in diabetes-specific social media groups. People with type 2 diabetes reported their interest on a study-specific website hosted by Uppsala University or directly to the research assistant via email or telephone. Thereafter, they were contacted by the research assistant who informed them about the study. People who were still interested provided written consent to participate. Thereafter, the research assistant checked the inclusion and exclusion criteria preliminarily and ensured that the participant had a pedometer app on their smartphone or helped them install one.

Participants were sent a home testing kit for HbA1c, which meant that they took a blood sample at home and sent it to an accredited laboratory for analysis. As recruitment proceeded, the authors recognized that the wait time for baseline HbA1c test results could be long (mean 15.6, SD 6.4 days). Therefore, we decided to include and randomize participants before the HbA1c test results arrived and exclude them afterwards if necessary; 4 participants were excluded on this premise.

All questionnaires were administered using the Uppsala University Psychosocial Care Program (U-CARE) Portal (the portal). The participants answered the questionnaires at the time of randomization and 8 weeks later (a delayed response of a maximum of 18 days was allowed). Randomization occurred in the portal (see the following paragraph), was totally automated, and occurred in blocks of 6 immediately after the completion of baseline questionnaires.

Those randomized to the intervention were supported in downloading the Sukaribit smartphone app and had a brief user education via telephone. They also received instructions in a PDF brochure. The intervention group was asked to share their blood glucose measurements in the app. Additional follow-up support was requested by 5 participants, as they were uncertain of particular features of the app (eg, input of medications). Those randomized to the control group received standard care [18]. All participants were contacted 2 months later for follow-up data. Those who participated in the intervention were also asked to participate in a semistructured interview about their experience with the intervention. Of those invited to the interview, 16 participants accepted (3 people declined) and were interviewed via telephone by 1 of the 2 research assistants.

### Preliminary Effect Sizes

In addition to the feasibility of the app, the preliminary effect sizes of the Sukaribit smartphone app were also explored. They could be used to calculate the sample size for a fully powered study. Effect sizes were studied for (1) HbA1c, (2) number of blood glucose measurements reported the previous week, (3) physical activity, (4) general self-rated health (visual analogue scale from the EQ-5D) [19], (5) diabetes self-management, and (6) diabetes-related distress. This study only explored the changes in these measures, as the study was not sufficiently powered to detect efficacy.

HbA1c was analyzed from a home testing blood test at an accredited laboratory. The blood glucose measurements were recorded by the participants in their own diary of choice and reported in the portal as an outcome. The intervention group could use the app to record their measurements. Physical activity was measured as steps via pedometers on the participants’ smartphones, and the last 7 days were reported in the portal.

Participants also reported the number of occasions per week over the last month they had exercised more than 30 minutes for fitness purposes. Diabetes self-management was measured using the Diabetes Self-Management Questionnaire (DSMQ) [20,21]. The DSMQ has 16 items divided into 4 subscales, namely (1) glucose management, (2) dietary control, (3) physical activity, and (4) health care use, with a maximum score of 64. A higher score indicates higher frequency of diabetes self-care behaviors. DSMQ has shown good psychometric properties in several contexts [21]. The Diabetes Distress Scale (DDS) was used to measure diabetes distress [22]. The DDS has 17 items divided into 4 subscales, namely (1) emotional burden, (2) physician-related distress, (3) regimen-related distress, and (4) diabetes-related interpersonal distress, with a maximum score of 102. A higher score indicates more distress. DDS has shown good psychometric properties in several contexts [22].

The Intervention

The intervention group used the smartphone app Sukaribit (version 1.1) for 2 months. In this app, participants entered their medication list, blood glucose levels, and (optionally) blood pressure levels. Participants could choose to send the recorded measurements to the study physician or not. They were encouraged to send blood glucose measurements at least once a week. The physician was a specialist in family medicine and an associate professor in general practice. She actively participated in the design of the study and evaluated and proposed changes to the app. When measurements were sent, the physician responded with feedback to the participant. All communication occurred through the Sukaribit app. The physician encouraged participants who did not send measurements on their own initiative to register and provide the requested information. This was done at least once for each participant at the start of intervention and regularly approximately once a week if no measurement was sent by the participant during that time. The physician checked messages and measures once a week and replied. There were 2 versions of the app: one for Android and one for iOS.

Data Analysis

The collected data on recruitment and intervention use were compared with the prespecified progression criteria to decide if they matched. Qualitative data were analyzed with quantitative content analysis [23]. Data from both the interviews and open-ended questions were analyzed together. Within and between-group effect sizes (Cohen d) were calculated for HbA1c and self-reported outcomes, dividing the mean differences with pooled SDs, with the aim of being the basis for statistical power and sample size calculations for a future study. The between-group effect sizes used the pooled baseline SDs as recommended by Morris [24]. A value of $d>0.8$ is classified as a large effect size, $d=0.5$ is classified as a medium effect size, and $d=0.2$ is classified as a small effect size according to Cohen [25]. Preliminary inference statistics were also performed utilizing linear regression analysis with the posttreatment value as the outcome and group allocation, baseline values, sex, and age included as covariates. The adjusted estimate can be interpreted as the adjusted mean difference for the treatment group when compared with the control group (the reference). $P<.05$ was considered significant.

Results

Participant Characteristics

Among the randomized participants (n=59), the majority were male (42/59, 71%), born in Sweden (54/49, 92%), and retired (32/59, 54%). The mean age was 61.1 (SD 10.3) years. Most participants (35/59, 59%) reported being lightly active at baseline (eg, practicing yoga, walking, and gardening), with main health issues including hypertension (39/59, 66%) and dyslipidemia (7/59, 46%). Diabetes complications, including eye disease, neuropathy, kidney disease, or sexual dysfunction, were reported by 29% (17/59). For a complete description of the participant characteristics, see Table 1.
Table 1. Participant characteristics at baseline (n=59).

Feasibility of Study Procedures

Table 2 summarizes the progression criteria fulfilment. There were 182 people that reported interest in participating in the study; of this group, the majority (176/182, 96.7%) registered their interest on a web page. That met progression criterion 1 (n\(\geq\)60) by a good margin. Of the 182 people interested, 133 were reached and assessed for eligibility. However, a considerable proportion of the participants who registered their interest were ineligible or unable to be included in the study; hence, progression criterion 2 (50% inclusion rate) was not met. The main reason for exclusion at this stage was a BMI <25 kg/m\(^2\) (n=26). In total, 55 people were excluded. Of those eligible, 19 people never logged into the portal even after being reminded. Finally, 59 (76%) of the 78 eligible participants were randomized in the study (treatment: n=28; control: n=31). For the complete recruitment flow, see Figure 2.

<tr>
<td>(5) At least 50% of those who participated in the intervention sent at least 8 blood glucose measurements during the 2-month intervention (about 1 per week).</td>
<td>11% (3/28; based on the “Number of sent diagnostic data”)</td>
<td>No</td>
</tr>
</tbody>
</table>
Progression criterion 3, at least 75% complete data at follow-up, was met regarding questionnaire data (81%). However, when also considering HbA1c tests, the completeness was 64%; thus, the criterion was not met. At baseline, 5 HbA1c test results were missing. At follow-up, 11 randomized participants did not complete their questionnaires, and there were 18 missing tests (Table 3). For baseline HbA1c, 41 manual reminders were sent in total; for the follow-up HbA1c, 63 manual reminders were sent. See Table 3 for details.
### Feasibility of the Intervention

Of the 28 participants in the treatment group who completed the study, 27 were active users of the app (i.e., they completed 2299 data entries in total [blood glucose value, blood pressure value, and medications] in the app and sent 211 of the entries to the physician at some point). In addition, they sent 28 text messages to the physician (see Table 3).

For the 4 participants who requested technical support while using the app, the reasons for contact included difficulties logging in, issues with iOS graphic data, messages not being sent, or that the app had stopped working altogether.

Considering progression criterion 4, 76% of the eligible people actually started participating in the study. This was slightly lower than the criterion of 80%. Regarding criterion 5, only 11% of the participants sent diagnostic data 8 times in 2 months; thus, this criterion was not met.

### Client Satisfaction and the Physician’s Evaluation

A summary of the interviews is presented in Table 4. The findings show that smartphones with the iOS operating system were the most commonly used among the responding participants (15/20, 75%). Concerning the overall quality of the app, a majority of the participants reported the app was of fair quality, with only a few of their individual needs having been met. The 4 technical issues reported to the developer mainly concerned the iOS version of the app. The physician had technical problems but thought the contact was rewarding when it worked. She also experienced varying activity from the participants (Table 4).
Table 4. Participants’ (n=20) answers from the telephone interviews and open-ended questions after completing the intervention, as well as the physician’s (n=1) evaluation.

### Overall impression

- The application did not improve self-care.  
- The app improved self-care.  
- The participants were positive about the concept and think the app should continue to be developed.

### The physician’s evaluation

- Lots of technical problems (messages, medicine list)  
- The contact and work were fun when the app worked.
- Disadvantage not being their attending physician  
- The app as a good complement to diabetes care; could consider using it with her own patients  
- Varying participation of the participants; some very active but others never replied  
- Room for many improvements  
- Part of the future

### Effect Sizes of Outcome Measures

The effects of treatment on a number of potential outcomes were analyzed based on complete data. No imputations were used. Both the within and between-group Cohen $d$ values suggested, at best, small effects. The largest between-group effect size ($d=0.36$) was achieved for the EQ-5D-VAS, and the effect was mainly dependent on the decrease in the control group. In the linear regression analysis, only the number of blood glucose tests per day was significant, indicating 0.57 more tests per day in the intervention group than in the control group (adjusted beta=0.57, 95% CI 0.09-1.06). This effect resulted from a reduction of tests per day in the control group, while the treatment group remained at a stable level. See Table 5.

Discussion

In this feasibility study, we explored the prerequisites for conducting a larger study (full-scale RCT) to investigate the effect of the smartphone app Sukaribit on glycemic control. Of the 5 prespecified progression criteria, only 1 was fully met, and 1 was partially met. This indicates that improvements should be considered both regarding study procedures and the intervention before further evaluations. The effect sizes were generally small. Given the low amount of participant activity, this was to be expected.

Feasibility of Recruitment and Data Collection

Considering the recruitment of participants, the number of responses to the advertisements met and even exceeded that specified in criterion 1. However, the proportion of people who could not be reached or were ineligible to participate due to criterion 2 was slightly higher than ideal. Some alterations to the exclusion criteria were already made during the recruitment phase of the study (ie, including people with an HbA1c <50 mmol/mol or age >65 years). This could potentially have resulted in the inclusion of participants with relatively well-managed diabetes (HbA1c <50 mmol/mol) and participants with less technological experience (age >65 years). The remaining exclusion criterion of a BMI <25 kg/m² resulted in the largest number of exclusions. This was thought to exclude participants who would not likely benefit from the intervention.

Adding to the loss of potential participants in the early recruitment phases, the proportion of eligible and initially willing people who did not finally start participating was also slightly lower than that specified in criterion 2 (76% vs 80%). However, we could relatively easily compensate for these losses in recruitment with a longer and more aggressive recruitment campaign and by reconsidering the arguments for the BMI exclusion criteria.

Although data collection from self-reported questionnaires worked well, meaning that progression criterion 3 was partially met, the collection of HbA1c data through home testing kits did not work well. The first problem was the long administration time. The mean time from sending the kits out until the results were received by the project team was 16 days, with the main delay appearing to be at the participant’s home. There was also a large amount of missing data due to both defective tests and missing tests, even though several manual reminders were sent. Hence, there is a need to make the collection of HbA1c data more reliable and efficient. Previous studies have also reported difficulties using these test kits [26]. Better or additional instructions, more telephone reminders, another test kit brand, or another lab are things to consider. Most likely, the biggest advantage can be gained by improving the participant handling of the test and posting. Other ways to handle this could be to

Discussion

In this feasibility study, we explored the prerequisites for conducting a larger study (full-scale RCT) to investigate the effect of the smartphone app Sukaribit on glycemic control. Of the 5 prespecified progression criteria, only 1 was fully met, and 1 was partially met. This indicates that improvements should be considered both regarding study procedures and the intervention before further evaluations. The effect sizes were generally small. Given the low amount of participant activity, this was to be expected.

Feasibility of Recruitment and Data Collection

Considering the recruitment of participants, the number of responses to the advertisements met and even exceeded that specified in criterion 1. However, the proportion of people who could not be reached or were ineligible to participate due to criterion 2 was slightly higher than ideal. Some alterations to the exclusion criteria were already made during the recruitment phase of the study (ie, including people with an HbA1c <50 mmol/mol or age >65 years). This could potentially have resulted in the inclusion of participants with relatively well-managed diabetes (HbA1c <50 mmol/mol) and participants with less technological experience (age >65 years). The remaining exclusion criterion of a BMI <25 kg/m² resulted in the largest number of exclusions. This was thought to exclude participants who would not likely benefit from the intervention.

Another way to facilitate the recruitment process could be to add inclusion or exclusion questions on the study-specific website to better be able to reach the right target group.

Adding to the loss of potential participants in the early recruitment phases, the proportion of eligible and initially willing people who did not finally start participating was also slightly lower than that specified in criterion 2 (76% vs 80%). However, we could relatively easily compensate for these losses in recruitment with a longer and more aggressive recruitment campaign and by reconsidering the arguments for the BMI exclusion criteria.

Although data collection from self-reported questionnaires worked well, meaning that progression criterion 3 was partially met, the collection of HbA1c data through home testing kits did not work well. The first problem was the long administration time. The mean time from sending the kits out until the results were received by the project team was 16 days, with the main delay appearing to be at the participant’s home. There was also a large amount of missing data due to both defective tests and missing tests, even though several manual reminders were sent. Hence, there is a need to make the collection of HbA1c data more reliable and efficient. Previous studies have also reported difficulties using these test kits [26]. Better or additional instructions, more telephone reminders, another test kit brand, or another lab are things to consider. Most likely, the biggest advantage can be gained by improving the participant handling of the test and posting. Other ways to handle this could be to
conduct this kind of trial within the health care system so that the blood test is managed by health care professionals and not by the participant. Another thing that we could have done differently is to not have HbA1c as an inclusion criterion. In a full-scale trial, the participant’s glycemic control at the start of the intervention could be a minor issue, since it is the effect of the intervention (the difference) that is measured.

Feasibility and Acceptability of the Intervention

Not all eligible participants who signed up for the trial started the intervention (progression criterion 4). We do not know the reasons for this; possibly, they just regretted the enrollment. When or if conducting a larger study, the possibility that not all who are accepting of study participation will actually join the study needs to be considered.

A few of the participants in the qualitative evaluation thought that the app improved self-care, but the majority did not think so. Many participants appeared to have been less active than anticipated, especially based on the amount of diagnostic data and messages sent to the physician. This was progression criterion 5, which was not met. Some participants described technical issues that interfered with the use of the app (eg, lack of access to pedometer data in the app as well as difficulties logging medications and viewing summary features). These problems could most often be related to the iOS version. This could have had an impact on user motivation leading to less activity. Participants also suggested improvements in the message function and added features when logging data (eg, in the calendar function, graph) in order to make the app more user-friendly. For the app to be beneficial, it is important that it is used. Previous studies [12] have shown that unsatisfied users will be less active and therefore will not benefit from using this kind of app. Multistep tasks, difficult system navigation, limited functionality, and limited interaction are generally the most common and important usability problems.

To improve user activity, the instructions given to the participants could be improved or routine follow-up telephone calls could be conducted with the participants in the treatment group. The intervention itself could have been more specific, with more guidelines for the participants to enhance their participation, and that might have led to more active self-care. However, this might have been perceived as a bigger effort. Nevertheless, the basic features of the app (ie, self-monitoring and facilitating patient-caregiver communication) appear to be valued by participants. For some, it facilitated a shift in routines toward more frequent blood glucose measurements and a larger understanding of the underlying causes of variations in their blood glucose levels. A feature that may enhance patient engagement is personalized content; for example, individual messaging between the caregiver and user seems to have positive effects in other studies. However, this is something that has not been adequately studied [27].

Effect Sizes

The effect sizes were small or not existing. Due to the feasibility concerns already raised, it would be premature to calculate a sample size for a full-scale RCT based on these results. If one still would, the only significant result was the number of blood tests, which had an effect size of 0.19. This would result in a necessary sample size of 870 (435 per study group; power=.80, α=.05). Based on the HbA1c results, the required sample size would be close to 1000. One could, based on the almost nonexistent effect sizes, reconsider the choice of self-rated outcome measures. However, with the low activity levels, it is difficult to say if the measures were not sensitive enough or if the intervention did not have a large enough impact.

Clinical Significance

The results of this study demonstrate the importance of conducting a feasibility trial in order to avoid unnecessary financial as well as study burden for those involved. In order to proceed with a larger clinical trial, a number of problems both in study design and the intervention, as described in the previous sections, need to be addressed. The next step then is to perform a sufficiently powered RCT. If the results are favorable, this will be the first step toward clinical evidence for the intervention, and a new digital treatment helping people to better manage their type 2 diabetes may be available shortly [28].

The participants who signed up for this study were particularly interested in mobile apps; therefore, the results from this study are applicable for patients with type 2 diabetes who want a digital aid. The app could complement standard care and possibly increase empowerment and self-care management. The main advantage of this app is that it enables a new and, maybe, faster way for communication between the person with diabetes and the diabetes nurse or general practitioner. This app, along with other available apps, could be suitable for health care now as well as in future, more digital health care [29].

Limitations

The smartphone app needed improvements during the trial period. Both the participants and study physician experienced development problems. This probably affected the participants’ experiences with the app. Another possible area of development is of the intervention itself, perhaps with a bigger focus on lifestyle and possibly with other professions involved such as a dietitian, physiotherapist, or diabetes nurse. A possible bias in this study was that the study physician was part of the study team. Since she followed the study protocol and was not involved in the data collection, we believe this issue to be of minor importance. However, an independent physician or diabetes nurse would be preferable. The most preferable option would have been to involve the participants’ own family physician or diabetes nurse, who would have had personal knowledge of the patient. Another bias could be that the participants who signed up for this study were particularly interested in mobile apps. Therefore, the results from this study are applicable for people with type 2 diabetes who want a digital aid and not for the entire population.

Strengths

A strength of this feasibility study is that the trial was rather large and comprehensive for being a feasibility trial. Another strength is that the app and study methods have been evaluated in several ways with both quantitative and qualitative data, and the evaluation placed a lot of emphasis on the participants’
views. It is important to use different types of methods and validated instruments to get a more comprehensive evaluation of a diabetes app [30].

**Conclusion**

Recruitment of participants to a future fully powered study may work with adjustments. The collection of HbA1c using home testing constituted a major problem, and an alternative strategy for this measure is warranted. Finally, the app was not used by participants as intended, and further development is needed. In summary, in order to proceed with a larger randomized study, the app and study procedures need improvement.

**Acknowledgments**

The authors would like to thank the study participants. We also thank Michael Nahashon of Maishabit AB for making the Sukaribit app available and providing technical support.

The study was funded by Uppsala University Innovation and Uppsala University Project AB.

**Authors' Contributions**

EMGO and MH conceptualized the study. EMGO, UP, and MHed supervised the study. TL performed project administration. EMGO and MH designed the methodology. EMGO curated the data. CJ and EMGO performed the formal analysis. CJ created the visualizations. CJ and TL wrote the original manuscript draft and performed the investigation. CJ, MH, UP, MHed, and EMGO reviewed and edited the manuscript.

Generative AI was not used in any portion of the manuscript writing.

Abstract

Background: COVID-19 and the prospect of future pandemics have emphasized the need to reduce disease transmission in workplaces. Despite the well-established link between good hand hygiene (HH) and employee health, HH in nonclinical workplaces has received little attention. Smart sanitizers have been deployed in clinical settings to motivate and enforce HH. This study is part of a large project that explores the potential of smart sanitizers in office settings.

Objective: Our previous study found that for office workers to accept the deployment of smart sanitizers, they would need to find the data generated as useful and actionable. The objectives of this study were to identify (1) the potential uses and actions that could be taken from HH data collected by smart sanitizers (2) the concerns of office workers for the identified uses and actions and (3) the circumstances in which office workers accept HH monitoring.

Methods: An interview study was conducted with 18 office workers from various professions. Interview questions were developed using a framework from personal informatics. Transcripts were analyzed thematically.

Results: A wide range of uses of smart sanitizer data was identified including managing hygiene resources and workflows, finding operating sanitizers, communicating the (high) standard of organizational hygiene, promoting and enforcing organizational hygiene policies, improving workers’ own hygiene practices, executing more effective interventions, and identifying the causes of outbreaks. However, hygiene is mostly considered as a private matter, and it is also possible that no action would be taken. Office workers were also concerned about bullying, coercion, and use of hygiene data for unintended purposes. They were also worried that the data could be inaccurate or incomplete, leading to misrepresentation of hygiene practices. Office workers suggested that they would be more likely to accept monitoring in situations where hygiene is considered important, when there are clear benefits to data collection, if their privacy is respected, if they have some control over how their data are collected, and if the ways in which the data will be used are clearly communicated.

Conclusions: Smart sanitizers could have a valuable role in improving hygiene practices in offices and reducing disease transmission. Many actionable uses for data collected from smart systems were identified. However, office workers consider HH as a personal matter, and acceptance of smart systems is likely to be dynamic and will depend on the broad situation. Except when there are disease outbreaks, smart systems may need to be restricted to uses that do not require the sharing of personal data. Should organizations wish to implement smart sanitizers in offices, it would be advisable to consult widely with staff and develop systems that are customizable and personalizable.

Introduction

Hand Hygiene in Workplaces

Recent pandemics (such as severe acute respiratory syndrome 1, H1N1 influenza, Middle East Respiratory Syndrome, and COVID-19) have demonstrated that public health threats are synonymous with occupational health threats [1]. Good hygiene protects people from acquiring and spreading gastrointestinal infections and respiratory infections [2]. When employees work in close proximity with others (colleagues, clients, and customers), share spaces (such as offices, kitchens, and break rooms) and share resources (such as computers, photocopiers, water coolers, and sinks), infectious diseases can be easily spread [3]. Hygiene practices such as using sanitizer, washing hands, and disinfecting surfaces have proved to be effective in reducing pathogen spread [4,5] and reducing illness in workplaces [3] and may be adopted more readily than other public health measures such as mask wearing [6].

Several studies have found that good hand hygiene (HH) reduces both absenteeism and presenteeism (attending work when ill), increases productivity [3,7], reduces the pressure on health services, and helps to tackle antimicrobial resistance through the reduced use of antibiotics [8]. How much time is lost to work owing to poor hygiene is difficult to quantify [9] as hygiene-related absences may be brief organizations tend not to report them to authorities, and it is often not possible to directly connect an acquired illness with poor hygiene practice (eg, without specific tests, what led to an employee’s stomach upset is speculative). Nonetheless, many of the studies cited previously indicate that much time is lost to work because of poor hygiene practices. Furthermore, before COVID-19, for many workers, attending work was rarely considered a risk to health, but now, employees may be highly anxious about infections in the workplace [10].

The COVID-19 pandemic led to a proliferation of guidance about reducing infection transmission in the workplace [7,11,12]. People were, and still are in some settings, encouraged to work from home where possible, keep socially distant, wear masks, wash and sanitize hands, and get vaccinated. Workplaces can also use 3 strategies to control infections [13]. First, they can try to prevent infections from entering the workplace through health screenings and by reducing or eliminating contact between workers (eg, working-from-home policies). Second, workplaces can help stop the transmission of infection through ventilation strategies and by erecting barriers and screens to prevent movement of aerosols. Finally, workplaces can help protect the worker from acquiring infections with personal protective equipment. However, despite many of these measures being introduced into workplaces, infectious disease transmission remains as a challenge [1]. This matters because it is vital that workplaces are in a position to adopt infection prevention and control strategies as and when required for current and future infectious diseases [1].

Smart Sanitizers

Smart sanitizers are already on the market and deployed in clinical settings. In this study, we consider the potential of smart HH systems in offices. Also known as automated hand hygiene monitoring systems (AHHMS) and electronic monitoring systems, smart sanitizers are Internet of Things devices. The device (the “thing”) stores and dispenses soap when activated by a sensor. Sensors within the device collect information about soap consumption (activation of the soap dispenser and fill level of the dispenser). When networked with other sensor data, such as movement of people (eg, entry to a room or building) and person tags (such as staff ID cards), the smart system can monitor a person’s HH based on where they are and what they are doing. The individual or aggregated data can then be shared on personal devices and apps, with sanitizer users and anyone else on the network. The system can also send messages and reminders and give feedback to registered users. The basic functionality has been established for >10 years and continues to develop and evolve. Recently, there has been a move to develop smart systems that can measure hand washing quality (correct technique and adequate time) [14].

Smart sanitizers have been adopted in clinical settings where HH is operationally crucial to help stop the spread of health care–associated infections, and there is a requirement to audit health care workers’ HH when caring for patients [15,16]. In clinical settings, smart sanitizers are generally considered to be effective in increasing HH, at least in the short term [17]. As HH is an important part of health care workers’ professional practice, many health care workers welcome the use of technology to improve hygiene adherence [18,19]. However, there are concerns about the loss of privacy and the potential for coercion, with many health care workers expressing a preference for systems that do not collect any personal data [14,19,20]. Health care workers are also concerned that the data collected may not accurately represent hygiene practices if the technology is prone to error, deliberately manipulated, or the context of HH (or rather, lack of HH) is not taken into account [14,18–20]. Furthermore, there are concerns about infrastructure costs and the potential for side effects of using systems that use radio frequency interference and UV light [14].

There has been little deployment of smart sanitizers outside clinical settings. Whether office workers would be as open as health care workers to adopting this technology needs further investigation, particularly because acceptance of smart sanitizers is dependent on organizational culture and how monitoring is implemented [17,18]. Moreover, as the professional concerns differ, how the technology is deployed and used in office settings may be different.

In 2021, Zivich et al [21] conducted a feasibility study for collecting HH data in offices and data about person-to-person contacts. Sensors were installed in soap and alcohol sanitizers in 2 US offices, and those participating (n=43) also carried sensors. From the data collected, first, the study authors found that office workers likely overestimate the frequency of their HH practices and, second, those with supervisory roles had fewer in-person interactions than those without supervisory responsibility. The authors also found that study participants were willing to carry sensors and have their interactions tracked. However, participation in the study was not obligatory and those participating were appropriately incentivized with a US $25 gift card. It is therefore not clear whether these office workers would be happy with such tracking as part of their usual working...
practices, and in fact, some study participants suggested that they would need an increase in compensation to participate in a long study. Together, these findings suggest that smart sanitizers could be useful in (1) helping office workers identify their HH practices and (2) understanding and managing disease transmission in offices. However, it is not clear whether office workers would be willing in everyday life to have their hygiene data and contacts with other people collected.

Further to this, we investigated the attitudes toward the use of smart sanitizers in the workplace using a survey of workers in nonclinical settings (n=314), followed up with a qualitative questionnaire (n=12) and interview (n=3) [22]. Survey participants were generally in agreement that at work, high standards of HH is important and that smart sanitizers could usefully inform maintenance staff when to refill. However, there was little consensus with regards to the acceptance of collecting data that would give office workers an overview of their own HH practice, allow them to compare their own practices with those of others, provide them with personal messages, and give managers an anonymized view of HH practices. What was clear from the written responses and interviews is that participants thought it important that the data should only be collected if they can be acted upon, that is, the data should not just be collected because the technology allows it. This means that, before introducing smart sanitizers to the workplace, it is necessary to identify what actions could be usefully informed by the data. This led to our first research question (RQ1)—What actions could be taken from HH data collected by smart sanitizers?

However, whether these actions would be accepted by office workers requires further investigation, because survey participants were also concerned that HH data could be misused and misinterpreted. In particular, participants were concerned that collecting HH data could be an invasion of privacy, and the data collected may not be accurate. What HH data are needed will depend on how the data are to be used; therefore, it would be helpful to know the concerns associated with possible actions. This led to our second RQ: RQ2—For the actions identified, what, if any, are the data collection concerns of office workers?

Finally, the survey was conducted during the pandemic (July 2021 to August 2021), at a time when participants may have considered HH as particularly important. Concern for their health could have influenced the extent to which participants were willing to accept monitoring. When else, if ever, office workers would be more likely to accept smart sanitizers is not known. This led to our final RQ: RQ3—Under what circumstances would office workers accept HH monitoring?

**Methods**

**Overview**

This study was conducted as part of a large project to develop a smart hand sanitizer for the office environment. The project is a collaboration between the University of Sheffield (Information School) and the University of Leeds (School of Design), together with Savortex (a manufacturer of HH technology). The study reported in this paper, including data collection and analysis, was conducted solely by the universities.

**Recruitment**

This was a qualitative study to identify the potential uses of smart sanitizers from the perspective of those who work in offices all or most of the time. Interviews were conducted either using video link or via telephone, and they occurred between January 2022 and March 2022. The questions were pilot-tested with 2 participants known to the project team. Participants from a previous survey of attitudes toward the use of smart sanitizers in the workplace [22], who had expressed interest in further participation, were invited to participate in this study: 11 participants consented. To elicit a range of views, additional 7 participants were recruited using the research team’s networks. Although half of the participants (9/18, 50%) were from the education sector, sector did not account for differences in responses in the previous survey [22]. There were 18 participants in total, 3 (17%) of whom had some responsibility for hygiene within their organization (Table 1).

Data Collection

To prepare for data collection, we turned to the field of personal informatics. Personal informatics systems “help people collect personally relevant information for the purpose of self-reflection and gaining self-knowledge” [23]. As such, smart HH systems can also be considered as personal informatics systems because individuals can use them to collect and track data about their HH practices. A semistructured interview guide was developed based on the stage-based model by Li et al [23]. This model is widely used in the design of personal informatics systems and holistically describes, from a user perspective, the stages of collecting and using personal data. A set of main questions (Table 2) relating to the 5 stages (preparation, collection, integration, reflection, and action) was prepared, together with several possible prompts. To allow for the identification of all the potential uses of HH data, we did not restrict the discussion to smart sanitizers that are currently on the market; at the beginning of the interview, participants were told that “By hand hygiene we mean using any kind of hand cleaning facility. This includes hand washing, using a wall sanitiser or using your own sanitiser from a bottle or a wipe.”

Data Analysis

Data were analyzed inductively using a “codebook” approach to thematic analysis [24], whereby a structured coding framework is used to analyze the data. Preliminary open coding was performed by the second author. At a follow-up meeting, developing codes were discussed with the first, third, and fourth authors and an initial codebook was compiled. The second author completed the coding of the remaining transcripts. The first author mapped the open codes to the RQs. This was then further reviewed by the second author.

Ethical Considerations

This study received ethics approval (038337) from the University of Sheffield Research Ethics Committee on February 16, 2021. All study participants received an information sheet about the project, and they were given opportunities to ask questions and advised that they could withdraw with no negative
consequences. All participants gave their informed consent. For confidentiality, their data are anonymized.

Results

RQ1: What Actions Could Be Taken From HH Data?

Overview

An exploratory approach was adopted for the first RQ, and all potential actions were identified. It was thought that HH data could be acted upon to (1) manage hygiene resources and workflows, (2) find operating sanitizers, (3) communicate the (high) standard of organizational hygiene, (4) improve own practice, (5) promote an organization’s hygiene policy, (6) enforce organizational policy, (7) target the training according to needs, (8) execute more effective interventions, and (9) identify the causes of outbreaks, and whether (10) any action would be taken was also considered.

Manage Hygiene Resources and Workflows

Facilities managers could find HH data useful when planning and maintaining hygiene facilities, including the purchase and decommissioning of sanitizers, purchase of soap and gel, optimal placing of sanitizers, and identification of when maintenance is required. Maintenance data could also make work processes and workflows more efficient:

_We then don’t have to send a cleaner every hour for no reason._ [P15]

Find Operating HH Facilities

If stock fill level data were shared with everyone, building users could act upon the data to find operating HH facilities:

_It’s a bit like “FindmyPC” isn’t it?... If there’s nothing [soap and gel] on [place] I can go to [place] and I can get the stuff there._ [P11]

Communicate the (High) Standard of Organizational Hygiene

Organizations could use HH data as tangible evidence to reassure employees and visitors that there is a high standard of HH in the building. This could be particularly useful for organizations that work with vulnerable people:

_This last calendar month we had 95% usage of all of our machines [that would communicate] we’re looking after our staff and the compliance of that._ [P15]

Improve Own HH Practice

Through managing, tracking, and understanding their hygiene practices, including evaluating their HH technique, individuals could act upon the data to improve their HH practices:

_Like, let’s say you have a ring, it’s not very clean around the ring, I would then know and I would spend more time obviously._ [P13]

If the system collected contextual data (including what the person is doing at the time, how they are feeling, and the current risk of catching an infection), the system could usefully identify trends, give insights, and make recommendations that would enable individuals to further act upon their HH data:

_Recommendations on my hand washing behaviour, like, you know: “In general, you do not seem to wash your hands very well on Tuesdays or on Wednesdays.” That might help me understand why that’s the case. Another thing that might be useful...then it might be nice to know if I’m washing hands when I’m meeting people more or if I have more meetings. So if it’s connected with the calendar then it might be able to give some more insight into why I think I’m not washing my hands more, when I’m washing them and where I’m going [next] so that might be good._ [P2]

Participants thought that having access to other people’s HH data could enable people to benchmark and contextualize their own results:

_If I could compare my handwashing with somebody else’s, and if mine looked that I was hand-washing too often, then I’d have to look at if we’re all doing the same number of visits in a day, am I sanitising my hands too much, but then if I’m not getting infections at the same rate as other people then maybe I’m not hand sanitising my hands too much._ [P12]

Promote an Organizational Hygiene Policy

Organizations can use smart systems to communicate their HH policy. Smart systems could help promote policies by sending reminders and keeping employees motivated through comparisons, competitions, and other incentives:

_I suppose they should have some sort of benchmark, you know, like “The rest of the organisation are all doing it really frequently and doing it for the right duration, but your team aren’t” so they have to have some sort of like benchmark as to where they fall on a scale, as it were._ [P4]

It was thought that smart systems could be useful when new routines are introduced:

_If there were changes in expectations, such as more restrictions were put in place, if there was another outbreak._ [P6]

This would also apply when new staff join the organization.

Enforce Organizational HH Policy

Organizations can use smart systems to identify compliance and changes in compliance. If a lack of compliance has been identified, organizations could target particular events (such as after using the toilet), individuals, teams, and departments to set hygiene goals that align with their policy:

_Showing trends, showing ups and downs, especially the downs, might highlight points to people to make them realise...you can use that to some effect then, can’t you, if you have a particular outbreak in a particular team or whatever. It might prompt people to take a bit more action to it maybe._ [P9]
The data could also be synced with door entry systems to prevent people from entering spaces (such as food preparation areas), but none of the participants (0/18, 0%) thought this was a good idea.

**Target HH Training According to Needs**

An analysis of HH data could also help to identify who needs training and what their training needs are:

> If they’re looking at training needs and compliance and safety and all those sorts of things, could use those to identify if there are any gaps. [P4]

**Execute More Effective Interventions**

Organizations and researchers could evaluate the effectiveness of interventions in real time and adapt them according to the results:

> It doesn’t have to be Coronavirus, it could be the flu or something, it would be useful to see that, and to see how people responded to prompts and reminders. [P6]

**Identify the Causes of Outbreaks**

Participants also discussed the possibility that if HH data were combined with other health data, it could enable researchers to gain a better understanding of the impact of HH on health and the cause of infectious outbreaks:

> Reporting that there’ve been a lot of stomach upsets, and that was linked in with the data on hand washing, which was very low, then you could put two and two together, and that could be useful. [P5]

**No Action**

Whether any action would be taken was also discussed. HH was often thought to be a personal matter and the responsibility of the individual. Several participants stated that they would not say anything or take any action if they knew their colleagues had inadequate HH practices:

> I do think it’s pretty disgusting if people don’t wash their hands, [pause] but it’s not for me to tell them to...I’ve just got to be responsible for myself. [P17]

**RQ2: For the Actions Identified, What, if Any, Are the Concerns of Office Workers?**

Office workers are concerned that (1) intentions and messages could be misinterpreted and that data could be used for (2) bullying and coercion, (3) unintended purposes, (4) inaccurate representation of HH practices, and (5) incomplete representation of HH practices. Next, we have discussed which actions raise the concerns.

**Intentions and Messages Are Misinterpreted**

It was thought that messages generated by a smart sanitizer may not be received as intended. Using HH data to reassure building users about the status of HH in organizations could instead make them feel anxious:

> Then again it could let people, like I say, who are socially anxious think “Oh my God, no-one’s cleaning their hands, it’s a really dirty place.” You will get people that will freak out about that. [P3]

Although organizations may install smart HH systems to reassure office workers, office workers may feel that monitoring could imply that a person is not able to manage on their own. The installation of devices that monitor HH could be construed as a message conveying lack of trust:

> It felt like if we monitored something like that, then it would damage trust, it would make people less independent and capable of taking care of their health because it would set an expectation that someone else is going to monitor it. [P10]

**Bullying and Coercion**

Many interviewees felt that the data would be of particular interest to managers, but using the data to promote and enforce HH policy could lead to bullying, be divisive, and encourage rivalries:

> I’d be concerned in some bits of the organisation that I worked in, that some managers would use it punitively to, not necessarily call out people publicly, but use it to...bully people or shame them or whatever. [P4]

Benchmarking one’s own HH against others was thought to be helpful in improving one’s own HH practice, but it was also thought that office workers may feel harshly and unfairly judged:

> If my whole team does it, then if I don’t do it then I’m gonna surely [be] judged for, like, not cleaning my hands even though it [my reason for refusing] has nothing to do with that. [P13]

**Used for Unintended Purposes**

Participants thought that HH data could be (deliberately or inadvertently) used for purposes that do not benefit the organization or their employees. Moreover, HH data may reveal other personal information that would not be appropriate for organizations to know:

> You might feel forced to say, “Oh, actually, I’ve got a bit of morning sickness. I think I might be pregnant,” and then you might have a miscarriage or something like that, so then it could – that might all – oh, dear, yeah. Or you might – say it could be an emotional reason why you’re going to the toilet. You might be going because you’re very upset about something. But I think, yeah, it could reveal all sorts of things about human behaviour, and actually, in an unintended way, reveal things about that person that are very private. [P5]

There was some concern that manufacturers of sanitizers and cleaning products would use the data to increase sales:

> If the outcome is, how can we sell more hand sanitizer, what if we connected our hand sanitizer product to the internet...I don’t think that’s a good outcome, and I don’t think it comes from a good place. [P10]
Inaccurate Representation of HH Practices

Whether the data collected would be an accurate representation of HH practices and, therefore, whether any conclusions can be drawn from the data collected was also a concern. Participants worried that the use of smart systems could be manipulated, and therefore, the resulting data would be inaccurate and would misrepresent organizational HH practices:

I know some people who are just going to go round and just put their hand under every time they walk past just so they’ve triggered it whether they’re washing their hands or not. [P12]

Incomplete Representation of HH Practices

Participants expressed the concern that smart systems could not capture all the data necessary to represent all HH practices, and this also adds to concerns about whether any conclusions can be drawn from the data. First, smart systems alone cannot capture all HH events (such as an employee’s use of their own sanitizer and wipes, which may be a personal preference or a necessity, e.g., if a person has allergies to a particular substance):

Maybe you think, “I don’t want to touch the wall hand sanitizer because everybody else has touched that, so I’m going to stick to my personal sanitizer,” in which case, that wouldn’t capture any of that, so you would need both, for a true figure. [P5]

Second, employees may work from home or in other locations outside the aegis of the organization, where it would be difficult for smart systems to capture HH events. Furthermore, for improving their own HH practices, people would want data beyond the work context:

How long I’m spending washing my hands, gaps in between, but also if there’s any variation in days. So, I mean, Saturday and Sunday might not be different if I’m out and about, on a personal level, than the Thursday or Friday if I’m working. I would expect there to be, but if I was shopping, and I went in 20 shops on a Saturday, that might reflect that I was handwashing the same as I was in a working day. [P12]

Finally, to fully interpret HH practices, it would also be necessary to collect data about what the employee was doing at the time and where. Otherwise, there is a danger that the system may incorrectly interpret HH practices as missing. Participants also questioned whether using HH data to draw comparisons between different departments would be meaningful, as different roles may have different HH requirements:

If I’ve just come from the toilet and I’ve washed my hands and walked past a hand sanitiser, if I got a pop up on my machine...that says “You’ve been past a hand sanitiser and you haven’t used it” I would expect to be able to interact with it and explain to it why I haven’t used it. [P4]

If it went like comparing groups within an organisation, then how do you know you’re comparing like with like? [P5]

RQ3: Under What Circumstances Would Office Workers Accept HH Monitoring?

The concerns expressed previously suggest that there will likely be some resistance to many of the uses of HH data. However, office workers suggested that they are more likely to accept HH monitoring (1) if they or others could not be identified, (2) in situations where HH is considered important, (3) when events considered as private are not recorded, (4) when data collection can be customized, (5) when data are used for a beneficial purpose, and (6) when uses of the data are clearly communicated.

When Identity Is Protected

Participants expressed little or no concern about organizations accessing data from sensors in which no personal data are collected and were therefore generally accepting of the uses of HH data for resource planning purposes.

Most participants thought that data about individuals should not be shared with others. However, 11% (2/18) of the participants thought that attributed personal data should be seen by senior managers (P4 and P6) and another 11% (2/18) thought that attributed personal data could be seen by team managers also (P12 and P14):

So with the data and reports, the only things that I think that someone else should be seeing about me are aggregate. So nothing where people can be identified. [P2]

Senior management team or board level or Health and Safety Executive should have all the information by teams or by individuals but the individual managers...I wouldn’t want my manager of my department to have individualised data that makes them be able to say “[name] is not washing her hands often enough.” I would prefer that it’s anonymised at that level. [P4]

Although participants were generally uncomfortable with personal data being shared with others, they were mostly comfortable with personal data collection if they or their colleagues could not be identified in any reports:

I think aggregated reports should be available to everyone, as a comparison purpose. I think maybe a little bit more detailed aggregated reports, for example, with a maximum, minimum, with a band, with a percentile band, with the longer period of change can be available to health and safety officer, can be a department manager, or what they call the senior manager group, steering committee. [P8]

Situations Where HH Is Considered Important

Monitoring was thought to be more acceptable when the importance of HH is clear. Therefore, monitoring was seen as more acceptable in certain settings, notably, health care and food preparation, and for certain teams or roles, for example, food technicians and carers:

If I worked in a food environment, it’d be very different. [P17]
It was also thought more acceptable during infectious disease outbreaks:

Suppose there’s another virus outbreak and it’s demonstrated that hand washing is key to preventing its spread, and that you’re doing it for the public good...if it was, like, three years ago, I would’ve said this is ridiculous. Now, I think maybe, OK, in the right circumstances, I would go along with it, because the context seems to have changed. [P7]

It was thought to be acceptable at places in buildings where HH is important such as food preparation areas and toilets:

I would like to know that the people preparing my food wash their hands, that would be a good thing to know, because it’s crucial for there. The rest of them, I don’t need to know that. I don’t think...Although, I would prefer it if people washed their hands before they left the toilet -- if an alarm went off there. [P5]

When Events Considered Private Are Not Recorded

Although it was thought helpful to capture HH data in locations where HH is important, data capture was felt to be more acceptable in some parts of the building than others. For example, monitoring HH on building entry was less controversial than monitoring outside a toilet:

Some people might think that it’s a bit of an invasion of privacy, being monitored in the toilet as well. Is there nowhere safe? Is there nowhere that I can just not be monitored? [P4]

When Data Collection Can Be Customized

It was thought that office workers would be more likely to accept monitoring if they can customize the system and control what data are collected and how they are presented:

I think perhaps like with the alerts, perhaps [they] could have the option to turn that on [recommendations, encouragement, advice] if you so desired, but it shouldn’t be a requirement. [P5]

The system should allow users to correct any errors in data collection and add explanations, so that managers do not unfairly target individuals:

So that you’ve got the chance to correct yourself if you need to, like, you see I would be going back to my computer and I would expect then to have a message on my computer that says “You’ve walked past a hand sanitiser and you didn’t use it. What was the reason?” [P4]

When Data Are Used for a Beneficial Purpose

Participants felt that data need to be collected for a purpose. The purpose needs to be justified, and the data should be retained only for as long as necessary. Furthermore, systems should be used to support individuals rather than punish them:

If there was a real, proper reason that they were collecting it for, then they could collect it for the relevant time period. So if there was some sort of disease outbreak and it lasted six months, then collect it for six months...it has to be justifiable...it’s not right to just collect it and hold that data. [P5]

It depends on what people perceive is the overall intention of whoever’s putting this policy in place. If it’s used-- if the perception is it’s used to beat people up about hygiene because it’s going to lead to a poor sick record or more transmissible covid than that is a different intention to “Well, I’m really bothered about how sore your fingers are becoming with all your hand washing.” [P12]

When Uses of the Collected Data Are Clearly Communicated

Participants recommended that the uses of the data need to be transparent and clearly communicated including how the data will be used and reported, who has access to what data, where and for how long the data are stored, and whether it is possible to opt out of data collection:

Why they’re doing it, who’s going to hold the data, who’s going to see it, how’s it going to be reported, who will it be shared with, yeah, where will the data go, how long will they hold the data for, and can I opt out, how do I opt out. [P2]

Discussion

Principal Findings

Our previous study found that office workers thought HH data should only be collected if they can be acted upon [22]. In this study, office workers were able to identify several actions that could usefully be informed by HH data (RQ1). These included using the data to manage hygiene resources and workflows, find operating sanitizers, communicate (high) organizational standards of hygiene, improve workers’ own practice, promote and enforce an organization’s hygiene policy, target the training according to needs, execute more effective interventions, and identify the causes of outbreaks. However, hygiene is mostly considered a private matter, and it is possible that no action would be taken in practice. Furthermore, office workers expressed concerns (RQ2) that the data could be used to bully, to coerce and for unintended purposes. Moreover, the data could be misinterpreted, inaccurate, and an incomplete representation of hygiene practices. Office workers suggested that they would be more likely to accept monitoring for the identified uses (RQ3) when their privacy is respected, they have some control over how their data are collected, and how their data will be used is clearly communicated. Monitoring is also more likely to be accepted in situations where hygiene is considered important and there is a clear beneficial purpose for data collection.

HH Is (Mostly) a Personal Matter for Office Workers

Although the findings of this study suggest that facility managers, health and safety officers, departmental managers, building occupants and visitors, hygiene resource suppliers, researchers, and those interested in public health would find HH data useful, HH was thought to be a personal matter [25]. Several office workers reported that they would not take any action if they found that their colleagues’ HH practices were inadequate. For all the uses of HH data, there was a strong
preference for personal data to be anonymized or not collected at all. However, acceptance of HH monitoring is dynamic and dependent on the situation and the context within which the data are used. The findings of our study suggest that it is much more likely to be accepted during disease outbreaks, in certain locations (eg, entrance to buildings), and in sectors (eg, health and food) where HH is important to the ethos and culture of the organization (ie, will also influence office workers). Although none of the office workers (0/18, 0%) thought it acceptable to enforce HH by restricting access to areas (by syncing HH data with door entry system data), it is possible that under extreme circumstances and in certain locations, this could be acceptable.

Need for a Shared Understanding of “Good” Office HH

For those concerned about catching infectious diseases in the workplace [10], HH data could be used to reassure visitors to a building about the high standards of hygiene within the building and to promote and enforce organizational HH policies. In health care settings, smart sanitizers are already used to audit compliance and enforce the health sector’s policy of sanitizing hands before, during, and after patient care. Overall, 3 factors are likely to make smart sanitizers more acceptable in health care settings. First, they are used to enforce an HH policy that is considered important in professional practice [18]. Second, smart sanitizers can collect data that measure the compliance with policies such as the 5 moments for hygiene [26] that can be measured using the sanitizer supplied by the organization. Third, at least at a basic level, adherence to this policy can be monitored using room and sanitizer sensors, without the need for personal data collection.

For smart systems to be adopted in offices, it would help if there were an agreed-upon understanding of what is good hygiene practice, for example, how often and where (eg, entrances to buildings and exits from toilets) hygiene should be performed. Smart systems could then be used to reassure and promote HH in offices, if the policy can be complied with using office resources and without the need to collect personal data.

Office Workers Want Insights From All Their HH Practices

Health care workers may wish to track their HH practices around patients, as good HH is part of their professional identity [18], and having access to their personal HH data could help health care workers improve their HH practice [27,28]. Given that office workers are likely to be overestimating their HH practices [21], self-tracking could be beneficial. However, office workers in this study did not link self-tracking of HH with professional expectations and standards; rather, they were interested in gaining insights into their overall HH practices including in all locations (office, home, and when they are out of the office and across all facilities (sanitizer, soap, wipes, etc). No smart system (as yet) can automatically detect HH with such detail. This would only be possible if office workers were prepared to input data manually, and this would require considerable motivation.

Office Workers Share Health Care Workers’ Concerns

Many of the concerns that office workers expressed are similar to those of health care workers. Similar to health care workers [19,20], most office workers are concerned that personal data could be misused to punish or bully employees, and use of HH data should be clearly and transparently communicated. It would be advisable to consult with office workers early in the system design process to engage them, explain what purposes the organization intends for the data, and identify what purposes they feel are acceptable and useful.

Another concern shared with health care workers is whether smart HH systems can accurately represent HH practices, because, first, systems can be gamed and deliberately misused, and second, systems may incorrectly interpret events as missed HH opportunities because they are not registering the wide context within which the event did or did not occur [18-20]. Given the shift to more hybrid and flexible working [29], it may also be necessary to analyze HH data alongside work patterns. More generally, studies of workplace tracking have found that systems that enable employees to customize and control what data are collected are more likely to be accepted [30].

Office workers were also concerned that the data could be used for purposes other than what it was intended for. This is understandable given that misuse of technologies is widely reported in the media; for example, AirTags designed to track property have been used to stalk individuals [31].

Useful for Health Researchers

Using sensors to remotely collect HH data resolves some of the challenges for health researchers who need to evaluate hygiene interventions. Researchers may evaluate interventions by observing HH practices, but the presence of an observer may change the behavior of the person being observed, particularly because HH is a social norm. Instead, researchers may use proxy measures such as changes in soap consumption. However, manually collecting soap consumption data from organizations is time consuming, and sensors can help in saving time [32].

Although it is thought likely that poor hygiene could contribute to disease transmission in workplaces, little data are available to support (or oppose) this point [9]. Connecting smart HH system data with other health data (such as data relating to employee absence) could help researchers understand the relationship.

Data collected from digital technologies (such as mobile phones, social media networks, and search engines) have been used to communicate public health messages and monitor and control outbreaks [33]. Smart HH systems could usefully be added to the arsenal of digital data sources that have been used to support health authorities’ response to COVID-19 and any future pandemics.

When Personal Data Are or Are Not Needed

To a large extent, how well a smart HH system is accepted depends on whether personal data are collected. We next consider what data smart HH systems can collect and what is needed for the identified actions (Table 3).
Table 3. Data collected by smart hand hygiene (HH) systems and whether these include personal data (from sensors that track individuals, manual input, and personal devices) or do not include personal data (from sensors in dispensers of sanitizer, soap, etc and sensors [including cameras] that track anonymized movement and location).

<table>

</tr>
<tr>
<td>Contextualized use of HH facility (including what the person had been doing and where they had been)</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

For some uses of HH data, there is no need for personal data to be collected. For resource and workflow planning and to find operating sanitizers, data about soap levels and soap consumption including date, time, and location of use can be collected from sensors in smart systems without the need to collect any personal data. Similarly, smart systems can give immediate feedback to users to improve their HH technique without collecting any personal data. It is also possible to communicate the overall standard of HH in an organization without collecting personal data. Smart system data combined with data from sensors that track movement in and out of spaces can be used to identify the extent to which all employees are practicing HH and whether they use HH facilities as they move around the building (eg, at the lift and after using the toilet). The data collected could also indicate overall compliance with organizational policy and be used to identify the overall education and training needs of the organizations. The same system could also give feedback to individuals at the point where they are using the facility.

Personal data are required for several of the uses of HH data identified in this study, particularly the uses where individuals are pinpointed such as identification of individual practices and training needs and enforcement of organizational policy. Sensors that track individuals (installed on staff ID cards, apps, or other personal devices) would be necessary to capture each person’s use of a hand sanitizer (date, time, technique, and location of use) and to send reminders. However, these data can be anonymized and aggregated to identify the uses of HH facilities by different groups (not individuals) within the organization. Good practice would be to offer a manual override that would allow employees to correct any system errors. For smart systems to fully represent a person’s HH practice, it would be necessary to allow users to manually input their use of any and all hygiene facilities such as wipes and their own sanitizer gel. To capture a person’s contextualized use of HH facility (including what the person had been doing and where they had been), the system would need to connect to other personal data such as calendars and mobile phones.

Whether personal data are needed to evaluate interventions will depend on the nature of the intervention and what needs to be evaluated. Identifying the causes of outbreaks will likely also require the collection of other personal data (eg, who is ill).

**Limitations**

Through this interview study, a wide range of applications for HH data collected via smart systems has been identified. However, this is an exploratory study; further investigation is needed to determine whether office workers would use smart sanitizers for the identified purposes. Such studies could build on these findings to further investigate the implementation and adoption of smart sanitizers, with trials in offices.

**Conclusions**

Smart sanitizers could, feasibly, make a contribution to the improvement of hygiene practices in offices [21], but for smart systems to be accepted, any data collected would need to be actionable [22]. This study contributes to knowledge by identifying the many potential uses for hygiene data collected from smart systems. As smart HH systems have not yet been introduced into offices, identification of constructive uses for data is important for their design and implementation.

Although smart sanitizers are widely deployed in clinical settings, health care workers recognize that HH is an important part of their professional practice [18,19]. Given that office workers consider HH to be a mostly personal matter, it seems less likely that they will want to adopt smart sanitizers. When there are disease outbreaks, office workers may consent to the sharing of personal data and the monitoring of their own and their colleagues’ HH. At other times, smart sanitizers may need...
to be restricted to uses that do not require any personal data collection. Should organizations wish to implement smart sanitizers in offices, it would be advisable to consult widely with the staff and to develop systems that are customizable and personalizable. It should also be noted that office workers may find it more useful to have insights from all their HH practices, but these data cannot (yet) be automatically collected from smart systems.

In contrast to health care workers, as yet, there is no widely accepted HH policy for office workers. Future studies could usefully investigate what office workers would consider to be an appropriately high standard of hygiene and how often and where hygiene should be performed. A better understanding of what would be effective and acceptable HH policies in nonclinical settings would help to clarify how smart systems can be used and hence inform their design. Importantly, it could help workplaces adopt infection prevention and control strategies that are necessary for current and future infectious disease outbreaks [1].

Abstract

Background: Depression and anxiety are common among people with HIV and are associated with inadequate viral suppression, disease progression, and increased mortality. However, depression and anxiety are underdiagnosed and undertreated in people with HIV owing to inadequate visit time and personnel availability. Conducting population-level depression and anxiety screening via the patient portal is a promising intervention that has not been studied in HIV care settings.

Objective: We aimed to explore facilitators of and barriers to implementing population-level portal-based depression and anxiety screening for people with HIV.

Methods: We conducted semistructured hour-long qualitative interviews based on the Consolidated Framework for Implementation Research with clinicians at an HIV clinic.

Results: A total of 10 clinicians participated in interviews. In total, 10 facilitators and 7 barriers were identified across 5 Consolidated Framework for Implementation Research domains. Facilitators included advantages of systematic screening outside clinic visits; the expectation that assessment frequency could be tailored to patient needs; evidence from the literature and previous experience in other settings; respect for patient privacy; empowering patients and facilitating communication about mental health; compatibility with clinic culture, workflows, and systems; staff beliefs about the importance of mental health screening and benefits for HIV care; engaging all clinic staff and leveraging their strengths; and clear planning and communication with staff. Barriers included difficulty in ensuring prompt response to suicidal ideation; patient access, experience, and comfort using the portal; limited availability of mental health services; variations in how providers use the electronic health record and communicate with patients; limited capacity to address mental health concerns during HIV visits; staff knowledge and self-efficacy regarding the management of mental health conditions; and the impersonal approach to a sensitive topic.

Conclusions: We proposed 13 strategies for implementing population-level portal-based screening for people with HIV. Before implementation, clinics can conduct local assessments of clinicians and clinic staff; engage clinicians and clinic staff with various roles and expertise to support the implementation; highlight advantages, relevance, and evidence for population-level portal-based mental health screening; make screening frequency adaptable based on patient history and symptoms; use user-centered design methods to refine results that are displayed and communicated in the electronic health record; make screening tools available for patients to use on demand in the portal; and create protocols for positive depression and anxiety screeners, including those indicating imminent risk. During implementation, clinics should communicate with clinicians and clinic staff and provide training on protocols; provide technical support and demonstrations for patients on how to use the portal; use multiple screening methods for broad reach; use patient-centered communication in portal messages; provide clinical decision support tools, training, and mentorship to help clinicians manage mental health concerns; and implement integrated behavioral health and increase mental health referral partnerships.

**Introduction**

**Barriers to Depression and Anxiety Diagnosis**

Depression and anxiety are common mental health conditions among people with HIV, with a prevalence of 20% to 45% [1-10]. People with HIV experiencing symptoms of depression or anxiety are more likely to miss appointments and have lower medication adherence, higher HIV viral loads, and higher mortality rates than those without depression or anxiety [1,2,5,10,11]. However, depression and anxiety are often underdiagnosed and undertreated in people with HIV, particularly among African Americans and Hispanics, because of the perceived stigma of mental health disorders, racial discrimination, HIV-related discrimination, and medical mistrust [1,3,5,12,13]. In the HIV Cost and Service Utilization survey of people with HIV identified as experiencing depression, only 45% had a formal depression diagnosis in their medical chart [14].

For people living with chronic conditions, such as HIV, specialty care clinics often serve as their primary source of health care [3,4]. Given the frequency of visits people with HIV have with their HIV care team, establishing mental health screening in HIV clinics is a key opportunity to address depression and anxiety underdiagnosis in people with HIV [3,4]. Patients and physicians have noted that depression screening in clinics is helpful in identifying, assessing, and treating depression [3]. However, competing demands and priorities during appointments, a lack of staff to complete assessments, and a shortage of resources to offer patients after diagnosis discourage clinicians from screening and treating depression [1,3,6,7,9,15,16].

**Novel Mental Health Screening**

A novel strategy to increase depression and anxiety screening in people with HIV is to perform screening at the population level using the patient portal. In recent years, health care systems have increased the adoption of electronic patient portals, and patients have increasingly used portals to facilitate their health care [8,9,17-20]. Studies in primary care settings have found that depression screening rates increased significantly when clinics adopted portal-based screening [3,7,18]. Notably, a population-level portal-based depression screening intervention, in which patients were invited to complete a depression screener regardless of having a scheduled appointment, also increased depression screening and diagnosis rates [21]. This population-level portal-based approach identified more patients with moderate to severe symptoms than screening during clinic appointments [22]. Moreover, portal-based screening increases the likelihood of discussing depression diagnosis and treatment during an appointment [7,19,20,22].

Population-level portal-based screening has been shown to be promising in primary care settings but has not been examined in HIV care settings. Guided by the Consolidated Framework for Implementation Research (CFIR), we conducted and analyzed qualitative interviews with clinicians at an urban HIV clinic [23]. This study explored clinicians’ perspectives on facilitators of and barriers to implementing population-level portal-based depression and anxiety screening for people with HIV. The objective of this formative study was to use the identified facilitators and barriers to develop implementation recommendations for HIV clinics.

**Methods**

**Study Design**

We completed a qualitative study to inform the design and implementation of population-level portal-based depression and anxiety screening at an HIV clinic. This paper reports the results of interviews conducted with clinicians and clinical staff.

**Study Setting**

The study was conducted in the Ryan White HIV Care Clinic at an academic medical center on the South Side of Chicago, the main provider of HIV care services for Chicago South Side residents. The South Side of Chicago is one of the communities most impacted by the HIV epidemic in the United States [24]. The clinic provides care for >6,300 people with HIV, most of whom are African Americans and publicly insured. Currently, staffed with 15 physicians, 6 fellows, a nurse practitioner, a licensed practical nurse, 2 pharmacists, and 2 licensed social workers, the clinic also provides mental health services.

In November 2020, the HIV clinic adopted a protocol for conducting depression and anxiety assessments during in-person clinic visits. Medical assistants were asked to complete the 2-item Patient Health Questionnaire (PHQ) and the 2-item Generalized Anxiety Disorder (GAD) scale with patients due for annual screening, as indicated by health maintenance topics and best practice advisories in the electronic health record (EHR) [25,26]. Scores of ≥3 were reflexed into the PHQ-9 and GAD-7, respectively. Medical assistants were also asked to complete the PHQ-9 and GAD-7 with patients with a history of depression or anxiety, respectively, who were due for ongoing symptom monitoring or surveillance. Physicians and advanced practice nurses were alerted via a critical, noninterruptive best practice advisory to scores of ≥3.

Concurrent with this study, a population-level portal-based depression screening intervention was tested in the primary care clinic at the academic medical center. Patients were invited to complete depression screening using the patient portal regardless of having a scheduled appointment [21]. The clinic saw an increase in screening and identification of depression [21]. These advances in screening in the primary care clinic at the institution motivated us to gauge the interest in and feasibility of integrating population-level portal-based screening in the HIV clinic.
Study Participants

All clinicians at the HIV clinic were eligible for study enrollment, including physicians, advanced practice nurses, pharmacists, nurses, and social workers. HIV clinicians were informed about the study at a clinic meeting and by email, and if interested in participating, they were instructed to contact the study project manager. The participants verbally consented before each interview.

Data Collection

Semistructured interviews were conducted one-on-one with each participant from January to April 2021, after the newly adopted in-clinic screening protocol was implemented. Demographic information was collected via electronic surveys in the REDCap (Research Electronic Data Capture; Vanderbilt University). Interviews were conducted over Zoom (Zoom Video Communications) and lasted for approximately 60 minutes. The interview questions were created by the research team using the CFIR interview guide tool for all 5 CFIR domains. The full interview guide is available in Multimedia Appendix 1. The following are example questions by domain:

- Innovation characteristics: “Do you think assessing anxiety and depression using the patient portal will be effective? Why or why not?”
- Inner setting: “What is the general level of receptivity in the clinic to using the patient portal?”
- Outer setting: “Do you think measuring anxiety and depression using the patient portal will meet the needs of the patients served by your clinic? Why or why not?”
- Process: “Who are other key influential individuals to get on board with assessing anxiety and depressive symptoms using the portal?”

Data Analysis

Descriptive analysis was used to summarize the characteristics of the participants interviewed. Initially, the original CFIR domains and constructs from the codebook were used for our interview analysis. During the initial coding phase, research team members identified additional themes and subthemes to be added to the interview analysis. Once consensus was achieved on the codebook for our analysis, 2 independent coders analyzed each interview transcript, and coding discrepancies were discussed until a consensus was reached. Analysis of coded transcripts was performed in the web-based software Dedoose (version 9.0.17; SocioCultural Research Consultants, LLC). A total of 2 research team members independently reviewed the coded excerpts to find common themes within each domain, identified each as a facilitator or a barrier, and discussed them to consensus. On the basis of these facilitators and barriers, the 2 research team members proposed implementation strategies and presented these strategies to the entire study team for validation and refinement.

Ethical Considerations

The study was reviewed and approved by the University of Chicago Biological Sciences Division Institutional Review Board (20-1313). The research team obtained oral consent from participants before the beginning of the interviews. Interview audio was recorded, and transcripts were deidentified before qualitative coding. The data were accessible to the research team only. Participants were given a US $40 e-gift card for interview completion.

Results

Participant Characteristics

Interviews with HIV clinicians continued until the team agreed that data saturation was met, as indicated by the lack of new themes emerging in the interviews. In total, 10 HIV clinicians completed the interviews. The participants ranged in age from 31 to 64 years. Most participants were identified as White (8/10, 80%) or male (6/10, 60%). As shown in Table 1, 70% (7/10) worked as physicians at the HIV clinic, and the remaining staff included a social worker (1/10, 10%), a nurse (1/10, 10%), and a pharmacist (1/10, 10%).

Current Depression and Anxiety Screening Practice

When asked about their current mental health screening practices, most participants mentioned informally screening patients by asking how they were feeling or if the patient was experiencing any thoughts of self-harm or suicidal ideation. As 1 participant said, “Within the review of systems [during patient intake], I often will ask if any depression and anxiety-type symptoms [were experienced] recently, but there is no standard way I approach every patient” (Participant 6, physician). Participants reported that patients expressing depression or anxiety would typically be screened with the PHQ and the GAD questionnaire. A few participants spoke of the newly implemented in-clinic mental health screening procedure put in effect before the interviews were conducted. However, they stated that the screening protocol was not regularly followed during the clinic visits.

Similarly, the participants mentioned that initiating mental health services relied on patients requesting services or bringing up suicidal ideation or self-harm. The clinic relies on HIV-trained clinical social workers to connect patients with mental health resources based on the individual’s insurance. One participant explained, “I’ll have our social worker call them and set them up with a resource and have her—obviously she’s more trained in that than I am, I believe—and have her assess them and provide appropriate resources” (Participant 9, physician). Before the COVID-19 pandemic, patients were regularly introduced to social workers during in-clinic appointments. The participants emphasized that these in-person interactions were valuable, as they built trust between the patient, the social worker, and the physicians to increase intervention uptake.

Perceptions of Population-Level Portal-Based Screening

Overview

Facilitators of and barriers to population-level portal-based depression and anxiety screening were identified within the 5 CFIR domains (Tables 2 and 3).
Table 2. Facilitators to population-level portal-based depression and anxiety screening from qualitative interviews with HIV clinicians.

<table>
<thead>
<tr>
<th>Domain and facilitators</th>
<th>Facilitator quotes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Innovation characteristics</strong></td>
<td></td>
</tr>
<tr>
<td>Advantages of systematic screening outside clinic visits</td>
<td>“I like the idea that it feels like it would make it a little less stressful on the clinic visit because it’s done independently of that. And then it might come up during the visit, but at least the initial screening and questions doesn’t get added to that clinic workflow. So from that standpoint, it’s a little bit relieving. Because we do want to do this, but you don’t want to have anyone having too much work or too many things on their plate. So from that standpoint, it feels like a good method to go about it.” (Participant 2, physician)</td>
</tr>
<tr>
<td>Expectation that assessment frequency could be tailored to patient needs</td>
<td>“I think if we did it this way, then we would have the information at the beginning of a visit, and could then walk into the visit knowing this. And maybe even have some additional background from our social worker, if they’ve reached out to them in the meantime, between the time they filled this out and got these results, and then the time we see it for an appointment.” (Participant 8, physician)</td>
</tr>
<tr>
<td><strong>Outer setting</strong></td>
<td></td>
</tr>
<tr>
<td>Greater respect for patient privacy</td>
<td>“I kind of think that’s where you get the most honest answers, in the patient’s environment. In clinic, the patient’s mental status is, I’m ready for clinic. So they have that person put on, their clinic person. And unless something is like really, really outstanding, they’re not forthcoming with their information, right?” (Participant 4, nurse)</td>
</tr>
<tr>
<td>Normalizing mental health screening</td>
<td>“…what I’m thinking is I really liked the way it is being approached as making it a routine part of HIV care... just desigmatizing and routinizing those questions for people. I think once that becomes routine as part of your, whatever, yearly check-in, I think that’s helpful.” (Participant 3, social worker)</td>
</tr>
<tr>
<td><strong>Inner setting</strong></td>
<td></td>
</tr>
<tr>
<td>Compatible with clinic culture, workflows, and systems</td>
<td>“Overall positive feelings towards it. I like the idea that it feels like it would make it a little less stressful on the clinic visit because it’s done independently of that. And then it might come up during the visit, but at least the initial screening and questions doesn’t get added to that clinic workflow. So from that standpoint, it’s a little bit relieving. Because we do want to do this, but you don’t want to have anyone having too much work or too many things on their plate.” (Participant 2, physician)</td>
</tr>
<tr>
<td>Protocol for addressing positive screening results</td>
<td>“Would be nice to have a pathway that’s somewhat predetermined. So, it’s like, ‘Okay, we identified this patient has this. We’re not sure if they’re going to be able to see a mental health provider because it might take 2 months to get in... But in the meantime, this is the plan. This is our protocol for what we should do. These are first-line medications. This is the plan from our social work standpoint of how we’re going to follow up with them.’ So, things like that. That would make it easier once we do identify the need to take some of the guesswork out of what the next steps are.” (Participant 8, physician)</td>
</tr>
<tr>
<td><strong>Characteristics of individuals</strong></td>
<td></td>
</tr>
<tr>
<td>Participant beliefs about the importance of mental health screening and benefits HIV care</td>
<td>“Some of it could be a little bit more work within the appointment if you’re then talking about some of these issues and how they affect their other medical care, but I think it would be time likely worth spent and gratifying, and probably maybe more time spent in the front would help decrease time later needing to if it were something that could be addressed and then would improve compliance, that would be very meaningful and worth discussion.” (Participant 6, physician)</td>
</tr>
<tr>
<td>Participant interest in evidence-based practices and desire to learn from prior implementation</td>
<td>“I think there’s a strong need to do it in general.... I haven’t read all the literature on it.... Most likely this needs to happen. We need to screen people. And then the question is just, ‘What’s the best way to screen?’ And looking at everything and talking through the pros and cons, it feels like this would probably be a good way to do it.’” (Participant 2, physician)</td>
</tr>
<tr>
<td><strong>Process</strong></td>
<td></td>
</tr>
<tr>
<td>Team-based approach that leverages strengths of all clinic staff</td>
<td>“Our patient population is a bit delicate, which is why we have different levels to our team approach, because what patients wouldn’t share with their doctor they will share with me, because they easily identify with me. So they accept it on an extended family member kind of like basis. So their level of trust is greater. And we use that. It’s very effective.” (Participant 4, nurse)</td>
</tr>
<tr>
<td>Clear planning and communication with staff</td>
<td>“In general having something that’s standardized is good. Having something that doesn’t totally disrupt the workflow in clinic. So using the portal patient is excellent. And having a really clear plan for what the follow-up is for the patient. I think those are the really important things. And if those are well communicated to the clinic, to the section beforehand... We have our Monday meetings at noon, something like that.... So that way everyone’s comfortable. I would be comfortable going forward with something like this, but making sure that everyone’s on the same page.” (Participant 2, physician)</td>
</tr>
<tr>
<td>System that empowers patients to communicate about their mental health</td>
<td>“But most of our patient population is a very secretive population. So I believe being able to have something on their own terms...[The social workers could] be like, ‘Hey, if you ever feel A, B, and C... Hey just answer these questions. I get an alert and I will respond or someone will respond in a reasonable timeframe.’ Yeah. So if patients have the information that you can use MyChart to let us know if something is going on, I think that would be more successful than just screening patients as they check-in in clinic.” (Participant 4, nurse)</td>
</tr>
</tbody>
</table>
Table 3. Barriers to population-level portal-based depression and anxiety screening from qualitative interviews with HIV clinicians.

<table>
<thead>
<tr>
<th>Domain and barriers</th>
<th>Barrier quotes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Innovation characteristics</strong></td>
<td>“I’d want to make sure that with this screener that we’re assessing for suicidal or homicidal ideation and that somehow that gets like flagged to be address immediately because when you’re in the clinical setting, you can address it immediately. But over the portal, I worry that it might just like sit there, and then what happens if someone is actively suicidal and they fill this out and nobody addresses it.” (Participant 8, physician)</td>
</tr>
<tr>
<td><strong>Outer setting</strong></td>
<td>“And the reality, with my patient population, there has been issues with just accessing MyChart for a variety of patient problems, if you will. Lack of technical skills, lack of just having no laptop or any way to do that, or just feel comfortable with that kind of thing.” (Participant 5, physician)</td>
</tr>
<tr>
<td>Limited patient access, experience, and comfort using the portal</td>
<td>“Our barrier is the resource pool that we have to select from...we’re extremely limited...if someone is not a threat to themselves or someone else, however they’re battling their issues that are too much for them to really handle, where do we refer our patients to? And the destinations are booked out. And I personally believe that time is a factor when we’re dealing with depression and anxiety.” (Participant 4, nurse)</td>
</tr>
<tr>
<td>Limited availability of mental health services</td>
<td>“I think a lot of the physicians I work with don’t even check their in-basket, answer My Chart messages...I mean, I’ve been using it and I do like it... But I think a lot of the people I work with... They trained in a different time, none of this was around then. A lot of them give out their cell phone numbers to their patients and that’s how they end up communicating.” (Participant 10, physician)</td>
</tr>
<tr>
<td><strong>Inner setting</strong></td>
<td>“We have a list of our own priorities that we need to address every visit. I think sometimes I’m like, ‘Well, they have a primary care physician. That’s the appropriate person that should assess and counsel, and hopefully they’re doing that.’ I kind of rely on that. And probably we’re often not as good at realizing when someone is in some kind of mental health distress. We see someone and they might seem like they’re doing okay and I’m like, ‘I don’t need to ask them how their mental health is. But obviously under the surface could be a very different story.’” (Participant 9, physician)</td>
</tr>
<tr>
<td>Clinician variation in the use of electronic health records</td>
<td>“I think that a lot of the actionable information or the action that I’ll most likely take will eventually fall on the [infectious disease] clinic social worker [based] on my previous behavior.... I’m not likely, to be honest, to start any medication. I just don’t feel well-versed enough or practiced enough to really prescribe pharmacologic interventions. So usually the interventions I would take are to refer them to their provider or have our social worker kind of provide resources in some way. I don’t feel equipped to provide nonpharmacologic interventions related to anxiety/depression or pharmacologic.” (Participant 9, physician)</td>
</tr>
<tr>
<td>Limited capacity to address mental health concerns during HIV visits</td>
<td>“As you know, it takes patient buy-in to be able to feel like you’re not...exploiting people almost.... You’re getting into mental health and that sometimes can be a touchy subject to do in an impersonal manner. I would imagine, through something like an email or a text or MyChart.... I can envision certain patients not really warming up to it, just because it is impersonal and you’re just filling out.... I’m sure the patients, if they have the idea that this is totally for their upcoming visit and we just want to make sure we’re being complete and we want to take care of you, if there’s any concerns in the realm of depression/anxiety, we’d like to be able to address them appropriately.” (Participant 5, physician)</td>
</tr>
<tr>

</tbody>
</table>

**CFIR Domain 1: Innovative Characteristics**

Codes within the innovation characteristics domain focused on the attributes of population-level portal-based screening. The participants spoke about its relative advantage, adaptability, complexity, evidence base, and design quality.

**Facilitator: Advantages of Systematic Screening Outside Clinic Visits**

The participants thought that population-level portal-based mental health screening would help make screening more consistent without imposing additional work or disrupting the clinic workflow. With screening completed ahead of time via the patient portal, the participants felt that they would be better prepared to address these concerns during the visit.

**Facilitator: Expectation That Assessment Frequency Could be Tailored to Patient Needs**

Participants generally thought that sending assessments via the portal every 6 months or once a year would be ideal; however, they mentioned that they would defer to the evidence on screening frequency best practices. The ability to send patients mental health screeners at a custom interval appealed to participants as it would keep them aware of the mental health concerns that arose. The participants also expressed interest in tailoring the screening frequency based on symptom severity.

**Barrier: Difficulty Ensuring Prompt Response to Those in Imminent Risk to Themselves or Others**

A common concern raised during the interviews was the complexity of responding to patients who indicated suicidal risk, self-harm, or homicidal ideation on the screener.
Participants were worried that patients with immediate mental health needs would not receive timely interventions if screening were performed via the portal.

**CFIR Domain 2: Outer Setting**

Codes within the outer setting domain focused on external factors that might affect the implementation of population-level portal-based screening, particularly the needs and resources of the patient population served by the clinic.

**Facilitator: Greater Respect for Patient Privacy**

Participants spoke about how patients seen at the HIV clinic value privacy. They thought that using the portal might increase screening uptake and encourage honest responses by allowing patients the flexibility to complete screening in environments where they are most comfortable.

**Facilitator: Normalizing Mental Health Screening**

Participants recognized the stigma associated with mental illness for some patients. Implementing a routine depression and anxiety screening process was seen as an approach to destigmatize mental health assessments. In addition, participants believed that consistent depression and anxiety screening would frame mental health as part of patients’ general health care, compared with the sporadic mental health assessments in current practice.

**Barrier: Limited Patient Access, Experience, and Comfort Using the Portal**

The participants did not know if patients were familiar enough with the portal to complete the assessments electronically. The participants reported that several of their patients did not know how to access their laboratory work via the portal. Therefore, they were not confident that the patients could complete screeners via the portal without assistance or training. The participants were also concerned about usability issues regarding the small text and reading levels associated with using the portal.

**Barrier: Limited Availability of Mental Health Services**

Participants emphasized that accessible mental health referral pathways and resources were needed before the clinic could implement population-level portal-based screening. Otherwise, patients would be diagnosed without the proper resources to be treated. Although the clinic has existing partnerships with external mental health facilities, waitlists were long. Furthermore, transportation, insurance, and cost barriers limited patients’ access to mental health treatments. In addition, concerns about the capacity of the current referral network to handle an influx of newly diagnosed patients were expressed by participants.

**CFIR Domain 3: Inner Setting**

Codes within the inner setting domain focused on the clinic’s characteristics and readiness to implement population-level portal-based screening. Participants spoke about compatibility, available resources, access to knowledge and information, networks and communication, and culture.

**Facilitator: Compatibility With Clinic Culture, Workflows, and Systems**

Participants strongly expressed interest in implementing population-level portal-based screening for depression and anxiety through the portal and thought their colleagues would also be receptive. Participants stated that this would help create an open relationship with patients while prioritizing clinical values to provide holistic care to their patients. Participants said that using the portal for depression and anxiety screening would provide crucial information on patients’ mental health status without adding significant stress to clinical workflows.

**Facilitator: Protocol for Addressing Positive Screening Results**

Participants wanted a systematic process to manage patients who screened positive to avoid delays in connecting patients to resources. Specifically, participants expressed a desire for detailed guidance on available resources, referral pathways, and a follow-up plan for symptomatic patients. A few participants were interested in additional training or decision support tools to help them interpret screening results, connect patients to resources, and prescribe first-line medications.

**Barrier: Clinician Variation in the Use of EHRs**

Participants expressed concern that screening results in the EHR might be overlooked because clinicians did not always check their electronic in-baskets reliably because of variations in their proficiency and comfort with the EHR.

**Barrier: Limited Capacity to Address Mental Health Concerns During HIV Visits**

Participants raised concerns about having adequate personnel, time, and expertise to manage depression and anxiety. They reported limited time during appointments to address their patients’ health issues and social needs, and there may not be enough time to address depression and anxiety management.

**CFIR Domain 4: Characteristics of Individuals**

Codes within the individual characteristics domain focused on the participants’ knowledge, beliefs, and self-efficacy.

**Facilitator: Participant Beliefs That Mental Health Screening Is Important and Benefits HIV Care**

Most participants agreed that mental health screening was essential and valuable. They saw population-level portal-based screening as an opportunity to learn more about their patients and to address concerns that might not otherwise arise during appointments. Participants recognized the effects of mental health problems on HIV outcomes and were hopeful that addressing depression and anxiety would improve engagement with care and general health.

**Facilitator: Participant Interest in Evidence-Based Practices and Desire to Learn From Prior Implementations**

Participants indicated their willingness to abide by evidence-based mental health screening and management recommendations. They expressed a desire to learn more about how population-level portal-based depression and anxiety screening had been implemented in the primary care clinic so that the lessons learned could be applied to the HIV clinic.
**Barrier: Participant Concerns About Limited Knowledge About Mental Health Treatments**

Some participants were hesitant to implement population-level portal-based mental health screening because they thought that they lacked adequate expertise in mental health treatment and navigating mental health resources.

**CFIR Domain 5: Process**

Codes within the process domain focused on planning the intervention and engaging clinicians and patients.

**Facilitator: Team-Based Approach That Leverages the Strengths of All Clinicians**

Participants believed that a team approach would be crucial for successfully implementing population-level portal-based screening. Social workers were identified as key team members to provide knowledge on available resources and support connecting patients to care. Participants also indicated that engaging clinicians with strong relationships with patients would help lower patient hesitancy to engage with the portal.

**Facilitator: Clear Planning and Communication With Staff**

Participants emphasized the importance of having a standardized protocol that included details on which staff member was responsible for each step, especially in response to positive results, and training for all clinic personnel on this protocol before implementation. Participants highlighted the need for clear communication throughout the intervention’s preimplementation, implementation, and sustainability phases. They advised monitoring the intervention logistics and collecting iterative feedback from staff and patients throughout the intervention rollout.

**Facilitator: A System That Empowers Patients to Communicate About Their Mental Health**

Participants thought that population-level portal-based mental health screening could prompt patients to discuss their mental health with their care team. The participants believed that providing patients with the flexibility to complete screening assessments at their convenience and through their preferred screening method would empower them to inform their care team about their symptoms. Some suggested that screeners should always be readily available in the portal so patients could report their mental health symptoms as they feel them.

**Barrier: Impersonal Approach to the Sensitive Topic of Mental Health**

Participants expressed concerns that portal-based screening might be impersonal and that unexpected messages about mental health might seem invasive or cause anxiety in some patients. The participants emphasized that clear and patient-centered conversations would need to occur to explain the purpose of mental health screening. Otherwise, the participants feared that patients who did not understand the purpose or context of mental health screening would be unlikely to respond. The participants believed that if patients were informed about how these assessments pertained to their general health, they would be more likely to complete the screeners.

**Discussion**

**Principal Findings**

This qualitative study explored facilitators of and barriers to implementing population-level portal-based depression and anxiety screening in an HIV clinic. A total of 10 facilitators and 7 barriers were identified across 5 CFIR domains. Facilitators included the following: advantages of systematic screening outside clinic visits; the expectation that assessment frequency could be tailored to patient needs; evidence from the literature and previous experience in other settings; respect for patient privacy; empowering patients and facilitating communication about mental health; compatibility with clinic culture, workflows, and systems; staff beliefs about the importance of mental health screening and benefits for HIV care; engaging all clinic staff and leveraging their strengths; and clear planning and communication with staff. Barriers included difficulty in ensuring prompt response to suicidal ideation; patient access, experience, and comfort using the portal; limited availability of mental health services; variations in how providers use the EHR and communicate with patients; limited capacity to address mental health concerns during HIV visits; staff knowledge and self-efficacy regarding the management of mental health conditions; and the impersonal approach to a sensitive topic. Several barriers mentioned by participants, such as limited appointment times and limited access to mental health resources after diagnosis, are common challenges cited in similar implementation efforts [2,3,6,7,25,27].

Findings from our analysis have been used to compile a list of proposed implementation strategies to help integrate population-level portal-based depression and anxiety screening into practice within the HIV clinic setting.

**Clinician-Focused Implementation Strategies**

**Strategy 1: Conduct a Local Assessment of Clinicians and Clinic Staff**

Clinicians and clinic staff are essential to successfully implementing population-level portal-based depression and anxiety screening in the HIV clinic. To increase the feasibility and sustainability of the intervention, clinicians and clinic staff should be asked how the intervention would fit with their beliefs and values, the clinic culture, and its current clinical workflows. Clinicians’ and clinic staff’s thoughts should be incorporated into the implementation plan to assist in intervention compatibility and uptake.

**Strategy 2: Engage Clinicians and Clinic Staff With Various Roles and Expertise to Support Implementation**

The success of the intervention depends on clinicians’ engagement through the implementation process to inform the intervention using clinicians and clinic staff’s strengths. Clinicians and clinic staff in various roles may have different perspectives and ideas on implementing the intervention. Therefore, diversifying the staff perspective may provide crucial implementation strategies that might not be known by only interviewing clinicians.
Strategy 3: Highlight Advantages, Relevance, and Evidence for Population-Level Portal-Based Mental Health Screening

Before implementing population-level portal-based mental health screening, the advantages of depression and anxiety screening must be communicated and emphasized to all clinicians. These benefits should highlight how timely mental health discussions between patients and clinicians make efficient use of the limited appointment time. Information on relevant evidence and current clinical screening guidelines should also be provided to garner clinician support. Describing barriers encountered and lessons learned in other practices that have implemented similar interventions could ease concerns about implementation challenges.

Strategy 4: Communicate With Clinicians and Clinic Staff Throughout Implementation and Provide Training on Protocols

Training and involving clinicians throughout the rollout of the intervention will facilitate iterative feedback to troubleshoot any challenges that arise and help aid clinicians and clinic staff uptake. As clinicians and clinic staff tend to have established relationships with their patients, receiving their and their patients’ concerns will aid clinicians, clinic staff, and patient engagement throughout the intervention rollout.

Patient-Focused Implementation Strategies

Strategy 5: Provide Technical Support and Demonstrations for Patients on How to Use the Portal

Providing technical support and conducting training on using the portal might increase intervention uptake among patients. Demonstrations could decrease technology-related barriers and encourage patients to use the portal to complete assessments.

Strategy 6: Use Multiple Screening Methods for Broad Reach

Multiple screening approaches might be needed to reach all patients attending the clinic. For example, options could include completing depression and anxiety screening in the waiting room before an appointment, over the phone, or during an in-person appointment (eg, during intake before the clinician enters the room). Providing additional screening options for patients who are not technologically proficient or have limited access to technology may increase patient uptake of depression and anxiety screening.

Strategy 7: Use Patient-Centered Communication in Portal Messages

Patient-centered messages emphasizing privacy and framing mental health screening as part of routine care can provide a context for portal-based screeners and decrease patient hesitancy to answer questions about the potentially sensitive and stigmatized topic of mental health. Using the patient portal to send patient-centered messages will also allow patients to ask questions about population-level patient-based screening and address concerns.

IT-Focused Implementation Strategies

Strategy 8: Make Screening Frequency Adaptable Based on Patient History and Symptoms

Adaptability of screening frequency and leveraging the staff-patient relationship may improve intervention uptake. Clinicians could adjust the frequency of depression and anxiety screenings based on their relationship with the patient. By allowing staff to adjust the screening frequency, the clinic can check in on patients experiencing uncontrolled depression and anxiety symptoms. Likewise, the staff can lengthen the screening intervals when the patient is in remission for depression and anxiety. This adaptability will signal to patients that the clinic is prioritizing the patient’s health needs.

Strategy 9: Use User-Centered Design Methods to Refine How Results Are Displayed and Communicated in the EHR

When designing how portal-based results will be stored and displayed in the EHR, clinicians and clinic staff need to be engaged to ensure the utility of the screening information. Using a user-centered design with these essential stakeholders could increase the likelihood that portal-based depression and anxiety screening will be used in practice.

Strategy 10: Make Screening Tools Available for Patients to Use on Demand in the Portal

On-demand assessments would support patient autonomy and allow patients to signal when they are experiencing depression and anxiety symptoms. This patient-centered approach could enhance the clinic’s capacity to treat patients when needed. This differs from the traditional annual one-time screening, which aims to identify depression and anxiety in asymptomatic patients. Traditional screening may increase the demand for services and reduce the clinic’s ability to provide timely and appropriate care for symptomatic patients. Moreover, prioritizing on-demand assessments outside of appointment times could facilitate outreach between appointments and reduce the time to treatment.

Clinic-Focused Implementation Strategies

Strategy 11: Create Protocols for Positive Depression and Anxiety Screening Results, Including Those Indicating Imminent Risk

Establishing a standardized protocol for patients who are symptomatic of depression or anxiety may ease concerns about managing patients who are at imminent risk to themselves or others. For example, the protocol can describe who will contact the patient after the clinic has received a positive PHQ or GAD and how to assist patients in crisis. This will ease clinicians’ concerns about screening patients for depression and anxiety via the portal.

Strategy 12: Provide Clinical Decision Support Tools, Training, and Mentorship to Help Clinicians Manage Mental Health Concerns

Providing evidence-based information on treatment or referral strategies through decision support tools, ongoing training, and
clinician mentorship for managing mental health treatment would support clinicians’ confidence and ability to manage symptomatic mental health concerns in their patients. Through shared collaborations with mental health specialists and community mental health services, clinicians will be equipped to manage a potential influx of symptomatic patients via the portal.

**Strategy 13: Implement Integrated Behavioral Health and Increase Mental Health Referral Partnerships**

In concurrence with strategy 12, the clinic will need to invest and establish partnerships with local mental health sites to support the clinic’s capacity to treat newly diagnosed patients. Expanding the clinic’s referral network would create a safety net that the clinic can leverage to refer patients. This would prevent long wait times for treatment after a depression or anxiety diagnosis. By creating a behavioral health referral network, HIV clinicians can provide trusted resources to expand the clinic’s internal infrastructure, facilitate warm handoffs with community partners, and continue to support patient care.

**Limitations**

The study was conducted at a single academic HIV clinic. Therefore, the results of this qualitative analysis may not be generalizable to other HIV clinics with different patient populations, staffing needs, available resources, and portal uptake. The implementation strategies are merely recommendations from a single HIV clinic and may need to be adapted to fit the implementation setting. At the time of the interviews, clinic staff did not have experience with population-level portal-based mental health screening; therefore, their perspectives were based on how they perceived the intervention would be for patients and themselves once implemented. Although our study included perspectives from clinicians in various clinical roles, most interviewees were physicians, limiting available insight. Gaining patient perspectives through patient-focused interviews would provide further insight into facilitators, barriers, and intervention implementation strategies.

**Conclusions**

Our study provides information on clinicians’ views on population-level portal-based mental health screening within the HIV clinic setting. Participating clinicians expressed concerns about the accessibility of prompt mental health resources, patients’ perceptions of mental health screening, variation in clinician use of Epic (Epic Systems, Verona Wi), and limited clinician training on mental health management. Nevertheless, clinicians were interested in establishing population-level portal-based screening at the HIV clinic and were amenable to creating protocols for addressing positive mental health screening, to participating in training about available mental health resources and best practices, and to feeling it was compatible with the clinic. Others may build upon this work by exploring and identifying additional facilitators, barriers, and implementation strategies that were not found in our analysis.

Abstract

Background: The integration of medical and dental records is gaining significance over the past 2 decades. However, few studies have evaluated the opinions of practicing dentists on patient medical histories. Questions remain on dentists’ information needs; their perception of the reliability of patient-reported medical history; satisfaction with the available information and the methods to gather this information; and their attitudes to other options, such as a health information exchange (HIE) network, to collect patient medical history.

Objective: This study aims to determine Indiana dentists’ information needs regarding patients’ medical information and their opinions about accessing it via an HIE.

Methods: We administered a web-based survey to Indiana Dental Association members to assess their current medical information-retrieval approaches, the information critical for dental care, and their willingness to access or share information via an HIE. We used descriptive statistics to summarize survey results and multivariable regression to examine the associations between survey respondents’ characteristics and responses.

Results: Of the 161 respondents (161/2148, 7.5% response rate), 99.5% (n=160) respondents considered patients’ medical histories essential to confirm no contraindications, including allergies or the need for antibiotic prophylaxis during dental care and other adverse drug events. The critical information required were medical conditions or diagnosis, current medications, and allergies, which were gathered from patient reports. Furthermore, 88.2% (n=142) of respondents considered patient-reported histories reliable; however, they experienced challenges obtaining information from patients and physicians. Additionally, 70.2% (n=113) of respondents, especially those who currently access an HIE or electronic health record, were willing to use an HIE to access or share their patient’s information, and 91.3% (n=147) shared varying interests in such a service. However, usability, data accuracy, data safety, and cost are the driving factors in adopting an HIE.

Conclusions: Patients’ medical histories are essential for dentists to optimize dental care, especially for those with chronic conditions. In addition, most dentists are interested in using an HIE to access patient medical histories. The findings from this study can provide an alternative option for improving communications between dental and medical professionals and help the health information technology system or tool developers identify critical requirements for more user-friendly designs.

Introduction

More than 20 years ago, the first US Surgeon General’s Report on Oral Health in America established oral health as an essential component of overall health and well-being [1]. In 2021, the National Institutes of Health (NIH) reemphasized the importance of establishing integrated medical and dental care in their updated report on Oral Health in America [2]. In addition, the NIH identified integrating medical and dental records as critical to enhancing medical and dental care [2]. The integration of medical and dental records is gaining significance for several reasons. First, increased evidence during the last 3 decades indicates strong associations and shared risk factors between oral and systemic diseases such as diabetes and heart diseases [2,3]. Second, the siloed systems of dental and medical data create challenges in information sharing [2,4,5], often resulting in incomplete or inaccurate patient medical information, which may cause significant patient care and safety issues in dental care [6-9]. Third, recent studies have revealed discrepancies in medical conditions and medications in the electronic dental record (EDR) versus electronic health record (EHR) [3,6,10-14] and demonstrated substantial delays when dentists are required to request additional medical information from physicians [15]. Other reasons for the increased significance of integrated medical and dental records include the rapid development of information technologies, which provides a solid base for integration, and the impact of the COVID-19 pandemic, which proves the urgency and importance of integrating medical and dental records [16-18].

The use of an integrated EDR-EHR system has been growing in large health care organizations (HCOs) such as the Veteran Affairs health care systems, Department of Defense, health maintenance organizations, and federally qualified health centers, where medical and dental practices are colocated and share patient care and records [19-21]. Numerous studies have reported physicians using integrated EDR-EHR systems to refer patients to dentists and vice versa for preventive and comprehensive care [19,21-23]. However, for most dentists who work in small independent practices, patients continue to be the primary source of their medical history and dentists’ communications with medical providers are limited [24]. Nevertheless, the solo and small-group dental practices, which constitute 50% of the dental workforce [25], cannot adopt such integrated systems without being credentialed to a major HCO. It is also not practical for dental practices to have separate interfaces to different EHR systems, which may interfere with their clinical workflows and business processes, such as billings and regulatory policies [3].

With the support of several federal policies, such as the Health Information Technology for Economic and Clinical Health Act and the 21st Century Cures Act [26,27], and the financial incentives established by the Centers for Medicare and Medicaid Services [28,29], community and regional health information exchanges (HIEs) have expanded significantly since 2009. HIE systems provide another option for integrating medical and dental records [24]. In an earlier study by the team, we modeled 3 methods for dentists to access their patient’s medical histories: the patient-reported medical history followed by the optional medical consults method, the integrated EDR-EHR, and the HIE approaches [24]. Our models showed that the HIE approach could provide benefits for reducing unnecessary medical consultants, avoiding the delay of care, improving information quality, and cutting additional technical and financial overheads for small independent practices. In addition, a report published in 2021 indicated a decrease in dentists working solo [25]. Nevertheless, an HIE-based integrated solution can help small and large group practices improve data completeness and compliance by obtaining data from multiple HCOs and taking advantage of expert services provided by an HIE. However, efforts to connect dentists with an HIE are minimal compared to the extensive studies on integrated EDR-EHR [19-22].

Despite the widespread interest in integrating dental and medical care, few studies have evaluated the opinions of practicing dentists on patient medical histories [26,30]. For example, a recent study published by the American Dental Association Clinical Evaluators Panel reported that most dentists gathered their patients’ medical history and medication list via patients’ self-report and recorded vital signs during dental visits [30]. However, questions remain on dentists’ information needs; their perception of the reliability of patient-reported medical history; satisfaction with the available information and the methods to gather this information; and their attitudes to other options, such as an HIE, to collect patient medical history.

Given this knowledge gap, we surveyed dentists in 1 US state about their information needs and practices concerning retrieving patient medical history information. Our objectives were to determine their information needs regarding patients’ medical information and their opinions on accessing it via an HIE.

Methods

Recruitment

We administered a web-based survey to the Indiana Dental Association (IDA) members from March 19, 2021, to April 30, 2021. All participants are general dentists or specialists either currently or previously practicing in the State of Indiana. We only included dentists in this survey because they are responsible for diagnosing and planning treatments, which also involve ruling out contraindications. The survey was administrated through the Indiana University–approved Qualtrics Experience Management platform XM. We sent emails to 2148 IDA members over 6 weeks, including 1 initial invitation, 5 reminders, and 1 final thank you note.

Ethical Considerations

Participation in the survey was voluntary, responses were anonymous, and participants could only respond once (configurations blocked multiple responses in the web-based survey tool). Participants gave informed consent by accessing the link provided in the study invitation email. The patients were not compensated. This study received exemption approval from the Indiana University Institutional Review Board (Protocol #2012972646).
Survey Construction and Validation

The survey included 27 questions covering 3 topics: 12 on demographics, 11 on information needs and gathering, and 4 on exchanging patient medical information (Multimedia Appendix 1). Demographic information included sex, years in practice, primary practice information (type of practice, general practitioner or specialist, typical procedures, patient age groups), and EDR use. The information needs and data gathering section included questions related to dentists’ information needs, existing methods for collecting information, and challenges in these approaches. Finally, the exchange of patient medical information section included dentists’ opinions on using an HIE-based information platform to receive and share patients’ medical information. The survey had 23 multiple-choice questions, two 0-10 Likert-scale questions, and 2 open-ended questions. We administered the survey after assessing the face validity and content validity of the questionnaire. The face validity was assessed with research team members who were not involved in the development of the survey questions, and the content validity was assessed with 3 dentists—2 from the Indiana University School of Dentistry and 1 from private practice. These tests ensured that the survey was appropriate, understandable, and could be completed within a reasonable time.

Statistical Analysis

Data analysis included only completed responses. Partially answered surveys were eliminated from the final analysis. Data were summarized using frequencies and percentages for categorical variables and mean and SDs for continuous variables. Associations between characteristics of dentists (years in practice, dental professions, and current access to an HIE or a hospital or medical practice–based EHR [hereby referred to as HIE-EHR]) and their opinions on the importance and reliability of patients’ medical histories and perceptions of accessing patients’ medical histories via an HIE were examined using multivariable regression. The ordinal logistic regression model was used due to the ordinal nature of these variables. All statistical analyses were performed using SAS (version 9.4, The SAS Institute). *P* < .05 were considered statistically significant.

Results

At the end of 6 weeks, 219 (10.2%) out of 2148 IDA members accessed the survey, and 188 (8.8%) members responded to at least 1 question, of which 161 (7.5%) members reached the end of the survey.

Demographics

A total of 64.6% (102/158) of the respondents were male (Table 1). Their average years in practice was 25.72 (SD 13.52) years. A total of 74.5% (120/161) of the respondents were general practitioners, and the rest were dental specialists (Table 1). A total of 8 dental specialties were reported: oral and maxillofacial surgery (10/41, 24.2%), periodontics (8/41, 19%), orthodontics (7/41, 16.7%), pediatric dentistry (7/41, 16.7%), endodontics (4/41, 11.9%), operative dentistry (2/41, 4.8%), prosthodontics (2/41, 4.8%), and oral and maxillofacial pathology (1/41, 2.4%). The total percentage is more than 100% since some respondents reported more than 1 specialty.

</table>
In all, 78.8% (126/160) of respondents reported working in private practices as owners or associate dentists (Table 1). Approximately half (75/160, 46.9%) of the respondents reported having 1 dentist in their primary dental practices, while 10% (16/160) of respondents reported their primary practice having more than 10 dentists. Most respondents’ (110/160, 68.3%) primary practices had 2-5 hygienists, while 19% (31/160) of respondents’ practices had no hygienists. The 3 most frequently performed procedures were diagnostic and preventive such as an examination, X-rays, scaling, prophylaxis, sealants, fluoride, etc (136/161, 84.4%); restorations or fillings (125/161, 78.1%); and tooth-supported or implant-supported crowns (105/161, 65.3%). The respondents served a diverse age group of the patient population, with an average of 19.6% (31/157) of patients 18 years or younger and 22.5% (35/157) of patients 65 years or older (Table 1).

About 4 in 5 (128/161, 79.5%) respondents reported using an EDR for not only billing or scheduling but also for clinical or patient data management. The top 3 brands of EDR were Dentrix (145/161, 35.7%), EagleSoft (19/161, 15.1%), and axiUm (14/161, 11.1%; Table 1).

### Dentists’ Opinions on the Importance of Medical Histories and Reliability of Patient-Reported Medical Histories

Almost all respondents (160/161, 99.5%) considered patients’ medical histories highly or moderately important during dental care (Table 2). They reviewed medical histories to (1) verify no contraindications exist to undergo a dental procedure (37/161, 23.2%), (2) confirm no need for antibiotic prophylaxis before the dental procedure (36/161, 22.7%), (3) rule out any allergies or adverse drug reactions (35/161, 22%), (4) assist with determining the prognosis of an oral disease or treatment outcomes (35/161, 21.7%), (5) detect normal and abnormal laboratory results (14/161, 8.4%), and (6) for other purposes (3/161, 1.9%). Only 1 respondent considered patients’ medical histories unimportant since they felt gathering medical history to be procedural and not essential for dental care. Regarding the reliability of patient-reported medical histories, 8% (n=13) of respondents considered them highly reliable, 79.5% (n=128) moderately reliable, and 12.4% (n=20) unreliable.

\(^a\)HIE: health information exchange.

\(^b\)10-level Likert scale was used with ranges as follows: 1-5=not important or reliable, 6-8=moderately important or reliable, and 9-10=highly important or reliable.
**Dentists’ Information Needs Regarding Their Patient’s Medical History**

The 3 most needed information categories for new and existing patients were medical conditions or diagnosis, current medications, and allergies. Other categories included hospitalizations in the last 2 years, substance abuse, procedures in the previous 5 years, laboratory results from the last 6 months, and immunization records. The respondents evaluated the information needs of new and existing patients separately, and there were no significant differences in the results (Table 3).

**Dentists’ Access to Their Patient’s Medical History**

We also asked the dentists how they collected patient-reported medical histories and obtained additional information if needed. Paper-based health history forms constituted the most used method (127/161, 78.9%), followed by web-based health history forms (62/161, 38.5%) and electronic devices such as tablets (35/161, 21.7%). The total percentage is more than 100% since some respondents reported using more than 1 method. The top 3 challenges in collecting patient-reported medical history were as follows: (1) patients do not remember or recall medication names and dosage (156/161, 96.9%); (2) patients do not recall previous procedures and medical conditions (129/161, 80.1%); and (3) patients’ reluctance to share their medical history (84/161, 52.2%). When the respondents needed additional information, most (158/161, 98%) contacted physicians’ offices or health care providers directly via phone, fax, or email. Other communication methods included paper-based medical consult forms through the patient (46/161, 28.6%), patient’s pharmacy (39/161, 24.2%), state-based HIE (19/161, 11.8%), exchange capability between dental software and electronic medical record system (5/161, 3.1%), integrated dental-medical record system (4/161, 2.5%), and other (9/161, 5.6%). However, they experienced challenges such as the need for multiple attempts (97/161, 60.2%), not receiving information on time (80/161, 49.7%), physician offices being nonresponsive (66/161, 41.0%), need to contact multiple providers or specialists (55/161, 34.2%), need for patient intervention (44/161, 27.3%), and not receiving requested information (35/161, 21.7%).

**Dentists’ Perceptions of Accessing Patient History via an HIE**

A total of 69.6% (113/161) of respondents considered access to a regional HIE useful (Table 2). If such a system were available, 69.9% (n=113) of the respondents would consider using it to access their patient’s medical information, and 61.5% (n=99) would be willing to allow other health care providers to access their patients’ clinical information (Table 2). Furthermore, 91.3% (n=147) of the respondents expressed various interests in participating in a service to access an HIE (Table 2). However, they expressed concerns over the design and implementation of such a system, including data accuracy, data security and HIPAA (Health Insurance Portability and Accountability Act) compliance, cost of implementation (both time and money), and system usability.

The association between respondent characteristics (including dental profession, number of years in practice, and current access to an EHR or HIE) and their opinions on the importance and reliability of patients’ medical histories and perceptions of accessing patients’ medical histories via HIE based on multivariable ordinal logistic regression is displayed in Table 4. Dental profession type (general practitioner vs dental specialist) does not significantly affect one’s opinions toward the importance (P=.98) and reliability (P=.31) of patients’ medical history. However, respondents with more than 40 years in practice were less likely to consider obtaining up-to-date patient information important compared to those with less than 40 years in practice (odds ratio [OR] 0.351, 95% CI 0.139-0.889; P=.047). In addition, respondents with access to an HIE-EHR were more likely to consider obtaining up-to-date patient information important compared to those who do not have access to an HIE-EHR (OR 2.267, 95% CI 1.011-5.084; P=.047). Regarding the respondents’ perceptions of using an HIE to access patients’ medical histories, we found that dental specialists were more interested than general practitioners in participating in service to access patient information via an HIE (OR 2.267, 95% CI 1.174-4.378; P=.02). Compared to respondents without current access to an HIE-EHR, those with access to an HIE-EHR were more likely to think it worthwhile to access such a system (OR 6.306, 95% CI 2.671-14.886; P<.001), more likely to consider using such a system to access their patient’s information (OR 5.538, 95% CI 2.379-12.892; P<.001), more likely to allow other providers to access their patient’s data (OR 2.943, 95% CI 1.342-6.456;

Discussion

Principal Findings

We surveyed Indiana dentists to determine their information needs regarding patients’ medical histories and their opinions on accessing patient-specific medical information via a community or regional HIE. The survey respondents’ demographics distribution closely matched the dentists’ demographics in the 2020 Indiana oral health workforce data report [31]. In addition, the response rate of 7.5% (161/2148) is comparable to previous surveys of health care professionals, especially web-based surveys [32-34]. The results demonstrated dentists’ high priority in obtaining their patients’ medical diagnoses or conditions, medication histories, and allergies to provide optimum dental care. The survey respondents also reported challenges in getting medical information from patients and medical providers, although they considered patient-reported medical histories moderately or highly reliable. It is also significant that 70% (112/160) of surveyed dentists who work primarily in community practices (Table 1) expressed willingness to use and participate in a service to access and share their patients’ medical histories via an HIE.

Nevertheless, the participants commented that usability, data accuracy, data safety, and implementation costs would drive dental providers’ use of such services. Integration of dental and medical record data is critical to promote communication and care coordination between dental and medical providers and has gained tremendous attention in recent years [2]. However, existing studies only highlight case studies of integrating dental and medical care in large health care systems [19-21]. Through this study, we determined community practice dentists’ information needs and attitudes toward accessing patient medical information via an HIE. These study results contribute to dental professionals’ high-priority information needs and HIE functionalities for successfully using the expanding HIE network in the United States and other countries. In the sections below, we discuss the relevant findings in detail.

Dentists with <40 years of experience or having access to an HIE-EHR system felt patients’ medical histories were more critical than those with >40 years of experience, even though almost 90% (145/161) of the dentists considered patients’ medical histories essential (Table 2). This difference could be because, until 2 decades ago, only limited information technology existed for dentists to access their patient’s medical information except for patient-reported medical history and medical consults. This limited access to EHR data may explain why dentists with more than 40 years in practice were more likely to think patient-reported information as reliable (Table 4). Additionally, dentist respondents who already have access to an HIE-EHR system felt patients’ medical histories were more accurate and may have better quality of information.

Our survey found that the most needed information categories were medical conditions or diagnosis, current medications, and allergies (Table 3), which was consistent with a previous survey [26]. Together these findings showed that some categories of patient medical information were more helpful to dentists during dental care. These findings can also be used to optimize the user interface design in either an EDR-EHR system or an HIE to avoid information overload. However, our team’s earlier studies on medical consultations discovered that dentists’ most requested information categories were laboratory values and written diagnostic reports, followed by recommendations or medical
clearances [15]. The inconsistency of these results indicates that dentists’ information needs can evolve based on access to relevant information. As they gain access to EHR information, they can ask more specific and informed questions when consulting their medical colleagues, leading to increased responses from medical colleagues. This improved information access may enhance dentists’ patient management and treatment planning. The results also indicated dentists’ information needs for new and existing patients were almost identical (Table 3).

Future studies should continue investigating dentists’ information needs as they gain direct access to patients’ up-to-date medical information via an EDR-EHR system or an HIE.

The survey respondents, especially those with access to an HIE-EHR, showed clear interest in using the HIE to optimize the information collection process (Tables 2 and 3). For instance, 11.8% (19/161) of the respondents reported access to a state-based HIE, which was higher than expected. This higher access rate could be attributed to dental providers’ access to state-wide information systems, such as Indiana’s Prescription Drug Monitoring Program, and may have mistaken it for an HIE. Nonetheless, several state-wide HIEs are promoting dentists’ use of HIEs to improve access to patient information [35-37]. However, the overall use during dental care remains low. For instance, a study of New York dentists’ use of the Rochester regional HIE demonstrated a 0.17% rate of use of the HIE during dental encounters [35]. This low use is not surprising given that the use of community HIEs, even by nondental providers, is still growing, with 1% to 5% use in all patient visits. In the New York dentists’ study, they accessed the HIE primarily for patients with chronic conditions, gingival and periodontal diagnosed diseases, and during the first dental visit [35]. The most frequently visited sections were the laboratory and radiology sections within the HIE, which is consistent with our earlier study results of dentists’ medical consult requests [15].

Although the emergence of community and vendor-supported HIEs has improved medical providers’ timely access to patient information [38-41], inefficient and cumbersome processes and poor user experiences are significant barriers to HIE use [42,43]. Previous studies in medical settings reported that some HIEs require users to have multiple logins; interrupt their workflow; and display overloaded and poorly arranged information [42,43]. Our study respondents expressed similar concerns about the usability of HIEs, such as difficulty accessing data, information overload, and nonintuitive interface designs that could prevent dentists’ use of HIEs. Therefore, future HIE tools’ design and development should focus on the accuracy and integration of the data (content) and the information display and navigation (presentation). Few respondents including those willing to use an HIE expressed concerns about accessing patients’ medical histories via an HIE due to data safety and HIPAA compliance concerns. This issue needs to be addressed both at the technical level with more new tools and methods to ensure safe data sharing and exchanging and at the regulatory level with new protocols and rules to support the use of HIEs. Furthermore, most respondents agreed that patients should be able to control the use of their health care information, and their consent must be received before any information exchange and sharing occur.

Limitations

This study only invited Indiana dentists who are IDA members. A more geographically diversified pool of participants may help improve the results’ validity and generalizability. In future studies, we also want to include other dental professionals, such as dental hygienists and dental assistants. We are aware of the relatively low response rate to the survey, which is not rare in surveys of health care professionals, especially web-based surveys [32-34]. This was an exploratory study and our initial step to determine dentists’ information needs and to help improve their information access. Based on the results of this survey, we will conduct key informant interviews and focus group studies to include a broader group of participants. Another limitation was that dentists may not be familiar with some of the terminologies used in the survey such as state-based HIEs. Terminology definitions and examples should be included in future survey designs.

Conclusions

Patients’ medical histories are essential for dentists to provide high-quality dental care. In addition, information such as medical conditions or diagnosis, current medications, and allergies are more relevant to dentists’ clinical decision-making. Paper-based health history forms and medical consultants are still the most widely used methods to gather information. However, electronic forms and integrated systems are gaining attention to have direct access to information. Most dentists are interested in using an HIE to access patient medical histories. The findings from this study can provide an alternative option for improving communications between dental and medical professionals and help the health information technology system or tool developers identify critical requirements for more user-friendly designs.

Abstract

Background: Individuals with autism often experience heightened anxiety in workplace environments because of challenges in communication and sensory overload. As these experiences can result in negative self-image, promoting their self-efficacy in the workplace is crucial. Virtual reality (VR) systems have emerged as promising tools for enhancing the self-efficacy of individuals with autism in navigating social scenarios, aiding in the identification of anxiety-inducing situations, and preparing for real-world interactions. However, there is limited research exploring the potential of VR to enhance self-efficacy by facilitating an understanding of emotional and physiological states during social skills practice.

Objective: This study aims to develop and evaluate a VR system that enabled users to experience simulated work-related social scenarios and reflect on their behavioral and physiological data through data visualizations. We intended to investigate how these data, combined with the simulations, can support individuals with autism in building their self-efficacy in social skills.

Methods: We developed WorkplaceVR, a comprehensive VR system designed for engagement in simulated work-related social scenarios, supplemented with data-driven reflections of users’ behavioral and physiological responses. A within-subject deployment study was subsequently conducted with 14 young adults with autism to examine WorkplaceVR’s feasibility. A mixed methods approach was used, compassing pre- and postsystem use assessments of participants’ self-efficacy perceptions.

Results: The study results revealed WorkplaceVR’s effectiveness in enhancing social skills and self-efficacy among individuals with autism. First, participants exhibited a statistically significant increase in perceived self-efficacy following their engagement with the VR system ($P=.02$). Second, thematic analysis of the interview data confirmed that the VR system and reflections on the data fostered increased self-awareness among participants about social situations that trigger their anxiety, as well as the
behaviors they exhibit during anxious moments. This increased self-awareness prompted the participants to recollect their related experiences in the real world and articulate anxiety management strategies. Furthermore, the insights uncovered motivated participants to engage in self-advocacy, as they wanted to share the insights with others.

**Conclusions:** This study highlights the potential of VR simulations enriched with physiological and behavioral sensing as a valuable tool for augmenting self-efficacy in workplace social interactions for individuals with autism. Data reflection facilitated by physiological sensors helped participants with autism become more self-aware of their emotions and behaviors, advocate for their characteristics, and develop positive self-beliefs.

autism; virtual reality; workplace; self-efficacy; social skills; data reflection

**Introduction**

**Background**

Approximately 40% of individuals with autism experience anxiety because of difficulties in socializing, sensory sensitivities, and other factors [1-3]. Specifically, workplace environments can amplify anxiety in individuals with autism, such as sensory overload, communication barriers, and unplanned interactions [4-8] as these environments are often designed with neurotypical expectations in mind. When people with autism constantly encounter situations that elicit anxiety, it can cause them to have negative self-beliefs about their skills and performance, which can lower their self-confidence in the workplace [9]. Therefore, self-efficacy—the personal judgment or belief in one's ability to succeed in prospective situations—is crucial for people with autism because it can help individuals approach challenging workplace experiences from a positive perspective, as opposed to focusing on failure [10,11].

Virtual reality (VR) interventions have demonstrated potential effectiveness in promoting the self-efficacy of people with autism, as they provide a safe yet realistic environment to master specific social skills by offering opportunities to repetitively practice them [12-18]. Although this exposure and repetition are useful for mastering skills, gaining a deeper understanding of specific social situations that trigger anxiety can better prepare users to effectively manage those situations in the real world. An individual’s understanding of anxiety-inducing situations and crafting self-beliefs that they have the capabilities to succeed in those situations align with 2 key constructs of the self-efficacy theory by Bandura [19,20]—physiological states and verbal persuasion. Notably, VR can also support physiological state awareness and verbal persuasion. It can identify the VR situations that prompt significant changes in a user’s physiological data, enabling the user to reflect on these experiences and formulate strategies to respond effectively [18]. This process can empower the development of self-efficacy [19]. However, existing VR interventions often limit the scope of self-efficacy to mastery experiences only [21] and fail to provide the extended theoretical rationale or background of self-efficacy on the design or outcomes of the system.

In this study, we expanded the current VR system by incorporating a feedback model in which the user’s behavioral and physiological sensor data can be reviewed immediately following the experience simulation, allowing for situational reflection.

Our research aimed to increase self-efficacy through a VR-based social skill training system for individuals with autism. Furthermore, we investigated how the facilitation of self-understanding through incorporating reflection of physiological and behavioral data immediately after the social skills practice can impact self-efficacy in preparation for real-life scenarios.

**Objectives**

This study had 2 main objectives. First, we developed WorkplaceVR, a VR application that allows people with autism to engage in simulated work-related scenarios to help understand their performance through data-driven reflection, with users’ behavioral and physiological data collected during the VR experience. Second, we evaluated the feasibility of the WorkplaceVR by conducting a deployment study with 14 young adults with autism. Using a mixed methods approach, we investigated the changes in self-efficacy among users with autism using pre- and postsurvey questionnaires. In addition, we conducted interviews to identify how participants with autism use, expect, and encounter challenges in the VR experience.

**Methods**

In this study, we designed and implemented WorkplaceVR, a VR-based system that offers simulations of work-related social situations and data-driven reflection of users’ behavioral and physiological responses (Figure 1).
Figure 1. WorkplaceVR is a virtual reality–based system that offers immersive experiences of work-related social situations. With WorkplaceVR, our participants practiced their social skills in a simulated café environment in 2 basic-level and 2 advanced-level scenarios. Our findings highlighted that participants with autism were actively engaged in WorkplaceVR: placing their hands on the physical desk where the virtual counter was (top) and turning to face the virtual manager when conversing (bottom).

Phase 1: Development of the VR System (WorkplaceVR)

Inclusive and Iterative Design for the VR Program Development

Our user-centered design approach to developing the VR system is to ensure inclusivity; technology must empower a more diverse and inclusive society [22,23]. We aimed to build a safe and less stressful virtual environment for people with autism, where they can become familiar with the workplace environment and practice interacting with others without fear of failure. Moreover, with inclusive design in mind, we conducted an iterative design process to incorporate the voices of people with autism into the VR program.

We first conducted a preliminary study to draw design suggestions for the VR program [24]. To elicit end-user feedback, we created a 5-minute video prototype demonstrating the overarching concept and the use scenario of the WorkplaceVR program. Using the video prototype, we conducted semistructured interviews with 20 participants, including individuals with autism (employees, job seekers, etc), managers of companies where people with autism are currently working, psychiatrists, and professional counselors, to uncover the various needs of individuals with autism at workplaces. Through the interview results, we identified the following key design insights. First, the participants emphasized the importance of designing realistic VR scenarios to help users engage in the program by reflecting on their personal experiences or challenges at work. Second, the system should guide users to reflect on their emotions and behaviors. Finally, during the data reflection phase, participants with autism should be able to take control of expressing their thoughts and behaviors and build confidence.

With insights from the preliminary study, we developed our WorkplaceVR program (Figure 1). The system comprises 2 parts: the simulation VR scenario and the physiological data visualization interface. WorkplaceVR was developed using the Unity3D engine (Unity Technologies) and the SteamVR plug-in (Valve Inc) and runs on a Windows 10 (Microsoft) PC with an Intel Core i7, GeForce RTX 2070 graphics card, and 16 GB RAM. A head-mounted display (HMD), VIVE Pro Eye VR headset (HTC) [25], and Empatica E4 wristband (E4 band, Empatica Inc) [22] were worn by the users for viewing the virtual world and sensing physiological signals.

We conducted a pilot study with 4 neurotypical participants to assess the study protocol and identify any risks and challenges that users might experience in trying WorkplaceVR. The participants were introduced to the VR system, experienced WorkplaceVR using an HMD, and then asked to provide feedback on the overall experiences, including task difficulty and scenario length, visual components of the interface, and side effects of the VR experience if there were any (eg, motion sickness, headache, and visual disturbance). On the basis of participants’ suggestions, we added additional visual cues, such as a shining effect to objects (eg, the bill receipt) for users to quickly find and interact with in the 3D environment and an arrow user interaction icon to lead the eye to a specific direction or object to draw attention to specific objects or areas of interest when needed. Another problem raised by the users was regarding the test environment setup. To facilitate an environment where the users can feel safe and private, we placed a blackout curtain in front of the desk where they stood during the experiment.

WorkplaceVR: System Design

In this section, we elaborate on the features and design considerations of the VR system, WorkplaceVR, based on the self-efficacy theory by Bandura [19,20].

Designing VR Contents for Mastery Experience

VR can offer mastery experiences by simulating real-world scenarios that can engage users with autism to accomplish tasks related to workplace settings. To achieve this, our design
approach focused on three key factors: (1) the inclusion of authentic work scenarios, (2) the integration of evidence-based social skills, and (3) the incorporation of multiple levels of difficulty within the scenarios.

1. Realistic work scenarios: we used café scenarios with work-related realistic visuals and auditory stimuli that provide a sense of surrounding in the immersive environment. For example, we designed café furniture and appliances (eg, a cash machine and a coffee machine) and instrumental background music to create a relaxing café atmosphere. Specifically, we selected a situation in which the barista must inform a customer that the drink they ordered is ready from among the situations that are required when working in a café (eg, greeting customers upon entry and taking customer drink orders).

2. Evidence-based social skills intervention: in specific café-based scenarios involving interactions between a barista and a customer, we incorporated evidence-based social skills (eg, active listening, initiating conversations, and not interrupting when someone else is talking) derived from interventions supported by previous research [26,27]. In addition, we included context-specific skills (such as informing customers about available options, verifying order accuracy, and problem-solving in unforeseen circumstances) sourced from the café service training manual [28,29].

3. Levels of scenarios: for the users to build self-efficacy, it is important to help them reduce anxiety and fear of failure by designing attainable goals that gradually increase in difficulty [19,30-32]. Thus, we designed 4 scenarios with 2 levels of difficulty: basic and advanced. The basic level requires the users to explore and interact with a simulated 3D environment to practice basic conversational skills as baristas. Following this, the users are involved in starting a conversation with a customer avatar by offering a polite greeting, taking orders, and serving beverages such as coffee. The 2 scenarios at this level have the same structure but different order details (number and types of beverages). When the users perform these tasks successfully, they are moved on to the advanced-level scenarios. At the advanced level, the scenario adds complications that arise within the conversation with the customer avatar (eg, a customer avatar claiming that their drink order is wrong).

**Physiological Data and Visualization Interface**

In the self-efficacy theory, Bandura [19,20] explains that people can shape their perceptions and beliefs about their capabilities by examining one’s physiological and emotional states. Therefore, one of our goals in designing the VR program was to help users better understand their emotions and behaviors by identifying their physiological states and behaviors in social situations [12,33]. We aimed to support people with autism to become more aware of their physiological and emotional states when they face stressful or anxiety-raising situations in the virtual work environment. Hence, we collected the users’ behavioral and physiological data during the VR intervention using the E4 band and HMD. We synchronized the time stamp information transmitted from E4 with the HMD time stamp information using the open-source framework Flask [34]. In addition, we presented a data visualization interface for users to understand and interpret their data along with their recorded performance videos, as illustrated in Figure 2. On the interface, we present (1) anxiety-related physiological measures (eg, temperature, electrodermal activity [EDA], and heart rate [HR]; Figure 2B); (2) changes in voice volume (Figure 2C); and (3) detection of eye contact (Figure 2D). The following explains how we defined, processed, and visualized each data type: anxiety moments, voice volume, and eye contact.

1. Anxiety moments: anxiety moments were defined using the time stamp on data collected when the sensors detected radical changes in the signal because of the users’ physiological reactions to the stimuli. We calculated anxiety moments using an anomaly detector provided by the Microsoft Azure machine learning algorithm [35]. This involved 5 sensor types—HR, EDA, temperature, interbeat intervals, and blood volume pulse—provided by the E4 band. We presented the anxiety moments on the interface with a time stamp range in seconds; each time stamp is linked to the exact time of the performance video. Users can click on a time range to watch their performance video on the left, as shown in Figure 2A.

2. Voice volume: voice data were collected using the microphone of the HMD. We then presented the voice volume level as a graph with time stamps to help users recognize changes in their voice tone and volume (Figure 2C).

3. Eye contact: to help participants understand their eye movements during their moments of anxiety, we used a region of interest (ROI), which is a specific area within an image or video selected for analysis. In our study, we set the faces of the customer and manager avatars as ROIs. We used the box collider of Unity3D and measured whether a user gazes at ROIs through Tobii G2oM [36], which is a machine learning algorithm that can accurately ascertain on which objects a user focuses. If the participant looked anywhere in that location, it was labeled as seen (1); if they looked at another area, it was labeled not seen (0) in 1-second units. On the basis of the labeling results, we presented the seen labeled periods as a bar graph to help users understand how they make eye contact with people during VR scenarios, as presented in Figure 2D.
Verbal Persuasion Through User-Driven Insights

In this study, we focused on facilitating a data-driven reflection process to leverage verbal persuasion for users with autism to engage in the sense making of their physiological data. Our goal was to provide an opportunity for users with autism to navigate their physiological and behavioral data results, identify their own strengths and interests, and gain confidence in speaking about themselves. Thus, the participants were given an active role in interpreting their data and answering questions such as What insights have you gained from the data about your characteristics or strengths? and What are your goals, taking data into account?

Phase 2: Implementation of the VR Program With Participants With Autism

We recruited participants with autism aged >16 years who are either currently employed or unemployed but plan on job searching in the near future. Our inclusion criteria for participants with autism were people who (1) have been diagnosed with autism; (2) can verbally articulate their thoughts, feelings, and experiences; (3) have no difficulties wearing an HMD for VR (eg, sickness or headaches while in VR or vision impairment, such as anisometropia); and (4) understand the study procedure and agree to participate. We posted the study posters to autism-related web-based communities on social networking services and web-based bulletin boards of autism-related institutions (eg, developmental disability social welfare centers and employment agencies for people with disability). In addition, we placed the flyers on the offline bulletin board of a child and adolescent psychiatry outpatient clinic in a hospital and a private counseling center for individuals with autism to outline the participant demographics.

Ethical Considerations

To ensure ethical conduct, our study received approval from the Institutional Review Board of Seoul National University Bundang Hospital (institutional review board number: B-2202-736-302). As this study involved the collection of sensitive information (eg, physiological data) from participants, we informed the participants about the data collection process and obtained their informed consent before they participated in the study. The researchers explained the consent form to the participants with autism in easily understandable terms. We also clarified to the participants with autism that any personal information, VR data and sensor data collected during the research would be anonymized for analysis and securely discarded to protect their privacy. In addition, we offered a compensation of US $50 for the research participants.

Measures

Perceived Self-Efficacy for VR Social Skill Training Scale

We developed the Perceived Self-Efficacy for VR Social Skill Training Scale (PSES-VR), an 8-item questionnaire with a 5-point Likert scale, to evaluate whether our VR intervention changed people’s beliefs regarding the self-efficacy of practicing social skills at the workplace. We developed this scale by modifying the Perceived Self-Efficacy questionnaire based on the theory of perceived self-efficacy by Bandura [37] and referencing existing scales, including the Perceived Social Self-Efficacy Scale [37], Perceived Improvement Scale [38], and Self-Efficacy Scale for Social Workers [39]. The questionnaires were revised to address the target social skills in the VR scenario. The 6 items consisted of communication skills required in general conversation situations. The 2 items evaluate whether participants respond appropriately to the situation required in the VR program scenario. Higher total scores on the items indicate better self-efficacy related to the social skills of the participants. The participants were asked to complete the same PSES-VR survey before the user study session and after the VR experience. All items of the PSES-VR are attached in Multimedia Appendix 1.
iGroup Presence Questionnaire

We used the iGroup Presence Questionnaire (IPQ), a 14-item questionnaire with a 7-point Likert scale, to investigate how users perceive a sense of presence of our VR system. The IPQ scale consists of 4 components: a general sense of being there (1 question), the sense of spatial presence (5 questions), involvement (4 questions), and experienced realism (4 questions), measuring the level of perceived presence during the VR experience [40]. Higher scores on the 4 components, as well as the total scores, indicate a better sense of presence in the VR system as perceived by the participants. All items of the IPQ are attached in Multimedia Appendix 1.

Study Procedure

Our study procedure included three stages: (1) pre-experiment, (2) VR experiment, and (3) postexperiment reflection phase. Figure 3 presents a summary of the procedure.

![Figure 3. Overview of the study procedure: (A) before the experiment, (B) virtual reality (VR) experiment, and (C) after the experiment.](image)

**Before the Experiment**

To start, the researchers provided a brief overview of the study purpose and conducted a brief interview with participants, asking questions about their work-related experiences and previous experiences with VR. Next, the researchers introduced WorkplaceVR with explanations of the contents of the VR system and sensor devices that the participants should wear during the VR experiment. After that, the participants had a tutorial session to learn the 2 basic-level scenarios through video and scripted role-play.

**VR Experiment**

When the participants were ready for the VR experiment, they were asked to wear the E4 band, which is used for sensing the physiological signals, and to put on the VR headset. We informed the participants that they could stop at any time if they started experiencing motion sickness. After they wore the devices, we asked the participants to explore the café environment to adjust to the VR environment. Then, all participants performed the same 4 scenarios in the order of basic to advanced scenarios in VR for approximately 10 to 15 minutes.

**After the Experiment**

After the VR experience, we took a 5-minute break and conducted a data reflection on their VR performance with sensor data. In the data reflection process, participants were presented with various types of data related to their own anxiety moments, voice volume level, and eye contact while video recording their performance in VR using the interfaces and were asked to reflect on their performance based on these data. Here, we informed the participants that the data may not be accurate because of technical issues, so there can be errors or missing data in the interface. In the data reflection process, we asked the following to help participants reflect their data, such as “How was your performance in the VR scenarios?” “What were your strengths and challenges while performing the VR scenarios?” or “Did you find anything new about your behaviors while reviewing the data?” After the data reflection, we conducted a semistructured interview about the overall VR experience and data reflection. We asked participants how the VR content (eg, tasks and levels of scenarios, VR environment, and avatar design), data-driven reflection, and protocol (eg, watching a video and role-playing before the VR experiment) could be used to better understand their emotions and responses in potential workplace settings. We also asked questions to elicit feedback on the usefulness of data-driven reflection and its potential impact on their self-understanding of their behavior.

**Data Analysis**

For qualitative data analysis, the interview data were transcribed, coded, and analyzed based on open coding and thematic analysis [41] using ATLAS.ti (version 7; Scientific Software Development GmbH). A total of 3 researchers individually read the interview transcripts and generated open codes that were discussed among the research team to identify patterns and build themes around VR experience and data-driven reflection regarding self-efficacy. The coding procedure was iterative; it concluded once the researchers agreed that the themes were consistent and a distinct set of themes surfaced. Interviews and surveys were conducted and documented in Korean, and analyses were performed in the same language. This ensured that the original responses were analyzed with the utmost precision. For the quotations used in the article, an English-Korean bilingual-speaking researcher initially translated the responses into English and then revised them through consultation with a proofreading expert.

For quantitative analysis, we analyzed the scale results (IPQ and PSES-VR) of the participants with autism. As a case-control
group was not included in this study, it was difficult to confirm the statistical significance of the IPQ scale in identifying the presence of the VR system in participants with autism. For the IPQ scale, we calculated the mean and SD of the items corresponding to each of the 4 IPQ components and used it descriptively to analyze the VR presence of participants with autism. For the PSES-VR, we performed a paired 2-tailed t test to analyze whether there was a statistically significant change in perceived self-efficacy after using our VR system. For anxiety moments and eye contact sensor data, we conducted a 1-way ANOVA to analyze whether there was a statistically significant difference among the 4 scenarios in WorkplaceVR.

**Results**

**Overview of the VR Experience**

A total of individuals with autism participated in the study, including 2 women and 12 men, with an age range of 16 to 34 years. Table 1 shows the baseline characteristics of the participants.

There were no participants who reported difficulties such as motion sickness and headache during the VR experiments. Most (12/14, 86%) participants succeeded in completing the advanced-level scenarios without any support. In total, 2 participants (ND8 and ND13) completed the advanced-level scenario with minimal prompts from the researchers, such as guiding participants to find where the receipt was placed in the table.

Quantitative Assessment of the VR System Use

Our results showed a significant increase in the perceived self-efficacy of participants with autism ($P=.02$) before and after experiencing WorkplaceVR. In the IPQ result, the mean scores for “general presence” (or the “sense of being there”) and “experienced realism” were higher than the mean scores for the other 2 components (spatial presence and involvement). Table 2 presents the results of the questionnaires.

Table 3 presents the physiological sensor data of the participants in the 4 VR scenarios.

Our hypothesis was that participants with autism would experience more anxiety moments in the advanced scenarios. Consistent with the hypothesis, the participants had more anxiety moments in the advanced scenarios than in the basic scenarios ($P<.001$). This result shows that our physiological sensing data can effectively act as a proxy indicator for anxiety experienced by participants with autism. This is because individuals with autism tend to encounter elevated levels of anxiety in unexpected situations, such as the more advanced scenarios that we introduced.

aAnxieties are defined as the timestamps detected by the Azure algorithm’s anomaly detector when sensor signals (eg, electrodermal activity and heart rate) display fluctuations in response to users’ physiological reactions to stimuli.
bThere were significantly more anxiety moments in the advanced scenarios than the basic scenarios.

Qualitative Analysis of the VR System’s Impact on the Self-Efficacy

In this study, qualitative data analysis revealed 3 major themes that correspond to 3 of the 4 constructs of the self-efficacy theory by Bandura: physiological responses, verbal persuasion considered as encouragements, and mastery experience [19]. Below, we report how these findings can shed light on the feasibility of using the WorkplaceVR system to promote self-efficacy.

Impact of the VR Program on Self-Efficacy of Participants With Autism

Self-Awareness of Physiological and Emotional State Through Data Reflection

In the data reflection process, we provided an interface for visualizing the sensor data (ie, anxiety moments, voice volume level, and eye contact) to help the participants better recognize their emotions and behaviors in relation to their VR experiences. All our participants reviewed whether the presented data accurately reflected their emotions and behaviors. While reviewing their physiological signals (eg, HR, IBI, and EDA) presented by the VR system, the participants explained what they were feeling, thinking, or doing. For example, ND6 noticed that his HR increased when he was experiencing tense situations in VR and reported that he was aware of the stressors and reactions, drawing from his prior experiences:

_I know that my heartbeat increases when I am in situations that make me anxious or nervous. I remember my heart beating so fast on the night of June 29th. There was also thunder that night [...] It was like the nervous feeling I get when I check my grades._ [ND6]

In addition, participants noted that the physiological data visualization provided valuable insight into their emotional states that may have otherwise been difficult to discern:

_I don’t think I felt bodily sensations like stress or anxiety during the VR experience. But now, looking at the physiological data, I am convinced I was anxious in these situations [pointing at the “anxiety moments”]._ [ND12]

Moreover, the participants recognized and described the patterns of when and why they felt anxious in certain situations. By watching the recorded video of their performance at “anxiety moments,” participants actively described when they were most stressed or anxious while carrying out the simulated workplace tasks (eg, when a customer avatar approaches or when a customer avatar makes a sudden request to the user). For instance, ND2 had 3 events marked as “anxiety moments,” all of which were related to tasks where the user was required to start a conversation with the customer avatar. After playing back the recorded videos for all 3 events, ND2 reported that the data well represented his characters and that he usually becomes anxious when he has to initiate conversations with people at work:

_Oh, I’m quite sensitive sometimes, especially before I start talking, because I feel like I have to say_
something important. I also tremble when I start talking or see someone for the first time. [ND2]

By reflecting on their physiological and emotional states and behaviors in advanced scenarios, it enabled participants to recollect their related experiences in the real world and talk about goals to tame anxiety. For example, after reflecting on anxious moments, ND6 discussed ways in which he can improve his comfort in similar situations in the future:

I don’t want to panic again when a problem arises. For example, I shouldn’t be too stressed about my exam results. Whether it be a good or bad result, what’s important is accepting the result and looking beyond it. [ND6]

ND4 realized that he almost always becomes exhausted after meeting other people:

When I come home after meeting someone, I get so tired and have a headache. I always wondered what the reason was. Now that I think of it, I think it was because I got so nervous and tense in social situations. [ND4]

In addition, some participants suggested that having more diverse data (e.g., facial expressions, body movements, and gestures) could help them better reflect on and understand their behaviors:

It would be helpful to see how I make gestures and move my body because it is something that is hard to notice in real life. Having an observation camera might work. [ND7]

Verbal Persuasion Through Self-Expression in Data Reflection

We found that the data-driven reflection process of our system can help participants with autism better understand themselves and build positive self-beliefs about who they are and what they can achieve. This opportunity allowed participants with autism to engage in verbal persuasion experiences of self-efficacy [42,43], which means that they could speak about their own strengths and interests and gain confidence in expressing themselves:

I was worried that I am not usually good at making eye contact. But seeing the data, I am surprised to realize that I am, in fact, doing quite well on this. I’m feeling more confident about myself. [ND10]

In addition, some participants reported that they wanted to use behavioral and physiological data to explain the strengths and characteristics they recently discovered to others so they could express their thoughts or arguments more clearly. For example, ND12 reported that she feels misunderstood by people when they have the wrong impressions or ideas about her. She proposed ways to use the data to effectively communicate her opinions to decrease potential conflicts with others:

I often find myself in a state of persistent frustration when communicating with others. I believe that people do not truly understand or accept my thoughts or feelings. [...] However, with the physiological sensor data I currently possess, I am confident that I can convince others. [ND12]

Mastery Experience Through Realistic VR Scenarios

Our interview results suggested that participants with autism experienced a sense of mastery while using the VR program. For example, the participants with autism reported that the successful completion of realistic workplace interpersonal situations in a VR environment boosted their confidence in handling similar situations in the real world:

You have to taste the fruits of success in order to gain confidence and not be afraid of failure. I felt this was an important factor for me to go on to the advanced level because failure can have a huge damaging effect. [ND4]

This mastery experience was also supported by our VR system design that gradually increases the level of task difficulty from the basic-level scenarios to help users respond to unexpected situations with confidence:

Although it was new, it didn’t deviate too much from what I already experienced, so I could handle it. [ND14]

Consistent with the IPQ result, the participants also reported a high level of presence in WorkplaceVR. The participants explained that this was because our VR program provided high-fidelity simulation embodying realistic visual content (e.g., “Face Mask Required” signs on the walls of the virtual café considering COVID-19 pandemic situations) and immersive scenarios where they could have a naturalistic social interaction with virtual customers and colleagues (e.g., using gestures to communicate and giving receipts to customers). For example, notable observations indicating high engagement included participants attempting tasks such as making coffee or using the cash machine, even though these actions were not part of the assigned tasks (Figure 1). The lifelike experiences participants experienced during our VR program could have played a role in cultivating a sense of mastery.

Discussion

Principal Findings

Overview

This study demonstrated that the VR program, which enables individuals with autism to experience work-related social scenarios and reflect on their VR practice through physiological and behavioral data visualization, can significantly increase the individuals’ perceived self-efficacy in practicing social skills within a workplace context. The interview data further showed how the data reflection of VR practice can influence self-efficacy. The user-driven data review practice allowed individuals with autism to reflect on their physiological data, that is, by promoting self-awareness of their emotions, gaining insights into their real-world behaviors that they were unaware of, and self-advocating their characteristics to others based on their data. In particular, participants could understand when and why they feel anxious, enabling them to proactively devise strategies for self-comfort in anticipation of similar anxiety-provoking situations. Moreover, the increased self-awareness about the underlying causes of their anxiety and
related behaviors motivated them to communicate their experiences and advocate for their needs with others.

**Promoting Self-Efficacy by Promoting Self-Awareness About Physiological States**

We found that the physiological data reflection helped individuals better understand their emotional responses. This increased self-awareness that participants with autism obtained through our VR system motivated them to take their learnings from reflection in the real world to better explain and advocate for themselves to others. Therefore, in this section, we discuss how the self-reflection interface should be designed to present physiological and behavioral data in a way that encourages individuals to reflect on their experiences.

According to Bandura [19], recognizing and managing one’s own emotions and physiological states is essential in promoting self-efficacy, as this affects people’s decision-making process and performance. In line with the theory, our study found that behavioral and physiological sensor data (eg, eye contact, voice volume, EDA, and HR) could be used to support people with autism to become aware of their emotional states and, in turn, establish strategies to respond effectively to intense emotions. The participants became aware of their current affect state by mapping their physiological responses on the interface and sometimes wanted to examine data in depth to improve their self-understanding (eg, facial expression, standing posture, and hand gestures). Specifically, reflecting on the physiological data taken during the VR experience while watching the playback of the sessions allowed participants with autism to revisit how they felt and behaved in VR situations in specific moments that heightened their anxiety. This reflection reminded them of similar situations that induce anxiety in their daily lives, such as when they had to initiate conversations or when a conversational partner is approaching them. This increased self-awareness about their emotional responses—why they were anxious or nervous at specific times—further allowed participants with autism to make a resolution: how they might manage their emotional reactions in everyday lives.

Moreover, we found that the data reflection allowed participants with autism to gain insights about their real-world behaviors that they were unaware of (eg, “Why I was anxious when I had a conversation with coworkers?” or “Why I was always tired when I went to a place with a lot of people?”). Therefore, VR interventions for promoting self-efficacy could be designed to provide opportunities for users to investigate their emotional reactions through data reflection and connect the insights to their real-world practices. To encourage reflection, Fleck and Fitzpatrick [44] suggest incorporating reflective questions into technology to prompt users to think about their behaviors and provide justifications or explanations for knowledge, actions, or events. Therefore, VR systems can present reflective questions such as “What about this scenario made you feel anxious?” to accompany data reflection and to provide scaffolding for individuals with autism to consider how their performance in the scenarios relates to their real-world experiences.

Finally, when reflecting on the physiological data marked during the VR simulations, the system can guide users to raise their emotional awareness by relating it to their real-world experiences. It is important for them to understand what factors trigger their emotional and physical responses, why these factors affect them in a certain way, and how they should respond to such emotions. Previous research suggests that careful observation of one’s behavior, either by themselves or by others, might be the most informative and applicable source of emotional self-awareness [45,46]. Similarly, in our study, participants with autism identified the situations where they felt anxious while reviewing the anxiety moments data and watching the recorded videos of their VR performance and described their feelings by recalling prior related experiences. Through this process, they planned more specific ways to respond to anxiety, which could be applicable to their real-world interpersonal situations.

**Toward Data-Driven Self-Advocacy**

Verbal persuasion, involving encouragement from others and self-advocacy practice, is an important source of self-efficacy because it can help individuals shape self-beliefs that they have the skills or knowledge to succeed in a given situation and have confidence in themselves [19,47].

Our study suggests that the data-driven reflection process could have a similar effect as verbal persuasion. Our participants with autism reported that they often received negative feedback about their behaviors from others but experienced validation of behaviors through our system, for example, when the data interface indicated that their voice volume was lower than they expected. These results show that data reflection creates an opportunity for individuals with autism to experience verbal persuasion through identifying what they can do well in VR scenarios and fostering internal motivation to apply what they learned about themselves in the real world.

Furthermore, the participants with autism wanted to advocate for their characteristics or strengths identified in the data reflection to others to resolve conflicts or difficulties in their interpersonal relationships (eg, family members’ negative comments on the behaviors of autistic individuals). This finding suggests that data reflection could help individuals with autism to advocate for themselves in their daily lives and workplace. To design systems that can effectively support self-advocacy, our findings suggest the importance of presenting data relevant to their daily lives and supporting them to use the data to reflect on their behaviors, build confidence, and foster self-advocacy.

In our study, reflective questions [48] enabled users with autism to take time to understand themselves and translate their thoughts and concerns into positive resolutions based on the data. The questions included the following: “[reviewing the anxiety moment data] Have you ever encountered a similar situation in real life? If so, why did you feel that way? How do you typically respond to stressful events that make you anxious?” Although the participants could not directly manipulate the data visualization interface, future studies are needed to uncover how the interface can be designed to engage users with autism to better reflect on their personal interests, skills, and experiences. This could be approached by visualizing data with metaphors familiar to individuals with autism and...
customizing the user interface to reflect users’ priorities and topics of interest [49-51].

Limitations
Although our VR system could provide individuals with autism with opportunities to promote self-efficacy, there are several limitations. First, in our study, we only included participants with autism who are able to communicate and interact with others. This decision was made in our study because WorkplaceVR was designed to focus on a specific population with autism. However, future research should explore how VR interventions can also benefit participants with autism who have different communication abilities. To estimate anxiety moments, we used the algorithm offered by Microsoft Azure. Although our participants confirmed that the anxiety predictions were aligned with their subjective feelings (e.g., anxiety and nervousness), future studies should investigate and apply more rigorous algorithms that can predict the anxiety levels of participants. In this study, we used the PSES-VR, a questionnaire written in Korean, and the IPQ, which was translated into Korean. However, neither of the 2 measures had been previously validated in the Korean population. Finally, we could not confirm whether participants’ experiences in the study would translate to their real-life situations through poststudy observations.

Conclusions
This study investigated how the VR system promotes the self-efficacy of individuals with autism for their success at work. For this, we presented WorkplaceVR, a VR system that allows users to experience work-related social situations and data reflection of the user’s behavioral and physiological data. Through the VR experiment and data reflection, we confirmed that the VR system significantly improved the perceived self-efficacy of participants with autism. Our study results revealed that the VR system provided participants with autism with an opportunity to have a mastery experience in VR scenarios, self-awareness of their emotional states, and self-advocacy of their strengths and characteristics through data reflection. By addressing the expectations and challenges in the VR system for people with autism, these results contribute to not only supporting researchers who design the technology for autistic people but also helping individuals with autism have a successful work experience.

Abstract

Background: Cardiometabolic conditions including acute coronary syndrome (ACS) and type 2 diabetes (T2D) require comprehensive care and patient engagement in self-care behaviors, and the drivers of those behaviors at the individual and health system level are still poorly understood.

Objective: We aim to gain insights into self-care behaviors of individuals with cardiometabolic conditions.

Methods: A convenience sample of 98 adult patients with ACS and T2D was recruited in the United States, Germany, and Taiwan to participate in a mixed methods study using ethnographic methods. All participants completed 7-day web-based diaries tracking their level of engagement, and 48 completed 90-minute web-based semistructured interviews between February 4, 2021, and March 27, 2021, focusing on themes including moments of engagement. Qualitative analysis identified factors influencing self-care practices and a Patient Mind States Model prototype.

Results: Patient reports indicate that many patients feel social pressure to adhere to treatment. Patients’ experience can be understood within 5 categories defined in terms of their degree of engagement and adherence (“ignoring,” “struggling,” “juggling,” “controlling,” and “reframing”).

Conclusions: For people living with ACS and T2D, the self-care journey is defined by patterns of patient experiences, which can identify areas that tailored digital health care interventions may play a meaningful role.

Introduction

The development of effective self-care behaviors is essential for patients living with chronic health conditions [1]. However, the definition of self-care behavior varies considerably between medical disciplines. From recent concept analyses, a broad term for self-care has been defined as “the ability to care for oneself through awareness, self-control, and self-reliance in order to achieve, maintain, or promote optimal health and well-being” [2]. Indeed, inadequate engagement in these self-care ability driving areas, suboptimal adherence to medication, and failure to enact healthy behaviors (eg, smoking cessation and physical activity) can compromise patients’ quality of life and health outcomes [1]. Self-care is particularly important for patients diagnosed with cardiometabolic conditions such as acute coronary syndrome (ACS) and type 2 diabetes (T2D) [3,4]. Despite this, rates of adherence to a care plan including but not limited to medication and lifestyle modifications remain suboptimal for this population [5-8], and a number of patient-specific factors (eg, depressive symptoms, attitudes toward management, and daily activities) that impact self-care and outcomes have been identified [9].

Despite efforts to establish the psychosocial factors underlying self-regulatory or self-management behaviors [10,11], the typical driver of such studies is to assess how these factors may impact adherence. Behavioral models have been considered within this research, such as the capability, opportunity, motivation, and behavioral model and intervention mapping; however, the volume of frameworks available and a fragmented, confusing taxonomy remain barriers to their effective use [12]. Equally, these frameworks are often generalized and applicable in a range of clinical scenarios and are not exclusive to diabetes or ACS.

This model design approach from a general perspective may explain in part why these models have had a limited impact in diabetes or cardiovascular care, where individual behavior plays a dominant role in patient outcomes [13]. Establishing a behavioral framework that is tailored for those with a cardiometabolic condition will form an important step toward understanding attitudes in clinical care and how these may innately fluctuate over time.

The determinants of effective self-care practices among people living with cardiometabolic diseases have been well-established and include self-efficacy, social support, cognitive skills, and positive attitudes [14-16]. Health care professionals (HCPs) and care systems play a central role in influencing self-care through these determinants as well as by optimizing health service delivery, addressing financial burdens, promoting engagement with technology, and encouraging community support initiatives [17,18]. As self-care determinants include both patient-level and system-level drivers, effective interventions must address both environmental factors and individual patient needs to achieve sustainable effects [19,20]. Designing these interventions requires a deep understanding of patients’ needs as well as their broader life context [21]. Patient activation–focused frameworks such as the Patient Activation Measure (PAM) or the Social, Psychological, Usage, Rational model have helped design interventions that improve medication adherence and lifestyle behaviors [22,23]. However, given ongoing changes in health systems’ use of digital patient support tools in the context of the COVID-19 pandemic, the ways in which tools such as the PAM and Social, Psychological, Usage, Rational model can best be used to support patient self-care needs further exploration. In particular, the COVID-19 pandemic has led to major shifts in clinical practice, including an increase in the use of digital health care approaches [24].

To better understand the ways in which health systems can support patients using digital support tools in the era of the pandemic, we conducted a survey of adult patients with ACS and T2D as well as their caregivers in the United States, Taiwan, and Germany. Our goal was to help establish a behavioral model based on the survey results, which would help inform how digital solutions may be utilized to improve adherence to therapy. This series of interviews and diaries, which drew on grounded theory and phenomenology, aimed to (1) provide deep human-centric insights into the behavioral dimension of the patient experience for people living with T2D or ACS and (2) identify the moments and motivational triggers in a patient’s life that have a strong impact on behavior and health outcomes.

Methods

Research Design

The survey consisted of 2 distinct phases, with all participants completing 7-day web-based, ethnographic diaries tracking their level of engagement in self-management and 48 participants completing web-based, semistructured interviews focused on themes including moments of engagement.

This survey used methods from the field of qualitative research, grounded theory [24] and phenomenology [25,26]. Grounded theory has been used to understand the processes through which patients manage new or chronic health problems [27], and as such, it has particular relevance to elucidating chronically ill patients’ experiences. Using grounded theory, data are collected and analyzed, and then a theory based on the resulting data was developed. The approach was designed to generate a theoretical explanation using both inductive and deductive approaches to a social phenomenon (ie, chronic disease self-care in this survey) from empirical data rather than a preconceived framework. Phenomenology is well suited to study the self-care of new or chronic health problems as it is based on the assumption that there is an essence to what people live with every day, and it aims to depict the basic structure of this experience [25]. As a qualitative research method that is particularly useful to study affective, emotional, and intense human experiences, phenomenology is a study of people’s conscious experience of their everyday life and social action [25].

Ethical Considerations

Informed consent was obtained from all individual participants included in this survey. The research is a qualitative behavioral research survey but not a clinical study or clinical survey. This research was conducted in accordance with the organization’s intended regulations for qualitative market research studies and no personal data or sensitive information were collected or presented in this publication. Information was recorded by the
investigator in such a way that the identity of the human subjects cannot be directly or indirectly ascertained. This study was exempt from the institutional review board oversight in accordance with exemption guidelines listed in the 45 Code of Federal Regulations Part 46 and the Secretary’s Advisory Committee on Human Research Protections Recommendations on benign behavioral intervention of the Health and Human Services regulation in United States [28, 29]; the 2022 European Pharmaceutical Market Research Association Code of Conduct for the market research conducted in Germany [28]; and Article 5 of the Human Subjects Research Act of the Ministry of Health and Welfare, Republic of China (Taiwan), and the “Exempt Review Categories for Human Research” announced by Department of Health, Taiwan [29, 30].

**Sampling Methods**

Patients diagnosed with either ACS or T2D and cardiovascular comorbidities were identified and recruited in 3 countries: the United States, Germany, and Taiwan. These countries were selected based upon the Hofstede 6D model of cultural dimensions. The 3 countries were noted for their diversity of cultural dimensions that may influence and nurture patient behavior while holding similar maturity of health care systems.

We aimed to recruit equal proportions of men and women as well as patients with a variety in types of health insurance. Potential patients were members of an ongoing research panel who have agreed to be approached for research studies and have provided basic demographic and health status information. Patients with ACS and T2D were screened for eligibility using elements for ACS and T2D patient profiles, as well as survey-specific data regarding demographics, digital behavior, and personality profiles. As part of the screening process, patients were asked if they use any technology, either app or device, to manage their condition. All patients screened were interested and open to the idea of digital health care (ie, the use of digital tools to support tracking or managing measurements used to help manage their condition).

Screening was conducted by an external recruiting agency who preselected relevant candidates out of their patient panel. In total, 32 participants per country were selected out of approximately 48 recommended profiles per country from an external recruiting agency. An appropriate mix of people was selected by the research lead, striving for maximum variation in the sample among those who fulfill the sampling criteria.

Our goal was to recruit 16 patients with ACS from each country, including 8 patients who had undergone an invasive procedure (eg, percutaneous coronary intervention and coronary artery bypass graft). We also sought to recruit roughly equal numbers of patients with ACS who were aged 40-50 years and 50-70 years. All patients had to be eligible for enrollment in a cardiac rehabilitation program (whether this was digital or analog was recorded); approximately 60% (10/16) should have attended rehabilitation, while 40% (6/16) should not. A focus was placed on those with higher severity levels for their condition and those with progressed treatment regimens. Eligibility for enrollment in a cardiac rehabilitation program was determined as a proxy for ACS severity levels and an indicator of having undergone a medical procedure. In recruiting patients with ACS, our goal was to represent a diversity of family situations (single, married, and with or without children) and a range of experiences using self-care technology for managing cardiovascular conditions.

Finally, we sought to recruit 10-16 caregivers of patient with ACS to assist in setting up patient support with the diaries, 8 of whom would also serve as interview participants.

Our goal was to recruit 16 patients with T2D from each country, with equal numbers having less severe (eg, hypertension) and more severe (eg, heart arrythmia and heart failure) comorbidities. These groups were then further equally split into those on oral antidiabetic drugs and those who had initiated basal insulin in the past 12 months (18-24 months if recruitment was difficult). All participants in the T2D sample were aged 40-70 years, with the group being split equally between those who currently use health care technology (an app or device) and those who are considered lapsed users of health technology. Within the screening process, patients with T2D were asked if they use any technology, either an app or device, to manage their disease. Lapsed users confirmed that they used technology to manage their condition but no longer do so.

Both the ACS and T2D samples were split into equal-sized groups of patients deemed to be fully adherent with medical advice and treatment and those considered either partly adherent or nonadherent. This was based on the assumption that the behavioral reasons for partial and nonadherence were similar. Adherence levels were determined based on patients’ self-reported assessment during the respondent recruitment process. Patients were asked a range of multiple-choice and open-ended questions, the results of which were used to quantitatively determine their adherence level. For instance, patients were asked to what extent they agree with the statement: “I am confident that I can follow through on medical recommendations my health care provider makes, such as changing my diet or regular exercise;” with which they could strongly agree, somewhat agree, somewhat disagree, or strongly disagree.

**Data Collection**

To increase internal validity of the survey through triangulation, 2 methods of data collection common in grounded theory and phenomenology research were used [26]. First, patients were asked to complete web-based diaries for 7 days, in which they recorded information including their daily experience of engagement with notable life events, health, and conditions (eg, photos and video) for acute versus chronic; a mind map of helpers (people, tools, and institutions); and observations of self-concept versus reality (projections and narratives around the self-care experience).

The diaries consisted of 5 chapters, with each one completed once within 7 days. Each chapter was completed in consecutive order: (1) “Me and My Body,” (2) “My Story,” (3) “My Day-to-Day Life with My Condition,” (4) “My Daily Health Regimen,” and (5) “My Helpful Tools and Resources.” Daily diary exercise was recorded based on open-ended questions with private responses recorded via video, audio, photographs, a map, or written statement.
Specifically, respondents were asked to answer a range of open-ended questions over the course of 5 days. They were structured in six thematic buckets: (1) personal background, (2) me and my body, (3) daily health regimen, (4) day-to-day life with my condition, (5) helpful tools and resources, and (6) my health story. In topic 2, we asked, for instance, “Please recall particularly pleasurable and positive moments during the day when you felt happy, in control, proud of yourself, content with regards to a) general state of mind, b) relating to health, and c) relating to your condition.”

For the interviews, participants were screened by an external recruiting agency, relying on their patient panels, and an appropriate mix of people was selected by the research lead, striving for maximum variation in the sample among those who fulfill the sampling criteria. In the ACS sample, patients and their caregivers took part in dyad interviews. In the T2D sample, interviews were carried out on a one-to-one basis between interviewers and patients. These interviews aimed to capture key moments of engagement to gain an understanding of levers of change or opportunities; elucidate the role or influence of the caregiver; and explore a prototype of the patient experience map produced from patient diary content. The “SturmundDrang” team of cultural researchers and anthropologists created the interview guide in an iterative approach. This guide provided information on field research preparations. Designed as a rough framework of topics and themes to explore, this document offered guidance for the ethnographic video interviews. The same discussion guide was used across all countries, providing open-ended questions and sufficient room for exploration in different cultural contexts. The respective researcher could modify the guides in each country, if deemed necessary.

Data Analysis

Data were analyzed using a constant comparative method [31], which involves comparing 1 segment of data in an interview with another segment of data to determine similarities and differences [26]. The diary data was treated as 1 hermeneutic unit that was then qualitatively analyzed in direct comparison with the interview data. The interview data formed a second hermeneutic unit. Diaries and interviews were conducted within 2 weeks, allowing the researchers to pursue a close comparative approach. These 2 hermeneutic units were then compiled in a comprehensive raw field note document for each market, outlining the total qualitative data set that could then be analyzed.

Analysis was guided by the principles of horizontalization, where all data are treated with equal weight, and phenomenological reduction, which is the process of continually returning to the essence of the experience to derive the inner structure (of disease self-care) in and of itself [26]. We grouped data together on similar dimensions of (1) patient modes of engagement and experience domains, (2) the ongoing process of gaining self-care expertise, and (3) patient mind states regarding disease self-care. Furthermore, we identified beliefs and biases, drivers of engagement and challenges to disease self-care.

In particular, interviews were analyzed to identify emerging themes through established social-scientific methods of data gathering, including writing semistructured fieldnotes [32], qualitative data analysis [33], and ethnographic insights building [34]. To establish key patient mind states, the data were clustered using spatial clustering, iterative loops, and narrative listening. Spatial clustering of codes and signals was used to group themes into a figure of overarching mind states to provide a framework for qualitative interpretation and a hypothesis. Following data collection, the resulting map was refined through iterative loops, whereby the data and theory were examined and re-examined by a team of 3 researchers; with each loop, the number of clusters and mind states was adapted and refined. During the final iteration loop, the mind states and their names were co-designed with the patients to ensure a patient-centric outcome. Narrative listening was used throughout, with patients describing and naming the chapters of their journey to allow for patient-led clustering and refining of the mind states [35].

Results

Sample Characteristics

In total, 98 patients with ACS or T2D and cardiovascular comorbidities were recruited, 32 from the United States and 33 from each of Germany and Taiwan. All 98 patients who were recruited completed the survey. All patients completed the 7-day ethnographic diaries (Germany or United States: February 4-11, 2021; Taiwan: February 17-24, 2021). Patients spent approximately 5 hours to complete the research questions. In total, 48 web-based interviews were conducted (Germany or United States: March 3-15, 2021; Taiwan: March 22-27, 2021), 24 with patients with T2D and 24 with patients with ACS and their caregivers. Respondents were selected for further interviews based on the depth of patient journey detail.

Survey Results

Overview

From the survey conducted through interviews and diaries, a number of theoretical themes were identified.

Insights Into the Behavioral Dimension of the Patient Experience

Interviews with patients living with T2D indicated that the disease continues to extract a heavy emotional toll. Participants commented: “The nurse made me feel like some pig, that all I do is sit around and eat and be obese”; “I used to eat gourmet food anywhere, anytime, and now all I have left is pay attention to controlling my diet”; “If I were to buy something to eat – I almost never do – then I would have to take everything apart and weight the ingredients individually; I can then calculated what units I need to inject afterwards”; and “I thought I’d just take a pill and everything will be ok, so I didn’t take it as seriously as I should.”

These patient insights highlighted how T2D is still a chronic condition that complicates every aspect of one’s life. Overarching themes from these interviews indicate that the condition is widely perceived to be a self-inflicted lifestyle disease; patients experience feelings of stigma, shame, self-blame, and a need to justify their lifestyle choices to acquaintances and HCPs. The general experience is underscored
by patient sacrifices and unsolicited social pressures to adhere to treatment regimens; generating a depressive, restrictive atmosphere rather than the positive outlook that could help patients pursue a better quality of life. The need for constant monitoring and tracking of the body increases adherence pressure and creates a heightened focus on hemoglobin A1C levels. Patients can also initially find diabetes easy to underestimate and ignore, adopting an acute rather than chronic mindset that makes it difficult to take ownership in the long term.

Acute events often are perceived by patients as inevitable consequences of living with chronic conditions. For example, 1 patient with ACS commented: “I learned that even without heart disease, unhealthy habits as far as eating and exercise can lead to stroke and heart failure. This really opened my eyes. At that point my life changed dramatically. I changed the way I shopped, I started eating healthier meals, and I began exercising regularly.” However, acute conditions may have a longer-term impact on social behaviors. ACS can lower social and career performance expectations; patients may feel forced out of the “rat race” by their condition or voluntarily take steps to reduce work-related burdens and pressures, as indicated by 1 patient who commented: “I see people around me going to work and realize how much my health prohibits me from working.”

Based on these moments and experiences, patients may feel that rehabilitation is a challenge and may not fully comprehend or appreciate the potential benefits. Once the advantages of rehabilitation are clearly communicated, the offering is compelling to patients if logistical barriers are no issue. Participants also described the gradual acquisition of self-care expertise as a journey, which can support them in working toward better health. They also see this journey as influenced by universal health-related experiences, where a patient undergoes a cognitive or emotional change regarding their health engagement and self-care. Although each patient journey is unique, we identified 3 modes of engagement that determine the engagement and behavioral patterns in self-care (Figure 1). Underlying these modes are clusters of experiences called “experience domains.” At different points in the patient journey, health-related experiences from any domain can affect the patient’s mode of engagement, in a process of fluid exchange and even overlap between domains.

Self-care can be seen as an ongoing process of gaining expertise on how to deeply incorporate management routines into patients’ day-to-day lives (Figure 2). Over the years of encountering the full breadth of health care-related experiences, patients work out the best ways to manage their conditions in the context of their individual lives. This process takes patients from awareness of the need for self-care, through acquiring the necessary practices and tools to learning how to use them successfully. A set of applicable self-care practices are developed, which become habits in the form of routines. Highly engaged patients eventually become informal self-care experts on their own body and health.

**Figure 1.** Patient modes of engagement and experience domains. HCP: health care professional.
Interviews and patient log data indicate that a patient’s willingness to engage in self-care and gain expertise may be shaped by the cultural context in which they reside. Some of the participants in the United States expressed a growing mistrust of medical expertise and institutions, with a lack of medical insurance also disrupting the continuity of care. For example, patients from the United States shared: “Never trust someone just because they have a medical degree.” And “I’m on Medicare and Medicaid, I’m disabled, cannot work and now I’m getting paid back for the things I used to say because the clinic won’t cover it.” Effective self-care may also present challenges in countries such as Germany, where many health care systems rely primarily on paper-based clinical records, owing to historical and ongoing data privacy concerns. This impacts the patient experience. A man with T2D from Germany shared: “I am fortunate that my two doctors are located in one facility and can therefore coordinate closely. All the information [about my treatment] is centrally stored and can be viewed at the facility at any time.” Pseudoscientific or alternative approaches to health care, such as homeopathic or organic products as well as spiritual practice, also remain prevalent in Germany and Taiwan; however, participants in Taiwan expressed a high level of trust in HCPs’ expertise and authority, with 1 participant commenting: “I’ll strictly follow the doctor’s advice as best as possible.”

These differing experiences across countries was a common theme during the survey. Although, patients in the United States expressed a mistrust toward institutions, those surveyed were enthusiastic about trying new digital health solutions. However, this attitude was not reflected in Germany, with privacy concerns limiting the uptake of digital solutions. Many patients remain cautious around such technologies. Further, 1 patient with T2D in Germany stated: “I don’t know what I would want [for a digital solution]...and what is possible privacy wise.” Both US and German attitudes toward digital health care stand in contrast with the opinions of those patients in Taiwan. There has been an increasing adoption of digital solutions among those with T2D in Taiwan, with many perceiving such innovations as convenient and readily integrable.

**Theorization of Patient Engagement: the Patient Mind States Model (PMM)**

Based on analyses of the survey through patient interviews, we identified 5 patient mind states according to degree of patient engagement, adherence, and the experience domains that drive engagement (namely, the condition-, context-, and self-driven experiences; Figure 3). These mindsets comprise what we have called the Patient Mind States Model (PMM), which articulates these 5 mind states regarding disease self-care. A mind state is defined as a patient’s mental and emotional attitude toward self-care; these states are not related to age, gender, sociodemographic criteria, or culture of persons living with cardiometabolic conditions. The mind state has a large influence on a patient’s receptivity toward support and their ability to develop more healthy behavior. Patients’ mind states are not constant; shifts in mind state can be driven by external forces such as seasonal cycles and life changes. Self-care engagement and maturity of patients with chronic conditions change with their mindset. The 5 mind states identified are the following:

- **Ignoring:** patients carry on with life as it was prior to their diagnosis; depending on their culture and the extent to which they are stuck in an acute mindset, they may believe that a drug can fix the problem. For example, a 68-year-old woman with T2D from Germany commented: “I don’t really feel sick, because I don’t notice anything. I don’t have a different life in terms of ‘before’ or ‘after’ the diagnosis. Actually, I ignore the disease.”

- **Struggling:** patients feel overwhelmed and anxious; in desperately trying to make sense of what is happening, they can be paralyzed and oscillate between desperation and overambition. A 59-year-old woman with ACS from Germany shared: “I sleep very badly, have fears about my health. I feel completely overwhelmed and don’t know how to get out of this dilemma.”

- **Juggling:** people want to focus on positive aspects of life, which are viewed as part of the healing process; they see themselves as trying to find a balance between their own wants and the demands of their condition. One 64-year-old man with ACS from Germany commented: “Life should still be fun, you have to continue to participate in it, even if you are sick...I do not want to miss on the taste of a beer, a glass of wine or a good meal.”

---

**Figure 2.** The ongoing process of gaining self-care expertise.
• Controlling: patients have high familiarity with the effects of food and exercise on their body; they constantly learn more about their condition and have a high use of tools to maintain control and promote a feeling of self-reliance. As noted by a 63-year-old man with T2D from the Unites States: “Being in touch with my body, it has an equal ‘voice’ in determining what is best for me. This helps me to maintain an aggressive mindset and to immediately determine any abnormalities I might be experiencing and take appropriate action.”

• Reframing: people have learned to control their disease and focus on achieving life goals; they use organic methods and vitamins or supplements combined with physical exercise, breathing techniques and meditation to reduce stress. A 61-year-old man with T2D indicated: “Just because someone has a Medical degree doesn’t mean they don’t make mistakes, listen to their advice, but also do some research for yourself. Never blindly follow anyone or anything but find your own ways.”

These mind states may share common traits through their drivers for engagement, as detailed in Figure 1. Through this survey, each mind state is not exclusively self-, context-, or condition-driven, with each having a predominant motivation.

**Figure 3.** The Patient Mind States Model (PMM)—this model contains patient mind states regarding disease self-care identified in patients with chronic cardiometabolic disease.

### Discussion

**Principal Findings**

Each mind state in the PMM is associated with specific beliefs and challenges and is susceptible to particular drivers of engagement that can be used to propel effective self-care behavior (Multimedia Appendix 1). In the ignoring mind state, these drivers of engagement include a fear of mortality and sense of urgency, social pressure from loved ones, and relatable role models who defy the stigma. As for the “why me” frame of mind of the struggling mind state, affirmative feedback from HCPs, realistic prognosis that shows possible points for medical intervention, and a sense of urgency that prioritizes the disease serve as drivers of engagement. In the juggling mind state, a mind state that focuses on the positive aspects of life as part of the healing process, clear images of cause and effect, gratification through joyful activities, and companionship with peer patients on their disease journey drive engagement. Moreover, people in the controlling mind state are driven to engage through curiosity for, and excitement about, innovation and what is novel; recognition of progress and being awarded for success; and having a sense of medical expertise. When patients are in the reframing mind state, drivers of engagement include an awareness that certain rules are malleable, deep trust in the individual’s own capabilities, and joy of helping peer sufferers. These emotional and social drivers of engagement across each mind state highlight the need for a holistic approach beyond the current physiological and intellectual drivers of engagement in health care, from gratification through device use to feelings of self-efficacy via immediate feedback and to encourage patient self-care behaviors.

Partitioning a person’s mind state into different stages is not a recent concept, with frameworks such as the transtheoretical model (TTM) examining different behavioral states that evolve over time [36]. The TTM consists of several stages of change and different behavioral processes that drive people to transition to a different state (eg, contemplation, determination, and action). However, the underlying assumption behind this model that decision-making is linear and unidirectional does not recognize how people may move back and forth between such
states over their lifetime, further deviating from expected behavior change trajectory by exponentially changing social and technological context. The PMM described in this survey allows us to nuance further TTM by its nonlinear nature where patient mind states do not necessarily occur in sequential fashion and may even coexist.

It should also be noted that existing behavioral models are used as tools to support clinical decision-making. In diabetes care, the PAM has been leveraged to predict the potential course of outcomes and how underlying social factors may contribute to activation levels. Mean scores obtained from various PAM instruments, such as PAM-13, may offer a concise summary of a person’s knowledge, skills, and motivation. However, the assessment of drivers underlying activation levels and broader consideration of patient context and its evolution are often decoupled from a PAM assessment. In a recent study on patient activation in individuals with T2D, generic health status topics, distress, and social support were all assessed in questionnaires separate from the primary PAM survey [37]. The PMM may offer complementary perspective for assessment of the context for an individual’s mind state through 1 centralized survey and establish the patient modes of engagement and wider experiences, as detailed in Figure 1. Further studies will be required to elucidate how the PMM could form the basis of a behavioral tool in practice.

Opportunities for Future-Focused Digital Solutions

Digital health care has an important role in chronic patient journey. However, many digital patient support programs may suboptimally tailor and target their support based on these important differences, in part because of a lack of data integration across platforms. Guidance on the day-to-day implementation of digital solutions is lacking, so patients often achieve success through trial and error.

Given a patients’ potential frustration with digital tools, engendering a level of comfort and trust in the technology is an important step to effective self-care. Along with privacy concerns, evidence for digital solutions remains as key challenges in establishing digital health as a viable solution for patient self-care [38-40].

Each patient has a unique experience in self-care, with the previous discussion outlining how we can understand the changing mind state of these individuals and how digital solutions may proffer opportunities to improve self-care.

For chronic care digital interventions, our findings suggest that it is important to tailor support to a patient’s mind state, with personal drivers of engagement potentially leading to optimized patient outcomes, adherence, and self-care expertise. Guiding patients throughout their individual health journey to a life worth living is critical and should be based on the individual, attainable life goals, and intelligently balanced compromises that undergo constant revision in the ever-changing context.

These dynamic patient experience mapping refined with help of the PMM may form a more optimal basis in which to effectively integrate digital solutions that enable and support disease self-care, while considering more holistically the context of those living with cardiometabolic conditions. These insights also may warrant further studies in the field of patient adherence and sustainable behavioral change. It will be of interest to further investigate the underlying motivations behind a change in patient mind state and how digital health care may help move individuals from “struggling” to “controlling” mind states, for instance, and effectively ignite intrinsic patient motivation drivers.

These initial data may form a basis of future studies through the validation and refinement of the PMM and the relationship between patient mind states and chronic disease self-care. In particular, future research should clarify patient self-care behaviors and attitudes toward specific digital health care interventions as a critical part of digital intervention design and development processes and verify that the user experience of participants with these 2 conditions in these 3 countries is consistent with patients in other contexts. Equally, it will be critical to understand more deeply the levers of progressive self-care expertise acquisition and use by patients.

The limitations of this survey include its geographic profile (only 3 countries) and the limited sample size of the patient populations (owing to the specific inclusion criteria). Participants who completed the survey may not be representative of the general patient population, as the survey was conducted via the web and patients participated on a voluntary basis. This approach may have introduced a selection bias, such that only the most motivated or educated patients were included. The educational needs of a representative patient population may have therefore been underestimated. Further, the PMM has been generated based on the inputs from participants who were managing ACS and T2D and has not included people living with cardiovascular chronic conditions alone or type 1 diabetes. This may result in that the PMM may not fully embrace the whole spectrum of cardiometabolic patient profiles. The focus on the social aspect of survey respondents (role of caregivers in building patient’s self-care motivation) has not been sufficient to frame more distinctly in the PMM. However, this survey had reflected the real-life experiences of patients in different clinical and geographic settings.

Conclusions

Any single journey with an acute or chronic condition is consistently shaped by moments, as well as motivational triggers, which may impact a patient’s growing expertise in self-care. Through this behavioral science survey, a heuristically useful framework has been defined on the underlying nature of how patients engage with self-care, which requires further testing and adaptations. Patients will gradually gain expertise in self-care before acquiring more confidence in proactively using a range of practices and tools. However, this path may be shaped by the patient’s mind state, which will impact treatment adherence and their willingness to engage in self-care practices.

For digital health care solutions to be fully integrated into the patient care journey, it is important to understand how such tools should be tailored to a patient’s mind state and how these states may shift when digital solutions are adopted. It will also be important to understand that such solutions may adapt according to changes in patient mind states.

Abstract

Background: Text messaging is widely used by young people for communicating and seeking mental health support through chat-based helplines. However, written communication lacks nonverbal cues, and language usage is an important source of information about a person’s mental health state and is known to be a marker for psychopathology.

Objective: The aim of the study was to investigate language usage, and its gender differences and associations with the presence of psychiatric symptoms within a chat counseling service for adolescents and young adults.

Methods: For this study, the anonymized chat content of a German messenger-based psychosocial chat counseling service for children and adolescents ("krisenchat") between May 2020 and July 2021 was analyzed. In total, 661,131 messages from 6962 users were evaluated using Linguistic Inquiry and Word Count, considering the following linguistic variables: first-person singular and plural pronouns, negations, positive and negative emotion words, insight words, and causation words. Descriptive analyses were performed, and gender differences of those variables were evaluated. Finally, a binary logistic regression analysis examined the predictive value of linguistic variables on the presence of psychiatric symptoms.

Results: Across all analyzed chats, first-person singular pronouns were used most frequently (965,542/8,328,309, 11.6%), followed by positive emotion words (408,087/8,328,309, 4.9%), insight words (341,460/8,328,309, 4.1%), negations (316,475/8,328,309, 3.8%), negative emotion words (266,505/8,328,309, 3.2%), causation words (241,520/8,328,309, 2.9%), and first-person plural pronouns (499,698/8,328,309, 0.6%). Female users and users identifying as diverse used significantly more first-person singular pronouns and insight words than male users (both \( P < .001 \)). Negations were significantly more used by female users than male users or users identifying as diverse (\( P = .007 \)). Similar findings were noted for positive emotion words (\( P = .01 \)). The regression model of predicting psychiatric symptoms by linguistic variables was significant and indicated that increased use of first-person singular pronouns (odds ratio \[ OR \] 1.05), negations (\[ OR \] 1.11), and negative emotion words (\[ OR \] 1.15) was positively associated with the presence of psychiatric symptoms, whereas increased use of first-person plural pronouns (\[ OR \] 0.39) and causation words (\[ OR \] 0.90) was negatively associated with the presence of psychiatric symptoms. Suicidality, self-harm, and depression showed the most significant correlations with linguistic variables.

Conclusions: This study highlights the importance of examining linguistic features in chat counseling contexts. By integrating psycholinguistic findings into counseling practice, counselors may better understand users’ psychological processes and provide more targeted support. For instance, certain linguistic features, such as high use of first-person singular pronouns, negations, or
negative emotion words, may indicate the presence of psychiatric symptoms, particularly among female users and users identifying as diverse. Further research is needed to provide an in-depth look into language processes within chat counseling services.

**Introduction**

Childhood and adolescence are known for their biological, social, and psychological changes as vulnerable periods, in which young people are at an increased risk for experiencing mental health problems. It is also known that an early age of onset of mental illness is a risk factor for poor mental health conditions in adulthood [1,2]. The use of mental health care services for adolescents and young adults can have a positive influence on their attitudes, beliefs, and behaviors, which are known to be important predictors of their later mental health [3]. A growing number of studies indicate that children, adolescents, and young adults use the internet to seek help for their mental health problems because the digital environment is familiar and easily accessible, offers anonymity, and accommodates their need for independence [4-8]. Nearly all young people aged 12 to 19 years in Germany (94%) own a smartphone [9].

With the increased use of smartphones, text messaging has become the primary communication tool for today’s youth [10]. Studies on text messaging usage with mobile phones have shown that adolescents experience text messaging as a quick, easy, convenient, playful, and inexpensive way of communication [11-14]. In line with this trend, a number of crisis helplines and similar services have begun to offer online support services such as chat or email counseling [15-18]. Studies have shown that adolescents prefer texting to talking when seeking help for mental health problems and find it easier to write than to express serious concerns verbally [18,19]. Recent studies support the acceptance, feasibility, and usability of online support services, especially among young people [7,20].

However, written language lacks nonverbal stimuli. Recent research has shown that facial expressions and prosody have an influence on the recognition of a speaker’s intention in face-to-face communication [21,22]. In fact, in comparison to face-to-face interactions, people report higher levels of miscommunication when texting. This might represent a barrier in messenger-based counseling and may make it difficult for young people to understand and interpret the intentions of online counselors [23,24]. This lack of nonverbal cues can also make it more difficult for crisis line counselors to establish and maintain a therapeutic relationship [25,26]. In some studies, counselors reported greater difficulty and a lower perceived ability to establish a therapeutic relationship in the digital environment compared to a face-to-face counseling or therapy setting [25,27]. In addition to nonverbal stimuli, language usage is an important source of information in the therapeutic context, and the way people use words conveys a great deal of information about themselves and their current situation [28].

Language reflects both conscious and unconscious thoughts and feelings [29]. Linguists distinguish 2 aspects in the study of language: the formal and the content features of language. The formal aspect concerns grammar, syntax, reaction speed, speech tempo, etc, whereas content features consider vocabulary and word choice [30]. The investigation of “lexical diversity” thus allows a better insight into the cognitive diversity of people [31,32].

Thus, in the 1970s, it was evidenced for the first time that language use can be a specific marker for psychopathology, especially depression [30]. It was found that individuals with depression use more first-person singular pronouns (ie, “I,” “my,” “me,” and “mine”) in both spoken and written language [33,34], supporting cognitive theories of depression [33], which indicate that depression is associated with an increased self-focus. Recent research has shown that increased use of certain words, for example, sad (eg, “crying,” “grief,” and “sad”) or sleep (eg, “asleep” and “bed”), correlates positively with higher levels of depressive symptoms [35]. Further studies also found gender differences in language usage. For example, it was found that women tend to use more language related to thoughts, emotions, senses, negations, and verbs in the present or past tense than men [36]. Furthermore, women were shown to be more likely to use first-person singular pronouns than men, which is consistent with the higher prevalence of depression in women [36,37]. Besides first-person singular pronouns and negative emotion words, causation words (eg, “because”) were also found to be used more by people having depression [34,38]. In line with this, research confirmed the Seligman theory for learned helplessness, which postulates that individuals at risk for depression attribute the cause of a negative event as being internal, global, and stable, by showing that young adults with negative attributional styles were more likely to develop clinically significant depression than those without such attributional styles [39]. There are also studies indicating negative attributional styles as predictive factors for developing depressive symptoms when experiencing negative life events [40-42]. Due to the trend of digitalization in mental health care, linguistic investigations have been conducted in the digital environment as well. In doing so, a positive association was found between Twitter posts indicating loneliness and mental health problems of the users [43]. In another study, which examined the language usage of users of loneliness forums, it was found that these users tended to use words associated with sadness or a desire for social contact, that is, their overall language leaned toward words with negative valence [44]. Regarding associations with psychopathology, the newest findings indicate that individuals with depressive symptoms used fewer complex syntactic constructions, such as adverbial phrases, perhaps because these require greater cognitive effort.
The population of young smartphone users and texters remains a vulnerable and underserved group in crisis counseling, which is why further research on outcomes and the effectiveness of specific communication and counseling strategies is needed [35,36]. To date, there have been no attempts to examine the chat content of crisis counseling services with regard to their linguistic structure. For this purpose, anonymized chat messages from a messenger-based psychosocial chat counseling service, krisenchat (German for ‘crisis chat’), were used to examine (1) which linguistic indicators and gender differences can be identified within the messages of chat users and (2) how these linguistic indicators are associated with the presence of psychiatric symptoms. Based on the existing literature, it was hypothesized that female users would be more likely to use first-person singular pronouns, negations, and insight words than male users and users identifying as diverse. Additionally, it was hypothesized that higher use of first-person singular pronouns, negations, negative emotion words, and words indicating causation would be associated with a higher likelihood of the presence of psychiatric symptoms among users.

Methods

Sampling and Data Collection
For the purpose of this study, anonymized chat data from all users receiving counseling between May 2020 and July 2021 were extracted from the krisenchat database. Data extraction and preparation were performed by authors affiliated with krisenchat (ME, SS, JT, and RW) so that chat content remained within the krisenchat database. The anonymized chat data included metadata on the chat (total number of messages and words sent by users during the whole counseling process, and number of sessions) and information about the user that counselors identified and noted during the counseling process (sociodemographic information, such as gender and age, and topics of users’ concerns). krisenchat counselors were volunteers and had a background in psychosocial studies. In addition, they underwent a structured 2-month training in chat-based counseling. Regarding gender, counselors had 3 options (male, female, and diverse) to mark in their documentation. They were encouraged to record the identified gender and not the biological sex of the users. The gender “diverse” included individuals identifying as nonbinary or diverse, or indicating to be unsure about their gender identity. For more information about the study design and the nature of krisenchat, we referred to the initial evaluation study of krisenchat [20]. Linguistic variables were determined using Linguistic Inquiry and Word Count (LIWC; see below for details).

The sample examined in this study was based on the previous evaluation of krisenchat, in which the sample consisted of those who completed a subsequent feedback survey after the counseling session [20]. Thus, out of a total of 11,031 users in the above-mentioned time period, 6962 (63.1%) completed a feedback survey. The chat messages of these 6962 users were analyzed. In total, 661,131 messages (mean 94.96, SD 259.46) from 26,614 chat sessions (mean 3.82, SD 6.24) with a total word count of 8,872,154 (mean 1274.37, SD 2954.57) were analyzed.

Ethical Considerations
The Medical Faculty of the University of Leipzig approved this study on August 3, 2021 (372/21-ek). Users were informed about the data protection and privacy policy of krisenchat when they first contacted the counseling service. The chat counseling only began after confirming the policy with “Yes.” Participants in the study confirmed informed consent via an opt-in function before taking part in the feedback survey.

Measures

Linguistic Variables
LIWC is a software for dictionary-based quantitative text analysis [29]. LIWC performs an automated 1-word analysis based on a lexicon with more than 80 categories (ie, language variables, descriptors, linguistic dimensions, psychological dimensions, concerns, informal language, and punctuation) including a total of 18,711 words. In 2008, the German version of the lexicon was developed, and good equivalence was confirmed for the majority of LIWC categories [47]. The tool has been used in various studies on personality, social, and clinical psychological frameworks and for the analysis of therapeutic essays, everyday communication, or computer-based communication, and it can therefore be considered a reliable software program for quantitative text analysis [47-52].

LIWC counts the number of words within the lexicon over a whole chat and assigns them to categories. The output file includes all categories of the lexicon. All variables, except summary variables, are expressed as percentages of the total word count of a respective chat. Based on previous findings [34-37,44,53,54], the following linguistic variables were considered in this study: first-person singular (eg, “I,” “me,” and “mine”) and first-person plural pronouns (eg, “we,” “us,” and “our”), negations (eg, “no,” “not,” and “never”), positive emotion words (eg, “love,” “nice,” and “sweet”), negative emotion words (eg, “hurt,” “worried,” and “sad”), cognitive process words such as words related to insight (eg, “think” and “know”), and words related to causation (eg, “because” and “effect”).

Psychiatric Symptoms
The presence of psychiatric symptoms was assessed during the counseling process and noted by krisenchat counselors. The identification of psychiatric symptoms was derived from the concerns reported by the users. Counselors distinguished between the presence of the following symptoms: depression, anxiety, suicidality, self-harm, addictive behavior, eating disorders, flashbacks, and obsessive-compulsive symptoms. Additionally, symptoms were summed up into a dichotomous variable “psychiatric symptoms” to indicate the presence or absence of psychiatric symptoms (0, “not present”; 1, “present”).

Statistical Analysis
Statistical analyses were performed using IBM SPSS Statistics version 27.0 (IBM Corp). A 2-tailed α value of .05 was applied to statistical testing. First, descriptive statistics were performed for sociodemographic variables and linguistic variables of the total sample. Additionally, Kruskal-Wallis H tests (because of nonnormality of the linguistic variables) were used to identify...
gender differences in use, that is, metadata for the number of sessions, messages, and words of each user. Then, a 1-way multivariate analysis of variance (1-way MANOVA) was conducted to test for gender differences in language usage controlling for word count. Gender was considered as an independent variable, and all 7 linguistic variables (ie, first-person singular pronouns, first-person plural pronouns, negations, positive emotion words, negative emotion words, insight words, and causation words) were considered as dependent variables. Post-hoc univariate ANOVAs were conducted separately for every linguistic variable. Bonferroni correction was applied to account for multiple testing. Then, binary logistic regression analysis was conducted to examine the predictive effect of linguistic variables (first-person singular and plural pronouns, negations, positive and negative emotion words, insight words, and causation words), age, and gender (recoded into a set of dummy variables with “male” as the reference variable) on the presence of psychiatric symptoms.

The amount of explained variance as shown by Nagelkerke $R^2$ was interpreted as follows: $R^2 > 0.20$, “acceptable” or small effect size; $R^2 > 0.40$, “good” or average effect size; and $R^2 > 0.50$, “very good” or large effect size [55]. Additionally, Spearman correlation coefficients ($\rho$) were reported between linguistic variables. Finally, with the aim to examine the deeper relationship between linguistic variables and psychiatric symptoms, explorative Spearman correlations ($\rho$) between all 7 linguistic variables and all categories of psychiatric symptoms (suicidality, self-harm, depression, anxiety, eating disorder symptoms, flashbacks, obsessive-compulsive symptoms, and addictive behavior) were computed and interpreted as follows: $\rho = 0.10$, small effect size; $\rho = 0.30$, moderate effect size; and $\rho = 0.50$, large effect size [56].

Descriptive Statistics of Linguistic Variables

In the total sample, the mean percentage of first-person singular pronouns among all words of a user during the whole counseling process was 11.59% (SD 2.46%), indicating that on average, more than one-tenth of all words written throughout all chat messages was a first-person singular pronoun (“I,” “me,” “my,” or “mine”). The next most used linguistic categories were positive emotion words (mean 4.85%, SD 1.70%) and insight words (mean 4.05%, SD 1.32%). The mean percentage of negations among all words of a user during the whole counseling process was 3.76% (SD 1.54%). Furthermore, negative emotion words were used with a mean percentage among all words of 2.93% (SD 1.04%). Finally, first-person plural pronouns were least frequently used with a mean percentage among all words of 0.43% (SD 0.63%).

Gender Differences in Linguistic Variables

Gender-specific descriptive statistics are displayed in Table 2. A 1-way MANOVA showed statistically significant differences in linguistic variables between genders ($F_{14, 1192}=8.945$; $P<.001$; partial $\eta^2=0.01$; Wilk $\Lambda=0.979$). Post-hoc univariate ANOVAs were conducted separately for every linguistic variable. Separate ANOVAs and respective Bonferroni-corrected post-hoc tests showed that when controlling for word count, there were statistically significant differences in the use of first-person singular pronouns between genders ($F_{2,5972}=49.780$; $P<.001$; $\eta^2=0.08$; medium effect size).

Results

Sociodemographic Characteristics

The average user was 17 years old (mean 16.55, SD 3.45 years; range 8-25 years), and most users were female (female: 4988/5978, 83.4%; male: 881/5978, 14.7%; diverse: 109/5978, 1.8%). A large number of all users (4841/6962, 69.5%) contacted the counseling service due to psychiatric symptoms. Further concerns identified were psychosocial distress (eg, school-related problems, family-related problems, bullying, etc; 2370/6962, 34.0%) or emotional distress (eg, grief, lovesickness, anger, and loneliness; 2101/6962, 30.2%) [20]. The users participated in an average of 3.82 (SD 6.24) counseling sessions and sent an average of 94.96 (SD 259.46; range 2-11,512) messages with an average of 1274.37 (SD 2954.57) words throughout the counseling process. Additional testing indicated that there were gender differences in the numbers of sessions ($\chi^2=22.849$; $P<.001$), messages ($\chi^2=14.863$; $P<.001$), and words ($\chi^2=33.036$; $P<.001$). The results are presented in Table 1. Subsequent post-hoc tests indicated that female users attended a significantly higher number of sessions ($z=-4.211; P<.001$; $r=0.05$) and sent significantly more messages ($z=-3.247; P<.001$; $r=0.04$) and words ($z=-5.349; P<.001$; $r=0.07$) than male users, whereas there were no significant differences between female users and users identifying as diverse (number of sessions: $P=.13$; number of messages: $P=.18$; number of words: $P=.22$). Users identifying as diverse also attended a significantly higher number of sessions ($z=-3.441; P<.001$; $r=0.04$) and sent significantly more messages ($z=-2.972; P<.001$; $r=0.04$) and words ($z=-3.693; P<.001$; $r=0.05$) than male users.

Gender Differences in Linguistic Variables

Gender-specific descriptive statistics are displayed in Table 2. A 1-way MANOVA showed statistically significant differences in linguistic variables between genders ($F_{14, 1192}=8.945$; $P<.001$; partial $\eta^2=0.01$; Wilk $\Lambda=0.979$). Post-hoc univariate ANOVAs were conducted separately for every linguistic variable. Separate ANOVAs and respective Bonferroni-corrected post-hoc tests showed that when controlling for word count, there were statistically significant differences in the use of first-person singular pronouns between genders ($F_{2,5972}=49.780$; $P<.001$; $\eta^2=0.08$; medium effect size).
The binomial logistic regression model was statistically significant ($\chi^2_{3}=25.0; \ P=.002$), resulting in a small amount of explained variance, as shown by Nagelkerke $R^2=0.124$ (Table 3). Of the 10 variables entered into the regression model, all but 3 contributed significantly to the presence of psychiatric symptoms: first-person singular and plural pronouns, negations, negative emotion words, causation words (all $P<.001$), and female gender ($P=.005$), while positive emotion words ($P=.08$), insight words ($P=.90$), and diverse gender ($P=.57$) showed no significant effects. Using first-person plural pronouns was associated with a lower likelihood of reporting psychiatric symptoms (odds ratio [OR] 0.39), as did using more causation words (OR 0.90). In contrast, a higher use of first-person singular pronouns was associated with an increased likelihood of reporting psychiatric symptoms (OR 1.05), as did using more negations (OR 1.11) or negative emotion words (OR 1.15). Finally, being female (OR 1.18) or having a higher age (OR 1.04) was also associated with an increased likelihood of the presence of psychiatric symptoms.

**Predicting Psychiatric Symptoms by Linguistic Variables**

The binomial logistic regression model was statistically significant ($\chi^2_{3}=25.0; \ P=.002$), resulting in a small amount of explained variance, as shown by Nagelkerke $R^2=0.124$ (Table 3). Of the 10 variables entered into the regression model, all but 3 contributed significantly to the presence of psychiatric symptoms: first-person singular and plural pronouns, negations, negative emotion words, causation words (all $P<.001$), and female gender ($P=.005$), while positive emotion words ($P=.08$), insight words ($P=.90$), and diverse gender ($P=.57$) showed no significant effects. Using first-person plural pronouns was associated with a lower likelihood of reporting psychiatric symptoms (odds ratio [OR] 0.39), as did using more causation words (OR 0.90). In contrast, a higher use of first-person singular pronouns was associated with an increased likelihood of reporting psychiatric symptoms (OR 1.05), as did using more negations (OR 1.11) or negative emotion words (OR 1.15). Finally, being female (OR 1.18) or having a higher age (OR 1.04) was also associated with an increased likelihood of the presence of psychiatric symptoms.

The results of an additional correlation analysis between all linguistic variables are reported in Table 4. Among others, significant findings included a negative association between first-person singular pronouns and first-person plural pronouns ($p=−0.24; \ P<.001$). In line with this, first-person singular pronouns were positively correlated with negations ($p=0.17; \ P<.001$) and negative emotion words ($p=0.15; \ P<.001$).

**Associations Between Linguistic Variables and Psychiatric Symptoms**

Finally, an exploratory correlation analysis indicated evidence for the relationship between linguistic variables and various psychiatric symptoms, which are displayed in Table 5. Suicidality, self-harm, depression, and anxiety showed the most significant correlations to linguistic variables. In particular, the use of first-person singular pronouns was positively associated with suicidality ($\rho=0.11$; $P<.001$) and self-harm ($\rho=0.10$; $P<.001$). The use of first-person plural pronouns was negatively associated with suicidality ($\rho=-0.10$; $P<.001$) and depression ($\rho=-0.14$; $P<.001$). The use of negations was positively associated with suicidality ($\rho=0.18$; $P<.001$) and self-harm ($\rho=0.12$; $P<.001$). Finally, the use of negative emotion words was positively associated with depression ($\rho=0.15$; $P<.001$) and anxiety ($\rho=0.15$; $P<.001$).

**Discussion**

**Principal Findings and Comparison With Prior Work**

The findings of this study provide first-time valuable insights into the psycholinguistic characteristics of children, adolescents, and young adults seeking psychosocial support through a messenger-based crisis counseling service (krisenchat). Previous findings that examined psycholinguistic characteristics in association with mental health, which however focused on texts (eg, from social media or online therapies), could be identified in the chat context as well. Specifically, linguistic variables were found to be associated with the presence of psychiatric symptoms [43,44,57]. The use of first-person singular pronouns, negations, and negative emotion words increased the likelihood of the presence of psychiatric symptoms, while the use of first-person plural pronouns and causation words was associated with a lower likelihood of the presence of psychiatric symptoms. Female gender was also associated with an increased likelihood of the presence of psychiatric symptoms, which is consistent with the higher prevalence of psychiatric symptoms in women [58]. Gender differences were found, with female users exhibiting more frequent use of certain linguistic features. Previous linguistic analyses, especially in the digital context, such as social media platforms, have been performed with a focus on the presence of psychiatric symptoms or associations with psychiatric symptoms, in particular, depressive symptoms [59]. Linguistic analyses of social media have proven useful in predicting depression, anxiety, loneliness, personality disorders, or other mental health issues [43,57,60-62]. As there are no other comparative studies in this field, the focus of the below comparison of the present results with previous findings relies on correlates of linguistic variables with the presence of psychiatric symptoms, especially depression or anxiety.

**First-Person Pronouns**

Starting with the most frequently used linguistic variable among those examined, an increased use of first-person singular pronouns was associated with a higher likelihood of the presence of psychiatric symptoms. Additionally, it was determined that they were used more often by female users and users identifying as diverse than by male users. In contrast, the linguistic variable of first-person plural pronouns was found to be the least used and did not predict the presence of psychiatric symptoms.
Taking into account the most frequently mentioned concerns among the users of krisenchat (see [20]), involving psychiatric symptoms, such as depression or anxiety, and the higher prevalence of depression in female samples [63], these findings are consistent with previous findings on language usage. Thus, in line with cognitive theories of depression (eg, according to [33]) indicating that depression is associated with an increased self-focus, previous research showed that individuals with depression used more first-person singular pronouns (ie, “I,” “my,” “me,” and “mine”) in both spoken and written language [33,34]. Similarly, first-person plural pronouns (ie, “we,” “us,” and “our”) were used significantly less by depressed individuals, which may be attributed to social isolation or lack of social integration and social engagement in the context of depression [64-66]. However, the increased use of first-person singular pronouns may also be a marker for increased vulnerability to stress and negative emotionality and not directly for depression [67,68].

Negations and Causation Words

Negations were found to be significantly associated with the presence of psychiatric symptoms and were used more frequently by female users than male users or users identifying as diverse. Contradicting the hypothesis, the present results indicate that the use of causation words reduces the likelihood of the presence of psychiatric symptoms, while no significant differences were found between genders. In line with this finding, previous studies indicated that low use of causation words is associated with positive treatment outcomes in treatment for personality disorders [53]. It was found that the use of fewer cognitive words, such as causation words, was associated with a more coherent personal story [69]. A recent study underlined this finding by pointing out that patients having depression tend to use significantly more aligned sentences than bringing them into a logical chain compared with a healthy control group [34]. This cross-sectional study design does not allow to draw conclusions about the trend of the use of causation words throughout the chat counseling. The meaning of these divergent results deserves further specific longitudinal research on the development and change of language use across chat counseling.

Negative and Positive Emotion Words

Elevated use of negative emotion words was associated with an increase in the presence of psychiatric symptoms. Negative emotion words were found to differ between genders, that is, more negative emotion words were used by female users than by male users. This is in line with previous research indicating a significantly higher general use of emotion words by women than men, while men were found to use more anger words [70,71]. This is also in accordance with findings showing that more frequent use of negative emotion words, including anxiety, sadness, and anger words, was positively correlated with higher anxiety and depression levels [54].

Depressive Symptoms

Taken together, the results underline a higher likelihood of depression (or anxiety) in users using more self-focused language (first-person singular pronouns), and more negative and fewer positive (emotion) words. The response style theory of rumination in depression, which could also be proven for worry in generalized anxiety, explains that symptoms of repetitive self-focused negative thinking become habitual over time [72,73]. In terms of language usage, this theory suggests that people with high levels of depression or anxiety might communicate using more self-focused language (ie, more I-related pronouns), and more negative and fewer positive words, and that this tendency may become habitual and outside of conscious awareness. In line with this, linguistic analyses of text-based therapy found reductions in the use of first-person singular pronouns, even though language usage was not being focused on in the treatment [74]. Moreover, changes in the use of positive and negative emotion words and words indicating certainty (eg, “always” and “never”) could be identified during the treatment for depression. Researchers interpret these findings as changes in cognitive processes [75].

Suicidality

In relation to depression, it is also important to keep suicidality in mind because messenger-based chat counseling services are used in acute crises, such as suicidality [76]. In accordance with the present findings, previous studies found that suicidal behavior is associated with the use of more I-related pronouns [77]. Likewise, in accordance with the present findings, previous literary analyses indicated that suicidal poets also used fewer first-person plural pronouns than nonsuicidal poets [66]. In addition, these studies showed that the use of more absolutist language, that is, superlatives and intensifiers (eg, “absolutely,” “completely,” “all,” “none,” etc), was associated with suicidality [60,77,78].

The results of this study indicate that by considering language usage, differences in the user population can be discovered and may also be linked to psychopathology. Thus, language usage should be integrated into the counseling strategy. In the context of computer-based analyses, it was found that in addition to the standardized diagnostic tools used to confirm a psychiatric diagnosis, linguistic research showed that systematic analyses of clients’ language may be used to reliably classify them into diagnostic groups [34]. Additionally, computer-based methods were shown to distinguish persons with depression from other clinical subgroups [79]. Thus, linguistic or, in general, qualitative analyses of text messages seem to be advisable to examine chat-based counseling services in more depth. This is even more true than for social media platforms because text messages are less influenced by social desirability, facilitating more granular visibility into changes in linguistic patterns [80].

Implications for Counselors in Chat-Based Counseling

Multiple implications for psychosocial chat counseling have emerged from the findings. First, counselors may use psycholinguistic analyses as an additional tool for assessing the mental health state of users. By monitoring the usage of specific linguistic features, counselors can identify individuals at risk for psychiatric symptoms and tailor interventions accordingly. For example, in cases of elevated use of first-person singular pronouns, negations, and negative emotion words, particularly for female users and users who identify as diverse, a more in-depth exploration of psychiatric symptoms, especially

Abstract

Background: Stark disparities exist in maternal and child outcomes and there is a need to provide timely and accurate health information.

Objective: In this pilot study, we assessed the feasibility and acceptability of a health chatbot for new mothers of color.

Methods: Rosie, a question-and-answer chatbot, was developed as a mobile app and is available to answer questions about pregnancy, parenting, and child development. From January 9, 2023, to February 9, 2023, participants were recruited using social media posts and through engagement with community organizations. Inclusion criteria included being aged ≥14 years, being a woman of color, and either being currently pregnant or having given birth within the past 6 months. Participants were randomly assigned to the Rosie treatment group (15/29, 52% received the Rosie app) or control group (14/29, 48% received a children’s book each month) for 3 months. Those assigned to the treatment group could ask Rosie questions and receive an immediate response generated from Rosie’s knowledgebase. Upon detection of a possible health emergency, Rosie sends emergency resources and relevant hotline information. In addition, a study staff member, who is a clinical social worker, reaches out to the participant within 24 hours to follow up. Preintervention and postintervention tests were completed to qualitatively and quantitatively evaluate Rosie and describe changes across key health outcomes, including postpartum depression and the frequency of emergency room visits. These measurements were used to inform the clinical trial’s sample size calculations.

Results: Of 41 individuals who were screened and eligible, 31 (76%) enrolled and 29 (71%) were retained in the study. More than 87% (13/15) of Rosie treatment group members reported using Rosie daily (5/15, 33%) or weekly (8/15, 53%) across the 3-month study period. Most users reported that Rosie was easy to use (14/15, 93%) and provided responses quickly (13/15, 87%). The remaining issues identified included crashing of the app (8/15, 53%), and users were not satisfied with some of Rosie’s answers (12/15, 80%). Mothers in both the Rosie treatment group and control group experienced a decline in depression scores from pretest to posttest periods, but the decline was statistically significant only among treatment group mothers ($P=.008$). In addition, a low proportion of treatment group infants had emergency room visits (1/11, 9%) compared with control group members (3/13, 23%). Nonetheless, no between-group differences reached statistical significance at $P<.05$.

Conclusions: Rosie was found to be an acceptable, feasible, and appropriate intervention for ethnic and racial minority pregnant women and mothers of infants owing to the chatbot’s ability to provide a personalized, flexible tool to increase the timeliness and accessibility of high-quality health information to individuals during a period of elevated health risks for the mother and child.

Trial Registration: ClinicalTrials.gov NCT06053515; https://clinicaltrials.gov/study/NCT06053515
Introduction

Background

Maternal morbidity and mortality have remained persistent problems in the United States and disproportionately affect women and birthing people from racial and ethnic minoritized backgrounds owing to embedded racism and bias across the medical and public health systems [1-3]. More concerning, >80% of maternal deaths in 2019 were designated as preventable by the Centers for Disease Control and Prevention’s (CDC’s) maternal mortality review committees [4]. In particular, the perinatal period is associated with high risk of depression and anxiety among mothers and is a leading cause of maternal mortality in the United States [1,4,5]. Other leading causes include hemorrhage, cardiovascular and coronary conditions, and substance use disorders [4,5].

Timely and reliable health information may help to reduce the adverse outcomes during pregnancy and in the postpartum period [6]. Children of single parents, with low household income, of a minority group, or whose parents perceived them as being more susceptible are seen more frequently in the emergency department [7-10]. Health education interventions have been shown to reduce emergency department use among infant caregivers [11]. Seeking health information on websites is common among soon-to-be and new parents; however, the quality of information and sources found on the web about pregnancy, birth, parenting, and maternal health were rated by pregnant women and new parents as having varying quality, or the information found was not sufficiently specific to fully answer questions [12,13]. Currently, some popular programs for these vulnerable populations involve resource-intensive home visits, which face challenges in scaling to assist more mothers owing to staff and cost constraints, or nonpersonalized SMS text messages that may not directly address an individual’s questions [14-18].

Recognizing that facilitating maternal and child health equity in the United States will require intervention at all levels of the socioeconomic model to address the deficits in medical and public health research and practice, our research team selected an innovative approach. This approach consisted of developing a maternal and child health information chatbot that would be iteratively improved through a multiyear, community-engaged research process. The chatbot addresses some limitations of previous strategies by providing personalized health information based on the users’ needs, is readily available at any time, and can include participants nationwide. Rosie offers timely health information from verifiable websites such as children’s hospitals or the CDC to help parents navigate infant care and find clinically correct information to tackle health issues as they arise. In addition, Rosie offers reminders about preventive care visits for infants (eg, well-baby visits) that can also encourage greater continuity of care, which have been shown to reduce emergency department visits for infants [19].

The research team developed the chatbot, named Rosie, to be able to respond to user questions about parenting, pregnancy, and infant development with vetted, trustworthy web-based sources. Question-answering (QA) chatbots such as Rosie, unlike informational sites and frequently asked questions (FAQs) pages, support their users with personalized responses based on the user’s input. They provide users with the unique opportunity to enter their questions in their own words and receive responses to their questions. We built the corpus or index of maternal and child health information using the information derived from expert sources such as federal agencies (eg, the National Institute for Child and Human Development), hospitals (eg, Mayo Clinic), and professional medical organizations (eg, the American Academy of Pediatrics). These sources provided vital information regarding topics such as pregnancy, parenting, infant development, maternal health, and postpartum care.

Chatbots developed to support maternal mental health and parenting have been shown to be a promising intervention needing further evaluation [20-22]. A mixed methods review of literature led by Chua et al [20] suggests that maternal and child health information chatbots have high acceptance among pregnant women and new parents; however, the reviewed papers noted that both development teams and test users expressed preferences for refining the language used in the responses to be more humanlike and for the chatbots to be familiarized with informal, descriptive language to be more adept at generating answers for users who may be describing symptoms or may not know the medical term for the topic of interest. Recognizing these recommendations from the literature, our research team used a multimethod approach to receive substantive, high-quality feedback from participants when launching our pilot evaluation of our maternal and child health information chatbot, Rosie.

Study Objectives

We conducted an experimental pilot study to examine the feasibility, acceptability, and appropriateness of Rosie for our target audience. The pilot study also allowed us to test all the software and equipment, study protocols, and staff coordination to enable remedies before scaling to a full randomized controlled trial. Pilot data were also used to enhance the accuracy of Rosie’s responses by refining the existing models and fine-tuning the mechanisms and heuristics. The focus was on determining access to the resources and the capability of implementing the components and activities of the intervention as planned. Challenges in the provision of any component or the performance of any activity of the intervention were identified and potential solutions were determined. A sample size of 30 was chosen to be within the typical sample size range of a phase 1 clinical trial, according to the National Institutes of Health guidelines.
of Health definitions, to conduct the study protocols and elicit participant feedback about the Rosie app with sufficient representation from our target group. Preintervention and postintervention tests were completed to qualitatively and quantitatively evaluate Rosie and describe any changes across key health outcomes including postpartum depression and frequency of emergency room visits to inform the full trial’s sample size calculations. Analyses of these data allowed us to present the preliminary findings, which should be interpreted as preliminary evidence, given that the pilot study was not powered to assess treatment-control differences, and this was not the main objective of the pilot study.

Methods

Development and Functionality of Rosie, the Chatbot

Rosie was customized to meet the needs of the target audience through continuous community feedback. Over the course of 3 years, our research team conducted community listening sessions, >20 community demonstrations of Rosie [23], and focus groups with pregnant women and new mothers of color. With this feedback, we customized Rosie to respond to health topics that mothers requested such as feeding tips, sleep advice, and information about rashes and fevers. To the Rosie app, we also added a set of the most popular questions that were asked by mothers as an FAQs page and provided a list of additional resources (eg, Supplemental Nutrition Assistance Program) benefits and emergency hotlines). Moreover, we added the requested video library that features things such as how to swaddle a baby, change a diaper, or perform cardiopulmonary resuscitation.

To build Rosie’s robust knowledge base, we collected, scraped, and extracted text from 60 sources, including websites of government agencies, hospitals, and professional medical organizations. A corpus of documents about maternal and infant health was built by scraping text from these vetted web domains using Trafilatura, a Python package and a web document processing tool called Scrapy that extracts text from HTML source code [24]. Each web document was then parsed into approximately 73,000 passages by applying a set of heuristics that retain sentence context. These passages were edited as necessary to serve as answers to the mothers’ questions and were used in a question generation model, probably asked questions (PAQs), to produce likely questions from users. The generated questions and their source passages were reviewed by annotators, who either edited both the question and the passage as necessary or discarded the pairs that were unhelpful, inaccurate, or incomprehensible. The answers augmented the existing knowledge base.

In addition, the research team supplemented the knowledge base by manually writing 350 question-and-answer pairs based on feedback from focus groups and community events with pregnant women and new mothers of color, who asked Rosie questions and identified topics of particular interest (eg, rashes and infant sleep). Only verified sources of health information were used in Rosie’s knowledge base. Sources with sponsored or commercial content were excluded.

Rosie’s underlying QA system uses an unsupervised, dense passage retrieval model. When users ask questions to Rosie, the retrieval model finds relevant content from the knowledge base that best answers the questions. Rosie also provides a source link in her responses, which can direct users to the websites from where the answer was extracted.

To better communicate with the users and understand their needs, we implemented an intent classification model using Rasa, a conversational artificial intelligence software. This classification model is used to categorize users’ text and respond accordingly. For example, it can identify greetings, thank you messages, and requests for information. It is also able to detect potential mental and physical health emergencies and send alerts via Slack, an instant messaging program, to our team members. Upon detection of a possible health emergency, Rosie sends emergency resources and relevant hotline information. In addition, a study staff member, who is a clinical social worker, reaches out to the participant within 24 hours to follow-up.

Rosie was built using Flutter, an open-source user interface software platform by Google, and designed to be compatible with both iPhone and Android devices. The Rosie mobile app has a log-in page with Google authentication, a chat window page that allows users to ask Rosie questions and rate the answers, an FAQs and resources page, and a medical disclaimer page reminding users that Rosie is an informational tool that does not replace professional medical advice and care (Figure 1).
After downloading and logging into the Rosie app, users are asked to enter their estimated due date or their infant’s date of birth. With the users’ permission, Rosie sends push notifications with daily health tips that are generated based on the due date or birth date, thus allowing for personalized advice based on the week-by-week progression of the user’s pregnancy or infant’s health. The past 7 days’ tips are also saved on an app page for users to refer to if needed. The app development team also created an app monitoring system that can detect server-related issues or app interruptions and notify team members via Slack for prompt troubleshooting and resolution. All conversations between users and Rosie were securely stored in Firebase Database.

Recruitment and Enrollment

This was a prospective randomized controlled pilot study involving a mobile app intervention, Rosie the chatbot. To clarify the methods, we followed the CONSORT (Consolidated Standards of Reporting Trials) checklist (Multimedia Appendix 1). From January 9, 2023, to February 9, 2023, participants were enrolled on a rolling basis until the target sample size was met (N=30) for the 3-month randomized pilot study. Participants were recruited using social media posts, including targeted advertisements, and through partnerships with community-based organizations. In addition, our research assistants contacted mothers who had completed an interest form at a previous Rosie community event or focus group. Interested potential participants completed a screening questionnaire to determine eligibility. Inclusion criteria included being aged ≥14 years, being a woman of color, and either being currently pregnant or having a baby aged ≤6 months. Research assistants contacted each of the 248 potential participants to complete a brief video call to assess eligibility, explain study details, and obtain informed consent for participation. We identified fraudulent interest forms through video calls and review of interest survey meta-data, including IP addresses, to filter out potential participants who were falsely claiming to meet the inclusion criteria or were residing outside the United States.

Eligible participants were randomized into the control group (a monthly children’s book club) or the treatment group (Rosie, the chatbot) using a web-generated table with 15 slots for each study arm, for a total of 30 enrolled participants. After a participant assigned to the Rosie treatment group was unable to fully enroll owing to technical issues, we recruited an additional participant as a replacement. In addition, a mother in the control group experienced a stillbirth during the pilot study and did not complete the postintervention test. Thus, the final analytic sample was 52% (15/29) Rosie treatment group members and 48% (14/29) control group members (Figure 2).

Among the 29 participants who were successfully recruited for the pilot study, 3 (10%) were recruited from partner organizations, 6 (21%) were recruited based on our interest forms at past Rosie events, and the remainder (n=20, 69%) were recruited using social media advertisements.
Figure 2. CONSORT (Consolidated Standards of Reporting Trials) diagram of participant enrollment.

The control group participants were mailed a children’s board book once a month. The control group was modeled after similar programs across the United States that provide free monthly books to children [25]. Books were selected based on feedback from focus groups and community demonstrations with new parents or pregnant women of color, who expressed a desire to have books featuring diverse families.

At the initial enrollment meeting, our research team provided the Rosie treatment group participants instructions about how to install the Rosie app on their smartphones and provided a walkthrough of how to use the app and how to provide feedback about Rosie’s responses to their questions. We emailed each participant a weekly user engagement summary and sent reminder SMS text messages to encourage the use of the app.

Data Collection, Outcome Measures, and Analysis

We assigned each participant an identification number to link pretest and posttest data and to track progress through the pilot study using clinical trial management software. Enrolled participants completed a pretest and posttest Qualtrics survey. Pretest surveys included questions about demographics (maternal age, race and ethnicity, education, household size, and health insurance), whether they were pregnant or parenting a young infant, and their due date or their baby’s birth date (as applicable). Pretest surveys also included the Patient Health Questionnaire–9 (PHQ-9) depression scale [26] and assessed the frequency of emergency room visits for infants.

Posttest surveys administered at the 3-month follow-up assessed pregnancy outcomes (birth weight and gestational age), emergency room visits for infants, PHQ-9 depression scale, and group-specific questions. Rosie treatment group members were asked how often they used Rosie and whether they experienced any of the following issues while using the app (eg, “application crashed,” “took too long to get a response,” “was difficult to use,” and “was not satisfied with the answer[s] to my question[s]”). In contrast, the control group members were asked to rate how much they agreed with the following statements on a 5-point Likert scale ranging from 5 (strongly agree) to 1 (strongly disagree): the books I received were of good quality, the content of the books I received is a good match for my baby’s needs, the books were helpful to me during my pregnancy or parenting my infant, the books were enjoyable to me during my pregnancy or parenting my infant, participating with the book club was easy for me, and I would recommend the book club to other parents.

Both groups were also asked open-ended questions to obtain qualitative feedback. Rosie treatment group members were asked the following open-ended questions: (1) Besides answering your questions, what other features would you like to see on an application like Rosie? (2) Do you have any concerns about using Rosie? If so, please tell us about them; and (3) Do you have any additional feedback to help us build the best Rosie app possible? In an open-ended question, the control group members were asked to provide any additional feedback or ideas about their experience with the book club.

Descriptive statistics of the study sample were calculated based on group assignment. Pretest and 3-month posttest values were examined for postpartum depression and emergency room visits for infants. To examine the statistical significance of between-group differences at baseline, Fisher exact tests were used for categorical variables and Wilcoxon rank sum tests were used for continuous variables. For the within-group pretest and posttest comparisons, paired 2-tailed t tests and McNemar tests were applied. Furthermore, 2-sample 2-tailed t tests were used to compare the between-group differences in the pretest to posttest changes. Qualitative feedback was organized and
presented separately for the Rosie treatment group and book club control group members.

**Ethical Considerations**

The consent form was read aloud by research assistants to each participant and verbal informed consent was obtained. Written consent was obtained through the completion of an web-based form, and a copy of the consent form was sent via email to each enrolled participant. Participants were also encouraged to use the app and were told that if they were continuously enrolled for 3 months and actively engaged with the app by asking questions to the chatbot at least once a week, they would receive a gift card worth US $50. In addition, participants were told that if, at the end of the 3-month pilot study, they were among the top 20% of active users, defined by the number of unique questions sent to Rosie, they would also receive a tablet preloaded with children’s books. Participants were also given a gift card worth US $15, disbursed through a participant incentive distribution platform, Tango, upon completing the pretest and posttest Qualtrics surveys. The study was reviewed and approved (institutional review board study ID: 1556200) by the institutional review board of the University of Maryland, College Park, based on procedures for studies involving human participants.

**Results**

**Overview**

Baseline key demographic characteristics were not statistically significantly different between the Rosie treatment and control groups (Table 1). The mean age of mothers for both groups was 31.7 (SD 4.7) years. Approximately half of the mothers (9/15, 60%) were pregnant, and the other half (6/15, 40%) took care of young infants. Among those with infants, the mean age of infants was 4 months among Rosie treatment group members and 4.6 months among control group members. Most participants (9/15, 60%) were African American or Black, with the remainder being Asian, Hispanic or Latina, or multiracial (Table 1).

To examine the statistical significance of between-group differences at baseline, Fisher exact tests were used for categorical variables and Wilcoxon rank sum tests were used for continuous variables.

**Acceptability of Rosie**

More than 87% (13/15) of Rosie treatment group members reported using Rosie daily (5/15, 33%) or weekly (8/15, 53%) across the 3-month study period. Most users reported that Rosie was easy to use (14/15, 93%), and that they received a response from Rosie quickly (13/15, 87%). The remaining issues identified included crashing of the app during attempted use (8/15, 53%), and they were not satisfied with some of Rosie’s answers (12/15, 80%; Table 2).

Health Results: Quantitative

Pilot results suggested better health outcomes for the Rosie treatment group compared with the control group; however, between-group differences did not reach statistical significance. The estimated change in Rosie participants’ PHQ-9 mean depression scores from baseline to posttest period was −3.66 (SD 4.55) among Rosie treatment group participants compared with −2.77 (SD 4.92) among control group members (Table 3). This decline in depression scores between pretest and posttest period was only statistically significant for the Rosie treatment group (P=.008) and not the control group (P=.07). None of the participants from either group reported any emergency room visits for infants at baseline, but this percentage increased to 23% (3/13) for the control group members versus 9% (1/11) for the Rosie treatment group members (Table 3). Notably, 10 (67%) out of 15 mothers who were pregnant at baseline gave birth by the 3-month posttest period, and it could be a possible reason why emergency room visits for infants increased during the posttest period for both groups.

aFor the within-group pretest and posttest comparisons, paired 2-tailed t tests and McNemar tests were applied. Paired 2-tailed t tests comparing pretest and posttest Patient Health Questionnaire depression scores were statistically different for the treatment group (P=.008). No other within-group comparisons were statistically significant at P<.05. Moreover, 2-sample 2-tailed t tests were used to compare the between-group differences in the pretest to posttest changes. P values assess pre- to postperiod changes for treatment versus control groups.

bThe sample size for emergency room visits was smaller because this outcome was assessed among mothers with infants (excludes currently pregnant mothers during the posttest period).

N/A: not applicable.

Rosie Results: Qualitative Feedback

The Rosie participants provided considerable qualitative feedback about their experiences (Textbox 1). Participants expressed that they liked having a personal library to ask all their pregnancy and parenting questions, but improvements were needed in both the user experience and the content of responses. Participants commented that the quality of Rosie’s responses to pregnancy-related questions seemed to be low in accuracy compared with questions about infant caretaking. Participants noted that they observed improvements in the app’s functionality as the trial progressed and that the addition of an FAQs library and daily tips about baby’s development were helpful.
**Textbox 1. Qualitative feedback about Rosie.**

### Domain and feedback

#### Strengths
- “I really enjoyed having a personal library to ask all the questions. Especially because after losing my baby, I didn’t receive a ton of targeted ads since my questions were limited to this app.”
- “I liked it when the daily tips were added to the app. Before that, they were only notifications that I couldn’t go back to and often couldn’t fully read. I also liked when the previous day’s answers became available for viewing, so I didn’t have to screenshot or save links.”
- “I like everything else.”

#### Points system
- “Additionally, the point system didn’t fit with the original study. We were asked to use Rosie a minimum of once a week with a preference for more frequent use. But then the points were awarded for daily use. It was discouraging to not earn points, but with a newborn at home it was a struggle to do anything other than feed him daily.”

#### Content and technical concerns
- “Perhaps some answers were not very accurate for the age of my baby; they were for younger or older kids.”
- “Answers were not specific enough, lots of glitches with the app.”
- “The answers to the questions were often inaccurate.”
- “It does not answer me well.”
- “Not efficient. All of the answers take you to the same website. Using the app was a waste of time.”
- “My pregnancy-related questions were often answered inaccurately. The baby questions were mildly better, but if the chatbot is intended for both than it needs more training related to pregnancy symptoms and side effects.”
- “I had some trouble with the push notifications as well. At first, they were accurate for the number of weeks along I was in my pregnancy. Then they started to speed up, telling me that I was as many as two weeks ahead of my baby’s gestational age [e.g., it said I was 38 weeks when I was really 36]. I went in and reset it, using the same due date that I started with, and it continued to be incorrect. The app itself didn’t seem to have the same problem, just the notifications.”
- “Due to the high number of inaccurate responses, I was not motivated to continue using the app. I tried to stick with it, but to be honest this chatbot and the accompanying app have a long way to go before they’re ready for implementation.”
- “Finally, last week I had some issues with the app where it was giving me answers in a mix of text and source code formatting. Everything looked like a hyperlink but the links themselves did not work. I received an update notification, updated the app, and the problem persisted. It did fix itself after a couple of days though.”
- “At times when typing a question at the moment of submitting the keyboard would stay open and would not allow the user to hit submit. I had to exit out the app completely and reopen it and it would work again.”
- “Sometimes I had urgent questions, it could’t be use because it was under maintenance often.”
- “Hard to update.”
- “Rosie crashed a few times [like over multiple days when I tried asking a question].”

#### Suggestions
- “Sometimes Rosie gave me some answers that were not related to what I wanted to know, I understand sometimes terms can apply to two different things but perhaps Rosie can ask Do you mean this (1) or this (2), and then one chooses what is closer to the question one is asking. It happened to me a couple of times but I don’t remember the specific question.”
- “Answers were not specific enough, lots of glitches with the app.”
- “More accuracy with the answers would be great!”
- “Just implement user feedback.”
- “It would be nice to see some statistics [e.g., x% of kids do x by whatever age].”
- “I was pretty unlikely to visit the website Rosie referred me to. I think I would be more likely to view info right on the screen [even a click box with additional text or pics etc].”
- “Random suicide hotline warning was a little bit abrupt and unexpected.”
- “Answers were unrelated sometimes.”
- “Maybe something more personal with the week we are on if its more geared for pregnancy.”
- “I would say maybe [a] different app for moms and another version for expecting moms only due to the fact that some symptom questions were meant for a child rather than me who is pregnant. Overall the app is a great idea and good help/support for all. Thanks for the opportunity.”
As a result of the feedback, the development team has added more source websites to Rosie’s knowledge bank and has expanded the FAQs section of the app to include topics such as descriptions of the full schedule of well-baby visits and immunizations in the first 2 years of life. As this pilot study was designed to be part of a broad iterative process, negative, neutral, and positive feedback are all integral parts of refining the app’s functionality and expanding its knowledge base.

**Book Club Results: Qualitative Feedback**

Participants were extremely positive in their feedback about the book club, with participants rating the books as being of high quality and as a helpful tool for parenting (Textbox 2 and Table 4). All participants (14/14, 100%) agreed that they would recommend the book club to other new parents. Participants appreciated the “diversity and bilingual aspects of the books” and that their infants “really enjoyed the Global Babies book and loved to stare at the faces [presented in the books].” A participant offered a recommendation for an additional children’s book by an author whose works focus on social justice leaders in the United States to be offered in the book club.

**Textbox 2.** Qualitative feedback about the book club.

**Domain and feedback**

**Strengths**

- “I so much love it.”
- “I loved the diversity and bilingual aspects of the books.”
- “Baby really enjoyed the global babies book and loved to stare at the faces.”

**Suggestions**

- “The book[s] were good, but I think there are more popular/exciting book options for babies, especially books featuring babies of color. I am thinking of all the books by Jabari Asim for example. The last book was great though and the overall idea for a book club is fantastic. I loved knowing that new books were coming each month.”
- “Oh, another thing: I got an automatic message from the book club quite frequently with the same message and it seemed redundant.”

**Table 4.** Acceptability statistics for the control group (n=13).

Health Results: Qualitative

A Rosie treatment group participant and a control group participant experienced pregnancy loss (a miscarriage and a stillbirth) during the study. An unexpected finding from one of the participants, who was assigned to the treatment group, was that using Rosie for maternal and child health information helped in shielding them from some emotional distress after their loss, with our participant stating the following:

I really enjoyed having a personal library to ask all the questions. Especially because after losing my baby, I didn’t receive a ton of targeted ads since my questions were limited to this app.

Recognizing that most of the currently available maternal and child health apps track user interactions for advertisers and feature advertisements, Rosie’s development as a no-cost, advertisement-free app may have additional benefits for mothers who value personal data privacy.

Discussion

Principal Findings

The pilot study demonstrates that Rosie is a feasible, acceptable, and appropriate intervention for pregnant women and new mothers of color. Rosie’s software was able to function with a given set of users and was generally able to generate responses to most of the asked questions. Our study found overall reduction in the PHQ-9 depression scale scores from baseline to the 3-month follow-up across both groups. However, the Rosie treatment group experienced a relatively large reduction from baseline to posttest follow-up. The reduction in maternal depression among both groups may correspond to known trajectories in maternal depression, which identified that depressive symptoms peak around birth and decrease as the infant ages [27,28]. Researchers have found variability in the timing and duration of perinatal and antenatal depression, but some studies have found that women who had depression symptoms during the antenatal period were likely to have more intense symptoms during pregnancy than during the postpartum period and that perinatal depression symptoms decreased over time [29,30]. With an expanded time frame of 12 months planned for intervention delivery during the full randomized controlled trial, the research team will be more able to precisely track trends in depressive symptoms and identify what, if any, congruence exists in our participants and the current literature about maternal depression and other mental health symptoms.

Although our small sample size and study design limit our ability to identify the causal pathways between Rosie and changes in depressive symptoms, our findings indicate that an association may exist between the use of the Rosie app and low maternal depression owing to increased parental confidence about their own health and infant caretaking through increased access to accurate health information. Rosie’s ability to provide rapid, accurate response with high-quality sources may also reduce the cognitive burden that pregnant women and new parents described in previous studies that emphasized that sorting through information, making comparisons, and determining the quality of the source of information were significant stressors. In addition, the Rosie app may also reduce maternal depression because it can help provide support to mothers who may not otherwise have access to many health-related supports and resources.

The low rates of emergency room use for infants in the Rosie treatment group compared with the control group aligns with previous study hypotheses that health information provided by Rosie can decrease acute health care use. Nonetheless, this could have occurred through multiple channels including potentially greater use of preventive health care services and Rosie assisting with the identification of relevant health information or clinical guidelines to support infant care.

The qualitative feedback the Rosie participants provided aligns with the conclusions obtained by Chua et al [20] during their review of maternal health chatbots that the first evaluations of these interventions often yield a need for improvement in the language models to understand the variety of ways in which users may ask questions about their pregnancy and child and to provide more precise and accurate responses to these questions.

New Rosie Features in Response to the Pilot Study

User experiences and feedback about the Rosie app has informed the further development of Rosie and continued precision of the QA model. For each of Rosie’s responses, users were able to click “thumbs up” or “thumbs down” to indicate their satisfaction or dissatisfaction with Rosie’s response to their question, and approximately 35% of questions received this additional level of feedback from users. The team analyzed this feedback and enhanced Rosie’s knowledge base by including topics that were not covered in previous iterations of the QA model and further refined the QA model based on the issues identified by the participants and the research team. We analyzed and discussed these interactions weekly with the goal of improving Rosie and initiating improvements in the user experience.

In addition, as a result of user feedback, we have expanded Rosie’s knowledge bank by >10 folds from 75,000 passages to >1.8 million passages extracted from 400,000 documents from verified health sources such as the CDC, National Institutes of Health, Mayo Clinic, and children’s hospitals. Rosie’s previous knowledge base was restricted to only maternal and infant care questions, but Rosie users had requested information about topics such as managing chronic conditions, food safety and preparation, mental health, and self-care. The expanded corpus now enables mothers to ask any health-related question.

Strengths

This pilot study adds to the existing literature about chatbots broadly and their application in the context of maternal and child health. The team’s findings specific to reduction in maternal depression will help address one of the CDC-identified preventable causes of maternal death. In addition, low emergency room visits for infants suggest potential improvements in infant care and avoidance of some health crises. Our qualitative findings concur with those of previous studies, showing that improved precision in responses is needed [13,20]. Overall, participants found the chatbot as a helpful tool, and this intervention is delivered in a way that is easily
accessible and usable. They also believe that it is an appropriate and acceptable approach for women of color who are pregnant or parenting an infant to receive reliable information. The feedback from our participants is invaluable in the preparation for scaling to a full randomized controlled trial. The use of a multimethod approach that obtained both quantitative and qualitative feedback resulted in a broad understanding of participants’ experiences and needs and addressed some gaps recognized in previous trials of chatbots designed for improving health knowledge.

Limitations
The recruitment of study participants was conducted primarily through web-based advertisements, potentially yielding a sample of participants who are overall more comfortable with using apps and their phones as their primary way of seeking health information than other women who are pregnant or parenting infants. Our sample, overall, was highly educated and the most (26/29, 90%) had health insurance, which may have reduced our ability to detect the experiences and health information needs of mothers without the same level of education or identify the needs of mothers whose lack of insurance may be associated with more variability in the use of emergency rooms. The small sample size of this pilot study resulted in low statistical power. Several health outcomes were found to be different in the posttest period when making between-group comparisons of the Rosie treatment and control groups, but differences did not reach statistical significance. In addition, detection of other between-group differences or predictive relationships between group assignment or demographic variables and outcomes of interest was limited by the small sample size. It was also not feasible to compare pregnant women and those parenting infants within groups at pretest and posttest periods to determine whether there were statistically significant differences owing to the small sample size. However, our approach helped to accomplish our goals for the pilot study and has facilitated a robust planning process for scaling to the full randomized controlled trial.

Conclusions
This pilot study showed that the prototype of the Rosie app is a feasible and usable innovation during pregnancy and postpartum period. This study provides valuable insight into using chatbots to help pregnant women and new mothers of color access reliable information the moment it is requested. Promising pilot results suggest that chatbots may reduce adverse health outcomes among ethnic and racial minoritized mothers; however, additional evaluation is warranted including a planned randomized clinical trial to evaluate the effects of Rosie on maternal and infant outcomes. If successful, chatbots such as Rosie can help address the existing health disparities in maternal and child health that have important intergenerational and downstream health consequences for the nation.

Acknowledgments
The study reported in this paper was supported by research grants from the National Institute on Minority Health and Health Disparities (QCN and EMA; grant number R01MD016037) and by the National Library of Medicine (QCN; grant number R01LM012849). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript. Authors do not have any conflicts of interests relevant to this study.

Data Availability
The deidentified versions of data sets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Authors’ Contributions
Study conceptualization, design, and implementation were completed by QCN and EMA. MJ and FXMG facilitated participant recruitment, enrollment, and data acquisition activities, with supervision from EMA. Development, build-out, and amendments of natural language process models and information corpus were completed by XY, HM, NPS, and JB-G. QCN, MJ, ACD, XY, HM, and XH analyzed, interpreted, and created the tables and diagrams based on the study’s quantitative data. MJ, ACD, and FXMG analyzed and interpreted the qualitative data. QCN, MJ, ACD, XY, HM, FXMG, and XH completed the analysis of current literature about chatbot interventions and implications of previous studies, provided critical analysis of integrated results, drafted and revised the iterations of the manuscript. QCN, EMA, MJ, ACD, XY, HM, NPS, FXMG, ND, XH, and JB-G edited and reviewed the manuscript.

Conflicts of Interest
None declared.

Abstract

Background: Personalized asthma management depends on a clinician’s ability to efficiently review patient’s data and make timely clinical decisions. Unfortunately, efficient and effective review of these data is impeded by the varied format, location, and workflow of data acquisition, storage, and processing in the electronic health record. While machine learning (ML) and clinical decision support tools are well-positioned as potential solutions, the translation of such frameworks requires that barriers to implementation be addressed in the formative research stages.

Objective: We aimed to use a structured user-centered design approach (double-diamond design framework) to (1) qualitatively explore clinicians’ experience with the current asthma management system, (2) identify user requirements to improve algorithm explainability and Asthma Guidance and Prediction System prototype, and (3) identify potential barriers to ML-based clinical decision support system use.

Methods: At the “discovery” phase, we first shadowed to understand the practice context. Then, semistructured interviews were conducted digitally with 14 clinicians who encountered pediatric asthma patients at 2 outpatient facilities. Participants were asked about their current difficulties in gathering information for patients with pediatric asthma, their expectations of ideal workflows and tools, and suggestions on user-centered interfaces and features. At the “define” phase, a synthesis analysis was conducted to converge key results from interviewees’ insights into themes, eventually forming critical “how might we” research questions to guide model development and implementation.

Results: We identified user requirements and potential barriers associated with three overarching themes: (1) usability and workflow aspects of the ML system, (2) user expectations and algorithm explainability, and (3) barriers to implementation in context. Even though the responsibilities and workflows vary among different roles, the core asthma-related information and functions they requested were highly cohesive, which allows for a shared information view of the tool. Clinicians hope to perceive the usability of the model with the ability to note patients’ high risks and take proactive actions to manage asthma efficiently and effectively. For optimal ML algorithm explainability, requirements included documentation to support the validity of algorithm development and output logic, and a request for increased transparency to build trust and validate how the algorithm arrived at the decision. Acceptability, adoption, and sustainability of the asthma management tool are implementation outcomes that are reliant on the proper design and training as suggested by participants.

Conclusions: As part of our comprehensive informatics-based process centered on clinical usability, we approach the problem using a theoretical framework grounded in user experience research leveraging semistructured interviews. Our focus on meeting
the needs of the practice with ML technology is emphasized by a user-centered approach to clinician engagement through upstream technology design.

**Introduction**

**Background**

Transparency, suitability, and adaptability are cited reasons for the chasm between advances in artificial intelligence (AI) and implementation in health systems [1]. Hindering implementation is a lack of transparency about the data used to make decisions and recommendations [2]. The conceptual suitability of, or aversion to, an algorithm in clinical use is practically governed by a clinician’s autonomous decision to engage with the tool [3]. The adaptability of the algorithm to local patient populations and unique workflows further increases the likelihood of adoption [4]. Logically, a proactive and systematic approach to addressing barriers to transparency, suitability, and adaptability may propel the wider implementation and adoption of AI in patient care [5].

Ultimately, the foundation of this approach is rooted in clinician engagement at the earliest stages of AI development [6]. Determining the user’s complex and diverse requirements for effective machine learning (ML)–based clinical decision support (CDS) tools requires a thorough understanding of the clinical utility of data sources and suitable designs to facilitate contact and response in appropriate settings [7]. This formative usability approach can be achieved through an empathetic and sustained relationship within a multidisciplinary team initiated by early-stage formative research and upstream technology design [8].

In a personalized medical practice aiming to optimize a clinician’s management of asthma, an efficient review of the condition’s characterizing features is critical [9]. Unfortunately, efficient and effective review of these data using electronic health records (EHRs) and timely clinical decisions are impeded by the varied format, location, and workflow of data acquisition, storage, and processing [10]. To support clinicians, we aim to develop an ML-based CDS tool that (1) predicts future risk of asthma exacerbation (AE; risk stratification and resource management), (2) provides this risk evaluation in the context of a summary of relevant information for asthma management (reduction of EHR review burden), and (3) offers options for actionable intervention.

As described in our published work, our AI evaluation plan uses a phased framework (Figure 1 [11]) to address technical performance, usability and workflow, and health impact, and iteratively follows our model documentation steps [12]. This paper describes how we conduct phase 0 and phase 1, highlighting user experience (UX) design and formative research through clinical user shadowing and interviews.

**Figure 1.** Phased research framework for evaluation of AI applied to the A-GPS project based on Park et al [11]. A-GPS: Asthma Guidance and Prediction System; AI: artificial intelligence; FDA: United States Food and Drug Administration; IRB: institutional review board; NASSS: Nonadoption, Abandonment, Scale-up, Spread, and Sustainability; UX: user experience.
Theoretical Framework

Literature detailing ML-based CDS tool translation indicates an ineffective balance of tool intelligence with explainability, creating gaps in translation, implementation, and accountability [13]. This suggests the need for early engagement with clinical users to mitigate present gaps by gaining a comprehensive and multidisciplinary understanding of present challenges, as well as identifying requirements for development and integration that prioritize both intelligence and practical usability. This formative research required a structured methodology to gather unstructured qualitative data and draw reliable conclusions, especially when diverse aspects and roles are involved. Therefore, UX research methodologies were adopted throughout phase 0 and 1, including the Double Diamond design framework and participatory design method that strategically engaged clinical users to derive unmet needs and identify user requirements [14,15]. The Double Diamond design framework (Figure 2 [16,17]), a graphical guide following the phases of the design process, is widely used to customize and standardize the progression of UX research by incorporating iterative loops and feedback opportunities to progress development [16,18].

Figure 2. Dan Nessler [16] developed this revamped version of the Double Diamond process based on the British Design Council’s Double Diamond [17] (reproduced from Nessler [16], with permission from Dan Nessler). This paper demonstrated how we went through each step in the first diamond to discover and define “user needs,” thus complete certain aspects on the Phases 0 and 1. HMW: How-Might-We.

Study Objectives

The A-GPS tool is an ML-based CDS tool accessible from “within” the EHR workflow. It aims to summarize all asthma-related context information extracted from the EHR on 1 screen page [9,22]. The tool will be embedded with a functional component of the AE risk model (AE risk model), which applies ML algorithms to predict a patient’s risk of exacerbation in 1 year [23]. This study’s objectives were to qualitatively explore clinicians’ experience with the current asthma management system, identify user requirements to improve algorithm explainability and A-GPS prototype, and identify potential barriers to ML-based CDS system use. Research questions were developed to probe the challenges and pain points of gathering asthma-related information within the current asthma management system, thorough evaluation of clinical team member workflows, user requirements for prototype optimization, algorithm explainability and display.
Methods

Participant Selection and Recruitment
We invited a group of clinicians representing the key roles in asthma management to collect user requirements and listen to their suggestions for future implementation. These roles include physician, nurse practitioner, nurse, and coordinator in primary care and asthma management specialty. Most of them are practicing in the Department of Pediatric and Adolescents Medicine and Family Medicine outpatient practices, where A-GPS will be implemented. A total of 14 participants were recruited by email using a convenience sampling approach and scheduled for a one-on-one, 30 to 60-minute virtual interview.

Data Collection
This formative usability research was directed toward an understanding of user requirements and to facilitate optimal workflow integration, estimate the potential impact of health care delivery factors, and work capacity constraints on achieved benefit. We aimed to collect different facets of qualitative data to identify all stakeholders, understand user needs, probe for optimal tool design to support clinical decision-making and routine workflow for each group in a comprehensive manner. To obtain the clinical context of how the tool will be used in practice, 1 researcher shadowed both sites and described the general patient flow. Next, we scheduled a 60-minute virtual interview with each recruited participant. An introductory statement provided background on the ML-based CDS tool prototype and explained the goal of the interview, developing rapport with interview participants. Each interview session was composed of 2 parts. Part 1 was a routine 30-minute semistructured interview. Interview guides were created for stakeholders, clinicians who were part of the A-GPS project or practice leadership, such as a division or practice chair, and users, defined as those with no stake in A-GPS but are practicing clinicians. Detailed interview guides were attached as supplementary material (Multimedia Appendix 1). Stakeholders were asked specific questions regarding their role as stakeholders in A-GPS and as potential users. Nonstakeholder participants (users) were questioned about their experience and needs as end users. Within part 2 of the interview session, participants were invited to demonstrate an EHR walkthrough on their working computer. During this time, we observed how the clinician routinely uses the system and defines the asthma-related information required to make a medical decision. Additionally, follow-up questions were asked to explore their cognitive process. While part 1 focused on clinicians’ reported problems and individual opinions, part 2 allowed us to observe the current problems and workflow objectively. Each type of data supplemented the other to achieve problem-probing and user needs consolidation.

Data Analysis
UX specialized translational informaticians engaged with practice components to evaluate usability and workflow to determine effectiveness, efficiency, satisfaction, ease of use, explainability, and usage, as described in the AI Evaluation Framework by Overgaard et al [23]. Interviews were transcribed, reviewed, and coded by team members LZ, JWO, KAJ, and TAB. Using a web-based collaboration tool MURAL (Tactivos, Inc) [24], transcripts were coded by identifying emergent themes and categorized into primary research questions asking what, how, where, and when. Other themes included challenges or pain points, barriers to adoption, novel ideas, new insights, and stakeholder considerations. Subthemes were presented as opportunities for change using an HMW question format [19]. Figure 3 provides a brief look into the synthesis and analysis work completed using the MURAL tool. As for the EHR walk-through, we used the data as a reference to make the list of the acquired information in the EHR system.
Ethical Considerations
This study was conducted as a quality improvement initiative defined by the Mayo Clinic Institutional Review Board and Mayo Clinic Policy. According to the Code of Federal Regulations, 45 CFR 46.102, the project does not require IRB review. Patient and provider consent were not required, but all participants provided oral consent. To protect participant privacy, the participant’s name and email were used for recruitment purposes only and never linked to audio or transcribed data. Data were used to improve the delivery of health care services at Mayo Clinic.

Results
Participant Characteristics
A total of 14 clinicians were interviewed across 4 Mayo Clinic Health System sites in Minnesota, including Rochester, Red Wing, Albert Lea or Austin, and Kasson. Of those who participated, 7 (50%) were women, 11 (79%) were physicians (Doctor of Medicine or Advanced Practice Registered Nurse) and 3 (21%) were nurses. Their roles included asthma specialist, allergist, pulmonologist, pediatrician, family medicine physician, asthma care coordinator, and medical resident.

Targeted Patient Population and Clinician Users of A-GPS Tool
Clinicians identified opportunities to enhance asthma management for the diagnosed and at-risk population through the use of the A-GPS tool. According to clinicians, the tool would best serve pediatric patients with a diagnosis of asthma and should also aim to cover pediatric patients not officially diagnosed but at high risk of developing asthma, including those identified with the following conditions: symptoms of wheezing or coughing, albuterol or oral steroids use, frequently reported respiratory conditions of pneumonia, lung infections, wheezing, or coughing.

Some patients probably have asthma that we don’t detect, but that’s where I think this tool would be helpful because maybe even though they don’t have a diagnosis of asthma, they’ve had wheezing, or other things listed in their diagnosis and problem list. That would be helpful to avoid missing those people. [P6]

Some kids had been given a bronchodilator because often at 18 months, they present with like viral induced wheezes, and we find it improves with albuterol. So, we get a response to albuterol, and we know that these kids are potentially likely to get asthma, but we typically don’t make that diagnosis until after two. [P4]

Patients with pediatric asthma may be seen by multidisciplinary clinical roles including allergy specialists, pulmonologists, pediatricians, asthma care coordinators, rooming nurses, emergency department physicians, and primary care providers. When identifying proper clinician users of the tool, it was reported that any role that needs to provide asthma management care in practice would benefit from accessing and using A-GPS tool. To capture potential role-based variance in user requirements, the routine workflows and information needs were asked for each participant. It was found that asthma management is coordinated care by dynamic care teams, however, participants demonstrated a preference for a shared view of the tool to gain a shared understanding of patient cases. Even though the responsibilities and workflows vary among different roles, the core asthma-related information and functions they requested were highly cohesive, which allows for a shared information view of the tool.

Usability and Workflow Aspects of the ML System
In general, clinicians welcomed the integration of the AE risk model into the patient’s EHR. In practice, the prediction results are expected to help facilitate preventive actions to support better asthma management. To accomplish this, the AE risk prediction results cannot simply be in the EHR, it also needs to notify clinicians and prompt the care team to follow-up with patients in an expedited fashion.

If risk prediction results are added and approaching the threshold, and you will get a message letting you know that that is happening, that would be the best way to go. Because then you can prevent the next exacerbation, rather than waiting to see the patient the next time they come to the clinic, by then patient might have been through a couple of exacerbations. [P2]

If we are getting this risk score and especially if it were telling them that this is somebody that is at high risk of relapses and recurrences of episodes, then we can make that effort to reach out to those individuals. That should be flowing in my mind. That should be going to our care teams. [P14]

Despite the goal of being proactive, obtaining clinician’s attention to the right patient at the right time in an acceptable format is an issue. Notification methods were suggested by participants and opinions varied based on roles.

When you open the chart, it be helpful to have that notification sent via an in-basket message so that we’re aware and could follow up sooner. There might be cases where we’re aware that they’re high risk, but we can just delete it if we already have that plan for follow-up. [P9]

Best Practice Advisory (BPA) kind of prompts the provider that some action needs to be taken in these areas. And it might be a nice opportunity. Or one of the things we have is emergency action plans. Some similar way that incorporates into an action that needs to be taken or addressed for this patient. [P6]

In-basket message was mentioned by many clinicians as a common type of active alarm. However, it is necessary to balance effective information delivery and alert fatigue as clinicians, especially physicians, receive various alarms and notifications from multiple channels in their daily work.

I would just like the color coding in the records. I do not know if an in-basket message would be effective because we get a lot of them. If it was, I like the message was really clear and can quickly know what it is for. [P13]
Probably not an alarm for high-risk cases. I can imagine people getting annoyed at that, but if it came up in care gaps on the storyboard, like a reminder of something needing to be reviewed, that would be nice. [P4]

I hate to say in-basket messages because that just generates another inbox that the provider doesn’t have time to handle. I think having these folks show up as high-risk followed up by our care coordinators is the right way of handling this. It should be a trigger to get care coordinators or nurses to schedule a visit with the patient, which is more important than notifying the provider. [P14]

Additionally, the alarm or notification should reach clinicians with proper guidance for the next steps.

In BPA, we see alarms as this bright red thing with exclamation points. We’re going to want to act on that, but how do you act on it? Like, does it prompt then if you go into your plan, will it prompt something where you get some choices, like high-risk, you know. Whatever the risk score is, here are some options for you and you click those, and it goes into an order set, and you can order it and you’re done. [P7]

User Expectations and Algorithm Explainability

Expectations and Perceived Impact

Participants reported that the A-GPS tool is expected to have a positive impact on clinicians’ workflow and patient experiences. Clinicians anticipate a positive impact on usability and workflow by (1) streamlining the review of asthma information, (2) providing patients with “proactive” rather than “reactive” care, (3) empowering patients with a deeper and more personalized understanding of their condition, and (4) improving outcomes. Participants find the tool can be helpful in several situations, such as preparing for an upcoming patient visit, following up on a patient’s condition remotely, and changing or refilling medications based on changes in a patient’s condition. With well-organized asthma information presented at the appropriate time in the workflow, clinicians expect they can save time reviewing information and the care team will have a consistent understanding of patient cases.

Importantly, proactive and preventive care is anticipated with the AE risk model, allowing the prioritization of resources to patients of greatest need, and reduction of AE, emergency department visits, and hospitalizations. Clinicians hope to perceive good usability of the model with the ability to note patients’ high risks and take proactive actions to manage asthma efficiently and effectively. Ideally, with attention-grabbing model output visualization, both patient and caregivers would be more engaged in home-based care after seeing future risks. The potential to further drive higher quality outcomes was identified in the potential to monitor the relationship between patient adherence to medication, symptoms, and other contributing factors.

Algorithm Explainability

User requirements of the AE prediction algorithm output emphasized interpretability, logical justification, and validation as is shown in Textbox 1. Specifically, known definitions and levels of risk categories must be explainable, leading to efficient patient classification and resource allocation. Visual indications of severity, such as red, yellow, and green to define high, medium, and low-risk categories paired with a numerical indication were required. Supporting contextual information such as flagging primary features impacting risk prediction and providing a summary of additional asthma management variables were key requirements. Supporting information should be easily accessible and presented as hovering capabilities or links to relevant data (eg, patient history and baseline diagnostics). To assist with algorithm explainability and informing next steps, users required supplemental information on how the prediction score was calculated, bolstered by comparative diagnostics (eg, individual and population baseline values). Clinicians expressed concern regarding accuracy and reliability without significant validation of the model. Requirements included documentation to support the validity of algorithm development and output logic, and a request for increased transparency to build trust and validate how the algorithm arrived at the decision. For successful integration, users require that strategic education and phased implementation must be offered. Education and regular reports on the clear demonstration of value was the preferred strategy to gain an understanding of appropriate A-GPS use and limitations. Examples of stated learning preferences included hands-on training, such as workshops presented at monthly meetings, regular follow-up communication and showcasing of successful use cases, and video tutorials. Importantly, users require a clear demonstration of value to ease adoption, achieved by a phased implementation approach (multisite).
Barriers to Implementation in Context

**Accuracy and Reliability**

Many participants expect the AI model given by A-GPS will be validated for accuracy and reliability. They also stressed the importance of making the model explainable and transparent to users. Clearly explaining why the model predicted a specific risk score will allow users to understand the logic of the model and its relevance to the patient’s current asthma condition. Without demonstrating validation or providing transparency clinicians will lack trust in the tool and likely not use it, limiting its clinical value.

**Clinician and Patient Concerns**

Clinicians recognized the potential benefits of A-GPS but voiced several ethical concerns regarding the AE risk model. As is shown in Textbox 2, one concern was the misunderstanding of AI’s role in clinical practice and that AI will override clinician autonomy to make clinical decisions. However, 1 participant asserted that the goal of AI is to provide complementary information and that the clinician would still make the final clinical decisions. A similar concern was the impact the risk prediction model would have on a clinician’s intuition. More specifically, when the AE risk model contradicts the clinician’s professional judgment, the possibility of legal or ethical issues may arise depending on what action the clinician takes.

Textbox 2. Examples of interviewees' statements about ethical concerns.

- Machine learning introduces a new wrench in things. Because now you’re not giving me a necessarily a recommendation, but you’re giving me insight that might either raise my intuition or lower it. How do you handle having that prediction result legally and ethically and everything else? [P12]
- As a pulmonologist, I am trying to understand how other systematic diseases impact asthma. So, I am also checking tests of other body systems and evaluating by talking to patients. For the populations I am seeing with asthma, hopefully, at some point artificial intelligence could help us, but I just do not see it at this point. [P2]
- This prediction score is not meant to override. This is complimentary information for you. I know you do mental calculations, but this is a data-driven calculation that gives you other complementary information. If there’s a discrepancy, is there anything you are thinking low in emotion, say “hi, just to think about it on this page.” So then, you know, you don’t have to go to that page, just look through another page of the sectional summary. [P5]

A patient-specific concern was the potential for unnecessary anxiety and emotional burden on patients and their caregivers when told the AE risk model deems the child at “high risk.” The fear that an asthma event could occur based on a prediction tool that many patients and caregivers may not fully understand may provoke unnecessary changes in the child’s daily activities, as shown in the example below.

Parents may worry about their child if the AI tool says, “high risk of AE” and subsequently change daily decisions, such as not sending their child to school or letting them play outside. [P7]

Discussion

**Principal Findings**

Principal results are discussed by identified themes. In each theme, we started with “How Might We” questions to inspire discussions on challenges and opportunities.

**Usability and Workflow Aspects of the ML System**

Challenges and opportunities of usability and workflow aspects of the AI system prompt key questions such as the following: How might we incorporate the A-GPS tool to support workflows of different roles? Clinicians are tasked with a workload that involves increasing patient volumes, more complex diseases, and an overwhelming EHR system. Further, 1 goal of A-GPS is to help alleviate the time clinicians spend in the EHR to find asthma-related information and supplement the clinical decision process required to minimize a patient’s risk of AE. Successfully
incorporating A-GPS into the current workflow of various clinical roles is arguably as important as the tool itself. Participants suggested placing the A-GPS tool in the same location within the EHR and having the same view, regardless of roles. This will allow easier navigation in the EHR within the care team’s current practice as clinicians, nurses, and care coordinators frequently view each other’s screens during patient care.

**User Expectations and Algorithm Explainability**

Challenges and opportunities of user expectations and algorithm explainability prompt key questions such as the following: (1) How might we communicate A-GPS results in a way that is explainable to patients? Although patients and caregivers were not interviewed, they will receive some level of information from the A-GPS tool communicated to them by the clinician or care team. How the outcome of the AE risk model is explained to patients will be important. Limiting unnecessary anxiety or misunderstandings while still effectively communicating the model results needs to be carefully addressed so families can make appropriate decisions that improve the patient’s outcomes. Properly educating clinicians on how to explain the AE risk model to families is 1 approach that could be tied into the overall education plan for A-GPS. (2) How might we remove barriers to adoption to increase clinician buy-in? The adoption of any new tool or technology rarely goes as planned, it takes time to achieve buy-in from users. To increase clinicians’ buy-in for A-GPS a few barriers should be addressed. First, clinicians need to see that the A-GPS tool is validated, accurate, reliable, and effective at saving time in the EHR. Communicating this data using various educational modalities can increase the reach among clinicians. Second, some clinicians will wait to see the value A-GPS brings to their colleagues before using it themselves. These individuals may be reached by leveraging clinician champions who believe the A-GPS tool improves UX with the EHR and patient outcomes. Ultimately, the best method to facilitate the adoption of the A-GPS tool is to ensure its functionality meets the user’s needs and expectations. Clinicians are more likely to use A-GPS if a clear and concise ML-based CDS tool is created that contains only asthma-related information with easy access to more detailed notes and test results. Moreover, clinicians may use and act on the AE risk model if they trust it, understand what the risk score means for their patient, and understand how the model came to its conclusion for their patient.

**Barriers to Implementation in Context**

Challenges and opportunities related to implementation and system use in context prompt key questions such as the following: How might we address ethical issues brought on by a difference between the AE risk model and a clinician’s professional judgment? The contradiction between the AE risk model and a clinician’s clinical assessment may pose an ethical and even legal issue. In practice, clinicians may feel pressured to act upon the model’s output in fear of legal challenges even if they believe the patient’s risk of AE is different based on their professional judgment. Although this topic deserves further exploration, it is reasonable to assume in educating clinicians that their clinical judgment supersedes the result from the AE risk model as the model does not take into consideration the multitude of variables the clinician assesses. Moreover, the reason for the development of the AE risk model in this context was to provide supplemental information to improve the care of patients with asthma, not replace the expertise of clinicians. Addressing this upfront with potential users should be a component of A-GPS implementation.

Acceptability, adoption, and sustainability of A-GPS are implementation outcomes that are reliant on the proper design and training as suggested by participants. Without following the guidance of clinicians given in this study the success of A-GPS will be limited, resulting in decreased user satisfaction and clinical effectiveness. To overcome potential barriers to implementation success several priority areas should be met. First, the A-GPS tool needs to be easily accessible within the EHR, in a location that is obvious and consistent across all clinical roles, contains all asthma-related information on a single page, and is visually concise and intuitive. To increase acceptability, the AE risk model needs to be validated for accuracy and reliability and made transparent to users. Transparency is necessary to build trust among clinicians and trust facilitates acceptance and adoption. The AE risk model output needs to be easily interpretable, clearly defined, and intuitive to improve adoption and sustainability. While the risk category output and descriptive statement is essential, an organized display of supporting information popping up in proper format is generally desired as part of the output. Except for the quality of model output, the importance of quality and strategy of education and training cannot be ignored. In a paper by Gordon et al [25], Mayo Clinic took a standardized and efficient approach to provide education and training sessions when implementing a new EHR system. The results demonstrated higher acceptance and confidence among users. This could be a good example for an A-GPS project in terms of successful implementation.

**Strengths and Limitations**

Conducting interviews with potential users of a new clinical tool not only gains insights into their needs but also encourages buy-in as seeking their input before implementation demonstrates that the research team values user feedback. To our knowledge, this study facilitated buy-in and support among participants as several thanked this study’s team for their efforts to understand user needs. For a broader scope of AI projects, the innovative multi-background collaboration between translational informatics, data science teams and engaged clinical stakeholders guided by the design framework at an early stage provides well-defined user requirements and implementation plans and delivers evidence documentation for upcoming implementation and validation stages. The method can be applied to a wide variety of CDS. In this project, the UX research method was used to engage with clinical stakeholders and prospective end users to gain a comprehensive and multidisciplinary understanding of the role A-GPS is expected to play in pediatric asthma care. Shadowing and interviewing clinical stakeholders were a source of engagement that gathered user requirements from the perspective of potential users, with the objective of informing tool development and translation efforts [21]. Once A-GPS tool is functioning technically, its fit
into the clinical workflow must be evaluated. Moreover, education and documentation must be provided to explain the algorithm and its limitations to effectively translate between the perspectives of experts who created and supported the technology and the perspectives of experts who use the solution to patients. Evaluating the interpretation needs of clinicians, preferences for the display of model output (eg, percentage vs binary threshold), and feature contributions will be assessed based on the data obtained from UX research efforts. Concurrently, the team will also engage clinician stakeholders in the development of model documentation to support explainability [26]. The data obtained from UX research will assist the translational informatics and data science teams in identifying the level of explainability needed to inform and validate the design of A-GPS and supplementally enhance existing workflows [27]. Strategic efforts to promote explainability include applying a documentation framework grounded in scientific research addressing known challenges. This encompasses interdisciplinary best practice reporting requirements that follow phases of model development (prepare, develop, validate, deploy, and maintain) for knowledge continuity throughout the solution's life cycle [12].

A limitation of this study is the generalizability of design and implementation suggestions as the practice environment of participants has different features. Even though they are all within Mayo Clinic Health Systems, some are working on hospital campuses, while some are from community-based primary care, which led to various user needs. Another limitation is that the perspective of patients and their caregivers were not evaluated in this study. This was purposeful as the intended users of A-GPS are clinicians but the impact the AE risk model may have on families, as stated in the Ethical Considerations section, should be explored further.

**Further Research**

Future research will evaluate the sustainability and scalability of user requirements for enterprise, national, and international adoption of the ML-based CDS tool. Ethical considerations of AI interpretation, patient engagement, and clinician autonomy warrant further investigation. Our research team will conduct multiple studies as we approach the future stages of efficacy and side effects, therapeutic efficacy, and safety and effectiveness planned in our phased comprehensive AI evaluation framework (stage 1). There are more questions to answer in the future: How might we demonstrate to providers the accuracy and reliability of the AI output? How might we define required transparency for AI output? How might we provide an efficient educational module for users and show validation measures to support and explain AI output? How might we handle alarm fatigue, including situations where patients do not respond to providers’ intervention? How might we improve ML-model predicting the risk of AE when the provider’s proper and timely intervention may reduce the performance of the model (eg, positive predictive value)?

**Conclusions**

We aimed to anticipate barriers to the translation of our pediatric asthma management ML-based CDS tool by engaging clinicians in prototype development and optimization leveraging UX research methodologies. In efforts to bolster the transparency, suitability, and adaptability of our solution we qualitatively evaluated user requirements and potential barriers in 3 overarching themes: usability and workflow aspects of the ML system, user expectations and algorithm explainability, and barriers to implementation in context. We presented findings specific to our tool’s risk evaluation in the context of a summary of relevant information for asthma management. This work contributes to phases 0 and 1 of our comprehensive informatics-based AI evaluation frameworks developed by our multidisciplinary team of clinicians, data scientists, translational informaticians, and UX experts at Mayo Clinic [23]. The transparent evaluation and documentation of AI applications in health care enhances clinician and patient trust, supports sharing of AI between hospitals, and increases standards and shared responsibility across the continuum of care. The results of this development study further enhance the model documentation of A-GPS aimed to ensure rigorous evaluation, transparency, and knowledge continuity [12]. A sustainability and scalability evaluation of user requirements will strengthen the potential for national and international adoption of A-GPS.

**Acknowledgments**

We would like to deeply thank Dr Manuel Arteta, Dr Valeria Cristiani, Joy Fladager Muth, Dr Gregory Garrison, Dr Margret Gill, Dr Jason Greenwood, Darcy Hall, Dr Martha Hartz, Dr Julian Lynaugh, Dr Donnchadh O’Sullivan, Dr Sarah Scherger, Dr Eric Schnaith, and Dr David Soma for finding their time for interview and sharing their valuable insights into usability of A-GPS in clinical practice setting. This project was supported by the Center for Digital Health, Precision Population Science Lab, the AI Program of Department of Pediatric and Adolescent Medicine. We acknowledge no generative AI usage in the preparation of this paper.

**Data Availability**

The data sets generated and analyzed during this study are not publicly available due to participants’ privacy, but are available from the corresponding author on reasonable request.

**Conflicts of Interest**

None declared.

Abstract

Background: Adolescence is a critical time in which many psychological disorders develop. Mental health promotion is important, especially during this period. In recent years, an increasing number of mobile apps geared toward mental health promotion and preventing mental illness have been developed specifically for adolescents, with the goal of strengthening their mental health and well-being.

Objective: This study aims to explore adolescents’ attitudes toward mental health apps, as well as the perceived usefulness of mental health apps.

Methods: In this mixed methods study, a total of 183 adolescents (mean age 15.62, SD 3.21 years) answered a cross-sectional questionnaire, with 10 questions (eg, “What do you think about mental health apps in general?”). To complement the quantitative findings, individual interviews were conducted with 9 adolescents, during which they could elaborate on their opinions about mental health apps.

Results: A total of 30% (56/183) of the adolescents in the quantitative study had used a mental health app. Over half of the respondents (77/126, 61.1%) reported that they would use a mental health app if they had a mental health problem as well as that they thought mental health apps were somewhat or very useful (114/183, 62.3%). Availability was the most frequently reported advantage of mental health apps (107/183, 58.8%). Possible associated costs of mental health apps were the most frequently mentioned barrier to their use (87/183, 47.5%). Findings from the interviews also pointed to the importance of the availability of mental health apps as well as their credibility and potential to provide adolescents with autonomy when seeking mental health advice and help.

Conclusions: Overall, the results indicate that adolescents have a positive attitude toward and an interest in mental health apps. However, adolescents are also more or less unaware of such apps, which might be one reason why they are often not used. The findings of this study have important implications for future research on mental health apps and for developers of mental health apps that target young people. The insights gained from this study can inform the development of more effective mental health apps that better meet the needs and preferences of adolescents.

Introduction

Overview

The World Health Organization defines well-being as follows: “Well-being is a positive state experienced by individuals and societies. Similar to health, it is a resource for daily life and is determined by social, economic and environmental conditions” [1]. In today’s society, reference is often made to the importance of working to improve young people’s mental health and well-being as adolescence is a critical, transformative, and challenging time [2]. Research indicates that 10%-20% of adolescents worldwide experience mental health problems [3,4], and in approximately half of all mental disorders, the onset of symptoms occurs before the age of 15 years [5,6]. This illustrates that mental illness in adolescence can have negative effects also on adulthood [6,7]. Today, the need for mental health care and tools for young people is high, and it is argued that provided mental health services for adolescents are not sufficient to keep up with the growing demand [8]. It is therefore important to work toward developing targeted measures and evidence-based interventions that can help young people cope with stress and different challenges [9,9]. Furthermore, it is important to provide supporting tools and resources that can promote healthy habits and behaviors that contribute to overall well-being in adolescence.

In recent years, it has been suggested that mobile devices and the internet represent ideal tools to deliver such interventions to young people [10], and an increasing number of developers and researchers have been following this suggestion [11-14]. In a systematic review, Grist et al [13] highlight the importance of digital interventions developed for young people being of good quality. Furthermore, they point out that the development of digital products, intended for young people, should be designed in collaboration with young people, in order to develop customized and high-quality products for the target group. Thus, a broad understanding of what young people think about specific digital interventions can be beneficial for developing effective products suitable for the target group.

Mental Health Mobile Apps

Mobile apps (ie, apps) are tools where users can receive digital health interventions or information, these health apps have the intention of improving the user’s overall health [12]. Along those same lines, mental health apps are designed to improve mental health and well-being among their users [14-16]. These apps can be designed to address specific mental health disorders [17,18], or they can be more general, focusing on promoting mental health and preventing mental distress through a variety of tools and resources such as emotional self-monitoring and coping strategies [19,20].

One important advantage of mental health apps is their availability [16]. Users can gain access to them anytime and anywhere with a smartphone or other mobile devices. This is particularly useful for individuals who may not have easy access to mental health services due to geographic barriers or for individuals who might benefit from receiving frequent reminders or immediate support [15,16]. Furthermore, mental health apps can reach larger segments of the population compared with in-person therapy, and, in some cases, they have shown promising cost-effectiveness [10,16].

Adolescents’ Engagement With Mental Health Apps

Young people spend a considerable amount of time on their smartphones and use them for entertainment, social purposes, and to access information on different topics, including mental health [21-23]. There are several mental health apps available for adolescents, but as Grist et al [13] point out, the quality of the assessment on these apps is scarce. Research on mental health apps for adolescents indicates that young people are generally satisfied with the access to and ease of use of mental health apps [13,24]. Kenny et al [25] highlight in their study that adolescents prefer mental health apps to be safe, engaging, and easily accessible. The use of mental health apps can also allow people to maintain anonymity when seeking mental health advice or guidance, which is appreciated by young people, who often have a high threshold for help-seeking due to a desire for autonomy and the negative attitudes or stigma surrounding mental health services [26-28].

Nevertheless, the level of user engagement in existing mental health apps is relatively low or moderate and repeated long-time use of mental health apps after downloading them is rare [13,29,30]. This may indicate that despite the fact that young people find mental health apps appealing, it is not sufficient to ensure sufficient use over a long span of time. Regardless of the reasons, it is possible that low user engagement could decrease the overall effectiveness of mental health apps. Research on the effectiveness of mental health apps on adolescent mental health outcomes has revealed mixed results. Some research has failed to illustrate any effect [13,31,32], and others have indicated that mental health apps are promising and have the potential to provide improvement in mental health outcomes [14,33,34]. Yet, there is broad agreement that more research on the effectiveness of mental health apps is needed to fully understand their capacity to improve mental health outcomes [13,32,33]. In order to understand more about the effect mental health apps can have on young people’s mental health, it is also beneficial to examine what young people think about mental health apps and how they should appear in order to be effective for the target group.

This Study

The aim of this study is to explore adolescents’ attitudes toward mental health apps, and their perceived usefulness, using both quantitative and qualitative data. While the quantitative study focuses more on the use and usefulness of these apps as well as on their perceived advantages and disadvantages, the qualitative study examines adolescents’ more general thoughts on mental health apps and how they may be of help to them. Together these data sets provide important insight for the development of mental health apps. The results can help to ensure more user-targeted products and more user engagement, which in turn can contribute to a greater effectiveness of mental health apps.

Methods

Overview

This study used a convergent, parallel QUAN + qual mixed methods design [35]. Quantitative and qualitative data were collected simultaneously, and the qualitative study was used to complement the results of the quantitative study. The quantitative data are based on a cross-sectional survey and the qualitative data are based on semi-structured interviews. A total of 2 authors (HK and SK) analyzed the quantitative data, and the other 2 authors (HH and MR) analyzed the qualitative data. The results of the 2 data sets are integrated in the discussion.

Quantitative Study

Participants and Procedure

Adolescents were invited to participate in the study during several events that took place in autumn 2022, including an innovation camp in Mosjøen (a municipality in Northern Norway), “The research days” at UiT The Arctic University of Norway, and the World Mental Health Day event organized by the municipality of Tromsø. To participate, adolescents were asked to scan a QR code, which led to a digital questionnaire [36]. Posters and flyers with the QR code were also distributed at various youth clubs and adolescent health centers in Northern Norway. The questionnaire was anonymous, and participation was voluntary. The final quantitative sample (N=183) consisted of 118 (64.5%) girls, 59 (32.2%) boys, and 6 (3.3%) adolescents that did not specify their gender. Participants were aged between 13 and 19 (mean 15.75, SD 1.65) years; 170 (92.9%) participants were Norwegian and 13 (7.1%) participants reported other nationalities (2.2% were Serbian, 1.1% were Swedish, and 3.8% did not specify their nationality).

Questionnaire

Overview

The questionnaire consisted of 10 questions. Information was collected on demographic characteristics like gender (boy, girl, and other), nationality (Norwegian, Serbian, Swedish, or other), and age (11 to 20 years). There were 5 or 6 questions about mental health apps that are described in the following and an open-ended question where the adolescents could give comments about the topic or the questionnaire in general.

Use of Mental Health Apps

Adolescents were asked 1 or 2 questions developed by Grist et al [37]: “Do you use (or have you used) any apps to help you with mental health problems?” with response options “yes” or “no.” Adolescents who answered “no” were asked a follow-up question: “If you had a mental health problem and there were apps available to help, would you use them?” with response options “yes” or “no.”

Perceived Usefulness of Mental Health Apps

Adolescents were asked: “What do you think of mental health apps in general?” with responses given on a 5-point Likert scale, ranging from (1) “not useful at all” to (5) “very useful.”

Advantages of Mental Health Apps

Adolescents were asked: “What do you think some of the advantages are of using an app for your mental health?” Adolescents were presented with 8 statements developed by Grist et al [37], such as “It is more private” and “I don’t have to talk to someone face to face.” One additional statement, “I can be anonymous” was added to the list by the authors. Adolescents could tick up to 3 statements with which they agreed the most.

Disadvantages of Mental Health Apps

Adolescents were asked: “What do you think some of the barriers are to using an app for your mental health?” Adolescents were presented with 9 statements developed by Grist et al [37], such as “I don’t trust apps,” “I am afraid someone will see the app on my phone,” and “It might cost money.” Adolescents could tick up to 3 statements with which they agreed the most.

Information About Mental Health

To examine where adolescents looked for information about mental health, they were asked: “Which media do you use to find information about mental health?” There were 7 response options as follows: Google, social media (eg, TikTok and Facebook), mental health apps, television, web-based newspapers, podcast or radio, and others, where adolescents could specify a different medium in an open-ended textbox.

Adolescents were asked to tick all the media they used with no limitations.

Data Analytical Strategy

Data were analyzed with SPSS (version 29; IBM Corp). Descriptive statistics were calculated and included means, SDs, and frequency distributions. A multiple linear regression analysis was calculated to predict adolescents perceived usefulness of mental health apps, with gender (1=boy, 2=girl), age (11-20 years), and previous use of mental health apps (1=yes, 2=no) as predictors. A significance level of less than .05 was applied.

Qualitative Study

Participants and Procedure

Adolescents who answered the questionnaire were invited to contact the researchers if they wanted to participate in an interview and share their thoughts and opinions about mental health apps. A total of 9 adolescents (all Norwegian) chose to be interviewed (Table 1); 7 elected to be interviewed remotely (via telephone, Microsoft Teams, or Zoom) and 2 elected to be interviewed in person. Before each interview, the adolescents were informed that they were expected to talk about mental health apps, which were defined as mobile apps “developed with the thought of helping people manage their own mental health and wellness” [16]. All interviews were audio recorded on an Apple iPad with the app Diktafon [38], encrypted, and sent directly to Nettskjema [36] before they were transcribed. Two adolescents requested to be interviewed together, hence, 1 interview was conducted with 2 adolescents present (informant 3 and informant 4). These adolescents were considered as individual informants despite being from the same interview.

**Interviews**

All interviews were conducted in Norwegian. The interviewer followed a semistructured interview guide, however, the adolescents were encouraged to talk freely without too much interruption from the interviewer. There were three key questions in the interview guide: (1) “What are your thoughts on mental health applications that are aimed at adolescents?” (2) “What do you think mental health applications can do with regard to adolescents’ knowledge about mental health?” (3) “How do you think mental health applications may be of help to young people?” The interviewer asked follow-up questions when it was natural to go more in-depth on the information the adolescent provided. The interviews varied in duration from 15 to 30 minutes.

**Analytic Strategies**

The qualitative data were analyzed using thematic analysis inspired by Braun and Clarke [39]. Our analysis was based on a constructionist epistemological position, assuming knowledge is socially constructed and developed through communication and interactions between people [40]. Audio recordings were transcribed by the first author, and transcripts were imported into NVivo [41] to support the organization and coding of the data. Transcripts were read carefully by the first and third authors to identify meaning and patterns in the data. Initial codes were created for the data material, which were then sorted into potential themes. The themes were reviewed and defined in order to identify the essence of each one and the relationship between them. All the codes, themes, and presented quotes are based on data from the Norwegian language. The translation was done using a contextualized hermeneutic approach to translation [42] where the data are presented as close to the original context as possible, hence the quotations in particular are directly translated from Norwegian to English.

**Ethical Considerations**

The questionnaire in the quantitative study was anonymous and no personally identifiable information was collected. To complete the questionnaire, adolescents had to scan the QR code of their own volition. Moreover, before they could access the questionnaire, the adolescents were presented with information about the study and they were told that they agreed to participate by answering the questions. The adolescents were also informed that they could stop answering the questionnaire at any time without consequences.

The qualitative study was evaluated and approved by the Norwegian Center for Research Data (reference 631424). Adolescents of 16 years or older could consent to take part in the interview themselves, while active parental consent was required from adolescents younger than 16 years of age. Consent was retrieved via a digital consent form in Nettskjema [36]. All interview informants received a cinema gift card with a value of NOK 150 (approximately US $15) as compensation.

**Results**

**Quantitative Study**

Of the 183 adolescents who completed the web-based questionnaire, 56 (30.6%) adolescents had used a mental health app. Among adolescents who had not used a mental health app (126/183, 68.9%), approximately half (77/126, 61.6%) said they would use one if they had a mental health problem and there were apps available to help, while 48 (38.4%) adolescents said they would not. When asked “What do you think about mental health apps in general?” 25 (13.7%) adolescents answered that they were not or not very useful, 44 (24.0%) adolescents answered “neither”, and 114 (62.3%) adolescents found them somewhat or very useful (mean 3.6, SD 1.1). The regression analysis to predict the perceived usefulness of mental health apps, identified only gender as a significant predictor ($\beta$=.35; $P<.001$) indicating that girls perceived mental health apps as more useful than boys.

The most frequently reported advantages of using a mental health app were as follows: “It will always be there when I need it” (107/183, 58.8%), “I don’t have to talk to someone face to face” (83/183, 45.4%), “It is more private” (75/183; 41.0%), and “I can be anonymous” (72/183, 39.3%; Table 2). The most frequently reported barriers were as follows: “It might cost money” (87/183, 47.5%), “I don’t know whether the information in them is accurate or true” (82/183, 44.8%), and “I am afraid someone will see the app on my phone” (78/183, 42.6%; Table 3). The most frequently cited media that adolescents used to find information about mental health were by far “Google” (151/183, 82.5%) and “Social media (for example Facebook, Instagram, TikTok)” (90/183, 49.2%; Table 4).

Qualitative Study

Theme 1: Accessibility—The Significance of Approachable Mental Health Apps

A central theme that arose from the interviews, was the experienced and perceived accessibility of mental health apps. The adolescents highlighted that mental health apps were a readily accessible alternative to use in order to find information about health care as well as to get help. Further, they pointed out that mental health apps could be a more accessible helping tool than person-to-person offers. In addition, the adolescents talked about accessibility in terms of knowing about mental health apps’ existence, how appealing they are, and potential costs related to using them.

Many of the young people pointed out that they had neither heard of nor used mental health apps.

I don’t really know about any health-promoting apps that young people use [informant 6]

Some adolescents reflected on reasons why they had not heard of them. For instance 1 adolescent stated that her lack of knowledge of mental health apps may be attributable to marketing campaigns that do not target young people directly or correctly.

I don’t think, for example, that the makers of such apps have managed to reach out to young people [...]. I don’t know if I’m perhaps in the wrong target group or something, but at least it hasn’t really caught on yet, so to speak [informant 1]

The adolescents also pointed out that the information in the mental health apps must be easy to understand and easy to comprehend, due to for example
the use of specialized terminology. Therefore, they highlighted that it is important that the information provided in mental health apps is specific to the topic that they want to learn more about.

I think that can be good, if you have a good app where the information is simply explained and that you understand it quite easily, then I think it can be used a lot [informant 1]

An app should be a place where people can read about exactly what they need and not so much medical stuff [informant 1]

The importance of free mental health apps was frequently mentioned in all interviews; adolescents stressed that apps should be equally accessible to everyone regardless of their economic situation. Further, some adolescents stated that charging a fee would weaken the credibility of such apps and call into question the developers’ intentions.

I’ve been on an app where it was obvious that they were going to make money off it. And then the information and everything seemed a bit wrong. Suddenly, I had to pay for a membership in order to continue to use the app; then they lost me [informant 3]

Theme 2: Trustworthiness—The Significance of Credible Mental Health Apps

Most adolescents stated that it is important that app developers are credible and that the information that is provided in apps comes from reliable sources.

It is important that young people find a reliable source. That it’s not just random journalists, or someone who is just trying to get clicks, but that it comes from someone who actually knows something about it. So that you know you are getting the right information [informant 2]

Some adolescents also assumed that it would be easier to judge whether the information on a mental health app is correct, as compared with determining the accuracy of the information on the internet. One adolescent stated that apps developed by established, credible sources would be easier to trust than those created by unknown sources.

I think it would be very easy to just take in everything that’s written there [in a mental health app]. Even the bad stuff. That is why I think that such an app should somehow be under Ung.no [a public information channel for young people in Norway] or something, some reliable sources [informant 5]

Theme 3: Autonomy—Mental Health Apps Can Help Adolescents Help Themselves

Several adolescents stated that self-determination was important to them, so they would appreciate an app, as it would allow them to manage their own mental health and difficulties without interference from adults.

In a way, you want to try to help yourself before it goes so far that you are dependent on others to help you [informant 1]

An app should contain information about what we can do ourselves to get better and where we can ask for help. Sometimes you may just need to get guidelines on how to do it yourself [informant 8]

Further, several adolescents pointed out that an app can be used to ask for help if one does not want to contact in-person services.

I think it’s good that there are apps like that, that you don’t have to go and talk to someone, but that you can have an app on your phone that you have all the time [informant 9]

Most adolescents stated that the apps should include a way to communicate with someone.

If it [an app] can be made so that you can communicate with someone, then perhaps the threshold [of asking for help] will be even lower [informant 1]

Mm, it would have been good if the app contained something like that, a way to talk to a person online [informant 2]

Adolescents were also interested in interacting within the app in ways that did not involve another person. Some suggested that the app could contain some predefined questions that could be used to give the user a more personalized experience, or that the app could refer them to the right professional.

Several adolescents also pointed out that contacting in-person services can trigger undesirable actions, which might make it easier to trust an app.

And you are probably afraid that it will somehow..., you want to deal with it, but at the same time you are afraid that, for example, a nurse or someone will tell someone else and that there will be a lot of actions at school, and then everyone will know about it [informant 1]

Finally, a frequently mentioned topic in the interviews was the importance of being anonymous in the apps. Adolescents cited the value they placed on anonymity both if they needed information and if they needed actual help with their mental health, as this could make it easier for the adolescents to seek help.

It is important that you can remain anonymous, because not everyone likes to talk about such things if you are recognizable [informant 6]

Discussion

Principal Findings

In this study, we examined adolescents’ attitudes and general thoughts toward mental health apps using a concurrent, mixed methods approach. This research is an important contribution to understanding what young people think about mental health-promoting mobile apps, as well as their thoughts on what they should include and how they should appear.

Overall, the adolescents expressed positive attitudes toward mental health apps, even though few had experience with using them. A large proportion perceived such apps as useful tools

https://formative.jmir.org/2024/1/e50222 JMIR Form Res 2024 | vol. 8 | e50222 | p.201 (page number not for citation purposes)
that can help them cope with normal stresses of life, which is important in order to promote well-being and prevent mental health problems [43,44]. In the quantitative section of the study, availability was the most chosen benefit of using mental health apps. This is not surprising as adolescents in Norway spend a lot of time on their phones and on social media [21]. Privacy, as well as the possibility of remaining anonymous, was the subsequent most chosen advantage. These results are in accordance with those reported in previous literature [16,25,37]. Further, in the interviews, adolescents expressed that mental health apps can be of help at any time of the day, also when in-person services are not available. However, the adolescents expressed, that for mental health apps to be accessible, they need to also be easily understandable and have no costs attached.

It is well-known that adolescents tend to be reluctant to seek help, despite the importance of obtaining help and support for improved well-being [45-47]. In this study, adolescents expressed that mental health apps can lower adolescents’ threshold for asking for help, by always being available and by offering anonymity in the help-seeking process. Several interviewees also highlighted the empowering potential of mental health apps. The adolescents valued how an app could provide them with the ability to help themselves without interference from others. Meeting young people’s need for autonomy is important to ensure that they ask for help when they need it [28]. The findings from this study concur with previous findings, which suggested that adolescents value the autonomy that mental health apps provide [48].

Further, the adolescents emphasized that mental health apps should provide an anonymous way for them to talk about their problems, with either a web-based assistant or a real person. In addition, some adolescents reported fear of someone else seeing a mental health app installed on their phone as a deterrent to using such apps. Anonymity is often mentioned as an important reason why adolescents use web-based services when searching for help or advice regarding mental health [16,49], our findings support that adolescents view anonymity as an advantage of using mental health apps, which agrees with previous findings [16,25].

Another important aspect adolescents highlighted was the difficulty they might have in judging whether the information contained in a mental health app was accurate. Most adolescents reported that they used the internet (ie, Google and social media) to search for mental health-related information. The adolescents stated that mental health apps should be developed by credible organizations or individuals that adolescents already trust. Adolescents also stated that, the information presented in the app should be clear and concise in order to be engaging for them. Previous research have also shown the importance of content and appearance to ensure engaging mental health apps [25,50].

Although adolescents generally have a positive attitude toward the increased development and use of mental health apps, few of the adolescents in our study sample were familiar with such apps. These results are in line with previous research which indicates that adolescents are not highly engaged in mental health apps [13,29]. Indeed, some adolescents believed that they had not heard of such apps due to poor marketing strategies. They stated that, if the apps were meant to target adolescents, then they should be marketed to young people directly. However, there are currently strict rules regarding advertising to children and adolescents in Norway [51], which may pose challenges in devising effective marketing strategies to reach adolescents.

Strengths and Limitations
By including both quantitative and qualitative data, this study provides valuable knowledge and insight into adolescents’ perspectives and opinions on mental health apps. However, there are several limitations that must be taken into consideration. In the quantitative study, the sample size was relatively small and not representative. One should therefore be careful about drawing general conclusions from the findings. However, the results can be an important contribution to the field of research on what adolescents think about mental health apps. Moreover, the interviews were of short duration, which may have influenced the depth of the answers. However, the adolescents were encouraged to speak freely, and they were not interrupted until they had concluded. Follow-up questions were asked when they brought up topics that the interviewer found interesting or considered meaningful for the adolescent to elaborate on. Furthermore, because the qualitative study was intended to complement the quantitative study, we perceive the length and depth of the interviews as sufficient.

One interview was conducted with 2 adolescents together, based on the participants’ own desires. Since they stated it would increase their sense of security during the interviews, the request was accepted. However, we cannot exclude the possibility that the presence of another adolescent influenced the answers the adolescents provided.

Conclusions
Mental health apps can be a useful resource for adolescents, and several apps geared toward adolescents have been developed. Our findings show that there is a lack of knowledge about the existence of mental health apps among adolescents. A large proportion of adolescents expressed that they would use these apps if they knew they were available. This study shows that apps directed toward adolescents should be easily accessible, free of charge, and provide easily understandable information. Adolescents also emphasized the significance that apps should be developed by credible sources or institutions, offer a choice between human and web-based support, and enable users to remain anonymous while seeking help. Future development of mental health apps should take these considerations into account.
Acknowledgments

The authors would like to thank the adolescents who participated in this study, both those who answered the web-based questionnaire and those who were interviewed. Further, the authors would like to thank Eirik Fjukstad and Annelene Moberg for helping with the recruitment and promotion of the study to adolescents in youth clubs and adolescent health centers in Tromsø. The publication charges for this paper have been funded by a grant from the publication fund of UiT The Arctic University of Norway.

Data Availability

The data sets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors provided substantial contributions to this study. HH and MR analyzed the qualitative data and HK and SK analyzed the quantitative data. HH wrote the first draft of the manuscript. HK, MR, SK read, edited, and approved the final manuscript.

Abstract

Background: In recent years, increasing numbers of parents, activists, and decision-makers have raised concerns about the potential adverse effects of social media use on both mental health and family functioning. Although some studies have indicated associations between social media use and negative mental health outcomes, others have found no evidence of mental health harm.

Objective: This correlation study investigated the interplay between social media use, mental health, and family functioning. Analyzing data from 314 users, this study explores diverse mental health outcomes. The study places particular emphasis on the Saudi Arabian sample, providing valuable insights into the cultural context and shedding light on the specific dynamics of social media’s impact on mental well-being and family dynamics in this demographic context.

Methods: We collected data through a subsection of an anonymous web-based survey titled “The Effect of COVID-19 on Social Media Usage, Mental Health, and Family Functioning.” The survey was distributed through diverse web-based platforms in Saudi Arabia, emphasizing the Saudi sample. The participants indicated their social media accounts and estimated their daily use. Mental health was assessed using the General Health Questionnaire and family functioning was evaluated using the Family Assessment Device Questionnaire. In addition, 6 mental health conditions (anxiety, self-esteem, depression, body dysmorphia, social media addiction, and eating disorders) were self-reported by participants.

Results: The study demonstrates a pattern of frequent social media use, with a significant portion dedicating 3-5 hours daily for web-based activities, and most of the sample accessed platforms multiple times a day. Despite concerns about social media addiction and perceived unhealthiness, participants cited staying connected with friends and family as their primary motivation for social media use. WhatsApp was perceived as the most positively impactful, whereas TikTok was considered the most negative for our Saudi sample. YouTube, Instagram, and Snapchat users reported poorer mental health compared with nonusers of these platforms. Mental health effects encompassed anxiety and addiction, with age and gender emerging as significant factors. Associations between social media use and family functioning were evident, with higher social media quartiles correlating with a greater likelihood of mental health and unhealthy family functioning. Logistic regression identified age and gender as factors linked to affected mental health, particularly noting that female participants aged 25-34 years were found to be more susceptible to affected mental health. In addition, multivariable analysis identified age and social media use quartiles as factors associated with poor family functioning.

Conclusions: This study examined how social media affects mental health and family functioning in Saudi Arabia. These findings underscore the need for culturally tailored interventions to address these challenges, considering diverse demographic needs. Recognizing these nuances can guide the development of interventions to promote digital well-being, acknowledging the importance of familial connections in Saudi society.

KEYWORDS
social media use; mental health; family functioning

Introduction

Individual’s lives worldwide are now mostly impacted by social media [1]. By enabling individuals to retain offline connections and provide a more welcoming setting for emotional self-disclosure and help-seeking, social media might have a positive influence on their lives [2]. However, there have been rising worries about the possible detrimental impact of social media on individual mental health among certain scholars, governmental organizations, and the public [3]. Prior research has related social media use to multiple mental health conditions including body dissatisfaction, eating disorders, depressive symptoms, and social anxiety [4]. Facebook users, for instance, report higher body dissatisfaction than nonusers, according to a study involving male and female adults [5]. Another example of female adults revealed that although there was no difference between Instagram users and nonusers in terms of body dissatisfaction, Instagram users reported greater body monitoring than nonusers [6,7]. However, each of these works studied these conditions separately, and the combination of these conditions and how they are impacted by social media use has been overlooked. Given this, it becomes evident that there is a pressing need to conduct more in-depth investigations into the specific factors related to social media use that contribute to the development or exacerbation of these mental health concerns.

Family functioning pertains to how well family members fulfill their responsibilities and navigate life challenges [8]. It involves their interactions, growth, and responses to external influences [9]. Research highlights the need to investigate the potential risks posed by mobile device use to family functioning [10,11]. This suggests that families with flexibility and limited mobile device use may experience better cohesion and functioning, emphasizing the necessity for a more in-depth examination of the relationship between family functioning and social media use. Excessive social media use may lead to decreased emotional well-being, which negatively affects relationships [12]. For example, recent Indonesian research connects social media addiction to mild depression in university students, emphasizing the importance of bracing mental health by promoting family relationships and religiosity while addressing social media overdose [13]. Another study of mental health outpatients suggested a potential association between family functioning and psychological distress [14]. Although research has explored the link between social media and factors such as social connectedness, friendship quality, emotional well-being, and interpersonal relationships [15,16], there is a research gap regarding the impact of social media use on family functioning. Thus, it is imperative to conduct comprehensive research on family functioning and mental health, while analyzing their correlation with social media use.

In this paper, we looked at the relationships between social media use, mental health, and family functioning. Specifically, we examined various mental health conditions such as anxiety, self-esteem, depression, body dysmorphia, addiction to social media, and eating disorders. We selected Saudi Arabia as our sample for this study because of the increasing rates of internet penetration and social media use (90%) [17]. This high prevalence provides a valuable opportunity to examine the potential impact of social media on mental health and family functioning in this specific cultural context. Family is a fundamental unit in Saudi Arabian culture, and understanding the dynamics altered by social media is essential to comprehending broader societal changes. Investigating this aspect will not only enrich the existing literature, but also provide valuable insights into the evolving role of technology in shaping familial relationships and dynamics within the Saudi Arabian context. Thus, Saudi Arabia offers a unique setting characterized by a blend of traditional values, rapid modernization, and an evolving digital landscape. These factors create an intriguing environment in which to investigate the effects of social media on mental health and family dynamics. Two studies on social media use in Saudi Arabia’s web-based community have been conducted, one highlighting the mental health problems associated with social media use [3] and the influence of social media on food consumption among individuals [18]. To our knowledge, there is no research on how social media use may affect family functioning in Saudi Arabia. Thus, our study aimed to provide insights tailored to this cultural context. We aimed to investigate the relationship between social media use and mental health outcomes, with a particular focus on age and gender differences. Gender plays a significant role in this context, and research indicates that women are more likely than men to experience these mental health issues and they also tend to use social media platforms more frequently than their male counterparts [19,20].

Methods

Procedures

The data collected in this study were gathered through a subsection of an anonymous web-based survey titled “The Effect of COVID-19 on Social Media Usage, Mental Health, and Family Functioning.” The survey was designed based on a review of previous studies and surveys on pandemic effects [21-24]. Recruitment for this survey used diverse web-based social media platforms such as Facebook and Twitter. The survey was distributed to participants in Saudi Arabia with a clear emphasis on targeting a Saudi sample. We obtained informed consent from all participants before they completed the survey. The survey was designed to be anonymous and voluntary. Participants were given the option to answer the survey in English or Arabic. The survey targeted social media users who were at least 18 years old, and included sections on demographics, COVID-19, social media use, and well-being. Refer to Multimedia Appendix 1 for more information on the survey.

Participants were asked to choose which of the following prominent social networking sites they had an account on: Instagram, Facebook, Twitter, Snapchat, Google+, Vine, Tumblr, Pinterest, YouTube, and others. Participants were also...
provided with the option to specify “Other” platforms or “I do not have any social media accounts.” Participants were asked to estimate how much time they would spend on each platform during a typical day of browsing. No time (0), <5 minutes (1), 5-15 minutes (2), 15-30 minutes (3), 30 minutes - 1 hour (4), 1-2 hours (5), 4-6 hours (7), 6-8 hours (8), 8-10 hours (9), or >10 hours (10). Participants were asked to respond to a variety of questions regarding the activities they engaged in on social media in general (not on specific platforms). Only participants who indicated that they had at least one social media account were presented with questions on social media activities. The web-based survey used in this study, designed based on a review of previous studies and surveys on the pandemic, can serve as a model for future research on the effects of social media use on mental health and family functioning.

**Measures**

**Mental Health Status**

We used the General Health Questionnaire-12 (GHQ-12), a well-established 12-item self-report assessment tool, to assess the mental health status of the survey participants. The Likert Scale was used to score all 12 questions in the GHQ-12, generating 3 distinct statistical indicators: typical, suggestive evidence of distress, and severe problems with psychological distress. This tool is widely used to assess psychological distress and mental well-being. The validity and reliability of this scale have been demonstrated [25-27].

**Family Functioning Status**

We used the Family Assessment Device Questionnaire (FAD) to estimate participants’ family functioning status. FAD is a self-reported scale specifically designed to provide insights into the overall dynamics and functionality within a family. It assesses family relationships and identifies areas of potential dysfunction by adhering to the McMaster Model of Family Functioning. Within the scope of this study, participants were presented with the general functioning scale of the FAD, comprising 12 questions and yielding 4 distinct statistical outputs: healthy, almost healthy, almost unhealthy, and unhealthy. FAD was chosen for this study because it best suited the study objectives and demonstrated its validity and reliability [28-30].

**Mental Health Conditions**

We present 6 mental health conditions—anxiety, self-esteem, depression, body dysmorphia, addiction to social media, and eating disorders—collected through direct survey questions where participants self-reported whether social media affected those conditions. The inclusion of these conditions in our study is justified based on their prevalence, established links to social media use, public health importance, diverse impacts on mental health, and practical implications for interventions and policies [31-34]. Notably, these issues are dominant, with a high incidence of social media addiction among individuals experiencing these mental health challenges [35].

**Pilot Testing**

To assess the initial survey, 4 participants participated in a pilot test. User feedback was collected to identify potential problems. The study had improved readability and validity because of this iterative process.

**Statistical Analysis**

Descriptive statistics were reported as numbers and percentages for categorical variables. The mean and SD are reported for the numerical values. A score was calculated based on the frequency of social media access and the average time spent on social media. The participants were classified based on their scores into 4 quartiles (Q1-Q4). Participants in the first quartile had the lowest social media use, whereas those in the fourth quartile had the highest social media use. To calculate the mental health score for the GHQ-12, we summed the assigned values (0-3) for each response, with higher scores indicating a greater likelihood of mental health issues. For family functioning using the FAD, we assigned values (1-4) to each response, with higher scores indicating a greater likelihood of unhealthy family functioning. To assess self-reported mental health conditions, including anxiety, self-esteem, and depression, we analyzed respondent’s answers to identify correlations with their social media scores. A chi-square test was performed to determine the association between social media use, mental health, and family functioning scores. Logistic regression was performed to identify the factors associated with mental health and family functioning. SPSS 28 (IBM Corp) was used for the analysis, and statistical significance set at \( P < 0.05 \) is considered statistically significant.

**Recruitment**

A total of 314 social media users who participated in this study were surveyed between the periods of 2021 to 2023 across 2 rounds to validate the results. Furthermore, 74.5% (n=234) were female, and 24.2% (n=76) were male. Most participants (n=293, 93.3%) were from Saudi Arabia, whereas the rest (n=21, 6.7%) represented other nationalities because of the nature of web-based sampling. The Saudi sample serves as an interesting case study for investigating the impact of social media on mental health and family functioning. First, Saudi Arabia is a highly conservative society that is undergoing rapid modernization, with social media playing a significant role in this transformation. According to recent statistics, 29.10 million social media users in Saudi Arabia access it through their mobile devices [17]. Second, there is a lack of research on the effects of social media on mental health and family functioning in Saudi Arabia. Finally, given that Saudi Arabia is a highly collectivist society, family dynamics play a significant role in shaping individual behaviors and attitudes, making it an ideal context to explore the interplay between social media use and family functioning. The largest group of participants was aged 35-44 years old (n=80, 25.5%), followed by 55-64 years (n=75, 23.9%). Regarding psychological and medical conditions, most respondents did not report having any psychological (n=271, 86.3%) or medical condition (n=216, 68.8%). Regarding the respondents’ educational background, the highest reported level of education was a bachelor’s degree (n=138, 43.9%), followed closely by a doctorate (n=81, 25.8%). A small proportion of respondents reported having a master’s degree (n=60, 19.1%), whereas a minority reported having a high school degree (n=26, 8.3%). Only a small percentage of the respondents reported having no formal education (n=9, 2.9%). Regarding participants’
race, most respondents identified as Arab (n=284, 90.4%), whereas a minority identified as non-Arab (n=30, 9.6%). Table S1 in Multimedia Appendix 2 provide more details on the sample demographics.

Ethical Considerations
The Effect of COVID-19 on Social Media Usage, Mental Health, and Family Functioning survey was ethically approved by King’s College London ethics committee LRS-19/20-19717.

Results
The purpose of this report was to summarize the results of a survey on the perceived impact of social media platforms on mental health.

Social Media Use
The data show that most respondents accessed social media frequently, with (n=115, 36.6%) reporting that they go on social media every couple of hours. When asked about the amount of time they spent on social media per day, the most common response was 3-5 hours (n=86, 27.4%), followed by 1-2 hours (n=58, 18.5%). When asked about the duration of their social media sessions, most respondents reported spending approximately 15 minutes or less logged in (n=129, 41.1%). A significant majority of respondents (n=238, 75.5%) reported that they did not feel it was healthy to spend much time on the internet. Most respondents (n=267, 85.03%) reported accessing social media in the evening, whereas 25.48% (n=80) reported accessing it at midnight. When asked about their addiction to social media, 41.1% (n=129) of the respondents reported feeling addicted. Table 1 provides more details on the social media use of the participants. The most common reason for using social media was to keep in touch with friends and family (n=243, 77.39%). Other reasons included inspiration (n=160, 50.96%), browsing or wasting time (n=135, 42.99%), and entertainment (n=130, 41.4%). Around 29.94% (n=94) of the participants reported using social media for work or business purposes, and only 5.1% (n=16) reported using social media for dating or romantic purposes. Table 2 elaborates the reasons for using social media.

Participants Attitudes

When asked if social media distracted them when they needed to be productive, 33.8% (n=106) of the respondents reported that it did. In contrast, 66.2% (n=208) of the respondents reported that social media does not distract them when they need to be productive. The data also revealed that a significant majority of respondents (n=238, 75.5%) did not care about how many people like or view their posts or pictures, whereas 24.5% (n=77) of respondents reported that they do care. When asked about cyberbullying on social media, 12.1% (n=38) of the respondents reported that they had been cyberbullied in some way, whereas 87.9% (n=276) reported that they had not. In terms of how social media affects self-esteem, only 30.9% (n=97) of the respondents reported feeling depressed when seeing posts about intriguing events in other people’s lives. When asked if they accept friend requests or followers from people they do not know to appear more popular, 84.7% (n=266) of the respondents reported that they did not, whereas 15.3% (n=48) reported that they did.

Social Media Impact via Self-Reporting

Participants were asked to rate each platform on a scale of 0 to 5, with 0 indicating that they did not use the platform and 5 indicating that it was the most positive social media platform in their opinion. After those who reported not using the platform, an average score was calculated based on each participant’s opinion, with a lower score indicating a negative impact and a higher score indicating a positive impact.

The platform perceived as having the most positive effect was WhatsApp (4.08), followed by Telegram (3.86), and Pinterest (3.85). The lowest score, indicating the most negative outcome, was observed for TikTok (1.98), followed by Snapchat (3.02).

Table S2 in Multimedia Appendix 2 presents a comprehensive analysis of the perceived impact of each social media platform, as reported by the participants. The effects of individual platforms are shown in Figure 1. In addition, Figure 2 provides an overview of the mean scores indicating the perceived impact of social media platforms. Regarding self-reported mental health conditions, the most common effects were anxiety (n=217, 69.09%) and social media addiction (n=206, 65.45%). Other reported effects included depression (n=108, 34.55%), self-esteem (n=97, 30.91%), body dysmorphia (n=69, 21.82%), and eating disorders (n=46, 14.55%) as illustrated in Table 3. However, 25.45% (n=80) of the respondents who reported an impact stated that social media did not affect them. Finally, when asked about the emotions they experienced when using social networking sites, the most common responses were inspiration (n=31, 9.87%), boosted self-esteem (n=64, 20.38%), jealousy (n=11, 3.5%), and rejection (n=9, 2.87%). Only 2.55% (n=8) of the respondents reported experiencing lower self-esteem when using networking sites. Table S3 in Multimedia Appendix 2 elaborates on social media use habits and their impact on participants.

Regarding the impact of social media on relationships with family members, 76.8% (n=241) of respondents reported that social media did not affect their relationships, whereas 23.2% (n=73) of respondents reported that it did. Among those who reported an impact, 15.3% (n=48) reported a positive effect, whereas 15.9% (n=50) reported a negative effect. When asked if they had a web-based persona, 91.1% (n=286) of the respondents reported that they did not, whereas only 8.9% (n=28) reported that they did.

Social Media Impact via Statistical Tools

Regarding mental health, most respondents ($n=274, 87.3\%$) had a score that indicated mental health within the normal range, whereas ($n=40, 12.7\%$) had a score that indicated affected mental health. For family functioning, most respondents ($n=269, 85.7\%$) had a score that indicated healthy or almost healthy family functioning, whereas ($n=45, 14.3\%$) had a score that indicated unhealthy or almost unhealthy family functioning. Table 4 shows the mental health and family functioning of the participants.

Statistical analysis using the chi-square test showed a statistically significant association between social media use and mental health ($P<.001$). Participants in the higher social media quartiles had a higher percentage of affected mental health (26.7\% for the fourth quartile and 14.6\% for the third quartile) as compared with participants in lower quartiles of social media use (9.1\% in the first quartile and 4.8\% in the second quartile). Table 5 shows the association between social media use and mental health. Statistical analysis using the chi-square test showed a statistically significant association between social media use and family functioning ($P<.001$). Participants in the higher social media quartiles had a higher percentage of unhealthy or almost unhealthy family functioning (30\% for the fourth quartile and 14.6\% for the third quartile) as compared with participants in the lower quartiles of social media use (9.1\% for the first quartile and 8.3\% for the second quartile). Table 6 illustrates the association between social media use and family functioning. Logistic regression was performed to identify the factors associated with mental health. Age and sex showed statistically significant results in the multivariate analysis. Female participants were more likely to have affected mental health as compared with male participants (odds ratio [OR] 4.69, 95\% CI 1.42-15.49; $P=.01$).

For age participants who were between 25 and 34 years were more likely to have affected mental health as compared with participants who were 18 to 24 years (OR 6.10, 95\% CI 1.42-26.15; $P=.02$). Table 7 illustrates the factors associated with affected mental health. Logistic regression was applied to identify the factors associated with unhealthy or unhealthy family functioning. The age and social media use quartiles showed statistically significant differences. For gender, female participants were more likely to have unhealthy or almost unhealthy family functioning as compared with male participants (OR 3.32, 95\% CI 1.17-9.46; $P=.02$). Regarding social media use quartiles, participants in the fourth quartile were more likely to have unhealthy or almost unhealthy family functioning as compared with participants in the first quartile (OR 4.22, 95\% CI 1.45-12.31; $P=.008$). Table 8 illustrates the factors associated with unhealthy or almost unhealthy family functioning.

Discussion

Principal Findings

This study’s insights, grounded in a sample from Saudi Arabia, provide a culturally specific lens at the intersection of social media use and mental health. The prevalence of frequent social media access and reported durations align with the global trend [36], highlighting the pervasive nature of these platforms in the Saudi context. However, it is crucial to interpret these findings within the cultural framework of Saudi Arabia, where familial and social ties are of significant importance [37]. The primary motivation for social media use, namely staying connected with friends and family, resonates strongly with the cultural emphasis on community bonds in Saudi society. This underscores the integral role that social media plays in facilitating and maintaining relationships, which is a culturally significant function. The findings of our study suggest that social media is a popular and frequently used technology in Saudi Arabia, with a significant proportion of users expressing concern about their use habits. Unlike previous research, which analyzed social media platforms and their effect on mental health [38-41], our study applied an in-depth investigation across platforms to evaluate each platform’s impact on mental health. We first tested the effect of time spent on each platform by participants and found no particular association between time spent on various platforms and mental health. Despite small negative correlations between time spent on YouTube, Instagram, and Snapchat and body satisfaction and a small positive correlation between time spent on YouTube and depressive symptoms. Our findings
imply that future research might benefit from changing attention from time spent generally perusing platforms to participant’s attitudes when engaging with social media platforms. The platform-specific analysis, with WhatsApp emerging as the most positively perceived and TikTok as the most negatively perceived, was influenced by cultural preferences and content norms in the Saudi context. Understanding these variations is essential for tailoring interventions and guidelines to align with the cultural values and sensitivities of the Saudi population. Participants’ attitudes toward social media platforms may have affected their mental health. For instance, these platforms may be a hotspot for frequent and unjustified comparisons of appearances, which might be harmful to mental health. Performing more appearance comparisons with others and thinking that others are more attractive than you are on social media were both independent predictors of lower body satisfaction, more eating disorders, and higher levels of eating disorders. Our results support previous research on teenagers and adults, emphasizing the significance of appearance comparisons as a potential mechanism through which social media use may be detrimental to mental health [42,43]. Our results further imply that, despite their emphasis on physical appearance, these comparisons may have a detrimental effect on issues that are not just related to beauty, such as body satisfaction and eating disorders, but also on general mental health (such as depressive symptoms and anxiety). In our results, compared with men, women frequently paid greater attention to and regarded their beauty as a measure of their self-worth. Therefore, women may be less satisfied with their appearance and more depressed than men are. This is because women may engage in more frequent appearance comparisons on social media [44,45]. The identified effects on mental health, particularly anxiety and addiction, have cultural implications. Given the societal importance placed on mental well-being in Saudi Arabia, these findings underscore the need for targeted mental health awareness and support initiatives within a cultural context.

Logistic regression findings indicate that age and gender are factors associated with affected mental health and unhealthy family functioning. This is in line with a study that emphasized the significance of demographic factors when studying mental health in a Saudi sample [46]. According to our logistic regression findings, age and gender significantly influenced mental health and family functioning in the Saudi context. Female participants had a higher likelihood of experiencing mental health issues (OR 4.69, 95% CI 1.42-15.49; P=.01), emphasizing the need for gender-specific support. In addition, participants aged 25-34 years were more likely to face mental health challenges than those aged 18-24 years (OR 6.10, 95% CI 1.42-26.15; P=.02), suggesting the importance of age-targeted interventions. In terms of family functioning, female participants were more likely to report unhealthy dynamics (OR 3.32, 95% CI 1.17-9.46; P=.02), whereas older individuals in higher social media use quartiles were more likely to experience such challenges (OR 4.22, 95% CI 1.45-12.31; P=.008). Recognizing these age and gender dynamics is vital for tailoring mental health and family support strategies in Saudi Arabia. The statistical tools revealed associations between social media use and mental health, as well as family functioning, emphasizing the need for culturally informed strategies to address potential challenges. The statistical analysis revealed significant associations between social media use, mental health, and family functioning within the Saudi Arabian context, underscoring the importance of culturally informed strategies. Higher social media quartiles exhibited a notable correlation with a greater likelihood of affecting mental health and unhealthy family functioning. These findings emphasize the nuanced interplay between web-based activities and individual well-being as well as the broader impact on familial relationships. Considering these associations, it is crucial to develop interventions and support mechanisms that are culturally sensitive and tailored to the unique sociocultural dynamics of Saudi Arabia. Recognizing the intricate relationship between social media use and mental health outcomes, along with its implications for family functioning, is the key to fostering digital well-being in this cultural context.

Limitation and Implications

It is important to consider the following limitations when interpreting the results of our study. More in-depth longitudinal studies are needed to explore the association between social media use and mental health over time. The sample’s specificity of the sample to Saudi Arabia’s demographic and cultural context may restrict the generalizability of the results to more diverse populations. To enhance the external validity, future research should aim for a broader and more representative sample that encompasses a range of cultural, socioeconomic, and demographic backgrounds. The study’s implications of this study are multifaceted and have significant relevance for the development of targeted interventions and public health initiatives in Saudi Arabia. First, the identified associations between social media use and mental health outcomes underscore the need for specific culturally sensitive interventions. Tailored mental health programs can address the distinct challenges faced by different demographic groups, such as female participants and individuals aged 25 to 34 years, who were found to be more susceptible to affected mental health. These interventions could include educational campaigns, support groups, and digital resources tailored to the cultural nuances of the Saudi context. Moreover, the observed link between social media use and family functioning emphasizes the interconnected nature of web-based behavior and familial relationships. Culturally informed strategies should not only address individual well-being, but also promote healthier family dynamics in the digital age. Public health campaigns can play a pivotal role in raising awareness of the potential impact of social media on family relationships and fostering open discussions within families and communities about responsible digital practices. This study not only contributes to the global discourse on social media, mental health, and family functioning but also offers nuanced insights specific to Saudi Arabia. Recognizing and understanding these cultural nuances are paramount for developing effective policies, educational programs, and support systems that promote positive mental health outcomes tailored to the sociocultural landscape of Saudi Arabia.
Conclusions
This study investigated the perceived impact of social media platforms on mental health and family functioning in a Saudi Arabian sample. The findings reveal important insights with implications for public health initiatives and targeted interventions. This study highlighted the observable association between social media use, mental health, and family functioning. Notably, age and gender have emerged as significant factors influencing mental health and unhealthy family functioning. This underscores the necessity for culturally sensitive strategies to address these identified challenges and tailor interventions to the specific needs of different demographic groups. Recognizing the nuanced associations observed in this study can inform the development of interventions that promote digital well-being, considering the crucial role of familial ties in the societal framework of Saudi Arabia.

Abstract

Background: Maintaining good communication and engagement between people with dementia and their caregivers is a major challenge in dementia care. Cognitive stimulation is a psychosocial intervention that supports communication and engagement, and several digital applications for cognitive stimulation have been developed. Personalization is an important factor for obtaining sustainable benefits, but the time and effort required to personalize and optimize applications often makes them difficult for routine use by nonspecialist caregivers and families. Although artificial intelligence (AI) has great potential to support automation of the personalization process, its use is largely unexplored because of the lack of suitable data from which to develop and train machine learning models.

Objective: This pilot study aims to evaluate a digital application called Aikomi in Japanese care homes for its potential to (1) create and deliver personalized cognitive stimulation programs to promote communication and engagement between people with dementia and usual care staff and (2) capture meaningful personalized data suitable for the development of AI systems.

Methods: A modular technology platform was developed and used to create personalized programs for 15 people with dementia living in 4 residential care facilities in Japan with the cooperation of a family member or care staff. A single intervention with the program was conducted with the person with dementia together with a care staff member, and for some participants, smell stimulation was provided using selected smell sticks in conjunction with the digital program. All sessions were recorded using a video camera, and the combined personalized data obtained by the platform were analyzed.

Results: Most people with dementia (10/15, 67%) showed high levels of engagement (>40 on Engagement of a Person with Dementia Scale), and there were no incidences of negative reactions toward the programs. Care staff reported that some participants showed extended concentration and spontaneous communication while using Aikomi, which was not their usual behavior. Smell stimulation promoted engagement for some participants even when they were unable to identify the smell. No changes in well-being were observed following the intervention according to the Mental Function Impairment Scale. The level of response to each type of content in the stimulation program varied greatly according to the person with dementia, and personalized data captured by the Aikomi platform enabled understanding of correlations between stimulation content and responses for each participant.

Conclusions: This study suggests that the Aikomi digital application is acceptable for use by persons with dementia and care staff and may have the potential to promote communication and engagement. The platform captures personalized data, which can provide suitable input for machine learning. Further investigation of Aikomi will be conducted to develop AI systems and create personalized digital cognitive stimulation applications that can be easily used by nonspecialist caregivers.

Introduction

Background

The lack of effective drugs for dementia [1] means that, for the foreseeable future, high-quality care remains the best option to maintain quality of life (QOL) for persons with dementia. However, cognitive decline and behavior changes associated with dementia increase the complexity and difficulty of caregiving, often making it challenging for families and care staff [2]. In particular, responsive behaviors, known medically as behavioral and psychological symptoms of dementia (BPSD), are a range of neuropsychiatric disturbances that affect most persons with dementia and can greatly disrupt caregiving, causing both poor QOL for the person with dementia and physical and mental stress for their caregivers [3]. Communication and engagement between people with dementia and their caregivers lie at the heart of good-quality caregiving [4,5], which is usually provided in dyadic or triadic structures [6] formed by the person with dementia and professional care staff and family caregivers. Communication plays a key role in the successful functioning and quality of care relationships in these care structures as well as greatly influencing the well-being and QOL of everyone involved [7]. Unfortunately, the progression of dementia can significantly impair the communication process for both persons with dementia and their caregivers and lead to inadequate or 1-sided interactions. Overcoming communication issues requires skill, patience, and sensitivity on the part of caregivers, which further adds to the difficulties and stress of caregiving [8]. In addition, the lack of time and resources available for caregivers can deprioritize communication as an activity in itself and result in it being conducted while performing other care activities, which may not be sufficiently personal or meaningful to maintain the psychological well-being of the person with dementia [9]. Communication and engagement are also integral to person-centered care [10], which has been shown to support QOL and help manage responsive behaviors and is widely accepted as best practice in dementia care. Communication difficulties between persons with dementia and their caregivers can prevent adequate expression and understanding of needs, desires, and intentions for both [11], presenting a major barrier to implementing person-centered care [12] including in Japan [13]. Communication and engagement are also important for implementing most psychosocial interventions [14], which are widely used to support caregiving activities to maintain well-being and QOL and manage BPSD. Many psychosocial interventions are based on different types of cognitive stimulation activities, such as cognitive training [15], reality orientation [16], reminiscence therapy [17], multisensory stimulation [18], and music therapy [19]. Several psychosocial interventions have shown promising clinical evidence, in some cases comparable with drug therapies, especially when implemented at the individual level. One of the most well-validated psychosocial interventions is cognitive stimulation therapy (CST) [20], which is based on person-centered care and consists of systematic protocols that combine reminiscence therapy and reality orientation designed to promote enjoyable and meaningful activities for persons with dementia. Clinical studies in groups have demonstrated improved cognition and QOL for persons with dementia [21] and improved caregiver relationships when conducted at the individual level (individual CST; iCST) [22]. Culturally adapted CST protocols have been developed for >20 countries, including CST-J for Japan [23], although its adoption in Japanese care settings remains limited, especially at the individual level.

The lack of trained care staff and practical difficulties associated with the regular and consistent implementation of psychosocial interventions have generated considerable interest in the use of digital technologies [24,25], a trend that was accelerated by the COVID-19 pandemic [26]. Recently, several applications have become available to promote personalized communication and engagement between people with dementia and their caregivers [27], and personalization has been recognized as an important factor in obtaining sustainable benefits [28]. Digital storytelling is a promising approach based on the well-established life story book concept in reminiscence therapy, which uses a person’s own and other relevant content to create fully individualized interventions [29]. In digital storytelling, the physical materials commonly used to facilitate life story book interventions, such as photographs, books, and memorable objects, are replaced with digital media, such as images, videos, and audio. In addition to engagement, digital storytelling aims to help the person tell their own story and has also been used outside dementia in other areas of mental health. Feasibility studies with digital storytelling applications have shown improvements in memory, QOL, and depression [30] as well as additional benefits from the use of digital media. Similar results have been observed in both Western and Asian contexts [31], indicating the wide potential of this approach. However, one of the difficulties of digital storytelling is that preparation requires digital skills, time, and effort [32], which presents a significant adoption barrier for many caregivers and families. The need to create personalized content is avoided through a digital iCST application [33] that uses a pool of precreated generic stimulation activities, including quizzes and games designed to promote engagement, that can be used according to the interests and content diversity was identified as an issue for maintaining engagement and long-term use. Given the importance of personalization, reducing the time and effort required for tailoring applications is a key concern to facilitate broader adoption by nonexpert care staff and families. Data generated by digital technologies can be used to develop artificial intelligence (AI) systems to support caregiving for dementia [35], which can aid the personalization process. However, the development of personalization applications is still at an early stage, and the lack of high-quality personalized data sets related to communication and engagement for people with dementia hinders progress in this area. To address this, a prototype
an application called Aikomi was developed to support communication with people with dementia while also capturing high-context personalized data, including behaviors, that would provide a suitable source for developing machine learning models to automate the personalization process. Such AI systems could reduce the personalization burden of digital cognitive stimulation applications and enable their use by non-specialist caregivers to support communication and engagement with people with dementia in real-world settings.

Aims and Objectives

The aim of this pilot study was to evaluate the Aikomi application in Japanese residential care homes for its potential to (1) create and deliver personalized cognitive stimulation programs and promote communication and engagement between people with dementia and their usual care staff and (2) capture meaningful personalized data suitable for the development of AI systems.

Methods

Technology Development

The Aikomi application was designed by a multidisciplinary team with expertise in occupational therapy (TO); clinical dementia care and psychiatry (KM); digital health (NH); engineering, data science, and machine learning (SG and SKP); the design process also received input from frontline care staff in Japan. The design goal was to create an application that could be routinely used by care staff and family members to promote communication with people with dementia living in both residential care and community settings and would not require expert knowledge, training, or long preparation times. The technology goals were to (1) construct the technology platform using a modular architecture with stand-alone applications for each key function to allow for “plug-and-play” integration of software and hardware applications and (2) incorporate an open connectivity platform to allow for convenient data flow between application modules and facilitate the development of machine learning applications. The connectivity platform used was Garuda (Garuda Alliance) [36], which is a community-driven open connectivity platform previously developed by one of the authors (SG). The modular design provides flexibility to develop fit-for-purpose applications as well as “future-proof” the platform to incorporate other technologies and data sources to enhance optimization and scaling of the personalization process.

A 6-step workflow for using the application was designed through informal discussions with professional care staff and families (Figure 1). The first step is to conduct an interview with families or care staff to obtain information about the person with dementia, including their life history, hobbies, interests, preferences, and abilities, which are used to create a standardized personal profile. On the basis of this personal profile, relevant digital media content is selected or created, and if available, the person’s private content obtained from the family is digitized (as necessary) and uploaded to the system. Next, relevant content is compiled into audiovisual stimulation programs, which are displayed as the intervention. Finally, the behavioral responses of the person with dementia during the intervention are recorded and analyzed to adapt and optimize the content and stimulation programs for the next intervention. To minimize the burden of the personalization process on families and care staff, their participation is limited to the initial interview and the intervention itself. The remaining personalization processes were conducted manually by the research team for this pilot study and will be automated in the future.

The software for all the components (modules) was developed as an independent web application whose integration was facilitated by the Garuda connectivity platform. The content management system (CMS) is a repository for generic digital media content, such as images, videos, and audio files. It allows users to upload, create, edit, and store content that can be used by all persons. A separate private CMS module performs the same function as the CMS for the private content of the person, but its use is restricted to this person only. The simulator module is a function to create stimulation elements (called STIMs) from the content in the CMS and private CMS. A STIM consists of a short audiovisual sequence created from combinations of image, audio, and video data and is the building block used to create stimulation programs. The user has complete flexibility to create and select STIMs and compile them in any sequence order to generate the stimulation program. The personal CMS and simulator modules operate at the level of each individual and are not accessible to other users and caregivers. The simulator module also includes a function to create and edit a standardized personal profile of the person. The home and control modules are both used to conduct the intervention. The home module displays the stimulation programs viewed by the person with dementia, and the control module is used by the caregiver to select and control the display of the stimulation program on the home module during the intervention. The control module has functions to pause the program to talk or go back to a previous STIM or forward to a new STIM depending on the response of the person with dementia. A web meeting function was integrated into the home and control modules to allow for the remote use of the Aikomi application, but it was not used in this pilot study, in which only in-person sessions were conducted. The design of the functions and user interfaces for the home and control modules was conducted in collaboration with care staff primarily for use with tablets, but they can also be used on a PC. An example of the home and control modules during use is shown in Figure 2.

The response dashboard module enables the storage, review, and data analysis of video recordings of the person with dementia during the intervention. It was intended for video recordings to be made using the camera on the home tablet; however, this function was not fully operational at the time of the pilot study. Hence, a remote camera was used to record the interventions, and the data were subsequently uploaded to the response dashboard. Each module was a separate web application integrated with the Garuda connectivity platform. The tablets used in the pilot study were installed with SIM cards to avoid the need to use the local network at the residential care home, which can sometimes be unreliable.
Figure 1. Aikomi workflow and system modules.

Aikomi workflow

- interview with family or caregiver
- create personal profile for user
- compile contents into cognitive stimulation program
- upload, select, create contents
- display program to user
- view and analyze user behavioral response to program
- manual processes
- processes to be automated

Aikomi system modules

- **Content management system**
  - upload, create, edit and store generic digital media contents

- **Private content management system**
  - upload, create, edit, and store a user’s own digital media contents

- **Simulator**
  - create, edit, store, and schedule stimulation elements and programs

- **Home**
  - display stimulation programs to person with dementia

- **Control**
  - caregiver operations to select and play stimulation programs

- **Response dashboard**
  - record behavioral responses of person with dementia to program

Figure 2. Home and control module display.
Pilot Study

Study Design and Participants

The study was conducted using Aikomi as a single intervention lasting approximately 30 minutes with 15 people with dementia living in 4 urban residential care homes in Japan and their usual care staff. The participants were nominated by the care managers at each facility based on the following selection criteria: (1) a diagnosis of dementia, (2) displaying negative BPSD such as anxiety or apathy, (3) no hearing or visual difficulties that would prevent using a tablet, and (4) agreement from their family to participate in the study. Participants with a diagnosis of frontotemporal dementia or who had other mental conditions were excluded from this study. All the care staff members who participated in this study were qualified professionals at the residential facilities.

Procedure

The protocol and timeline for the pilot study are shown in Figure 3.

Participant Selection

Care managers at participating care homes explained the details of Aikomi and the pilot study to the families of candidate persons with dementia using materials provided by the research team. After the explanation, written consent was obtained from the families who agreed to participate in the study.

Program Preparation

The research team conducted in-person or telephone interviews with family members to obtain information about the person’s life story, interests, and preferences as well as other topics that the family thought could be meaningful. In addition, the families were asked to provide any suitable family photos if they had them. In one case, a family member was not available for interview, and it was instead conducted with the care manager at the facility. The obtained information was used to create a profile for each person, and relevant digital content was selected and used to create STIMs that corresponded to items in the profile, such as hometown, childhood, family, work, life and cultural events, hobbies, sports, travel, pets, and music. The duration of each STIM ranged from 30 seconds to 3 minutes, and each stimulation program was created by compiling 10 to 20 STIMs in a sequential order expected to be easy for the person with dementia to follow. For this pilot study, all non–family-derived content was obtained by the research team from publicly available sources, and the programs were prepared by the research team within approximately 2 weeks following the family interview.

Intervention

The intervention was conducted as a 1:1 session with the person with dementia and the care staff member seated next to each other at a table in a quiet area of the care home. The home tablet was placed at a comfortable viewing distance for the person with dementia and the care staff member. The control tablet was operated by a research team member seated on the opposite side of the table. A camera was placed at an appropriate position to record the behavioral responses of the person with dementia and care staff member during the intervention. As the application was to be operated by the research team, the care staff were only given a brief overview of the device, and a rehearsal was conducted before the session to familiarize them with the intervention conditions. In addition, to allow the person with dementia to lead responses to the stimulation program as much as possible, the care staff were requested to adopt a passive role during the intervention and respond appropriately according to the person’s behavior and mood, although prompting according to their own judgment was permitted. The stimulation program was started as soon as the participant was seated and appeared comfortable, and apart from initial greetings, the research team member avoided direct interaction with the person with dementia during the session unless actively addressed by them. The intervention began with a few general reminiscence STIMs to act as a “warm up” and accustom the person with dementia to the device, after which STIMs related to personalized topics were played. The selection of STIMs was adjusted according to the mood and responses of the participant, and if a participant showed good engagement with a particular theme, the STIM was repeated or a related STIM was shown. In cases in which
the participant showed little engagement, the STIM was stopped and a STIM of a different topic was shown. The target time for each intervention was 30 minutes but was shortened if the participant appeared tired or uninterested, and the STIM was changed immediately if the participant appeared uncomfortable. The intervention was concluded by showing STIMs such as nature or landscapes as a “cool down” period, and if the participant was agreeable, smell stimulation was conducted using 5 synthetic smells that were embedded on paper strips (such as those used for sampling perfumes) supplied by a commercial smell product company [37]. The decision to use the smell sticks was made after asking each person with dementia and the care staff member after completion of the main stimulation program. The 5 smells used for the evaluation were chocolate, miso (fermented soy paste cooking ingredient), grass, earth, and soap. A smell stick was provided to both the participant and the caregiver without revealing the identity of the smell, and at the same time, a STIM related to the smell was displayed on the home module, for example, showing a bar of a famous brand of chocolate for the chocolate smell. Following the first smell, the remaining smell sticks were similarly used individually according to the participants’ interest in continuing.

Evaluation Scales

**Baseline**

BPDS assessment of the participants was conducted during the month before the intervention by the appropriate care staff using the Neuropsychiatric Inventory–Nursing Home version (NPI-NH) [38]. Cognitive ability was recorded using the most recent cognitive assessment conducted at the care home using one of the following cognitive scales: Mini-Mental State Examination (MMSE) [39], revised Hasegawa Dementia Scale (HDS-R) [40], or Nishimura Mental State Scale for the Elderly (NM) [41]. In total, 3 different cognitive scales were used because of the different types of cognitive tests routinely used at each participating care home.

**Intervention**

Engagement during the intervention was measured using a Japanese translation of the Engagement of a Person with Dementia Scale (EPWDS) [42] prepared by the research team. The EPWDS is a 10-item assessment measuring positive and negative engagement in 5 domains—affect, visual, verbal, behavioral, and social—and was administered soon after the intervention by the attending care staff member, who was also asked to provide their comments on the intervention. Psychological well-being was measured using the 6 motivational and emotional dysfunction items of the Mental Function Impairment Scale (MENFIS) [43]. The MENFIS assessment was conducted at the care home by a care staff member on 3 consecutive days spanning the intervention: the day before the intervention (day 1), on the day of the intervention a few hours after it was conducted (day 2), and the day after the intervention (day 3). The care staff member was also asked to provide their written comments for each assessment. All 3 MENFIS assessments were conducted by the same care staff member, who was not always the same care staff member who was present at the intervention. As the study was intended as a preliminary pilot study, the EPWDS and MENFIS scores were only used as a guide for the qualitative assessment of the intervention.

**Ethical Considerations**

Ethics approval was obtained from the Kobe Gakuin University Human Research Ethics Committee (sourin 18-14). Written approval to conduct the study was obtained from the directors of each of the participating care facilities as well as the families of all the persons with dementia participating in the study.

**Results**

**Overview**

The characteristics of the 15 participants enrolled in the study are shown in Table 1. A total of 5 (33%) people did not meet all the selection criteria: 2 (13%) were “suspected” to have Alzheimer disease but had not received a formal diagnosis of dementia, and 3 (20%) did not show BPDS as defined by the NPI-NH. However, it was decided to include all 5 in the pilot study as the primary purpose was to evaluate Aikomi for its acceptability and communication effects on persons with dementia, and there was agreement to proceed from the care staff and families. The people who did show BPDS were reported to have a wide range of symptoms.

**Engagement**

The responses of the persons with dementia during the intervention are shown in Table 2 and Multimedia Appendix 1. The duration of the intervention ranged from 15 to 38 minutes, most persons (13/15, 87%) showed strong positive responses to at least 1 of the STIMs, and none showed discomfort toward Aikomi or requested the session to be stopped. In total, 67% (10/15) of the participants had an EPWDS score of >40 (out of a maximum of 50), indicating both a high incidence of positive engagement and a low incidence of negative engagement. The remaining 33% (5/15) of the participants showed an EPWDS score of >30, which was due to low positive engagement scores (lack of engagement with the stimulation program) rather than the high incidence of negative responses such as anger, anxiety, or discomfort, which were not observed for any participant. Interestingly, person 14, who showed few positive responses during the intervention itself, spoke to thank the research team after the session was completed, which the care staff member said was highly unusual behavior for them.

The types of STIM topics and the responses they generated were analyzed from the video recordings and are shown in Table 3. The most common STIM topic to generate good engagement was family photos, which prompted self-initiated talk and the identification of persons they recognized. However, some participants (6/15, 40%) struggled to recognize their family members and even themselves. One person (person 3) showed no response, and person 4 responded most strongly to photographs of herself in early adult life rather than of her family. Music was also a popular STIM topic, prompting several participants to initiate singing and clapping to both traditional Japanese children’s songs (doyo) and Japanese popular music. The STIM of popular singers known to be liked by the persons with dementia often generated verbal dialogue with the care staff (persons 4, 6, 8, and 13). Japanese traditional arts, such as the tea ceremony, dance, and calligraphy, generated good responses from most women who had performed them (persons 2, 4, 7, 8, 11, and 13), and sports themes (baseball, sumo, and boxing) were popular for all the men (persons 1, 5, 6, and 9). Work-related themes induced mixed responses; however, STIMs related to actions performed during their work (eg, using a...
Japanese typewriter, counting money, or preparing fish) generated responses from 33% (5/15) of the participants (persons 2, 6, 7, 8, and 15). Wartime navy service STIMs generated strong positive engagement from person 1 and prompted a detailed recollection of his experiences; this is described in more detail in case study 1.

### Smell

A total of 60% (9/15) of the participants tried the smell stick stimulation in conjunction with paired audiovisual stimulation, and 13% (2/15) of the participants tried all 5 smell sticks. The responses are shown in Table 4. In most cases, the smell sticks led to pleasurable responses from both the participant and the care staff member, with more laughter than was observed during the audiovisual programs. Almost all the people with dementia (8/9, 89%) had difficulty explicitly identifying the smell; however, majority (6/9, 67%) were able to notice that the smells were different, and recognition of the smell identity did not appear to affect the engagement with the caregivers. Although it was not the intention, some participants perceived the smell program as a test, which may have caused some confusion (person 15) and prompted one person to say that she had lost her sense of smell (person 5). This shows that care must be exercised when using smell stimulation to reduce the risk of causing anxiety to users who may no longer have a sense of smell or be stressed by the inability to correctly identify the smells.

Well-Being and Behavior Changes

The results of the MENFIS well-being assessment of the persons with dementia conducted by the care staff over the consecutive 3-day intervention period are shown in Table 5. In total, 13% (2/15) of the participants showed improvement (reduction in MENFIS score) on the third day compared with the first, and 7% (1/15) of the participants (person 13) showed a reduction only on the second day (after the intervention). All other participants showed similar or identical MENFIS scores for all 3 days except for person 12, who showed worsening over the 3 days, which was attributed to her catching a cold during the period of the intervention. The data for persons 14 and 15 were disregarded as the care staff member mistakenly conducted the second-day assessment before the Aikomi session instead of after. In many cases, the participants had no recollection of the intervention the following day. Little inference can be drawn from the MENFIS data except that there appeared to be no adverse effects on the well-being of the people with dementia after using the Aikomi application.

## Selected Case Studies

### Person 1

Although not formally experiencing BPSD according to the NPI-NH, the care staff member said that person 1 usually displayed apathetic behavior, and the staff member was very surprised by the amount of self-initiated dialogue in response to the family and wartime navy service STIM, which was shown several times during the test. The STIM included a photograph of the ship he served on as well as a Japanese navy song. The person became conversational and could recall the names of former navy colleagues as well as events in detail, providing new information and anecdotes with every repetition of the STIM. The care staff used this information to continue to manually provide stimulation using photographs on the following day, which is likely to have contributed to the improving trend observed in the MENFIS score from the second to the third day. In contrast, person 2, who was his spouse and lived at the same facility but showed more advanced dementia symptoms, did not respond strongly to the same family STIM used for person 1. However, at the request of the care staff member, an additional session with the Aikomi application was conducted with both persons 1 and 2 watching the family STIM together. In this case, person 1 provided prompts to person 2, who showed a much stronger response than when she viewed the STIM with the care staff member.

### Person 10

The caregiver reported that the person had shown agitated behavior in the period before the intervention but was able to come into the room and quickly settled when the session started. She responded to several of the STIMs and actively talked about several of the themes presented. As she was an excellent athlete during her school days, the program included a STIM video of a modern high school girls’ 100-meter race, in which she showed great interest, including making a humorous comment about the lack of clothes worn by current athletes. In addition, she showed quiet concentration on the STIM related to her hobbies of watercolor painting and hill walking and told the care staff member that she wanted to do both again and recalled the names of several mountains that she had climbed. During the smell intervention, she laughed and engaged with the care staff member and research team and appeared to enjoy the experience even though she did not recognize any of the smells. The care staff member said that her behavior during the intervention was not usual and that she was not agitated when she returned to her living area. However, this was not reflected in the MENFIS score.
scores, which were assessed by a different care staff member and showed no changes over the 3-day period.

**Person 13**

During the intervention, she showed good responses to STIMs about her hometown (Tokyo), her hobby of playing the koto (musical instrument), and a popular Japanese singer. She momentarily cried on 2 occasions when viewing her hometown and the Japanese singer, but her sadness did not persist and was followed by self-initiated talk to the care staff member about her wartime childhood and the Japanese singer’s unhappy life story. The care staff member reported that she usually could not show good concentration, and they were surprised that she was calm and could concentrate during the intervention and recall her memories. In the evening after the test, the care staff member reported that she said that she felt good and that other residents noticed that she was not as agitated as usual; however, on the day after the test, her agitated behavior returned to normal, and this pattern was reflected in the MENDIS scores.

**Discussion**

**Principal Findings**

Maintaining communication and engagement for persons with dementia is integral to caregiving, implementing person-centered care, and managing BPSD. It is also vital for facilitating the positive aspects of care that foster good QOL and sustainable caregiving relationships [45]. Over the last decade, several digital applications have become available to support communication and engagement for people with dementia [27], and to the authors’ knowledge, this pilot study is the first investigation of a digital application for personalized multi-sense stimulation conducted in Japan. All participants in this study were able to accept viewing the programs on the tablet, and these preliminary findings are broadly consistent with those of previous studies that demonstrate the importance of tailoring cognitive stimulation content to the individual profile and abilities of each person to obtain good engagement [28]. As reported for other applications, themes based on personal photographs or music often generated positive responses from participants, although for many people in the study, these themes did not generate the strongest responses during the intervention (Table 4). Instead, a wider range of themes specifically associated with the person’s lived experiences, such as wartime service (person 1), and interests such as gardening (person 5) and Western movies (person 9) were often the ones that resulted in prolonged and in-depth participant-initiated communication with care staff. This is in agreement with digital storytelling studies that have demonstrated the need to use a diverse range of relevant topics to adequately personalize interventions to obtain good engagement [29,30]. In addition, the benefits of using applications that combine both generic activity-promoting content and personally sourced content have been demonstrated with the CIRCA and CIRCUS application [46]. The role of the care staff was important to facilitate engagement in this study, especially to allow persons with dementia sufficient time to respond to the stimulation. It has been reported that caregivers sometimes do not allow sufficient time for the person with dementia to respond, which can lead to carer-directed engagement and suppression of the person with dementia’s own ability to initiate and maintain conversation [47]. In several cases, participants did not respond immediately to the stimulation content and required some time to view and “acclimatize” to the content before responding. This suggests that adapting the duration and complexity of the STIM according to the responses of each person may enhance their ability to respond and avoid premature transition to the next STIM, which will be explored in the future. The example of a husband and wife (persons 1 and 2) suggests the potential of people with dementia using the Aikomi application together without the active presence of care staff when the content has a high personal meaning for both. In total, 13% (2/15) of the participants, who had advanced dementia (persons 12 and 14), showed almost no engagement; however, good engagement was observed with another 13% (2/15) of the participants, who had low cognition (persons 6 and 10), suggesting that other factors in addition to cognition, such as content relevance, mood, and care staff behavior, may also be important for engagement.

One of the features of the Aikomi platform is that it allows for flexible navigation through a sequence of personalized stimulation themes that provide options for caregivers to select and adapt the content of the stimulation program according to the mood and responses of the user. The usefulness of this function was illustrated in person 1, who showed an unexpectedly strong reaction to the war-themed pictures triggering extended dialogue with the caregiver that was facilitated by several repetitions of the same STIM. In contrast, when person 13 started to make negative comments while viewing a STIM, it was possible to quickly change to a new STIM about her hobby, after which she started to make positive comments. Furthermore, the ability of the Aikomi application to easily modify and add new content enables the convenient creation of new personalized stimulation programs each time the Aikomi device is used. This is important for longer-term use to minimize or avoid the repeated use of the same content, which may lead to reduced interest from users and caregivers and has been found to be an issue for applications restricted to a fixed pool of content [33]. In addition, the flexible use of personally targeted activity content has been reported to promote curiosity and encourage self-directed learning in people with dementia [48] and suggests that personalizable digital cognitive stimulation applications such as Aikomi may be able to expand the range and depth of self-expression of people with dementia.

A secondary objective of this study was to explore the potential benefits of using paired smell and audiovisual stimulation to promote improved engagement compared with audiovisual stimulation alone. Currently, the use of smell stimulation in dementia care is limited and mainly focused on aromatherapy approaches to improve mood and reduce responsive behaviors using natural oils. However, other studies have shown that smell may play a role in triggering autobiographical and implicit memory [49], and it was thought that synthetic smells associated with daily life experiences could encourage not only the person with dementia but also the care staff member to share their own experiences, as well as being enjoyable. The engagement during paired smell and digital stimulation appeared to involve more smiling and laughter for both the participant and care staff.
member compared with responses to the audiovisual program alone. Interestingly, this was the case even when the person with dementia did not identify the smell and suggests that the combined use of digital audiovisual stimuli with smell may be more effective than smell alone [50].

From its inception, the Aikomi platform has aimed to develop AI capabilities to minimize the time and expertise required by nonspecialist care staff and families to use personalized digital applications. This is a critical issue for adoption and sustained use in dementia care, where caregivers are often older and not “digital natives” and have limited time or support to learn how to use and personalize applications [51]. Currently, most digital applications support personalization using two types of approaches: (1) supported collaboration with families to create bespoke interventions or (2) provision of predesigned content for on-demand selection during application use [28]. The bespoke approach often focuses on personal reminiscence and identity-reinforcing applications such as digital storytelling [29,30] and memory books [52,53], but preparation requires extensive family involvement over weeks or months, which may be challenging to sustain. Conversely, on-demand selection approaches, usually providing content curated by expert research teams, allow for immediate use and scalability but may fall short of generating sufficient interest and maintaining long-term use and be more suitable for social interaction [54] and activity-based applications such as iCST [33], music [55], and games [56]. The data obtained by digital technologies open up new opportunities to use machine learning to develop automation that can overcome these personalization barriers as well as optimize and adapt interventions. However, the lack of available high-quality and personalized data sources for people with dementia has limited progress in AI development for dementia care [35], especially for applications to support communication and engagement. To address this, Aikomi’s modular architecture facilitates the seamless capture of user data across key function domains: personal profile, content tagging, sequence ordering, and response analysis. This approach can combine the precision of the bespoke approach with the convenience of using the preprepared on-demand content. In this pilot study, data from the interviews and the provided content were used with the preprepared generic content to create bespoke programs in approximately 2 weeks, a reduction from the 6 to 8 weeks reported for digital storytelling [28]. In addition, it was possible to evaluate the performance of personalization using high-context data such as personal profiles, content and sequence attributes, and behavioral responses captured by the Aikomi platform. A related approach was reported by another personalized digital application called Scrapbook, which demonstrates the importance of obtaining multiple personal context–related data inputs to enable analysis [57]. Although AI system development was not the focus of this pilot study and personalization was conducted manually by the research team, this study demonstrates the potential of using the Aikomi platform as a tool to generate personalized data for AI development, and a preliminary investigation was conducted to create machine learning models to automate the personalization process, which is reported elsewhere [58]. In addition, chatbot technology, pioneered by a reminiscence intervention called ReminX [59], demonstrates an alternative trajectory for AI-driven personalization in dementia care.

Although no effects on BPSD were expected from this single-intervention study, the transient behavior changes reported by care staff for some persons (persons 1, 10, and 13) after using the Aikomi application suggest that there may be potential for investigating Aikomi to affect more lasting behavior changes related to BPSD. Although there is currently only a weak clinical evidence base to support the use of cognitive stimulation to manage BPSD, the use of personalized digital interventions embedded with data capture functions may offer the potential to not only create more effective therapeutics but also generate personalized monitoring data that can provide more robust clinical evidence. In the last few years, digital therapeutics (DTX) has emerged as a new category of regulatory-approved medical products that are distinct from drugs and medical devices [60,61]. To date, no DTX interventions for dementia have received regulatory approval, but several applications have been developed for supportive care [62]. DTX for dementia was pioneered by ReminX [59], which was designated as a breakthrough medical device by the Food and Drug Administration (FDA), and more recently by CST Assistant [63], which is a clinical evidence–supported CST-based game application that is now commercially available in Europe. Given the continuing challenges in developing effective and affordable drug therapies for dementia and BPSD, digital interventions for personalized cognitive stimulation such as Aikomi may have potential for clinical development as DTX and offer nondrug options for the management of BPSD and improvement in QOL. In addition to the primary objective of addressing therapeutic goals, the importance of preserving care relationships and creating opportunities for positive aspects of care for caregivers is also gaining increasing attention in dementia care [64,65]. With the growing shortage of professional caregivers, which is particularly acute in Japan, digital technologies that can promote meaningful engagement and improve QOL for both people with dementia and caregivers may become important tools to foster greater participation by family and informal caregivers in caring for their loved ones.

**Limitations**

As this study was the first evaluation of the Aikomi application conducted in a care setting and limited to a single intervention to confirm its safety and acceptability for people with dementia, all inferences are preliminary and need to be confirmed via further multiple-intervention studies. Furthermore, although the aim was for Aikomi to be used independently by the care staff, the research team was required to be present during the interventions for this pilot study, which was a potential source of bias. This was necessary as the Aikomi platform was still a prototype, and the care staff were not familiar with operating digital technologies and required support to use Aikomi and overcome any technical difficulties. In fact, no application-related technical problems were encountered during the intervention, and connectivity issues were largely avoided by using tablets with SIM cards and addressed before the intervention. However, the provision of appropriate training and technical support for care staff to set up, use, and maintain the Aikomi application was not investigated in this pilot study.
Another limitation was that most staff members were unfamiliar with conducting EPWDS and MENFIS evaluations, and the evaluations of some participants were conducted by multiple care staff members because of shift changes, which may have led to some inconsistencies in the results. Furthermore, the EPWDS is not yet available in Japanese, and an unvalidated translation prepared by the research team was used. These limitations need to be addressed in future studies.

Future Research
The next step is to conduct multiple-intervention studies to investigate the effects of longer-term use of the Aikomi application when the program content of each intervention is adapted based on the behavioral responses of the person with dementia. The data derived from these studies will become the basis for developing machine learning models to create algorithms that can optimize personalization and increase the convenience for the care staff to use the system. To generate evidence to support the use of the Aikomi application in dementia care, it is necessary to conduct clinical trials to evaluate its effects on QOL and BPSD, from which its potential for further development as a digital therapeutic can be assessed. Separately, use by family caregivers in their own homes will be investigated to obtain feedback and data that will guide the development of the Aikomi application for community use. In addition, further work is needed to increase the pool of diverse and culturally relevant content that has been curated for people with dementia to reduce the lead time required to prepare stimulation programs. In this pilot study, all non–family-derived content was selected or created by the research team from publicly available sources, and copyright issues were not considered because of the noncommercial nature of this research. However, ensuring copyright compliance for the use of all digital media content, for both content owners and content providers, is a significant issue that must be addressed before the commercial deployment of personalized cognitive stimulation approaches. Finally, to enable more convenient use of smell stimuli with cognitive stimulation, automated smell delivery devices such as diffusers should be investigated for integration with the Aikomi platform.

Conclusions
This pilot study demonstrated that the Aikomi application was able to create personalized cognitive stimulation programs that were acceptable for use in Japanese care homes and may have the potential to promote communication between people with dementia and their care staff. The use of smell stimuli paired with audiovisual stimulation was found to promote enjoyable interactions for many users. In addition, the Aikomi platform captured several types of personalized data, including the behavioral responses during the intervention, which enabled a detailed analysis of the stimulation content preferences of each person with dementia. These results indicate that the Aikomi application has the potential to be used as a tool to provide personalized cognitive stimulation and also generate high-context data suitable for the future development of AI systems to automate the personalization process. Further research will be conducted to develop the Aikomi application as a communication tool that can be easily used by nonspecialist care staff and families in residential and community care settings to enhance care relationships and positive aspects of care and aid the therapeutic management of BPSD.

Acknowledgments
The authors would like to thank all the people with dementia and their families and participating care staff for their support and cooperation in participating in this study. The help and advice of the care managers at the participating care homes is gratefully appreciated. Ken Inoue (chief executive officer, Promotool Corporation) is thanked for his kind advice and supply of the smell sticks.

Data Availability
The data sets generated and analyzed in this study are not publicly available as the data contain information that could compromise the privacy of the research participants. The data are available from the corresponding author upon reasonable request.

Authors' Contributions
NH, SG, and SKP collaboratively developed the Aikomi technology platform. KM and TO provided guidance throughout the development as well as advice and supervision of the pilot study in Japanese care homes. NH supported the conduct of the pilot study.

Conflicts of Interest
NH is a cofounder and chief scientific officer of Aikomi. NH and the SBX Corporation are shareholders of Aikomi.

Abstract

Background: Mobile apps can aid with the management of gestational diabetes mellitus (GDM) by providing patient education, reinforcing regular blood glucose monitoring and diet/lifestyle modification, and facilitating clinical and social support.

Objective: This study aimed to describe our process of designing and developing a culturally tailored app, Garbhakalin Diabetes athawa Madhumeha—Dhulikhel Hospital (GDM-DH), to support GDM management among Nepalese patients by applying a user-centered design approach.

Methods: A multidisciplinary team of experts, as well as health care providers and patients in Dhulikhel Hospital (Dhulikhel, Nepal), contributed to the development of the GDM-DH app. After finalizing the app’s content and features, we created the app’s wireframe, which illustrated the app’s proposed interface, navigation sequences, and features and function. Feedback was solicited on the wireframe via key informant interviews with health care providers (n=5) and a focus group and in-depth interviews with patients with GDM (n=12). Incorporating their input, we built a minimum viable product, which was then user-tested with 18 patients with GDM and further refined to obtain the final version of the GDM-DH app.

Results: Participants in the focus group and interviews unanimously concurred on the utility and relevance of the proposed mobile app for patients with GDM, offering additional insight into essential modifications and additions to the app’s features and content (eg, inclusion of example meal plans and exercise videos). The mean age of patients in the usability testing (n=18) was 28.8 (SD 3.0) years, with a mean gestational age of 27.2 (SD 3.0) weeks. The mean usability score across the 10 tasks was 3.50 (SD 0.06; maximum score=5 for “very easy”); task completion rates ranged from 55.6% (n=10) to 94.4% (n=17). Findings from the usability testing were reviewed to further optimize the GDM-DH app (eg, improving data visualization). Consistent with social cognitive theory, the final version of the GDM-DH app supports GDM self-management by providing health education.
and allowing patients to record and self-monitor blood glucose, blood pressure, carbohydrate intake, physical activity, and gestational weight gain. The app uses innovative features to minimize the self-monitoring burden, as well as automatic feedback and data visualization. The app also includes a social network “follow” feature to add friends and family and give them permission to view logged data and a progress summary. Health care providers can use the web-based admin portal of the GDM-DH app to enter/review glucose levels and other clinical measures, track patient progress, and guide treatment and counseling accordingly.

**Conclusions:** To the best of our knowledge, this is the first mobile health platform for GDM developed for a low-income country and the first one containing a social support feature. A pilot clinical trial is currently underway to explore the clinical utility of the GDM-DH app.

**Introduction**

Gestational diabetes mellitus (GDM), defined as hyperglycemia with onset during pregnancy, is a major public health issue worldwide. South Asians, who represent approximately one-fourth of the world’s population, are at a disproportionately higher risk of GDM [1-3], and the prevalence of GDM is increasing rapidly in South Asian countries, including Nepal [3-5]. Geographically situated between the two epicenters of the global diabetes epidemic, India and China [6], Nepal has a reported GDM prevalence ranging from 6.6% to 28% [7-9]. These estimates are alarming as GDM is associated with serious adverse perinatal outcomes and unfavorable long-term cardiometabolic consequences in both women and their children [10-14]. Although the short-term health and economic burden of GDM is substantial [15,16], its long-term implications are even more concerning, particularly among South Asian populations who are known to develop cardiometabolic complications at a relatively lower BMI than people with European ancestry [17-19]. Among women with GDM, those with South Asian ethnicity are also known to have a significantly higher risk of developing type 2 diabetes (T2D) compared to other ethnic groups [3,20]. Scalable and cost-effective solutions are thus needed to address the growing burden of GDM and its sequelae, particularly in low-resource South Asian countries, such as Nepal.

Successful GDM management relies on patient adherence to a complex care regimen, including dietary modification, adequate physical activity, weekly-to-biweekly antenatal follow-ups, and regular blood glucose monitoring and logging. Providing dietary and physical activity recommendations is a critical part of GDM management, but in resource-limited settings, such as Nepal, time for diet/lifestyle counseling often competes with other components of care. Face-to-face counseling for diet/lifestyle is also fraught with low participation rates and high attrition, as it is resource intensive for the health care providers and poses time and travel barriers for the patients [21,22]. Additionally, in many countries like Nepal, GDM counseling is only performed once, which is not conducive to facilitating a meaningful behavior change in diet and lifestyle. Mobile health (mHealth) technology provides new opportunities to circumvent these challenges [23] and support the treatment and management of GDM in low-resource settings. Mobile apps can aid in the management of GDM by providing patient education, reinforcing regular glucose monitoring and diet/lifestyle modification, and allowing health care providers to communicate and exchange health information with patients [24]. Mobile technology may offer cost-effective strategies to improve outcomes in patients with GDM by augmenting clinical care and empowering patients with GDM to self-manage their condition, yet this approach has not been tested previously in any low-income country [24].

App-based lifestyle interventions for GDM management are not common, especially in low-income countries, such as Nepal, where its prevalence is rapidly increasing [23,25,26]. To address this gap, our goal was to develop a mobile app that supports self-management and treatment among women with GDM in Nepal. In addition to making the app culturally tailored, our priority was also to design an app that matches the user needs and technological sophistication of the target users. Thus, taking a user-centered design approach [27], we developed the Garbhakalin Diabetes athava Madhumeha—Dhulikhel Hospital (GDM-DH) app in collaboration with our target users, patients with GDM and providers, in Dhulikhel Hospital, a flagship university hospital in Dhulikhel, Nepal. Consistent with Bandura’s social cognitive theory (SCT) framework [28], the GDM-DH app supports GDM management by providing patient education, reinforcing regular blood glucose/carbohydrate monitoring, increasing self-efficacy for diet/lifestyle modification, and facilitating clinical and social support. Here, we aim to describe the app development process and features of the GDM-DH app.

**Methods**

**Overall Study Design**

The study was conducted at Dhulikhel Hospital, a community-based tertiary-level university hospital of Kathmandu University (Nepal). We took a user-centered design approach to develop a culturally tailored mobile app (GDM-DH)
for management of patients with GDM at the hospital. Figure 1 outlines the steps in GDM-DH app development. In the qualitative/requirement-gathering phase, patients with GDM were recruited for a focus group and structured interviews to show them the app prototype and obtain their feedback on its features and functions. Key informant interviews (KIIs) were conducted with clinicians and patients’ spouses. Incorporating and revising the app prototype based on user input, we built a minimum viable product (MVP), after which additional patients with GDM were recruited for usability testing including the think-aloud protocol [29]. The final GDM-DH app was developed following an iterative process of product design and user testing.

Figure 1. Schematic representation of the user-centered approach for GDM-DH app development among target users (women with gestational diabetes) in Dhulikhel Hospital, Nepal. GDM: gestational diabetes mellitus; GDM-DH: Garbhakalin Diabetes athawa Madhumeha—Dhulikhel Hospital; KII: key informant interview.

Recruitment Procedure and Inclusion Criteria
Located in a periurban setting, about 20 km from the capital city of Kathmandu in Dhulikhel, Nepal, Dhulikhel Hospital has a catchment population of 1.9 million people and delivers approximately 3000 babies annually. All pregnant women receiving antenatal care at the Obstetric Outpatient Department at Dhulikhel Hospital undergo routine screening for GDM at 24-28 weeks of gestation. Inclusion criteria were pregnant women who (1) received antenatal care at Dhulikhel Hospital, (2) received a GDM diagnosis (within the preceding year), (3) owned a smart phone, and (4) could understand and read Nepali. Patients with a confirmed GDM diagnosis were recruited into the study with the help of a senior obstetrician-gynecologist (OB-GYN; coinvestigator in the study) and other staff in the OB-GYN department at Dhulikhel Hospital. A convenience sampling strategy was used to recruit participants meeting the aforementioned inclusion criteria for usability testing (n=18) and qualitative user research (n=19); for the latter, participants were recruited until data saturation was achieved.

Ethical Considerations
The study protocol was approved by the Rutgers Newark Health Sciences Institutional Review Board (Pro2019001883) and the Ethical Review Board of the Nepal Research Health Council (NHRC; registration number 735/2019). Signed written informed consent was obtained from all participants by the research assistant at Dhulikhel Hospital. To ensure participant confidentiality, all documents including participant identifiers, such as the master list and consent forms, are stored separately in a locked cabinet and in a secure password-controlled Health Insurance Portability and Accountability Act (HIPAA)-compliant BOX folder. Only select research staff have access to the documents and folders containing participant identifiers and data. The participants (women with GDM and their spouses) received a mobile recharge card worth Nepalese rupees (NRs) 500 (US $3.77) to compensate for their time for the interview/focus group or usability testing.

App Development Stages

Prototype Development
A multidisciplinary team including experts in GDM, mHealth, and behavior and implementation sciences, as well as health care providers and patients at Dhulikhel Hospital, contributed to the development of the GDM-DH app. Content modules and features to be included in the app prototype were selected based on a literature review, theory-based behavioral strategies, discussions with subject matter experts, and international recommendations and guidelines (including the Package of Essential Noncommunicable [PEN] disease interventions for primary health care in low-resource settings) [30]. A series of meetings and a full-day workshop were conducted with the research team to select and finalize the features of the app prototype. During the meetings, app features were selected based on expected user needs, alignment with theory-based constructs for behavior change, and the logistical and economic feasibility of incorporating these features in the app. The meetings and deliberations spanned over several weeks until differences were resolved and consensus was reached.

Qualitative User Research
After finalizing the app’s content and features, a focus group and structured interviews were conducted to explore the perceived barriers to and facilitators of GDM management and to seek feedback on the GDM app prototype. A total of 12 women with a GDM diagnosis (either current or in the preceding 1 year) were recruited from Dhulikhel Hospital, 4 (33.3%) of whom participated in a focus group and the remaining 8 (66.7%) in structured interviews. KIIIs were also conducted with health care providers (n=5) and spouses of patients with GDM (n=2). All interviews were audio-taped and transcribed verbatim. A
thematic analysis [31] of the interviews was performed to generate interview themes and memos.

The focus group and interviews explored the in-depth understanding of the target users’ views and opinions about GDM and its management, including knowledge and treatment gaps, perceived self-efficacy and barriers to GDM management, strategies to increase adherence to dietary/lifestyle management of GDM, and related social, cultural, and environmental factors. At the end of the focus group/interviews, the participants were given a demonstration of the app’s wireframe prototype, which is a schematic illustration that shows the app’s proposed interface, navigation sequences, and features and function. Feedback was then solicited from patients/providers/spouses on (1) the app dashboard, layout, and navigation; (2) usefulness of app features; (3) data entry burden; (4) usefulness of educational modules covered (5) clarity of graphs and data visualizations; and (6) additional features and content.

Usability Testing

Incorporating and revising the app prototype based on user input, we built an MVP, the simplest-possible version of the GDM-DH app, which retained the key features and functionalities of the app. The MVP was user-tested with 18 patients with GDM via the think-aloud protocol [29]. Individual 1-on-1 usability testing sessions were conducted in a private space and overseen by 2 facilitators; 1 facilitator led the session, while a designated notetaker recorded patients’ verbalizations. Usability testing consisted of a 2-step think-aloud protocol [32], in which the patients were asked to verbalize their thoughts as they navigated and completed various specified tasks (eg, profile setup, diet entry, weight visualization review, open video lesson) on the app. Patients were also asked to rate the difficulty of completing each task on a 5-point scale ranging from very easy to difficult. Additionally, they were asked to provide feedback on how the features and functions of the app could be improved upon [33]. Content analysis [34] was used to analyze and summarize the notes and verbalizations from the think-aloud protocol.

Final GDM-DH App Development

The facilitators’ notes and observations from the usability testing were compiled and scanned for indicators of usability problems experienced by the patients, such as annoyance, doubt, confusion, and slow/incomplete task completion. Based on the findings of the usability testing and recommendations provided by patients with GDM, a list of recommended modifications was compiled and discussed with the app developer (Ayata Inc, Kathmandu, Nepal). The results were used by the app developer to address the key usability barriers and patients’ preferences/feedback and develop a final version of the GDM-DH app for testing in a pilot clinical trial.

Results

Prototype and Content Development

Based on discussions with subject matter experts over a series of conference calls and workshops, we decided that the GDM-DH app suite would have 2 components: a mobile app for patients and a web-based portal for health care providers and researchers. The features and functionalities of the GDM-DH app were guided by Bandura’s SCT [28], which was selected as it has been widely applied in the dietary/lifestyle management of chronic health conditions [35] and is shown to be a suitable framework for promoting healthy behaviors among pregnant women, including those with GDM [36,37]. We focused our intervention modules on the SCT constructs of self-efficacy (confidence in one’s ability to take action and overcome perceived barriers to a behavior change), self-regulation/self-control (ability to understand and manage feelings, behaviors, and actions to achieve goals), behavioral capabilities (knowledge and skills needed to perform a given behavior), reinforcements (responses to a person’s behavior that increase or decrease the likelihood of occurrences), and outcome expectations/expectancies (anticipated outcomes of a behavior and values a person places on the probable outcomes of a behavior) [38]. Behavior change techniques (BCTs) [39] for the GDM-DH intervention content were selected based on the published literature [40] that maps the BCTs with the SCT constructs for behavior change (eg, the BCT of information about health consequences aligns with the SCT construct of outcome expectations). The SCT constructs observational learning (acquiring a new behavior by watching someone else performing it and observing their outcomes) and environment (physically external factors that can influence a behavior) were not targeted, as it was not feasible to achieve them at this time using the mobile app.

Using the SCT framework for behavior change, we decided that the content and features included in the GDM-DH app would support self-management of GDM by (1) providing health education, (2) helping patients identify and set target health goals (for diet, physical activity, and glucose levels), (3) enhancing their self-efficacy to meet target goals, and (4) facilitating desired support from family members. In SCT, self-monitoring of behavior is the first and most important step in self-regulating appropriate behavior changes [28]. Self-monitoring is also known to be a powerful behavior change strategy for changing diet and physical activity [41]. Hence, we decided that the core features of the GDM-DH app would facilitate the users to record and self-monitor their blood glucose, blood pressure, carbohydrate intake, physical activity, and gestational weight gain (GWG). The app would use automatic feedback and data visualization to aid in self-monitoring, as well as innovative technological features to minimize the self-monitoring burden, including visual aids for estimating carbohydrate portion sizes and smartphone GPS and accelerometer sensors for obtaining physical activity data [42]. Health care providers would be able to use the web-based portal of the GDM-DH app to enter/review blood glucose readings, track patient progress, and accordingly guide treatment and counseling [42].

In many South Asian countries, women are not the sole health decision makers, with mothers-in-law and husbands having a strong influence on their health decisions during pregnancy [43-45]. Additionally, family members are closely involved in a pregnant woman’s food selection and preparation, thus influencing her dietary behaviors. Hence, the team decided that the GDM-DH app would be designed to garner social support
from family members by allowing the patient to add friends and family members to the app, providing them with access to track and follow the patient’s progress toward stated goals.

**Educational Modules**

The educational content for the app was adapted from international recommendations and guidelines, including PEN disease interventions for primary health care in low-resource settings [30]. The topics covered information included on GDM and associated risk factors, short- and long-term health consequences of GDM for mother and child, clinical and lifestyle management of GDM, dietary and physical activity recommendations for GDM, the role of social support in GDM management, and the proper use of insulin and a glucometer. The educational materials for the app included text- and image-based materials written at less than an eighth-grade reading level and brief 5- to 10-minute videos narrated by the health care providers in Dhulikhel Hospital.

**Qualitative User Research**

Qualitative findings from the focus group and interviews, which have been described in detail previously [46], provided insight into the app content and features, as well as design elements that needed to be added or modified. Briefly, we identified several facilitators of GDM management, including at the individual level (eg, concern for the baby’s health), family level (eg, spousal accompaniment to hospital visits, emotional support), and health system level (eg, universal GDM screening, team approach to management). Notable barriers included inadequate time for diet/lifestyle counseling during hospital visits, an abrupt change in the diet/lifestyle from pre- to post-GDM diagnosis, misconceptions around diet and physical activity, and social/cultural barriers, including food-centered traditions and festivities and a lack of decision-making power in the household. The majority of patients with GDM and their spouses indicated that they lacked sufficient information to manage GDM and were frustrated by frequent hospital visits.

They gave me a diet chart where it was written what to eat in the morning, daytime, and evening, but I didn’t receive any kind of other documents to read about my disease. [Patient with GDM on lack of information about GDM]

They think that like hypertension or thyroid medication, if they start to take an insulin injection, they have to use it throughout their life, and they think it is required for serious conditions only…you know there are a lot of myths. [Provider on common misconceptions]

There are traditions...you have to bless her and give her dai chiura; she has to eat many things. In that time, I think she ate curd and more sweet food; that is why her blood sugar level is high again. [Spouse of a patient with GDM on social/cultural barriers to blood glucose management]

All participants agreed that the proposed mobile app and features would be useful and relevant to women with GDM. They believed it would help overcome existing barriers by empowering pregnant women with information and tools to manage GDM and track their progress.

If we had seen this app before, I think we would have been able to control blood sugar levels, and we would have been able to plan. I think after seeing this, it would have helped, it would be useful. [Spouse of a patient with GDM on the GDM-DH mobile app]

Just knowing that this app on its own records and tells you about your physical activity makes us alert…we will know how much more activity we need to do…it makes it easier. [Patient with GDM on the GDM-DH mobile app]

However, both patients with GDM and health professionals requested more content with respect to medical management and diet/lifestyle modification for GDM. Based on findings from the qualitative study, we changed some app features and design elements (eg, data visualization), in addition to modifying the educational materials and other resources to further tailor the GDM-DH app culturally. For example, the educational modules were revised to address specific cultural and social challenges faced by our patients (eg, food-centered festivals, long-held dietary/cultural practices surrounding pregnancy), and appropriate strategies were provided to problem-solve around these barriers. Based on our target users’ suggestions, we added example meal plans with locally available and culturally staple foods, video demonstrations of safe and culturally staple foods, video demonstrations of safe and culturally relevant exercises during pregnancy (eg, yoga, mild hiking, walking), and revised visual aids for carbohydrate estimation to include standardized pictures of staple Nepalese foods with common portion sizes shown in locally used utensils, such as plates, bowls, and cups.

**Usability Testing**

In total, 18 newly diagnosed patients with GDM participated in the usability testing [29] with the MVP. The mean age of patients in the usability testing was 28.8 (SD 3.3) years. All patients were married, and slightly more than half (n=10, 55.6%) were homemakers. The mean gestational age was 27.2 (SD 3.0) weeks, and the average number of years of schooling was 13.3 (SD 2.8) years.

Results from the think-aloud protocol are described in Table 1. The mean usability score across the 10 tasks was 3.50 (SD 0.55; maximum score=5 for very easy). The task completion rates ranged from 55.6% (n=10) to 94.4% (n=17) across the 10 tasks, with the lowest completion rate for the task requiring the patients to look up their next scheduled appointment on the app. All patients except 1 (5.6%) were able to successfully complete tasks requiring them to enter their weight and systolic and diastolic pressure into the app.

**Modifications to the GDM-DH App After Usability Testing**

Findings from the focus group, interviews, and usability testing were reviewed to identify recurring themes of feedback with respect to the GDM-DH app’s content, usability, navigation, and functionalities. These findings allowed us to gain insight into participants’ thought processes with regard to app use, places where they encounter difficulties, and ways to improve the app’s usability. As shown in Textbox 1, these themes served as valuable insights that were used by the app developer to address the key usability barriers and participants’ preferences/feedback and develop a final version of the GDM-DH app for testing in a pilot clinical trial. For example, considering that nearly half of the usability testing participants struggled in identifying their upcoming antenatal appointments, we decided that the upcoming appointments would be shown in a list, in addition to the calendar. Additionally, we included a comprehensive video tutorial on how to navigate the GDM-DH app and use its features. In the web-based portal, in addition to the features decided on by the research team and software development company, we incorporated new features requested by the providers, including a patient finder tool, data export customization, and additional analytics in the dashboard, such as the average number of antenatal visits per patient and the percentage of patients under medical therapy for GDM.
Textbox 1. Modifications requested and incorporated in the Garbhakalin Diabetes athawa Madhumeha—Dhulikhel Hospital (GDM-DH) app based on user research and usability testing among target users (women with gestational diabetes mellitus [GDM]) in Dhulikhel Hospital, Nepal.

Educational resources
- Use simple and clear language in educational resources, avoiding jargon and using terms understandable to the target users.
- Provide clear guidance on healthy food selections and appropriate portion sizes, including example meal plans with locally available foods.
- Clarify common misconceptions around diet and physical activity during pregnancy.
- Address specific cultural and social challenges faced by target users with respect to diet/lifestyle modification and provide appropriate strategies to problem-solve around those barriers.
- Add information about the signs and symptoms of hypoglycemia, along with practical strategies for effective management.
- Clarify criteria for when insulin or medication is indicated for GDM.
- Add examples of physical activity and exercise videos that are appropriate for pregnant women.
- Include information about contraindications for physical activity during pregnancy, including warning signs to stop exercising.
- Add an educational module on how family members can provide support to women with GDM.

App interface and features
- Use bigger font sizes; enlarge and make the images clearer.
- Revise the visual aids to include standardized pictures of common food portion sizes in locally used utensils, such as plates, bowls, and cups.
- Add reminders to input blood glucose, weight, diet, and blood pressure data.
- Use pop-ups to confirm data input and avoid double entries.
- Use bar graphs instead of line graphs to present blood glucose, weight, and blood pressure visualizations.
- Make glucose, weight, diet, and blood pressure data visible both as a list and in graphical format.
- Show upcoming appointments in a list, in addition to the calendar.
- Add the hospital hotline number under Help and Support.
- Include a video tutorial on how to navigate the GDM-DH app and use its features.

Web-based portal
- Include a patient finder feature to search for a patient quickly.
- Add a function to customize data export based on specific parameters and layout.
- Add dashboard analytics based on patient data (eg, average number of antenatal visits per patient, percentage of patients under medical therapy for GDM)

The decision to retain or disregard the requested modifications was based on their potential influence on behavioral and clinical outcomes, budget feasibility, the implementation time frame, and their potential impact on the app’s scalability in the future. For example, meal plans were added because they could be easily incorporated with minimal time and cost but would have maximal health gains. However, our target users also suggested that we add a feature to connect and chat with other app users with GDM, as well as a platform to communicate directly with health care providers via the app; these features were not added due to logistical, technical, and funding constraints but may be considered in the future.

Final GDM-DH App
Based on the SCT framework, the final version of our culturally tailored GDM-DH app supports GDM management by providing patient education, reinforcing regular blood glucose/carbohydrate/weight monitoring, increasing self-efficacy for diet/lifestyle modification, and facilitating clinical and social support. A detailed description and justification of the app features as well as their alignment with the SCT constructs are provided in Table 2.
Table 2. Description and justification of the GDM-DH\textsuperscript{a} app features designed for self-management and treatment of Nepalese women with GDM\textsuperscript{b}.

Mobile App

The mobile app, which is patient facing, includes 6 feature icons on its home page: (1) Blood Glucose, (2) Food Intake, (3) Blood Pressure, (4) Weight, (5) Physical activity, and (6) Appointment (Figure 2). Using these features, the app allows patients to record and self-monitor their blood glucose, blood pressure, carbohydrate intake, physical activity, and GWG and track them over time. The app has a goal-setting feature and uses innovative technological features to minimize the self-monitoring burden, such as visual aids for carbohydrate estimation and integration with the Google-Fit app to automatically log physical activity data. Based on the data entered, the app provides automatic feedback about blood glucose, blood pressure, and GWG via a feedback engine that compares the user data to existing guidelines and recommendations. The app also generates visual displays summarizing their blood glucose, blood pressure, diet, physical activity, and weight patterns, allowing the user to easily monitor their alignment and progress toward target goals. In addition to the self-monitoring features, multimedia video- and text-based modules are included in the app as educational resources. The GDM-DH app also includes a social network “follow” feature, allowing the user to list 1 or more friends/family members as contacts in the app and give them the permission to view their logged data or progress summary. The app has an in-built calendar, which the users can use to record and view upcoming antenatal appointments.
Figure 2. Key app features of the GDM-DH app designed for self-management and treatment of Nepalese women with GDM. GDM: gestational diabetes mellitus; GDM-DH: Garbhakalin Diabetes athawa Madhumeha—Dhulikhel Hospital.

Web-Based Portal
The web-based portal can be securely accessed by researchers and health care providers from any device that supports modern web browsers. The web-based portal has features for patient management, data capture and review, and data dashboard/visualization. Health care providers can register a new patient; enter, update, or review clinical and other patient-related information (patient vitals, measurements, clinical notes, medications, etc); and schedule or make changes in appointments. Using Apache Kafka, the web-based portal syncs with the mobile app and allows providers to access data and graphs summarizing the patient’s diet, physical activity, weight, blood pressure, and blood glucose patterns. This streamlines the providers’ workflow and allows them to easily track patient progress and accordingly guide their treatment and counseling.
Researchers and admin users can use the web-based portal to add new users, add/update the app modules/images/visualization, and audit changes made by users.

Data Security

Data from the mobile app are stored in a HIPAA-compliant, secure server hosted by Amazon Web Services. MongoDB is used to implement the database service, which is a free, open source, no–Structured Query Language (no-SQL) database program tailored to support big data. It is encrypted and access-controlled using tokens to ensure it cannot be accessed outside the app. Apache Kafka is the core of the streaming service to ensure reliability, high availability, and scalability. All communications are transmitted using the Secure Sockets Layer (SSL) standard protocol, and data are encrypted at rest to ensure security. App access is controlled using a secure username-password combination.

Discussion

Principal Findings

Self-management of GDM is vital for controlling blood glucose levels and minimizing complications for both mother and baby [10,52]. In this paper, we described the design and development of GDM-DH, a culturally tailored GDM management app targeted for use among patients and health care providers in Nepal. Following the SCT framework [53], the GDM-DH app assists in self-management of GDM by enhancing the patients’ knowledge of and self-efficacy in adhering to blood glucose monitoring and recommended diet and physical activity regimens. With respect to the health care providers, the app’s web-based portal offers easy data visualization to track patient progress and treatment response, facilitating informed clinical decision-making at the point of care.

The growing literature highlights the importance of culturally tailoring health interventions, that is, adapting the intervention content and instructions according to the target users’ culture, diet, language, religion, customs, and beliefs [54-56]. Several studies [56-59], including systematic reviews [60], have found that culturally tailored programs and interventions are effective at improving disease knowledge, behavioral outcomes (eg, physical activity), access to care, and clinical outcomes, including glycated hemoglobin (HbA1C) levels in patients with diabetes. Our GDM-DH app development incorporated a user-centered design approach that actively involved end users and used ethnographic and human-computer interaction methodologies to better understand and meet their needs. The user-centered design approach is especially paramount to developing culturally tailored mobile interventions, ensuring app engagement, and promoting digital health equity in low-income countries, such as Nepal [54].

Although mobile technology has been widely applied and proven efficacious for self-management of diabetes outside of pregnancy [29,32,41,61], mobile app–based lifestyle interventions for GDM are just emerging, even in high-income countries [62-68]. To date, there are only a few published randomized controlled trials that have evaluated mobile app–based solutions for GDM management [63-68]. Two recent reviews [69,70] on app-based interventions for GDM concluded that most existing studies were of moderate quality and were underpowered to detect effects on perinatal outcomes but, overall, indicated improved glycemic control in the mobile intervention groups compared to standard care alone. However, most existing app-based interventions for GDM management focus on remote blood glucose monitoring, with manual feedback from health care providers [24,69,70], which can be resource intensive and burdensome for both providers and participants, thus limiting the potential for widespread dissemination and impact, particularly in low-resource settings, such as Nepal. Additionally, despite evidence showing that lifestyle and T2D interventions based on behavior change theory are more effective [71-73], we found only 2 studies [67,68] that incorporated relevant theories in their mobile intervention for GDM. Furthermore, only 2 studies [65,67] involved input from target users during app design and development, which is critical for ensuring the effectiveness and acceptability of evidence-based interventions [74].

Strengths

Our GDM-DH app overcomes existing limitations and represents an advance over previous mobile interventions for GDM as it provides a comprehensive solution for GDM management without the need for additional work from health care professionals and incorporates user-centered principles and theory-based BCTs to meet the specific needs and technological literacy of our target users. To the best of our knowledge, the GDM-DH app is also the first to contain a social support component by including a social network feature. Although the educational content and custom food tracker (and visual aids for calorie/carbohydrate estimation) in our GDM-DH app were specifically designed for our target population of Nepalese women, they can be easily adapted and scaled to other contexts and populations by applying similar user-designed principles.

Limitations

Several limitations of the GDM-DH app and its development process are worth mentioning. First, the number of participants in our usability study was limited. Additionally, during usability testing, we may have observed the best-case scenario for comfort and confidence in using the app, leading us to overestimate the true usability and technological proficiency. Second, we did not use a structured framework, such as the Delphi method [75], to organize and structure the discussions to guide our GDM-DH app and intervention development, which will make it difficult for others to replicate our study procedures. Nonetheless, we used many of the elements of the Delphi framework, including an iterative approach, the use of experts, and group-based responses. Similarly, although we did not use a structured framework to guide the modification and optimization of the GDM-DH app and intervention content, our prespecified criteria, including feasibility, scalability, and affordability, align with existing frameworks designed to optimize and evaluate an intervention prior to implementation (eg, multiphase optimization strategy, or MOST [76], and Acceptability, Practicability, Effectiveness, Affordability, Spill-Over Effects, and Equity, or APEASE [77], criteria). Due to resource limitations, we were unable to address all the needs and...
suggestions provided by our target users. For instance, the current version of the app has limited social support, but future versions could incorporate features such as a discussion forum to foster a stronger network and support system among users. The manual entry of blood glucose and blood pressure levels is also a limitation. Since the app was designed to address the cultural barriers and technological literacy of a specific population, generalizability is a potential issue, and adapting the app to other settings and contexts would require a similar level of user research and testing among the target populations. Large-scale cluster-randomized clinical trials at multiple urban and rural sites in Nepal are needed to establish the effectiveness and generalizability of the GDM-DH app to women with GDM across the country.

Future Research

In the future, we plan to further optimize the GDM-DH app by including Bluetooth-enabled data entry and advanced smartphone functionalities, such as multimedia push notifications, and gamification features, which have been shown to increase retention and improve engagement with mHealth interventions [78-80]. Push notifications enable on-the-go delivery of intervention content, providing the necessary trigger and reinforcement when the specific intervention is most needed or is most convenient for the user. Gamification (application of game elements) features provide entertainment and intrinsic/extrinsic motivation (eg, point scores, badges, levels, a leaderboard) to promote sustained engagement with the app [81-85].

Conclusion

The GDM-DH app targets specific needs identified by our target population in our pilot research and has unique features, including a social support feature, visual aids for carbohydrate estimation, and a comprehensive support system without imposing an additional provider burden. A proof-of-concept pilot clinical trial (NCT04198857) to study the feasibility, acceptability, and preliminary efficacy of the GDM-DH app is currently underway.

Abstract

Background: Clinically elevated preoperative distress and anxiety are common among patients undergoing cancer surgery. Preoperative interventions have been developed to mitigate this distress and anxiety but are inconsistent in efficacy and feasibility for broad implementation.

Objective: This preliminary pilot study aims to assess the feasibility and utility of a newly developed virtual reality (VR) intervention to expose patients awaiting breast cancer surgery to the operating room environment and a simulation of anesthetic induction.

Methods: Patients undergoing breast cancer surgery (N=7) were assigned to the VR intervention or control (treatment as usual) group and completed self-report measures of distress and anxiety before surgery, on the day of surgery, and after surgery (5 and 30 d postoperatively). Those in the intervention group trialed the VR simulation 1 to 2 weeks preoperatively and provided qualitative and quantitative feedback. We assessed the feasibility of recruitment capability and study design and evaluated participants’ impressions of the intervention using self-report rating scales and open-ended questions. We also descriptively examined distress and anxiety levels throughout the duration of the study.

Results: Recruitment occurred between December 2021 and December 2022 and progressed slowly (rate: 1 participant/7 wk on average; some hesitancy because of stress and being overwhelmed). All participants who consented to participate completed the entire study. All participants were female and aged 56 (SD 10.56) years on average. In total, 57% (4/7) of the participants were assigned to the intervention group. On average, intervention participants spent 12 minutes engaged in the VR simulation. In general, the intervention was rated favorably (eg, clear information, enjoyable, and attractive presentation; mean % agreement 95.00-96.25, SD 4.79-10.00) and as helpful (mean % agreement 87.50, SD 25.00). Participants described the intervention as realistic (eg, “It was realistic to my past surgical experiences”), impacting their degree of preparedness and expectations for surgery (eg,
"The sounds and sights and procedures give you a test run; they prepare you for the actual day"), and having a calming or relaxing effect (eg. "You feel more relaxed for the surgery").

Conclusions: This preoperative VR intervention demonstrated preliminary feasibility among a sample of patients undergoing breast cancer surgery. Results and participant feedback will inform modifications to the VR intervention and the study design of a large-scale randomized controlled trial to examine the efficacy of this intervention.

Introduction

Preoperative Distress
Preoperative distress, a situational emotional reaction (eg, fear, worry, and helplessness), is common among surgical patients [1,2]. Extant research has identified several adverse health-related perioperative outcomes of preoperative distress in both the presence and absence of a mental disorder [3-7]. In particular, patients undergoing surgery experience clinically meaningful elevated rates of preoperative distress, ranging from 23% to 77% in recent research [8-10]. Preoperative distress is also associated with various adverse health-related outcomes for patients undergoing surgery specifically, including increased postoperative pain, nausea, discomfort, and fatigue, among others [11-15]. In recognition of its detrimental impact, the National Comprehensive Cancer Network (NCCN) designated distress as the "6th vital sign" [16].

Preoperative Psychological Interventions
Receiving a cancer diagnosis is a significant and life-altering event, often intensified by the necessity for major surgical intervention and an uncertain health trajectory. In considering the adverse health implications of psychological distress, several preoperative interventions (eg, education, relaxation training, and stress management) have been developed that seek to improve psychological and physical functioning before surgery by establishing realistic expectations of the surgical process and helping patients cope with surgery-related uncertainty and distress [17-24]. However, the literature reveals conflicting evidence regarding the efficacy of many such interventions [17-23]. Importantly, the interventions that are supported by evidence require delivery by licensed health care providers [21,22] and often require multiple sessions, rendering them impractical for large-scale implementation, particularly within the constraints of a publicly funded health care system.

Virtual Reality Interventions
Virtual reality (VR) interventions have shown considerable promise in reducing psychological distress in nonsurgical contexts [25-30]. Research in this area has examined the effectiveness of VR exposure therapy for the treatment of anxiety and posttraumatic stress disorder [25,27,28,31-33], where the user virtually and systematically confronts feared content to overcome anxiety. Patients often prefer using VR for exposure therapy over traditional in vivo exposure [34,35], and it may also be more straightforward to administer. This innovative technology has also been gaining popularity in broader medical contexts and has shown promising results in pain management [36-40] and cognitive and physical rehabilitation among various medical populations [37,41-43]. In contrast to therapist-guided VR exposure used in mental health settings, which may be used as a component of one-on-one psychotherapy over a duration of months, VR interventions developed for use in medical settings do not typically require a specialized health care professional to administer and can often achieve desirable outcomes following a shorter duration of use [37,44-47].

Preparatory Interventions for Stress Exposure
In a preoperative context, VR could be used to psychologically intervene before patients develop clinically elevated distress and are affected by the adverse downstream effects of distress (while also targeting any existing distress about surgery). This is similar to stress inoculation training, a form of cognitive behavioral intervention, aimed at psychologically preparing individuals for future exposure to a stressful environment through preliminary exposure to elements of that environment [48]. This form of intervention has been adapted using VR technology [48-52], and preliminary evidence supports reductions in predeployment distress for military personnel using such interventions to prepare for combat [50,53,54]. In fact, similar methods have been applied to psychologically prepare patients before surgery, including operating room (OR) tours before surgery [55], given that the OR environment is noted as distressing for many surgical patients [3,56,57]. Although this intervention was associated with reductions in preoperative distress [55], it has limited feasibility for broad administration because of the infrequent availability of ORs for such purposes and the limited resources and personnel to implement this intervention.

Preoperative Applications of VR
The use of VR to expose patients to the OR environment and preoperative process resolves some of these limitations. A few studies have implemented such interventions to target preoperative distress and other perioperative outcomes, largely among pediatric patients (all but one of the identified studies) undergoing variable types of surgeries (eg, general, neurological, and plastics or ear, nose, and throat) [58-64]. Small-scale meta-analyses examining this literature support the initial efficacy of such interventions in reducing preoperative distress [65-67], although some studies have used VR distraction interventions (eg, using games or relaxation) as opposed to
exposing users to the OR environment. Importantly, this research is in its infancy, and only a few studies exist in this area to date, supporting the need for further exploration.

Gaps in the Literature

Although the preoperative VR interventions described in the preceding section demonstrate preliminary efficacy in mitigating preoperative distress and potential for broad implementation within the constraints of our health care system (ie, relatively low cost, do not require specialized professional training to administer, can be used repeatedly in different settings, translated into multiple languages, and adapted across surgery types), studies examining these interventions are not without limitations. First, most studies in this area have focused on samples of pediatric patients undergoing surgery; further research is needed to establish the efficacy of such interventions among adult patient samples. Second, no identified studies to date have evaluated a preoperative VR intervention using patients scheduled to undergo an oncological procedure, a population with elevated levels of preoperative distress [8-10]. Third, existing preoperative VR interventions have limited immersion capabilities (eg, lack of user embodiment [ie, the ability to visualize and manipulate virtual representations of the user’s body] and use of prerecorded virtual videos as opposed to a fully immersive virtual environment), which may weaken their impact on mitigating distress through reduced realism. Fourth, these studies lacked follow-up data beyond the acute postoperative phase (eg, <1 wk after discharge), which is needed to understand the long-term impact on postoperative recovery. Finally, many of these studies did not gather user feedback on the intervention, which is vital to help maximize the potential impacts of these interventions.

This Study

In light of these identified gaps, this study aims to assess the feasibility of, and preliminarily pilot (in case series format), a novel VR OR simulation targeting preoperative distress and anxiety among a sample of patients undergoing breast cancer surgery. Specifically, regarding feasibility, the aims are to assess recruitment capability and identify resulting sample characteristics, understand participants’ impressions of the study design and intervention, and evaluate data collection procedures and outcome measures. Finally, this study will also pilot-test the preliminary impact of the intervention on perioperative distress and anxiety in a case series format. The results of this study will inform modifications to the VR simulation and the design of a large-scale randomized controlled trial (RCT) to evaluate the efficacy of this intervention.

Methods

Overview

This study used a single-blind randomized design to assess the feasibility of and pilot the VR simulation to expose patients undergoing breast cancer surgery to the OR and preoperative process. This study represents an in-depth preliminary analysis of a larger pilot study (ClinicalTrials.gov; NCT04544618). Participants were assigned to the VR intervention group or the treatment-as-usual (control) group at the time of recruitment. Randomization was stratified according to the type of breast cancer surgery (with vs without reconstruction) and whether neoadjuvant chemotherapy was received to enable equal proportions of participants with these characteristics across study groups; research demonstrates differences in distress levels according to these factors [68]. All participants completed self-report measures 1 to 2 weeks before surgery (ie, baseline; VR group participants tested the intervention at this time), on the day of surgery, 5 days after surgery, and 30 days after surgery. Notably, the initial planned design included a third study arm (ie, non–surgery-related VR; Nature Treks), which was ultimately dropped because of recruitment challenges. Ethical amendments were approved supporting this change (and others noted in the Recruitment Capability and Sample Characteristics section), and the trial registry has been updated accordingly.

Participants

We recruited a convenience sample of adult patients undergoing breast cancer surgery by describing the study at patients’ surgical oncology appointments and preoperative information sessions and circulating study posters. Interested patients provided their contact information to enable a telephone discussion with the research coordinator and eligibility screening (those viewing the poster contacted the coordinator directly). Participants were eligible if they were being scheduled to undergo breast cancer surgery under general anesthesia at the Health Sciences Centre (a tertiary care hospital in Winnipeg, Canada) and could speak and read English. Those unable to provide informed consent or unable to participate in a VR intervention (eg, owing to visual or auditory impairment) were excluded. Our initial target was to recruit 15 participants per group, with a study aim to evaluate recruitment capability.

Procedure

Participants randomized to the VR group trialed the intervention 1 to 2 weeks before surgery (baseline). Those in the control group received no additional intervention beyond their standard medical appointments and optional preoperative information sessions (offered to all patients). All participants completed self-report measures at baseline (those in the VR group received additional measures to assess intervention feedback). On the day of surgery, preoperative distress and anxiety were reassessed while the participants were in the preoperative holding area and again in the OR before anesthetic induction. At 5 days and 30 days after the operation, all participants were readministered a subset of the baseline measures, and those in the VR group provided additional intervention feedback at the 5-day postoperative assessment. The participants in the VR group completed baseline measures in person (at the time of the intervention), and all participants completed the day-of-surgery measures in person. All other measures were completed online through the web-based survey platform, Qualtrics (Qualtrics International Inc).

Intervention

A VR development team at the National Research Council of Canada, in collaboration with coauthors (RE and JLS), developed the VR OR simulation for use in this research (a
technical paper describing the simulation more in depth is in progress). The simulation development stages included creating an initial prototype based on the observation of surgeries and consultation with medical personnel, developing an anesthetic induction script based on example scripts provided by several anesthesiologists, integrating input from an anesthesiologist (WACM) on the initial prototype, and refining the platform through multiple iterations of feedback from coauthors. The VR simulation begins with the participant sitting on an examination table (reflected as the OR table in the simulation), wearing the VR head-mounted display, and holding the controllers (enabling user embodiment and visualization and manipulation of virtual arms). The participant is instructed to imagine it is their day of surgery, including how they might be feeling that day. The participant then spends at least 5 minutes exploring the virtual OR, which includes relevant machinery and equipment, personnel, sounds, and details such as a mammogram displayed on a computer screen. This free exploration is followed by a scripted portion, where the participant is instructed to lie supine on the virtual OR table and is taken through a mock anesthetic induction process led by the virtual anesthesiologist and nurse; the patient is prompted to answer questions similar to those they will be asked on the day of surgery (eg, name, date of birth, type of surgery, and allergies) and is virtually prepared with monitoring devices by the nurse (eg, blood pressure cuff, a pulse oximeter, and electrocardiogram stickers and electrodes). The simulation ends after the virtual oxygen mask is placed on the patient’s mouth and the screen darkens (refer to Multimedia Appendix 1). We used the Oculus Rift S VR system (Meta Platforms) with a cable connection to a laptop computer for the intervention administration.

**Ethical Considerations**

This study was approved by the University of Manitoba Health Research Ethics Board (#HS23957). All participants provided written informed consent before participation. No participant-identifying information was included with the study data. Each participant was assigned a study identification number, which was used to collate participant data over the study duration. All participants were provided with a CAD $25 (US $18.94) gift card after completing the study, and the cost of parking for those attending an intervention appointment was reimbursed.

**Measures**

**Preoperative Distress**

A total of 4 self-report measures assessed preoperative distress, including 2 preoperative-specific scales (Preoperative Intrusive Thoughts Inventory [PITI] and Amsterdam Preoperative Anxiety Information Scale [APAIS]) and 2 nonspecific visual analog scales (NCCN Distress Thermometer and adapted “Anxiety Thermometer”). The PITI and APAIS were only administered at baseline and on the day of surgery, whereas the Distress and Anxiety Thermometers were assessed at all 4 time points (and in the OR before induction). At the 5-day postoperative follow-up, the participants were asked which measure best captured their experience of distress or anxiety, which will inform the selection of the primary outcome measure for the upcoming RCT. At 5-day postoperative follow-up, they were also prompted to retrospectively rate their level of distress/anxiety from 0 (no distress/anxiety) to 10 (extreme distress/anxiety) corresponding to 8 different “events” ranging from prediagnosis (average level of distress/anxiety before receiving a cancer diagnosis) until the 5-day follow-up.

The PITI is a validated and reliable 20-item self-report measure of preoperative anxiety [69]. Items (eg, “I worry that I won’t wake up”) are rated on a 4-point scale, ranging from 0 (not at all) to 3 (most of the time). Summing the items yields a total score ranging from 0 to 60, where a score ≥15 indicates clinically significant preoperative anxiety [69]. The APAIS is a validated and reliable 6-item measure of preoperative anxiety [70]. Items (eg, “I am worried about the procedure”) are rated on a 5-point scale, ranging from 1 (not at all) to 5 (extremely). A total score is calculated by summing all items, ranging from 6 to 30, where a score ≥10 indicates clinically elevated preoperative anxiety [70]. The NCCN Distress Thermometer is a visual analog scale that resembles a thermometer, with a scale ranging from 0 (no distress) to 10 (extreme distress) [71]. This has been validated among several oncology samples [72,73]. Distress is rated using a “past-week” timeframe (modified to present time in the OR), and a cut-off score of 4 indicates clinically elevated distress [73]. Because of the common interchangeable use of the terms distress and anxiety within the perioperative and oncology literature and the lack of clear differentiation between these terms, we adapted the Distress Thermometer to create an Anxiety Thermometer.

**VR Impressions and Feedback**

Participants provided self-reported feedback on the VR simulation at 2 different time points. Feedback measures were developed in accordance with previous research [74]. After trialing the intervention, the participants were provided with a list of statements about their experience using the simulation (eg, “I found the VR intervention was helpful”), which they rated from 0% (completely disagree) to 100% (completely agree). The participants are also asked whether they experienced any motion sickness during the intervention (0 [none] to 3 [severe]), followed by open-ended questions prompting intervention impressions (eg, what they liked or disliked) and whether they found the intervention worthwhile. Finally, the participants were asked about additional elements they wished to be included in the intervention and were offered multiple response options for selection (eg, being wheeled into the OR). At the 5-day postoperative follow-up, the VR participants provided additional intervention feedback (eg, overall impressions). The participants are then asked if or how they think the intervention impacted their surgery or recovery, whether they disliked anything about it, and if they have any other suggestions for improvements. The participants are prompted to elaborate on their responses to these questions.

**Presence**

The iGroup Presence Questionnaire [75] assessed the presence associated with the VR intervention at baseline, defined as the sense of being in the virtual environment. This valid and reliable (Cronbach α= .87) self-report measure is comprised of 14 items (eg, “I had a sense of acting in the virtual space, rather than
operating something from outside”), which are rated on a 7-point scale (−3 [fully disagree] to +3 [fully agree]). Items are summed to create 3 subscale scores (spatial presence, involvement, and realism), where higher scores indicate increased presence in the virtual environment.

Sample Characteristics
Participants self-reported their sociodemographic characteristics and health history at baseline, including age (assessed continuously), sex (female or male), marital status (single, married or common law, divorced or separated, or widowed), highest level of education (high school or less or some college or higher), stage of breast cancer, type of breast cancer surgery (eg, lumpectomy or single or double mastectomy with or without reconstruction), whether they are receiving chemotherapy before surgery, history of prior surgeries, mental health service use since receiving their cancer diagnosis, and history of receiving a mental health diagnosis. Various other self-report measures were administered throughout the study (eg, assessing depression, coping, and quality of life) to determine their feasibility for inclusion in the upcoming RCT (by calculating the proportion of missing data).

Analytic Strategy
Descriptive statistics assessed the consent rate, recruitment speed, attrition rate, and sample characteristics. We calculated the participation rate among the intervention and control groups, and we assessed quantitative and qualitative intervention feedback descriptively. We then calculated the proportion of missing data, and descriptive statistics determined which measure of preoperative distress or anxiety was rated most favorably. Finally, we presented participants’ levels of distress and anxiety across the perioperative period (baseline to 30-day follow-up) descriptively in a case series format.

Results
Feasibility Aims
Recruitment Capability and Sample Characteristics
Recruitment was initiated on December 1, 2021. Between initiation and December 1, 2022, a total of 14 prospective participants were identified (n=5, 36% were identified in the final 2 months of recruitment). Of these 14 individuals, 12 (86%) contacted the study coordinator directly, 1 (7%) had their information provided by a health professional, and 1 (7%) expressed interest while attending a preoperative information session (in-person sessions were suspended until November 2022). Of these 14 individuals, 7 (50%) consented and participated, 4 (29%) were ineligible (eg, required to isolate until surgery or already had surgery), and 3 (21%) withdrew after providing verbal consent but before providing written consent (reasons: n=1, 33% too many appointments and unable to focus on anything else; n=1, 33% unwilling to come in person to try the VR; and n=1, 33% overwhelmed with family responsibilities; n=2, 67% had been randomized to the initial third arm before dropping out). The approximate recruitment speed for those who consented was 1 participant every 7 weeks, on average. In total, 57% (4/7) of the participants were assigned to the intervention group. Of those who provided written informed consent, 100% (7/7) completed the study. Because of ongoing recruitment challenges, the study target population was broadened 5 months after the initiation of recruitment to include any patients undergoing cancer surgery, as opposed to patients undergoing breast cancer surgery only. To date, no patients undergoing non–breast cancer surgery have expressed an interest in participating.

The participants were aged 56.43 (SD 10.56) years on average, and all were female. The participants were most commonly married (3/7, 43%), and the majority (5/7, 71%) had some college education or higher. The breast cancer stage of patients was most commonly uncertain or unknown (4/7, 57%). The most common surgical procedure was lumpectomy (4/7, 57%), and 43% (3/7) of the participants were planning to undergo reconstructive surgery. Most participants (6/7, 86%) had not received chemotherapy before their surgery, and most participants (6/7, 86%) had ≥1 prior surgeries. A total of 57% (4/7) of the participants reported receiving a mental health diagnosis in their lifetime (depression, anxiety, or substance use disorder), and 29% (2/7) of the participants indicated that they sought professional mental health support after receiving their cancer diagnosis. Most participants (4/7, 57% to 6/7, 86%) had clinically elevated preoperative distress or anxiety at baseline (Table 1).

**Participant Impressions of the Study Design and Intervention**

All participants assigned to the control group completed the entire study. All participants assigned to the intervention group, who provided written informed consent, tested the intervention within 2 weeks before their surgery and completed the study. The participants in the intervention group spent 12 minutes engaged in the simulation, on average, and reported variable levels of presence while trialing the VR simulation (spatial presence: mean 8.75, involvement: mean 0.75, and realism: mean ~2.50; refer to Table 2 for maximum ranges); the participants reported having a sense of being physically present in the virtual environment, with only partial attention devoted to the virtual environment, and moderate ratings of realism.

Other elements you would have liked to be included, n (%)

- Being wheeled into the OR: 1 (25)
- Try on equipment (eg, oxygen mask) while engaged in the simulation: 0 (0)
- Learn about the various machines I saw in the OR: 1 (25)
- Ask the virtual anesthesiologist or nurse questions about surgery: 1 (25)
- None of the above: 2 (50)
- Other (“real time pulse/heart rate”): 1 (25)

a OR: operating room.

There were minor technical difficulties for all 4 participants during the simulation (eg, difficulty finding the correct position lying down when prompted by the VR nurse), and the program needed to be restarted midway for 2 of the participants. In general, the participants found that the intervention presented information clearly, was enjoyable, easy to understand, and had an attractive presentation (mean: agreement range: 93.75-96.25, SD range: 4.79-10.00). It was also generally rated as helpful (mean: agreement: 87.50, SD 25.00), and all participants considered participating in the VR intervention worthwhile considering the time commitment. The participants gave mixed ratings at baseline regarding the impact of the intervention on anxiety and concerns about the OR, anesthesia, and surgery. Given a list of suggestions for elements to be added to the intervention, a single participant selected each of the following: (1) being wheeled into the OR, (2) learn about the machines I saw in the OR, (3) ask the virtual anesthesiologist or nurse questions about surgery, and (4) other: “real time pulse/heart rate.”

Regarding open-ended feedback, multiple participants commented on the realism of the intervention, the impact of the intervention on expectation formation regarding surgery, and the calming or relaxing effect of the intervention (Textbox 1).
**Textbox 1.** Qualitative intervention impressions for patients undergoing breast cancer surgery assigned to the intervention group for the feasibility and pilot study evaluating preoperative virtual reality (VR; n=4).

### Open-ended feedback (at baseline)

- **What did you like about the VR intervention**
  - “It is very realistic”
  - “It was realistic to my past surgical experiences, it was interactive and could play a bit with it”
  - “What to expect”
  - “Just getting the feel of an OR” [operating room]

- **What did you dislike about the VR intervention**
  - “Nothing”
  - “Scary”
  - “The program calibrated my body position a few times and had to be reset which is why I was more present in the real world than in the VR world”
  - “Seemed like I was waiting for an hour until it told me to lie down”

- **If you found it helpful: in what ways was the VR intervention helpful**
  - “The sounds and sights and procedures give you a test run- prepares you for the actual day”
  - “Yes”
  - “Was helpful in that it reminded me of all the noises, lights, and people necessary in an OR”
  - “You feel more relaxed for the surgery”

- **Explain why it was or was not worthwhile**
  - “Gave me information and made me think of my feelings, made me feel better”
  - “I like to help with research and I’m curious about VR and mental health initiatives”
  - “Knowing what to expect”
  - “Think I can relax a bit now when it’s time for me to have my surgery”

### Assessed 5 d after surgery

- **Overall impression of the VR intervention**
  - “It was very good, very real to life. I liked it”
  - “Head set didn’t work well”
  - “I had past surgery and it was familiar from memory and with current surgery experience”
  - “I thought it was a good way to help calm some of my fears”

- **Elements from the OR that were missing from the VR which would have been helpful to include**
  - “No I think they covered everything”
  - “If when they are putting stickers on etc. you would maybe lightly touch the spot”
  - “Not that I remember. I wasn’t paying much attention to what everyone was doing or the equipment”
  - “More condensed room, just focus on the 2 people in your face”

- **Images or experiences from the VR intervention that stuck with you following the intervention**
  - “No”
  - “The mask at the end”
  - “The nurse moved in on my too quickly and startled me because she was so close so suddenly”
  - “The lights”

- **Components of in-hospital experiences on day of surgery that would have been helpful to include in VR**
• “The waiting in the surgical admitting area. Sitting for a long time in a chair in the gown with IV pick in”
• “I didn’t get to wake up in the VR but it may be cool to wake up. You aren’t alone when they wake you up in case that unknown freaks people out”
• “The actual experience happened a lot quicker than the virtual experience. Speed up the simulation”

How, if at all, do you think the VR simulation impacted your surgery or recovery
• “It makes a person more relaxed in the operating room”
• “Once they had me in the surgery room it was very fast”
• “If I didn’t have past experience then it would have helped me a lot but I was already familiar”
• “I believe it assisted me in that I was able to see the inside of an OR”

Was there anything you disliked about the VR intervention (if yes, please describe)
• “No”
• “Sadly the program had to be reset a bunch of times because...the orientation was off. It brought me out of it”
• “It was way too long just sitting there and waiting for something to happen”

Suggestions regarding how we can improve the VR simulation
• “No it was very informative”
• “Have the room smaller and things not so far away. People need to be closer to you”

Data Collection Procedures and Outcomes Measures
Across all the time points, only 0.7% of the data were missing. Most participants (5/7, 71%) reported that, of the different measures assessing anxiety and distress, the PITI best captured their experiences.

**Retrospective Reports of Distress or Anxiety**

As shown in Figure 1, among the control group, ratings of distress/anxiety remained stable (P1) or increased (P2 and P3) between baseline (within 2-wk preoperatively) and being in the OR on the day of surgery. Among the intervention group, ratings decreased between baseline (within 2-wk preoperatively; when VR was administered) and being in the OR for 50% (2/4; P4 and P5) of the participants.

**Figure 1.** Retrospective reports of distress/anxiety among the control group and intervention group for patients undergoing breast cancer surgery participating in the feasibility and pilot study to evaluate preoperative virtual reality (VR). Blue guidelines outline the period between when the intervention group trialed the VR and participants’ day of surgery.

**Discussion**

**Overview**

To our knowledge, this is the first study to date to examine the feasibility of, and preliminarily pilot, a novel preoperative VR intervention exposing patients undergoing breast cancer surgery to the OR and preoperative process. Overall, despite some recruitment challenges, the intervention was generally rated favorably and described, on average, as 87.5% (SD 25.00%) helpful by participants. The results of this study will inform modifications made to the VR intervention and the study design of an upcoming RCT evaluating this intervention.

The newly developed VR intervention exposed patients undergoing breast cancer surgery to the OR environment (including machinery, sounds, personnel, and other medical items [eg, surgical tools and mammogram]) and preoperative process (from being seated on the OR table until completion of anesthetic induction). The simulation was developed to mimic the real-life OR and preoperative experience based on a large tertiary care hospital in Winnipeg, Manitoba. Compared with other recently developed preoperative VR interventions [58-64], this was designed to be more immersive through the integration of user embodiment (including visualization of one’s virtual body and real-time manipulation of virtual arms) and is one of the few interventions designed for adult use and the only such intervention developed and tested in Canada.

Although some technical difficulties arose during the intervention (eg, simulation needing to be restarted and slight delay in progression because of imprecise positioning of participant arm or body), likely detracting from immersion, the participants described the intervention as realistic and commented on its impact on feeling more prepared or knowing what to expect for surgery and feeling more relaxed or calm about their upcoming surgery. The participants also rated the intervention favorably in terms of enjoyment, clarity of information, attractiveness, and helpfulness. Although the sample size of this study limits our ability to establish trends regarding the impact of the intervention on distress and anxiety, the participants rated 46% to 60% agreement (SD range 38.16%-47.96%), on average, that the intervention eased their anxiety, and for half of the intervention group participants (2/4, 50%), retrospective ratings of distress/anxiety declined between trialing the intervention and being in the OR. Notably, the participants also rated 25% to 38% (SD range 28.87%-51.96%) agreement, on average, that the intervention worsened their anxiety (immediately postintervention), although they did not indicate this when providing feedback postoperatively. This may suggest the activation of the “fear structure” within the simulation, which is noted as an important component of anxiety-based exposure interventions [76].
Although preliminary data support the feasibility of the VR intervention, we encountered challenges regarding recruitment for the study. This may have been impacted by various factors including changes to surgical scheduling during the COVID-19 pandemic (noted in recent research on patients with cancer [77]), prospective participants’ reported feelings of being overwhelmed and stressed by their own health or other commitments, and a strained health care system resulting in reduced resources to support recruitment (including canceling in-person preoperative information sessions for 10 months during the recruitment period, where recruitment was planned to take place). As noted, recruitment began improving over the final 2 months of the recruitment period, wherein 80% (4/5) of the individuals who expressed interest in the study provided consent to participate. Although speculative, this may suggest an impact of the changing centrality of the pandemic on recruitment capability. Interestingly, most participants (6/7, 86%) had a history of prior surgeries, which could have resulted in an increased willingness to participate. It may be worthwhile to consider modifications to our recruitment poster (eg, including the rationale for the intervention) to entice participation from those who have not undergone prior surgery. The study design elements, including data collection, intervention engagement, and participant retention, appear feasible based on the current data.

**Strengths and Limitations**

Despite the strengths of this study, including the novel preoperative VR intervention integrating user embodiment, evaluation of the feasibility of this intervention in a population with elevated estimates of clinically significant distress [8-10], collection of qualitative and quantitative intervention feedback, and inclusion of 2 iterations of postoperative follow-up data (5 and 30 days postoperatively; to be evaluated in an upcoming larger study), this study is not without limitations. First, recruitment challenges limited our sample size for this initial study; however, these challenges provided important information regarding the feasibility of implementing a larger study in the future. Second, there were a few technical difficulties encountered when administering the VR intervention, detracting from user immersion. Finally, although not directly investigated, distress in this population (and assessed using nonspecific measures) is likely to be influenced by many factors in addition to surgery. This particular intervention may not be very beneficial or impactful for those with primarily non–surgery-related distress.

**Implications**

Importantly, these limitations, along with the data collected as part of this study, provide important insights to inform modifications to the intervention and study design before the implementation of a large-scale RCT to evaluate the efficacy of this intervention. Regarding recruitment, we will consider ways to target enhancing the involvement of health care professionals in spreading awareness of the study to potentially eligible patients while continuing to attempt recruitment at the newly reinstated in-person preoperative information sessions. In addition, we will consider including additional information about the intervention (and thus removing participant blinding) as part of the recruitment process. Changes to consider for the VR simulation include modifying requirements for the user’s body positioning to avoid unnecessary interruptions and potentially adding elements that participants noted would have been helpful (eg, the opportunity to learn about OR machines and ask questions to the virtual anesthetist or nurse). On the basis of participant feedback, this intervention has the potential to reduce levels of preoperative distress/anxiety by helping participants form more realistic expectations of the day of surgery before their operation (thus potentially reducing their perception of threat associated with the preoperative experience and enhancing their perceived ability to cope with this stressor).

In line with recommendations based on other VR exposure-based interventions [78], having repeated exposure to the simulation may enhance the potential impact on mitigating distress/anxiety. Thus, it may be beneficial to assess the utility of providing participants with a 2D “screen-capture” video recording of their VR trial to watch on their own device multiple times in between trialing the intervention and their surgery. This may be an important avenue for future research evaluating this intervention.

Overall, this study established the initial feasibility of a novel preoperative VR intervention to expose patients undergoing breast cancer surgery to the OR and anesthetic induction process. These results will inform the study design of an upcoming large RCT to further examine this intervention. Participant feedback supports the utility and acceptability of this intervention and will inform future adaptations to the simulation. If demonstrated as efficacious in upcoming research, this intervention has the potential to be adapted across multiple surgery types and implemented on a broad scale to help mitigate preoperative distress.

Abstract

Background: Health misinformation can adversely affect individuals’ quality of life and increase the risk of mortality. People often fail to assess the content of messages before sharing them on the internet, increasing the spread of misinformation. The problem is exacerbated by the growing variety of digital information environments, especially social media, which presents as an effective platform for spreading misinformation due to its rapid information-sharing capabilities. Educational interventions have been developed to help consumers verify the validity of digital health information. However, tools designed to detect health misinformation on social media content have not been validated. Given the increased use of social media platforms, particularly WhatsApp, it is crucial to develop tools to help consumers assess the credibility of messages and detect misinformation.

Objective: The main objective of this study is to develop and assess an educational tool aimed at educating consumers about detecting health misinformation on WhatsApp. The secondary objective is to assess the association between demographic factors and knowledge levels.

Methods: The study used a single-arm, pre-post intervention design to evaluate the effectiveness of an educational video in improving participants’ ability to detect health-related misinformation in WhatsApp messages. In the first phase, an educational video intervention was developed and validated. In the second phase, participants were invited to complete a web-based survey that consisted of pre-evaluation questions, followed by the educational video intervention. Subsequently, they were asked to answer the same questions as the postevaluation questions.

Results: The web-based survey received 485 responses. The completion rate was 99.6\% (n=483). Statistically significant associations existed between knowledge level and age, gender, employment, and region of residence (P<.05). The video intervention did elicit a statistically significant change in the participants’ abilities to identify misinformation in WhatsApp messages (z=−6.887; P<.001). Viewing the video was associated with increased knowledge about the following concepts: checking the “forwarded” label (P<.001), looking for spelling and grammatical errors (P<.001), analyzing the facts (P=.03), checking links (P=.002, P=.001), and assessing the photos and videos (P<.001). There was a statistically significant difference in knowledge level before and after the intervention (P<.001).

Conclusions: This study developed and evaluated the effectiveness of an educational video intervention to improve health misinformation identification on WhatsApp among the Saudi Arabian population. The results indicate that educational videos can be valuable tools for improving participants’ abilities to identify misinformation. The outcomes of this research can contribute to our understanding of what constitutes an effective tool for enhancing health misinformation awareness. Such interventions...
may be particularly useful in combating misinformation among Arabic-speaking populations on WhatsApp, which may ultimately improve eHealth literacy. Limiting the prevalence and impact of misinformation allows people to make better-informed health decisions.

Introduction

Background

Researching health problems and learning about health via the internet has become a prevalent practice [1]. The level of credibility of this health-related information and the way it is used by patients, caregivers, and other health consumers has garnered the attention of health care providers and authorities [2]. There are many inaccurate sources of information on the internet, and this can lead to users becoming misinformed. According to Chou et al [3], health misinformation is defined as any health-related factual claim that is false according to recent scientific evidence. Misinformation about health can adversely affect quality of life and even increase one’s mortality risk [1].

When the COVID-19 pandemic first started, the amount of information related to this new global pandemic increased at an unprecedented rate. The volume of information, as well as the rate at which new information appeared, increased rapidly [4]. Global pandemics such as COVID-19 are likely to lead to the increased spread of misinformation as people explore massive amounts of information about the disease and its health implications. The term “infodemic” is used to describe the current media environment, which is characterized by an overflow of both true and false information. During the pandemic, individuals generally look for accurate, unbiased information, but these sources may be hidden among misinformation spread through the infodemic [5].

Due to its capacity to rapidly disseminate information, social media can serve as a platform for the propagation of misinformation. The abundance of available information can lead to the predominance of misinformation, thus negatively affecting cognitive, logical, and decision-making capacities. WhatsApp, Twitter, and Facebook are the most commonly used social media platforms for spreading false information. Since the beginning of the COVID-19 pandemic, internet use has expanded worldwide, which has resulted in the proliferation of incorrect information via social media [6].

Saudi Arabia, with a population of over 35 million, is the second largest Arab country [7]. The COVID-19 pandemic has had a significant impact on internet usage in Saudi Arabia, with a reported increase to 91.2% (n=28,775,889) in 2020. This represents a rise of 2.6 percentage points compared to the previous year [8]. Alshareef and Alotiby [6] used a web-based survey to investigate the most widely used social media platforms in Saudi Arabia, the proportions of Saudi Arabsians who used these platforms to share information, and these users’ perceptions of the medical information shared on these platforms. According to their survey results, WhatsApp was used by 52.4% (n=144) of health care workers and 51.3% (n=500) of non-health care workers to circulate information. The findings of their study concluded that WhatsApp is the most commonly used social network among Saudi Arabians. COVID-19–related information is, therefore, more likely to be shared on this application [6].

Another study by Alasmari et al [9] found that social media platforms, with their capacity to quickly disseminate information, comprised the primary source of falsehoods spread in the community. Based on an examination of the social media platforms, the study revealed that WhatsApp users accounted for approximately 46% (n=41) of rumor sources on the internet in Saudi Arabia.

Additionally, research by Tan et al [10] examined daily WhatsApp use for receiving, forwarding, or discussing COVID-19–related content a in 1-week period. The results indicate that almost every respondent participated in conversations about COVID-19. However, users were more likely to share or receive forwarded messages than to engage in active, original conversations about COVID-19. A high volume of forwarded messages was observed; this is concerning because the developers of WhatsApp have linked forwarded messages with misinformation.

People rarely assess the content of messages before sharing them on social media platforms, and they frequently fail to verify whether the messages are accurate. Educating consumers about identifying misinformation and dealing with the infodemic is essential. The false information epidemic compromises public health as misinformation spreads throughout social media. It is critical to increase awareness about the nature of social media and how to use it effectively. Personal responsibility is the first and most crucial step in safeguarding our community from the harmful phenomena of misinformation [11].

To effectively access health-related information on the internet, consumers must be able to assess the quality of the information that they find. This is a crucial aspect of eHealth literacy. It remains difficult for digital health consumers to determine the quality of the information placed in front of them. The problem becomes more complex as the digital information environment becomes more complicated and heterogeneous, especially with the rise of social media, where anyone can spread information about health and where low-quality and misleading information...
Several interventions have been developed to assist consumers in verifying the validity of digital health information [12]. A systematic review by Cusack et al [13] examined studies on educational interventions that aimed to improve knowledge of essential concepts, enabling health interventions to be evaluated for their impacts. According to the study, educational interventions, at least in the short term, can increase people’s knowledge and skills in evaluating health claims.

For the detection of health misinformation, interventions have been established based on instruments that allow anyone, including those with no prior medical background, to differentiate fact from fiction. However, these tools were designed for lengthy texts (such as text found on websites) and have not yet been validated for detecting health misinformation in social media content [14]. The majority of the tools developed were used to assess the quality of websites that provided health information. Considering the increased use of social media platforms—primarily WhatsApp—in Saudi Arabia for sharing health information, it is essential to develop tools that help consumers assess the credibility of messages and detect misinformation.

The first World Health Organization Infodemiology conference for managing the infodemic suggested evidence-based analysis and interventions to reduce the harmful effects of health misinformation during acute health events. Among the recommendations was the development of interventions that address factors that impact trust and resilience to misinformation at the individual, community, cultural, and societal levels [15].

**Theoretical Background**

A low level of health literacy has been recognized as one of the factors contributing to the infodemic. Other contributing factors include the widespread use of social media, quick publication processes, and preprint services. Rumor-spreading behavior also plays a role in the infodemic as do anxiety, distress, and fear [16]. According to a systematic review by Diviani et al [17], health literacy is essential when evaluating digital health information. Individuals’ abilities to find, evaluate, and use health information empowers them to actively deal with the misinformation they encounter on social media. In order to prevent people from automatically accepting health rumors as facts, health literacy must be improved [18].

In this research, the educational intervention concept was guided by the inoculation theory and the message interpretation process theory. According to the inoculation theory, previous experience helps individuals combat future attacks [19]. For example, literacy interventions may help audiences resist harmful media messages by providing them with the knowledge and skills necessary to reject them [20]. Based on the message interpretation process theory, exposure to message interventions influences subsequent decision-making when dealing with harmful information [21]. Both theories identify the role of an intervention or prior messages in influencing the cause of action [22].

The choice of the intervention media was guided by the cognitive theory of multimedia learning, which is built from the cognitive load theory and states that working memory contains 2 channels for acquiring and processing information: an auditory or verbal channel and a visual or pictorial channel. Although each channel has a limited capacity, the 2 can be used together to integrate new information more easily. Working memory can function at its best when both channels are used. However, 1 or both channels can become overloaded by a heavy cognitive load. It is possible to improve learning through the use of multimedia learning materials that manage the cognitive load across both channels. Furthermore, the cognitive theory of multimedia learning states that any learning should involve cognitive processing to be meaningful. Cognitive processing requires a learner to pay attention to the material presented, organize it mentally, and integrate it into prior knowledge [23].

**Objectives**

The main objective of this study is to develop and assess an educational tool aimed at educating consumers about detecting health misinformation on WhatsApp. The secondary objective is to assess the association between demographic factors and knowledge levels.

**Methods**

**Study Design**

The study used a single-arm, pre-post intervention design to evaluate the effectiveness of educational video in improving participants’ ability to detect health-related misinformation in WhatsApp messages. The study’s first phase was developing and validating an educational video intervention. In the second phase, participants were invited to complete a web-based survey that contained pre-evaluation questions, the intervention, and postevaluation questions.

**Participants**

A web-based survey was distributed among the general Saudi population from November 24 to December 25, 2022. The survey was disseminated through social media networks (WhatsApp, Instagram, Twitter, Facebook, and Telegram), and the data were collected using Google Forms. It has been estimated that 82% (n=29.50 million) of Saudis use social networks daily, with varying usage rates among different platforms. Among these platforms, WhatsApp is the most widely used social network with 87.4% (n=30.67 million) of internet users in Saudi Arabia, followed by Instagram (n=27.40 million, 78.1%), Twitter (n=25.23 million, 71.9%), Facebook (n=22.25 million, 63.4%), and Telegram (n=20.88 million, 59.5%) [24]. In order to target a wide range of the population, the web-based survey was disseminated across all of these social media platforms.

The study population consisted of social media users in the general population of the Kingdom of Saudi Arabia. The inclusion criteria were (1) having the ability to complete an anonymous survey questionnaire on the internet, (2) being at least 18 years of age, and (3) understanding Arabic.
The sample size was calculated using the Raosoft sample size calculator, based on the total population of Saudi Arabia (n=35,013,414), with a 95% CI [7,25]. This calculation yielded a minimum sample size of 385 using absolute error or precision of 0.05. This sample size is sufficient to detect a difference between pre and postscore with an effect size of 0.15 (small effect size) using a power of 80% and \( \alpha \) of .05.

The study population was targeted using a convenience sampling technique with no predetermined sampling frame. Convenience sampling is a nonprobability method in which individuals are sampled simply because they are “convenient” data sources [26].

Several specific methods were used for the recruitment process. First, as there are social accounts run by the public to share news and announcements related to each region in Saudi Arabia, the survey was distributed to these public social networking groups on various social media platforms. Second, the researchers approached social media influencers on different platforms to spread the survey to more participants. Third, the researchers asked all their social media contacts to consider completing the survey and sharing it with their contacts on social networks.

The web-based survey had 4 sections. In the first section, the participants were asked to provide demographic information. In the second section, they were given a set of pretest questions asking them to identify whether a WhatsApp message contained correct or false information. In the third section, the participants were shown an educational video. After finishing the video, the participants moved to the last section, which contained the same set of questions as the pretest.

There were no records of participant identity, and confidentiality was ensured. Upon completion of the survey, a message of thanks appeared. No incentives were offered for completing the survey.

### Intervention (Educational Video)

#### Educational Video Design

This study used a short video intervention. The content of the educational video was developed based on three sources: (1) the recommendations on WhatsApp’s official website regarding how to prevent the spread of misinformation; (2) the World Health Organization’s (WHO’s) advice on how to navigate the infodemic and identify misinformation; and (3) the CRAAP test, a tool for evaluating the quality of a social media source by assessing its currency, relevance, authority, accuracy, and purpose [27-29]. The educational tool introduced 6 concepts that could be used to assess and identify misinformation in WhatsApp messages. These concepts included checking the “forwarded” label, looking for spelling and grammatical errors, reading beyond the headline, analyzing the facts, checking links, and assessing photos and videos (Table 1).

#### Table 1. Concepts used in the video to evaluate and identify misinformation in WhatsApp messages.

\(^a\)WHO: World Health Organization.

The design of the educational video was based on literature guidelines for the design of health education messages [30]. Following Hugo recommendation, the construction of the educational material included the consideration of communication principles and sociocultural factors, including the literacy levels and language preferences of the audience, to design appropriate messages. When designing the audiovisual content, simplicity (text and visual composition) and the audience’s emotional involvement were considered [30]. The educational video was developed in classical Arabic to make it accessible to a wider audience. Multimedia Appendix 1 shows the developed educational video, while screenshots of the educational video are shown in Figure 1.
Educational Video Validation Process

Yusoff [31] recommended that when validating the content of a tool, a minimum of 6 (but no more than 10) experts should be involved in the assessment process. The validation of the educational material included assessments by 7 experts (Multimedia Appendix 2). For this study, it was essential that the specialists were well-versed in the Arabic language (spoken and written).

To identify the broad range of expertise needed, roles were categorized into different fields. Four roles were identified: (1) health informatics experts, (2) health education specialists, (3) infodemic managers, and (4) public health experts.

Each category was populated with a representative through purposeful sampling. A panel of experts was formed with at least 1 representative from each role; email was used to contact the representatives and provide information about the study. The validation forms and the educational video were delivered to the specialists via email.

The validation form was created by combining 2 tools from which items relevant to the study were selected. Questions Q2 through Q11 were adopted from the Educational Content Validation Instrument in Health developed by Leite et al [32], and questions Q1 and Q12 through Q17 were adopted from an audiovisual content evaluation instrument constructed by Rosa et al [33].

The final evaluation form contained 17 questions covering three areas: objectives, structure and presentation, and audiovisuals (Multimedia Appendix 3). The “objectives” section focused on purposes and goals, whereas the “structure and presentation” section emphasized organization, structure, strategy, sufficiency, and consistency. As for the “audiovisual” area, the emphasis was on the technological aspect. A score of 0 indicated disagreement, 1 indicated partial agreement, and 2 indicated strong agreement with the value of the items [34].

Educational Video Validation Result

A content validity index was used to analyze the results. Content validity indexes can be computed in 2 ways. One type of validity is item-level content validity indexes (I-CVIs), which consider the content validity of individual items. The other type is scale-level content validity indexes, which involve a scale’s overall content validity [35]. For the scale-level content validity,
calculations were conducted using the scale-level content validity index averaging method (S-CVI/Ave) as recommended by Polit and Beck [36].

The calculations were carried out manually. The items ranked “disagree” were scored as 0, whereas the items ranked “partially agree” and “strongly agree” were scored as 1 [34].

To obtain excellent content validity, the content of educational videos must have items with I-CVIs above 0.78 for (6 to 10 experts) and an S-CVI/Ave of 0.90 or higher [36]. When the I-CVI is below 0.78 and the S-CVI/Ave is below 0.90, the content modification should be considered for that particular educational video area.

As shown in Table 2, all items had I-CVIs greater than 0.78 (78%), indicating agreement between the experts’ answers. In terms of scale evaluation, all the 3 areas (objectives, structure and presentation, and audiovisual) had S-CVI/Aves above 0.90 (90%). In the objectives area, item 5 (“stimulates interest in the theme”) had the lowest specialist agreement score (6 out of 7 or an I-CVI of 0.86). The overall S-CVI/Ave for the objectives area was 0.97.

Table 2. A content validity index calculation using 7 expert ratings to validate the video’s content.

<sup>a</sup>I-CVI: item-level content validity index.

<sup>b</sup>The S-CVI/Ave and average proportion of items judged as relevance across the 7 experts for objectives is 0.97.

<sup>c</sup>The S-CVI/Ave and average proportion of items judged as relevance across the 7 experts for structure and presentation is 1.

<sup>d</sup>The S-CVI/Ave and average proportion of items judged as relevance across the 7 experts for audiovisual is 0.94.

The structure and presentation area had the highest level of agreement (100% S-CVI/Ave). In the audiovisual area, 2 items (“the illustrations are expressive and sufficient” and “the characters/images are appropriate for the target audience”) had scores of 6 out of 7 or I-CVIs of 0.86. The overall S-CVI/Ave for the audiovisual area was 0.94.
Data Collection Tool

Development of the Survey

The study aimed to develop and assess an interventional tool to educate the Saudi population on how to identify health misinformation in WhatsApp messages. The developed Arabic survey contained 4 sections: demographic data, pretest questions, educational intervention, and posttest questions.

The first section (sociodemographic information) included 7 questions about each participant’s background information, including gender, age, educational level, employment status, region of residence, city of residence, and nationality. The second section included 8 questions that assessed each participant’s ability to identify misinformation based on the WhatsApp messages evaluation concepts mentioned in Table 1. Multimedia Appendix 4 shows the complete list of questions that were assigned to the concepts. The third section included the educational tool, which discussed 6 concepts that could be used to identify misinformation in WhatsApp messages. The fourth section included the same 8 questions as the second domain to measure the effectiveness of the educational tool.

The assessment questions were based on real examples representing the different domains of WhatsApp messages. The 8 pre and posttest questions included 5 messages with misinformation (based on messages circulated during the pandemic) and 3 with correct information (obtained from the Saudi Ministry of Health’s official website) [37]. The evaluation concepts, selection of the messages, and their relevancy were assessed by 2 authors (EA and SA). EA collected the messages and placed them under each domain, and SA assessed the relevancy; any uncertainty was resolved by consensus. Finally, a summary of the study’s goal was included in the survey, as was a statement assuring the respondents’ confidentiality.

The highest possible score for the survey questions was 8 points (correct answers were scored as 1 point; incorrect answers and responses of “I do not know” were scored as 0 points). We used a modified Bloom cutoff value of 75% to categorize participants’ knowledge. As a result, we considered participants with scores ≥75% to have high knowledge. Participants with scores below 75% were considered to have low knowledge. This cutoff value is based on previous publications [38,39].

Pilot Survey

The web-based survey was pilot tested, and a total of 31 participants responded. During the first piloting stage, the survey was sent to 15 participants, 3 of whom commented that the instructions needed clarification. Subsequently, an instruction section containing a description of the other survey sections was added at the beginning, and the survey was distributed again to 16 participants. In the second stage, no further comments were received; all participants indicated that the survey was clear. The internal consistency of the final survey was measured using Cronbach α. The scale had a Cronbach α of .847, demonstrating good internal reliability. The final version of the survey can be found in Multimedia Appendix 5.

Ethical Considerations

The study was approved by King Abdullah International Medical Research Center (reference RYD-22-419812-107000). The survey included a summary of the study’s purpose and a statement that, by completing the survey, the respondents agreed to participate in this research. The confidentiality of the study participants was ensured by not collecting identifiable data, encrypting files, and requiring a password to open or modify files.

Statistical Analysis

The demographic characteristics of the participants were reported using descriptive statistics, such as frequencies and percentages. Categorical variables were analyzed using chi-square tests to determine the associations between the demographic variables and the knowledge levels of the participants. A modified Bloom cutoff was used to categorize the knowledge levels. The normality of the variables was analyzed using the Kolmogorov-Smirnov test and the Shapiro-Wilk test. The median scores from before and after the educational video were compared using the Wilcoxon signed-rank test. The McNemar test for categorical data was used to compare the answers and differences in knowledge levels before and after the educational video intervention. The analyses were performed using SPSS Statistics (version 29.0; IBM). A P-value of .05 or less was considered statistically significant.

Results

Characteristics of Study Participants

The web-based survey received 485 responses, and 2 did not agree to participate, giving a 99.6% (n=483) completion rate. In total, 483 responses were analyzed. The socioeconomic characteristics of the participants are shown in Table 3. Most of the study respondents (n=457, 94.6%) were Saudis. More than half of the participants (n=300, 62.1%) were female, and more than half were in the age range of either 18-24 or 25-34 years (n=130, 26.9% and n=173, 35.8%, respectively). More than half of the sample (n=275, 56.9%) had bachelor degrees. With regard to the employment status, 45.5% (n=220) of the respondents were employed. The highest number of participants came from the eastern region (n=181, 37.5%), followed by the central (n=132, 27.3%) and western (n=83, 17.2%) regions.
Despite some variations, the sample matched the age and sex distribution of the Saudi Arabian population. Similarities in regional distribution between our sample and the populations of certain regions were also evident in the sample, with 27.3% (n=132) from the central region and 9.9% (n=48) from the northern region aligning with the national census in Saudi Arabia (n=5,365,700, 28.5% and n=1,877,108, 9.9%, respectively). In the eastern region, our sample showed a higher representation at 37.5% (n=181) compared with 15.7% (n=2,949,854) reported in the census data [40]. Our sample also showed a difference in educational level, with 56.9% (n=275) of participants holding bachelor degrees, in contrast to the national statistic of 23% (n=2,812,477) [41].

### Association Between Knowledge Level and Demographic Variables

The highest possible score for the survey questions was 8 points (correct answers were scored as 1 point; incorrect answers and responses of “I do not know” were scored as 0 points). We used a modified Bloom cutoff value of 75% (6 points) to categorize the participants’ knowledge. A knowledge score of ≥6 indicated a high level of knowledge, while a score of <6 indicated a low level of knowledge.

The associations between knowledge about identifying misinformation in WhatsApp messages and demographic variables were assessed using chi-square tests (Table 4). There were statistically significant associations between knowledge level and age, sex, employment, and region of residence ($P<.05$).
Table 4. Chi-square tests to examine the association between knowledge about identifying misinformation in WhatsApp messages before the intervention and demographic variables (N=483).

</table>

Effectiveness of the Intervention
The Kolmogorov-Smirnov test and the Shapiro-Wilk test indicated that the knowledge scores before and after the educational video were not normally distributed (P<.001). Since the distribution was not symmetric, it is negatively skewed, and there are a few outliers on the left side contributing to the skewness; nonparametric tests were used to assess statistical significance.

The median scores were assessed both before (median = 7, IQR = 5-8) and after (median = 8, IQR = 6-8) the video intervention, using the Wilcoxon signed-rank test. This comparison revealed that the video intervention did elicit a statistically significant change in the participants’ abilities to identify misinformation in WhatsApp messages (z=-6.887; P<.001).

Knowledge Questions
The proportions of correct answers per individual test question before and after the video intervention were compared using the McNemar test. Significant differences in the participants’ pre- and postintervention knowledge about identifying misinformation were found for specific questions (Table 5). Viewing the video was associated with increased knowledge about the following concepts: checking the “forwarded” label (P<.001), looking for spelling and grammatical errors (P<.001), analyzing the facts (P=.03), checking links (P=.002, P=.001), and assessing the photos and videos (P<.001).

**Improvement in Knowledge Level**

The health misinformation education intervention involved 483 participants. Pretest results showed that 70.6% (n=341) of participants had high knowledge (score ≥6), while 29.4% (n=142) had low knowledge (score>6). After the posttest, 10.6% (n=51) of the sample had improved to high knowledge and 3.3% (n=16) had lower scores, indicating 77.8% (n=376) had a score of 6 or above. McNemar test determined that there was a statistically significant difference in knowledge level before and after the intervention (P<.001; Table 6).

Discussion

Overview

This study aimed to design and evaluate the effectiveness of an educational video to improve the abilities of participants in Saudi Arabia to identify health misinformation within the WhatsApp app. The study used a single-arm, pre-post intervention design and was conducted on the web. The effectiveness of the intervention was assessed. Furthermore, the participants’ knowledge levels about identifying misinformation were assessed before and after the intervention as were the associations between the participants’ characteristics and their knowledge.

The proliferation of health-related misinformation on social media has raised public health concerns in many countries [42]. Chen et al [43] found that people with limited health literacy were more likely to trust health-related information found on social media and blogs. Thus, improving the public’s ability to evaluate health information may be necessary. In Saudi Arabia, WhatsApp is the most popular social network, which is used by 87.4% (n=30.67 million) of internet users [6,24]. This platform has been identified as one on which misinformation may be easily spread [44]; therefore, it was the platform on which this study focused.

Principal Results

The participants’ ability to identify misinformation in WhatsApp messages significantly improved following the educational intervention (P<.001). This result supports the finding of a systematic review by Cusack et al [13], which showed that, at least in the short term, educational interventions could improve knowledge and skills. This finding is also in line with the message interpretation process theory and the inoculation theory, in which interventions and prior messages are identified as factors that effectively protect against the harm caused by misinformation [19,21].

Additionally, the findings of this study suggest that literacy interventions combined with visual multimedia may improve misinformation detection. Apuke et al [45] found that participants who received visual multimedia education had better knowledge of literacy concepts than those who were educated without visual multimedia. Thus, as previously mentioned in this study, multimedia enhances memory, as stated in the cognitive theory of multimedia learning. The receiver’s exposure to the various message components makes it easier to integrate new information [23].

In this study, the items that assessed the following concepts (checking the “forwarded” label, looking for spelling and grammatical errors, analyzing the facts, assessing the photos and videos, and checking links) were significantly associated with improvements in the participants’ knowledge (P<.05 for all). However, the item related to the concept of reading beyond the headline was not significantly associated with improvement (P>.05).

It was noticed that WhatsApp messages with misinformation are characterized by requests to forward the message to many people. Further, many forwarded messages include fake information sources such as links or names and are vague about timelines, authors, and origins. Consequently, most forwarded messages are found to contain misinformation [46].

By recognizing the most prominent characteristics of health misinformation, users can improve their abilities to identify it on social media. Some studies have proposed criteria such as accuracy, authority, objectivity, and currency, but it is challenging for laypeople to evaluate these indicators. The role of such criteria is quite limited for general users, who, by definition, are not professionals [47]. Li et al [47] proposed a feature scheme and incorporated semantic, grammatical, and peripheral features of messages in evaluating their credibility. Their developed feature scheme allowed users to improve both their abilities to recognize health misinformation and their levels of digital health literacy.

This study found a significant association between knowledge level and age, sex, employment, and region of residence (P<.05 for all). Bapaye and Bapaye [48] noted that those engaged in elementary occupations and those older than 65 years of age were most likely to get false information from WhatsApp in a developing country. Workers in the health care industry were not immune from the impact of false information and were found to be just as susceptible as those in other professions.

The pretest results showed that 70.6% (n=341) of participants had good levels of knowledge about identifying misinformation on WhatsApp. There may have been factors contributing to an increase in knowledge, such as public awareness campaigns and government efforts. During the pandemic, the Saudi Arabian Ministry of Health conducted a comprehensive media campaign that included television, websites, and social media. Taking advantage of social media platforms, the Ministry of Health also engages with the public and the media. In addition to these early initiatives, efforts have been made to combat rumors and misinformation and engage the public in prevention and control measures [49].

Higher health literacy levels are associated with more favorable perceptions of health information. However, health literacy varies depending on the situation, and thus even those with high levels of health literacy may need help occasionally. For instance, those unfamiliar with medical language may find it challenging to distinguish between materials that provide accurate information and those with inaccurate information. Health care professionals and organizations must evaluate the population’s level of health literacy in order to ensure that people have access to adequate information when it matters most. Strategies like awareness-raising campaigns, community engagement, educational interventions, and training programs should be implemented when needed [50]. In accordance with the first Infodemiology Conference of the World Health Organization, public health authorities must create, evaluate, implement, and adapt tools and strategies for managing infodemics in acute public health crises in a manner that is suitable for their countries and situations [15]. This study’s findings may provide insight to public health authorities about developing an appropriate intervention for the population.
Strengths and Limitations

The strength of this study is that it involved developing and validating an educational video in the Arabic language to identify misinformation on WhatsApp. Few Arabic educational materials exist to combat misinformation. The study’s limitations include some sampling bias due to the use of convenience sampling, which is a nonprobability sampling technique. While this technique may limit the generalizability of the results, it was appropriate for our study because it is more cost-effective, faster, and more direct than other sampling techniques.

Conclusions

Health misinformation is an issue threatening public health because it dominates social media. Training people on the characteristics and practical applications of social media is urgently necessary. This study developed and evaluated the effectiveness of an educational video intervention to improve health misinformation identification on WhatsApp among the Saudi Arabian population. The results indicate that educational videos can be valuable tools for improving participants’ abilities to identify misinformation. The outcomes of this research can contribute to our understanding of effective tools for enhancing health misinformation awareness. These interventions can be particularly useful in combating misinformation in Arabic-speaking populations on WhatsApp, which may ultimately improve eHealth literacy. Limiting the prevalence and impact of misinformation allows people to make better-informed health care decisions. Our findings may also be helpful for health care professionals and organizations deciding on interventions suitable for providing access to adequate information to certain populations when needed.

Acknowledgments

The authors appreciate the support provided by the Office of Research in KSAU-HS, especially Mr Ahmed Aldakhil, for his valuable biostatistics consultations. The authors gratefully acknowledge King Abdullah International Medical Research Center for funding the publication of this paper.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

The study was designed and planned by EA and SA. EA took on the task of developing the educational video and survey. Data collection, results interpretation, and manuscript writing were all carried out by EA, SA reviewed the work. EA and SA discussed the findings, contributed to the final manuscript, and shaped the research.

Abstract

Background: Many adults with attention-deficit/hyperactivity disorder (ADHD) experience difficulties related to emotion regulation. Such difficulties are known to substantially impact quality of life and overall functioning. Yet, there is a lack of treatment interventions specifically designed to address these challenges.

Objective: This study aimed to describe the development and assess the feasibility, along with the initial clinical outcomes, of a novel blended intervention for adults with ADHD. The blended intervention combines both face-to-face and digital components and is specifically designed to address emotion dysregulation in ADHD.

Methods: This intervention was an 8-week blended intervention combining weekly face-to-face group sessions with a supplementary digital companion app. The intervention is based on elements from dialectic behavioral therapy skills training and positive psychology. To evaluate its feasibility, we performed a 10-week feasibility study with an uncontrolled pre-post study design, including 16 adults with ADHD and co-occurring emotion dysregulation. The feasibility measures encompassed adherence, satisfaction, and perceived credibility of the intervention. Clinical outcomes were evaluated by self-reported symptoms of emotion dysregulation, inattention, hyperactivity-impulsivity, executive function, depression, anxiety, and a measure of quality of life. Paired sample 2-tailed t tests were used to analyze clinical outcomes with a Bonferroni-corrected significance level.

Results: Both treatment credibility and treatment satisfaction were rated favorably by the majority of the participants. In particular, the participants emphasized meeting others with ADHD as beneficial. In terms of adherence, 3 participants withdrew before initiating the intervention, while another 4 participants did not complete the intervention. On average, the participants who enrolled in the intervention attended 6.2 of the 8 group sessions and completed 6.7 of the 8 skills training modules in the companion app. In terms of clinical outcomes, there was a reduction in symptoms of emotion dysregulation from before to after the intervention ($d=2.0$). Significant improvements were also observed in measures of inattention ($d=1.1$) and hyperactivity-impulsivity ($d=0.9$). However, no significant improvements were found in the domains of depression, anxiety, quality of life, and executive functioning.

Conclusions: The results are encouraging, both in terms of feasibility and the preliminary clinical results on emotion dysregulation. The blended format, combining digital and face-to-face elements, may also seem to offer some advantages: the group-based format was valued as it facilitated peer interaction, while a rather high completion of modules in the companion app highlights its potential to enhance skills training between the group sessions. Future randomized controlled trials are called for to further evaluate the clinical effectiveness of the intervention.
Introduction

Attention-deficit/hyperactivity disorder (ADHD) affects approximately 2.6% of the adult population [1]. Although symptoms of ADHD initially present themselves in childhood, most individuals diagnosed with ADHD as children continue to experience symptoms and associated impairments into adulthood [2]. Moreover, there is a rising trend of individuals first receiving their ADHD diagnosis in adulthood [3]. ADHD manifests through symptoms of inattention, hyperactivity, and impulsivity that significantly disrupt the individual’s daily functioning [4]. Beyond these core symptoms, ADHD is accompanied by an array of co-occurring symptoms and difficulties, both somatic and psychological, which can further complicate and amplify the challenges associated with the diagnosis [5].

Emotion dysregulation is a common deficit observed across many mental health conditions [6]. It is characterized by challenges in effectively managing and modulating one’s emotions, including the emotional experience (e.g., intensity and duration) and expression [7]. Emotion dysregulation commonly coexists with ADHD, impacting as many as 34%–70% of the adults with the diagnosis [8]. Emotion dysregulation also occurs in adults with ADHD without the presence of other comorbid diagnoses [9], giving support to the notion that it is a core component of ADHD [10-12]. The co-occurrence of emotion dysregulation with ADHD is linked to a range of negative outcomes, including occupational challenges, interpersonal conflicts, financial struggles, parenting stress, as well as tendencies for self-harm, illicit drug use, and suicidal ideation [13-15]. Moreover, research indicates that emotion dysregulation serves as an independent predictor of impairment in ADHD [16]. Its adverse influence on self-esteem and quality of life has further been observed to exceed the effects of inattention and hyperactivity [17]. Given the high prevalence of emotion dysregulation in ADHD and the associated negative outcomes, adults with ADHD should be offered treatment interventions that specifically aim to strengthen their emotion regulation skills.

While pharmacological treatment remains the main treatment approach for the management of ADHD in adults, the UK National Institute for Health and Care Excellence recommends supplementing with psychological interventions, such as psychoeducation or psychotherapy [18]. Psychological alternatives are especially critical in cases where the individual does not want to take medications or when medications either do not lead to sufficient clinical improvement or result in unwanted side effects. This may be particularly relevant for those with co-occurring emotion dysregulation, as ADHD medications appear to be less effective for these difficulties [19]. A systematic review and meta-analysis showed that traditional ADHD medications, including methylphenidate, atomoxetine, and lisdexamfetamine, only had small to moderate effects on emotion dysregulation among adults, which were significantly lower than the effect sizes reported for core symptoms of inattention, hyperactivity, and impulsivity [20]. As such, the authors of the abovementioned review emphasize that there is a need for more research on both pharmacological and psychological treatments targeting emotion dysregulation in adults with ADHD [20].

There is limited access to psychological treatments among adults with ADHD, and most available interventions mainly address the core symptoms of inattention and hyperactivity [21,22]. To the authors’ knowledge, there are currently 8 studies that have included emotion dysregulation as an outcome measure in studies of psychological interventions for adults with ADHD, including 2 randomized controlled trials [23-30]. However, only 2 of the studies reported emotion dysregulation to be the primary treatment target [24,26]. Carroll et al [26] developed and tested the psychological intervention “Group Therapy for Improving Emotional Acceptance and Regulatory Skills in Adults with ADHD” (GEARS), which consists of 14 weekly group sessions. In an uncontrolled pilot study with 226 participants, both treatment credibility and treatment satisfaction were rated as high, and preliminary clinical effects showed a reduction in emotion dysregulation symptoms with large effect sizes [26]. These findings are also supported by other studies [23,25,27-29]. On the other hand, Halmoy et al [24] did not find any significant difference in measures of emotion regulation between the control group and the treatment group in a randomized controlled trial of a 14-week dialectic behavioral therapy–based intervention. With the current evidence, it is thus premature to conclude whether psychological interventions are effective for adults with ADHD with co-occurring emotion dysregulation.

Digital psychological interventions have become increasingly popular in the past decade. The inclusion of digital tools in treatment interventions for adults with ADHD may be useful in addressing common challenges such as forgetfulness, nonadherence to treatment, and incomplete homework assignments [31,32]. For example, content from face-to-face therapy sessions, such as coping skills or psychoeducation, could be made available on the web through a website or a mobile app. The increased accessibility of such treatment elements may facilitate the generalization of therapeutic skills in everyday life for the clients, which is a central aim of most psychological interventions [33]. Blended interventions, where elements from face-to-face and digital treatment formats are combined, could be advantageous as they use the strengths of both treatment formats [33]. A systematic review of blended...
interventions in mental health care suggests that these interventions may save clinician’s time, lead to lower dropout rates, and help to maintain positive changes made in psychotherapy over time [34]. However, there have been few studies examining a blended treatment format among adults with ADHD. To our knowledge, there has been 1 randomized controlled trial examining the effect of a mobile app to deliver psychoeducation in a group-based intervention for adults with ADHD [35]. In this study, it was found that the participants who used the mobile companion app had a greater reduction in ADHD symptoms and a higher completion rate of homework assignments as compared to participants who received a printed version of the psychoeducation [35]. As such, this study provides evidence that psychological interventions for adults with ADHD may be augmented by the implementation of digital tools.

The overall aim of this study was to describe the development of and assess the feasibility and preliminary clinical effects of a blended psychological intervention for adults with ADHD. This intervention integrates face-to-face group sessions with a digital companion app for skills training, designed to address emotion regulation. The developmental process and the core content of the intervention are outlined in the methods section. Through the feasibility study of the intervention, the following research questions were addressed:

1. How do participants with ADHD rate their satisfaction and the credibility of the intervention? 
2. What is the participants’ adherence level to the intervention? 
3. What are the preliminary clinical effects of the intervention on emotion regulation, inattention, hyperactivity-impulsivity, quality of life, anxiety, depression, and executive functioning?

**Methods**

**Phase 1: Development of Intervention**

**Participants**

The participants who took part in the development phase of the intervention included 5 adults with ADHD, 2 clinical psychologists, 1 clinical psychology student, 2 human-computer interaction experts, and 2 user experience designers. The adults with ADHD were originally recruited from the local ADHD patient association. The adults with ADHD received a gift certificate worth NOK 400 (US $37) in total for their participation in the design workshop and evaluation meeting.

**Methods of Development**

The intervention was developed over 2 years through an iterative process. Multiple methods were used during this development (Table 1 shows an overview of methods and findings).
Table 1. Overview of the methods applied in the development of the intervention and key findings in the 2-year developmental process.

| Synthesis of quantitative literature | A synthesis of previous studies examining psychological interventions targeting emotion dysregulation in ADHD was conducted. In this step, we examined the format, treatment approach, and common psychotherapeutic elements in the interventions. | - Various psychological frameworks have been used in interventions targeting emotion dysregulation in ADHD, including DBT, cognitive behavioral therapy, goal management training, and mentalization-based therapy.  
- A group-based format has been applied in previous interventions.  
- Most previous interventions apply a structured and manualized format.  
- Most previous interventions use homework assignments to generalize skills.  
- Common intervention elements were psychoeducation, mindfulness, acceptance strategies, self-monitoring, emotion regulation skills, behavioral analysis, planning and organization strategies, communication skills, and problem-solving skills. |
| Synthesis of qualitative literature | A synthesis of previous qualitative examining the experience of participating in psychological intervention for adults with ADHD was conducted. In this step, we sought to understand the needs and preferences of psychological interventions among adults with ADHD. | - In previous interventions, the opportunity to share experiences with peers was perceived as valuable by adults with ADHD.  
- Adults with ADHD report that they prefer an emphasis on strengths and solutions in treatment.  
- Incorporation of digital tools in treatment was perceived as useful by adults with ADHD. |
| Expert meetings                      | The development process included several expert meetings. In these meetings, the format and elements of the intervention were discussed and reviewed. Suggestions regarding intervention content and design were made based on clinical expertise and experience. | - Beneficial elements that should be included in the intervention based on clinical experience: group-based format, focus on positive aspects, option to choose from a variety of coping strategies, interactive in-class exercises and discussions, and short homework assignments.  
- Design considerations and suggestions for the companion app: clear structure, minimizing distraction, clear information, and use of rewards and praise. |
| Co-design workshop                  | The workshop included 5 adults with ADHD, 2 clinical psychologists, and 2 HCI experts. In the workshop, the adults were given information about the project and a general idea of the intervention. Following this, the adults were asked about challenging situations in terms of emotion dysregulation, common coping strategies, and their preferences for intervention content and features. | - Emotion dysregulation was a common challenge among adults with ADHD.  
- Perceived useful coping strategies by adults with ADHD: acceptance, self-compassion, distraction, reappraisal, time-out, and relaxation.  
- Useful features in companion app: reminders, note-taking, overview of coping strategies, calendar, peer support, and inclusion of videos. |
| Design sprint of companion app       | A design sprint lasting 5 days was conducted to create a prototype of the companion app. An HCI expert led the design sprint, with the inclusion of 2 UX designers and 1 clinical psychologist as participants. | - A prototype of the companion app was completed, including design and features in the app. |
| Co-creation of intervention manual  | The first author created the intervention manual based on the previous findings. The protocol was then reviewed and revised by 2 other clinical experts, including 1 expert with ADHD. | - A first version of the intervention manual was created. |
| Evaluation seminar with adults with ADHD | The evaluation seminar included the same participants as the co-design workshop. In the first part of the seminar, a clinical psychologist presented the content of 8 group sessions and the participants could give feedback. In the second part, an HCI expert presented a walk-through of the companion app, and participants could give feedback. | - Review of the intervention, both the group sessions and the companion app.  
- Revision of the intervention, including limiting the amount of text and clarifying instructions in companion app. |
| Consultations with software company  | We conducted several consultations with the software company that had the technical infrastructure for the companion app. | - A fully functioning version of the companion app was completed. |

HCl: human-computer interaction.

dUX: user experience.
The Emotion Regulation Intervention for ADHD

Overview

The development process led to the “Emotion Regulation Intervention for ADHD” (ERIA), which is a structured psychological intervention aimed at improving emotion regulation skills in adults with ADHD. The intervention is manual-based and includes components from dialectic behavioral therapy skills training and positive psychology. ERIA consists of 8 face-to-face group sessions and a digital companion app for skills training in between sessions. Table 2 contains an overview of the intervention content in ERIA.

Table 2. Overview of the intervention, including session themes, content for group sessions, weekly homework, and skills training assignments.

a ADHD: attention-deficit/hyperactivity disorder.
b N/A: not applicable.
Group Sessions
ERIA comprises 8 weekly group sessions. The group sessions are closed, and each group includes 6-8 adults with ADHD. In this study, the groups were led by 2 clinical psychologists with a minimum of 3 years of clinical experience. Each group session lasts approximately 1.5 hours, divided into 2 segments with a 15-minute break interlude. All sessions begin with a brief mindfulness exercise, led by 1 of the 2 psychologists. Afterward, group members are encouraged to share their reflections on the exercise. Following this, the group members share their experiences with the previous week’s homework assignment. After the break, the lead psychologist presents relevant theoretical and psychoeducational information and the new skills for the participants to practice at home. There are also discussion breaks and some practical exercises incorporated in the presentation of new skills.

Companion App
The participants are given access to a companion app, which they are asked to use for skills training at home between the group sessions. This app is organized with modules, where new skills training modules are released on a weekly basis following the course of the group sessions. The skills training modules include the weekly skills that the participants are to practice at home. In addition, the participants can use the companion app to message the group leader, log their skills training sessions, and access the PowerPoint presentations for the group sessions, as well as other relevant resources (eg, relevant websites or scientific papers on the weekly theme). The participants also receive an SMS text message reminder when the skills training modules are available and another SMS text message reminder if they have not accessed the module within 2 days. Given that this was a feasibility study, the app did not encompass all features originally present in its prototype. For instance, a peer-support feature suggested during the co-design workshop was excluded due to its resource-intensive nature. If the feasibility study yields encouraging outcomes, we intend to incorporate more sophisticated features in the app.

The app was a web-based application that could be accessed both through a computer and a smartphone. To access the app, the participants had to use the Norwegian web-based authentication platform, BankID, for a secure 2-factor log-in. BankID is a widely used platform for electronic identification for services within banking, health care, and education in Norway. The companion app was hosted on the eHealth platform developed by the software company “Youwell,” which is partnered with the Western Norway Regional Health Authority for clinical use and research. The platform has a patient and therapist portal, where participants can access the app through the patient portal, and the therapist can set up the program and monitor their patient’s progress in the therapist portal. The platform is also used for building the app and allows for the input of content, such as text, audio, videos, and images, to create modules. It has previously been used for other internet-delivered programs, including programs for ADHD [36], social anxiety [37], and cognitive residual symptoms after depression [38].

Figure 1 shows screenshots of the companion app. The first screen from the left shows the main page with an overview of the modules. The first box from the left reads, “Week 4: Emotion regulation I. This week we will practice skills in emotion regulation.” The second screen shows the instructions to a mindfulness skill with the text “Choose an option below and take 5 minutes to describe this in a nonjudgmental way.” The circles show 6 options they can choose from, which include describing (1) own emotions, (2) bodily sensations, (3) a tree or plant, (4) people walking by, (5) an object in the room, or (6) own thoughts. The third screen shows the side menu that participants can use to navigate within the module. This screen shows the mindfulness module and the side menu includes the specific module pages: “Welcome back,” “Skills,” “Observation,” “Description,” “Participate,” “Skills diary card,” and “Resources.”
Phase 2: Feasibility Study

Participants

Eligible participants for this feasibility study were adults with ADHD living in Bergen, Norway. The inclusion criteria for the study were as follows: (1) minimum age of 18 years; (2) a diagnosis of ADHD according to the DSM-5 (Diagnostic and Statistical Manual of Mental Disorders [Fifth Edition]) criteria; (3) current problems with emotion dysregulation as indicated by a score of ≥ 80 on the Difficulties in Emotion Regulation Scale (DERS); (4) having a smartphone or computer to access the companion app; and (5) the ability to attend in-person group sessions in Bergen, Norway. Exclusion criteria were (1) a high risk of suicidality, as indicated by having attempted suicide within the past year, having previously attempted suicide and reporting current suicidal ideations, or reporting current suicidal ideations and having a plan and preferred method; (2) co-occurring severe mental illness, including substance abuse disorder, psychosis, and major depressive disorder; and (3) current participation in another psychological treatment intervention. However, participants could still partake in the study if they had less severe psychiatric conditions, such as mild to moderate anxiety or depression, and if they received pharmacological treatment for their ADHD or other conditions.

Recruitment

Participants were recruited through the ADHD patient advocacy group “ADHD Norge,” which shared information about the study with its members through email and social media. The study opened for participants to sign up on November 24, 2022, and closed within a week (November 30, 2022) due to a large number of individuals signing up for the study. Interested participants signed up through a website that contained a screening survey to examine eligibility as well as information about the study. Eligible participants were contacted for a face-to-face screening with a clinical psychologist. During this screening, eligibility in terms of psychiatric comorbidities and suicidality was examined using the Mini International Neuropsychiatric Interview [39]. Participants were also asked about the date, clinic, and diagnosing clinician for their ADHD diagnosis. In addition, the participants were asked open questions about ADHD symptoms (ie, could you tell me about your current ADHD symptoms?) and everyday functioning (ie, how do you experience that ADHD affects you in your daily life?). The participants had to report symptoms and functional impairments that were in accordance with the DSM-5 criteria for ADHD, as assessed by a clinical psychologist. Those who were deemed eligible for participation following this screening were invited to take part in the study and to sign an informed consent form through the companion app.

Outcome Measures

Overview

The participants were given the preassessment 1 week before the intervention started and the postassessment 1 week after the intervention ended. The assessments were completed on the internet, except for the Behavior Rating Inventory of Executive Functioning–Adult version (BRIEF-A), which was given in-person at the first and last group session.

Credibility

The third item of the Credibility and Expectancy Scale (CEQ) was used to examine treatment credibility of the intervention [40]. The item states, “Would you recommend this treatment to a friend with similar challenges?” and the responses are given on a scale from 1 (not certain at all) to 9 (very certain).
Treatment Satisfaction
The participants were asked about whether they thought they would continue using the coping skills they had learned in the future and responded on a 4-point scale from 1 (not very likely) to 4 (very likely). They were also asked about which elements of the intervention they considered to be most useful (multiple choice with option to add own text). The participants were also asked about negative experiences with the intervention (yes or no), which they could elaborate on in an open-text field.

Adherence
Adherence was assessed by the number of group sessions attended and the number of completed skills training modules in the companion app. Participants that attended at least 6 of 8 group sessions were defined as treatment completers. The participants were also asked about how many days per week they practiced the coping skills.

Difficulties in Emotion Regulation Scale
DEdRS is a self-report questionnaire that is commonly used to assess emotion dysregulation in clinical populations [41]. The scale includes 36 items rated on a 5-point Likert scale ranging from 1 (never) to 5 (almost always), yielding a total score between 36 and 180, with 180 indicating the most severe problems with emotion dysregulation.

The Adult ADHD Self-Rating Scale
The Adult ADHD Self-Rating Scale (ASRS) is a self-report questionnaire that is used to assess symptoms of inattention and hyperactivity-impulsivity [42]. The scale includes 18 items, with 9 items reflecting inattentive symptoms and 9 items reflecting hyperactive-impulsive symptoms. Responses are given on a 5-point scale with options 0 (never), 1 (rarely), 2 (sometimes), 3 (often), or 4 (very often), giving a total score between 0 and 72 and a score between 0 and 36 for the inattention and hyperactivity-impulsivity subscales.

The Adult ADHD Quality of Life Measure
The Adult ADHD Quality of Life (AAQoL) measure is used to assess quality of life among adults with ADHD [43]. The scale includes 29 items rated on a scale from 1 (not at all or never) to 5 (extremely or very often), yielding a total score between 0 and 100.

Hospital Anxiety and Depression Scale
The Hospital Anxiety and Depression Scale (HADS) is a self-report questionnaire used to assess symptoms of depression and anxiety [44]. The scale includes 14 items, with 7 items reflecting anxiety symptoms and 7 items reflecting depressive symptoms. The response options range from 0 to 3, with 3 being the most severe level. The scale yields a total score between 0 and 42 and a score between 0 and 21 for the anxiety and depression subscales.

The Behavior Rating Inventory of Executive Functioning
BRIEF-A is a self-report questionnaire used to assess executive functioning in everyday life [45]. The scale consists of 75 items, which are rated on a 3-point scale (1=never, 2=sometimes, and 3=often). For this study, we report the Global Executive Composite score, which is an overall summary score including 9 clinical BRIEF-A subscales.

Statistical Analysis
SPSS software (IBM Corp) was used for all statistical analyses [46]. The participant demographics, adherence measures, and treatment credibility measures were assessed using descriptive statistics, which include calculation of means, frequencies, ranges, and SDs. To evaluate preliminary clinical outcomes, paired sample t tests were used with an initial significance level set at .05. Due to the risk of family-wise error (type I error) associated with multiple t tests, a Bonferroni correction was included. This adjustment was achieved by dividing the α level by the number of conducted hypotheses tests, that is, t tests (.05/8), resulting in a corrected significance level of .006. The choice of analytic approach necessitated the inclusion of cases with both pre- and postassessment. The magnitude of treatment effect was quantified using standardized effect sizes, estimated through Cohen d, with the formula (M2 – M1)/SDpooled. The pooled SD was calculated by √((SD12 + SD22)/2). Effect sizes were interpreted according to conventions, where d=0.20, d=0.50, and d≥0.80 are defined as small, moderate, and large, respectively.

Ethical Considerations
The study was reviewed and approved by the Regional Ethics Committee of Norway, Region West (494659). The participants were informed about the study and their rights both in-person and in writing. Before participation, all participants signed an informed consent form, acknowledging that they could withdraw their consent at any time without any repercussions. The data were pseudoanonymized and stored on a dedicated research server according to regulative standards at the university and hospital. The participants were compensated NOK 1000 (US $90) for their participation in the study.

Results
Participants
A total of 16 participants took part in this study (Table 3 shows participant characteristics). The majority were diagnosed with ADHD in adulthood, with the mean age for receiving the diagnosis being 30.4 (SD 11.7) years.

All participants were recruited within 1 week. During the recruitment period, 68 adults completed the digital prescreening, of whom 92.6% (n=63) met the inclusion criteria and provided contact information (Figure 2). However, due to the limited number of study places in this feasibility study, we only assessed the first 27 individuals who signed up for the phone screening, as this was sufficient to reach the maximum capacity of 16 included participants. We sent an SMS text message to the remainder of the people who signed up, informing them that the study was fully booked. To ensure a more balanced sex distribution in the study, 6 study places were reserved for men, as we wanted to make sure we received feedback from both sexes.

Treatment Adherence, Credibility, and Satisfaction

In terms of adherence, a total of 3 participants dropped out of the study before starting the intervention, making a pretreatment dropout rate of 18.8% (3/16). Among the participants who received the intervention (n=13), the average number of group sessions attended was 6.2 out of 8 sessions. A total of 4 (26.6%) participants were treatment dropouts, defined as participants who attended less than 6 group sessions. Consequently, the cumulative dropout rate, including the participants who dropped out before starting the intervention, reached 43.7% (n=7). Regarding the use of the companion app, the participants had a mean completion of 6.8 out of 8 modules. On average, the participants reported practicing the skills 4.3 days per week.

The intervention was generally well received in terms of treatment credibility with a mean rating of 7.1 (SD 2.6; range 1-9). Among the 10 participants who completed the postassessment, 7 participants reported that they were very certain or certain that they would recommend the treatment to a friend facing similar challenges as themselves; 2 were somewhat certain, whereas 1 was not at all certain about recommending it.

Feedback from participants highlighted overall satisfaction with the intervention, with a mean rating of 3.3 (SD 0.9; range 1-4). All but 1 participant planned to continue using the learned skills. The participants rated meeting others with ADHD (n=10), the in-person group sessions (n=7), the skills (n=7), and therapist support (n=4) as the most useful elements of the intervention. Their feedback also included suggestions for improvement, with 3 participants recommending more time for group interactions and discussions among the group members. Regarding this, 1 participant suggested that the group members should be able to interact between the sessions through the companion app. Other suggestions for improvements included an extension of the program by adding more group sessions, making the companion app available for direct download, incorporating more reminders, providing participants with a printed version of the skills, and involving an individual with ADHD as a group presenter for skills demonstration and experience sharing. While feedback was largely positive, 2 participants expressed negative experiences with the program: 1 found the skills in the crisis management module to be inadequate in emotional crises, and another felt that the intervention was not sufficiently tailored to ADHD. Importantly, there were no reports of clinical deterioration among the participants.
Clinical Outcomes

There was an overall statistically significant decrease in self-reported emotion dysregulation from before to after treatment, with a strong effect size ($d=2.0$). Table 4 shows the individual scores for emotion dysregulation, indicating a change in the positive direction for all participants.

Overall, the group of participants showed a significant decrease in secondary clinical outcome scores, reflecting the level of inattention and hyperactivity-impulsivity from before to after assessment. While initial analyses showed a change in quality of life and depressive symptoms, these changes were nonsignificant with a Bonferroni correction. No significant improvement was found in measures of executive functioning or anxiety symptoms (Table 5 contains an overview of all preliminary clinical outcomes).

Discussion

Principal Findings

The aim of this study was to describe the development and assess the feasibility of ERIA, a blended digital and face-to-face intervention targeting emotion dysregulation in adults with ADHD. Overall, the findings were promising and supported the feasibility of ERIA. Both treatment satisfaction and credibility were generally good, which aligned with findings from other psychological interventions targeting emotion dysregulation in adults with ADHD [26]. More specifically, the participants emphasized the group component and meeting others with
ADHD as useful aspects of the intervention. This is in line with previous studies showing that providing a forum where one can share experiences with peers is particularly valuable in treatment settings for this group of adults [47]. While the results are promising, there is room for refinements, including an even better tailoring of the intervention to ADHD. An important step forward would be to involve adults with ADHD in the review and refinement process to ensure that all key aspects of the interventions are well-adapted to the challenges and difficulties facing adults with ADHD. Nonetheless, the heterogeneous nature of ADHD requires finding a balance between including intervention components that fit most participants and including specialized strategies addressing the specific needs of a subset of individuals with ADHD.

This study highlighted concerns regarding treatment adherence, especially regarding pretreatment dropout. A total of 3 participants dropped out before starting the intervention, while another 4 participants did not complete the intervention. This finding aligns with well-known challenges related to treatment adherence among adults with ADHD [48,49]. The issues related to adherence in this study may be partially attributed to our community-based sample. Motivation for completing psychological treatment may thus have been lower than among clinic-recruited participants. However, there could also be intervention-specific factors related to dropouts, such as dissatisfaction with the intervention or finding the intervention too demanding. Yet it is also worth noting that although high levels of treatment adherence are generally seen as favorable for the patient, treatment dropout does not necessarily equate to clinical failure for the patients themselves. Still, when reviewing the current intervention, it may be necessary to include more strategies to prevent early termination of treatment. A literature review on the topic found that strategies such as pretherapy preparation, patient selection, time-limited treatment contracts, appointment reminders, motivation enhancement, facilitation of a therapeutic alliance, and facilitation of affect expression were specific strategies that could be applied to reduce premature termination of treatment across different psychiatric disorders [50]. As we progress, understanding the multifaceted factors associated with dropout will be crucial.

With regard to the companion app, it is interesting to note that the participants who initiated the intervention generally completed a high number of skills training modules in the companion app, with the majority completing all modules. This finding is in line with the results from Selaskowski et al [35], which showed that the inclusion of a mobile app in a group-based intervention for adults with ADHD was linked to higher homework compliance [35]. Given the importance of homework for behavioral change as well as the common challenges related to homework compliance in psychological interventions, facilitating methods to ensure high attrition of homework may be particularly useful [51]. However, it is important to note that with the design of this study, we cannot determine whether the companion app resulted in higher homework compliance as opposed to not including the app; this would be an interesting topic for future studies.

The results were promising in terms of preliminary clinical findings, with participants showing a significant and large reduction from pre- to post treatment in emotion dysregulation. These findings are in accordance with findings from other psychological interventions targeting emotion dysregulation in individuals with ADHD [26]. Significant improvements were also observed in the secondary clinical outcome measures, including inattention and hyperactivity-impulsivity. However, given the study’s small scale, nonrandomized, and uncontrolled design, the clinical findings must be considered with caution. Moreover, we found no significant changes in the measures of anxiety, depression, quality of life, or executive functioning. Regarding executive functioning, previous research has shown that measures of executive control remain stable in ADHD, regardless of remission or persistence [52]. More generally, the effect of interventions that are designed to improve cognitive abilities or executive functioning appears to be domain-specific and show mixed results [53,54].

Taken together, the results from this study were encouraging and call for further development of the intervention and a more extensive examination of clinical effects in a randomized controlled trial.

Limitations
This feasibility study has some limitations that should be noted, in particular the small sample size, the absence of a control group, and the lack of randomization. Due to these limitations, conclusions regarding the intervention’s clinical effects remain elusive, and we cannot rule out placebo or other random effects. Yet, the aim of this study was not to examine the effectiveness of the intervention but rather to assess its feasibility before paving the way for larger trials.

A further limitation is that 3 participants who took part in the intervention did not complete the postassessment. Therefore, it is possible that this could have impacted the treatment satisfaction and credibility scores of the interventions. Furthermore, the participants were recruited from the community and may therefore differ in some way from typical clinic-recruited adults with ADHD. The reliance on self-report scales to evaluate clinical outcomes in this study should also be considered a limitation. In future studies, it would be interesting to include other measures, such as those generated from sensor technology, clinician ratings, and performance on cognitive tests.

Conclusion
In conclusion, the results from this feasibility study support the potential of ERISA as a feasible intervention for addressing emotion dysregulation in adults with ADHD and call for further investigation in a randomized controlled trial. The blended approach, integrating digital and face-to-face elements, may offer some advantages compared to an exclusively digital or face-to-face treatment format. The in-person group sessions were especially valued because they provided opportunities to interact with peers. Meanwhile, the high completion rate of the companion app modules indicates their potential to facilitate skills training.
Acknowledgments

The study was funded by Helse Vest research funds. The authors would like to thank all the participants in this study and the experts to experience. We would also like to thank the patient advocacy group “ADHD Norge” for sharing information about this study. We would further like to thank Hedda Bakken, Sara Furuholmen, and Nanna Skram for their contributions to the project.

Authors' Contributions

ESN, AJL, and FG contributed to the development, idea, and design of the study. ESN conducted the statistical analyses, while AJL, FG, JK, SLA, and VS contributed to the data collection for the feasibility study. ESN was responsible for the drafting of the manuscript, while AJL, FG, JK, SLA, and VS critically reviewed and revised the draft. All authors approved the final version of the manuscript and take full accountability for the work.

Conflicts of Interest

JK has delivered talks at educational events sponsored by Medice; all funds were received by King’s College London and used for studies of ADHD. AJL has received speaker fees and travel expenses from Medice.

Abstract

Background: Many young people with mental health problems do not readily seek help or receive treatment and support. One way to address low help-seeking behavior is to improve access to information on mental health services and how to navigate the mental health system via a web-based tool. Seeking input from the end users (young people and parents or caregivers) on key features of the tool is imperative to ensure that it is relevant, engaging, and likely to meet their needs and expectations.

Objective: This study aims to investigate young person and parent or caregiver views on the design, content, functioning, and user experience of a web-based mental health navigation tool to support connection to mental health services for children and young people aged up to 25 years.

Methods: A total of 4 online focus groups were conducted: 2 with young people aged 16 years and older (total n=15) and 2 with parents or caregivers (total n=13). Focus groups were structured around a series of guiding questions to explore participants’ views on content, features, user experience, and design of a mental health navigation website. Focus groups were audio recorded with detailed notes taken. In addition, 53 young people aged 16-25 years and 97 parents or caregivers completed an online survey, comprising closed- and open-ended questions; open-ended responses were included with the focus group data in the qualitative analysis. All qualitative data were analyzed using thematic analysis.

Results: A total of 2 topic areas and 7 themes were developed. The first topic area covered the types of information needs of young people and parents. Identified themes concerned the scope of the navigation website, as well as the provision of up-to-date and practical information on how to navigate the whole help-seeking process. The second topic area covered website features that would be beneficial and included the consideration of the website design; search engines; supported navigation; and forums, reviews, and user accounts.

Conclusions: This study provides important insights into the navigation needs of young people and parents or caregivers in seeking mental health services. Key findings identified through this research have directly informed the development of MindMap, a web-based youth navigation tool providing a searchable database of local services, including a clear description, their location, and potential wait times. The website can be navigated independently or with support.

Introduction

Globally, mental disorders are common and often emerge during childhood and adolescence [1,2]. The worldwide pooled prevalence of mental disorders in children and adolescents has been reported to be between 12.7% and 13.4% [2,3], while suicide is one of the leading causes of mortality in this age group [4]. Timely access to appropriate services and supports for mental disorders and suicidal distress can mitigate the persistence of poorer health, academic, and social outcomes into adulthood [5].

Research suggests, however, that many young people do not readily seek or receive treatment or support for psychological distress, suicidal ideation, or suicidal behavior [3,6,7]. A recent systematic review and meta-analysis of the prevalence of mental disorders in children and adolescents in high-income countries found that only 44.2% of young people with mental disorders received any services for their conditions [3]. Another study conducted in Australia reported slightly higher rates of service use among children and adolescents, with 56% accessing services for emotional and behavioral problems [7]. However, Sawyer et al [8] reported that only 12% of Australian young people aged 6-17 years with a mental health condition received what was considered adequate treatment.

Several possible drivers of low help-seeking behavior among young people, parents, and other caregivers have been identified. A recent review found that limited mental health knowledge, embarrassment and perceived social stigma, a lack of perceived confidentiality and trust in mental health providers, financial costs, logistical barriers, and limited availability of services were common barriers to accessing professional help for mental health problems among young people [5]. Similar barriers were identified among parents seeking treatment for mental health problems in their children and adolescents, with a lack of knowledge of where or how to seek help and a limited understanding of the mental health system identified as key barriers to service use [9].

One way to address some of these barriers may be to provide young people and parents or caregivers with a navigation tool they could use to identify available services and traverse often complex and disconnected mental health systems. Similar to other high-income countries, there are multiple entry points into the mental health care system in Australia, but access is often dependent on the individual knowing about them. As such, being able to access all service options in the same place would overcome service knowledge barriers and save users’ time trying to identify what is available in their area. Providing such tools online through an interactive website would also make this information more accessible, as adolescents and parents report seeking mental health information online [10-13] and a website would allow greater reach and timely updating of service information. In a survey assessing parents’ help-seeking for their adolescent’s mental health, over 75% of participants indicated that they would use the internet to find information about services [14]. In developing such a website, it is imperative that young people and parents or caregivers are involved, as there is clear evidence in the literature that the involvement of end users is essential to ensuring uptake and that the website meets the needs and expectations of users [15,16].

This paper reports the outcomes of focus groups and online surveys conducted with young people, parents, and other caregivers to identify the design, content, functioning, and user experience of a web-based mental health services navigation tool for children and young people aged up to 25 years in the Australian Capital Territory (ACT). This study was conducted in partnership with the ACT Office for Mental Health and Wellbeing and provides unique insights into the navigation needs of this population, with a dearth of previous research in this area, and the importance of the consultation process in producing an interactive website that is relevant, engaging, and likely to meet the needs of end users.

Methods

Participants

A total of 4 online focus groups (N=28), with 5-10 participants each, were conducted. Of these focus groups, 2 focus groups (15/28, 54%; 10/15, 66% female) were conducted with young people aged 16 years and older. These groups were conducted with members of 2 existing youth mental health reference groups: the ACT Youth Advisory Council and the ACT headspace Youth Advisory Group, who had experience representing the wider interests and views of their peers. The other 2 focus groups involved parents or caregivers (13/28, 46%; 12/13, 92% female). Participants for these were drawn from expressions of interest from the community and included parents with and without mental health service experience. To attract diverse representation in the focus groups, we advertised for recruitment through ACT mental health sector newsletters and on the social media website Facebook. Facebook advertising targeted adults in the ACT who identified as a parent or caregiver of a child aged 10-25 years. The online modality for the focus groups was chosen to maximize ease of attendance and minimize potential COVID-19 exposure.

Alongside the focus groups, 150 people participated in an online survey to further garner the perspectives of young people and parents or caregivers. Participants were young people aged 16-25 years (53/150, 35%; 44/53, 83% female; mean age 20, SD 2.8 y) and the parents or caregivers (97/150, 65%; 90/97, 93% female; mean age 45.5, SD 7.6 y) of young people aged 0-25 years (0-6 y: 20/97, 21%; 7-11 y: 38/97, 39%; 12-15 y: 47/97, 48%; 16-18 y: 30/97, 31%; and 19-25 y: 37/97, 38%). Participants for the survey were recruited through Facebook advertising. The Facebook advertisements were delivered to 21,600 accounts, with 1,300 people engaging with the Facebook post and 374 clicking the link and commencing the survey. Of those who commenced the survey, 40.1% (150/374) went on to complete and submit the survey for analysis. The majority of participants reported English as their first language (47/53, 89% young people and 93/97, 96% parents or caregivers) and had accessed pediatric mental health services in the past (45/53, 85% young people and 86/97, 89% parents or caregivers). Just over half (28/53, 53%) of the young people who completed the survey identified as lesbian, gay, bisexual, transgender, intersex,
Ethical Considerations

Ethical approval for this study was obtained from the Australian National University Human Research Ethics Committee (protocol 2020/200). All participants were provided with an information sheet outlining the study. Participants in the focus groups were required to return a signed consent form via email before attending the online focus group, whereas survey participants consented to participate in the survey by checking a box at the beginning of the survey. All survey data were collected anonymously, whereas all focus group data were deidentified before analysis and data storage. All focus group participants were provided with a small honorarium of AU $60 (US $40) in recognition of their time and contribution to the study.

Materials

The focus groups were structured, with a series of guiding questions and prompts that explored the views of young people and parents or caregivers on the potential design, content, functioning, and user experience (eg, optional phone and email support) of a web-based navigation tool (the full list of questions and prompts is given in Multimedia Appendix 1). Questions and prompts were developed in collaboration with staff members from the ACT Office for Mental Health and Wellbeing to gather information required to progress website development from an early concept and include youth and parent perspectives in the design process. Participants were encouraged to share their perspectives verbally with the group or to note any thoughts or ideas in the chat function.

The online survey assessed a range of topics relevant to the development of a youth navigation tool including website features (eg, information, links, quizzes, and service contact details), features and topics by which services could be searched (eg, cost, location, age, and gender), navigation support (eg, phone and online), and possible account functions (eg, acceptable account details and storage of information). Questions were developed with iterative feedback from the ACT Office for Mental Health and Wellbeing and the Youth Coalition of the ACT (peak body for youth affairs in the ACT) to ensure that they covered key issues for website design and were appropriate and accessible for young people. Participants were asked to share their preferences through a combination of close-ended and free-text responses.

Procedure

Because of the COVID-19 pandemic, all focus groups were conducted online in June 2020 using the Zoom videoconferencing platform (Zoom Video Communications). Given that this study was conducted in partnership with the ACT Office for Mental Health and Wellbeing, all focus groups were cofacilitated by a member of the research team and the ACT Office for Mental Health and Wellbeing. A second member of the research team was also present at all focus group sessions. Their role was to take notes, assist with linking participants with clinical support (if required), and monitor any discussion via the chat function, which was encouraged. All focus groups ran for approximately 90 minutes, online discussions were audio recorded, and any chat conversations were also saved for inclusion in the analysis. One author (ARM) listened to each focus group recording and took detailed point-by-point notes on the content of participant discussions. These were combined with researcher notes taken during the session and participants’ chat conversations for analysis. Because of this approach, all illustrative quotes were drawn from survey data. Participants were provided with help-seeking resources at the conclusion of each focus group, and clinical support or debriefing was available on request.

Two separate surveys were developed for young people and parents or caregivers and were administered online in June 2020 using Qualtrics online survey software (Qualtrics). Surveys took approximately 20 minutes to complete. All participants were provided with a list of help-seeking resources at the conclusion of the survey.

Data Analysis

Qualitative data were managed using the NVivo 12 software (QSR International). A thematic analysis [17,18] was conducted by 1 author (ARM) on focus group data notes, chat conversations, and free-text survey responses to identify and summarize the key topics and preferences raised by parents and young people within each area of questioning, while preserving the breadth and diversity of perspectives presented. ARM is a lived experience academic with personal experience of mental health service use and professional expertise in youth mental health and service evaluation. Analyses and developing categories were regularly discussed with other members of the research team, including researchers and ACT Office for Mental Health and Wellbeing staff members present at the focus groups, to test assumptions and clarify developing categories. A combination of deductive and inductive approaches to coding was applied. Before commencing data analysis, an initial broad coding framework was developed based on the key areas of questioning during the focus groups: content, features, user experience, and design. Focus group data were deductively coded within each category. As coding progressed, subcategories of describing specific areas of preference and new categories not represented by the deductive framework were developed inductively. A detailed coding framework was developed from the focus group data, including the original broad areas of questioning and inductively developed categories and subcategories. This framework was applied to free-text survey responses, adjusting the framework as necessary to adapt to new information. Finally, data were examined across categories to construct common themes in participants’ preferences. The key topic areas were summarized and grouped under 2 broad categories: the most important types of information for a service navigation tool and important website features.

Results

Overview

The overarching topic areas arising from the focus groups and surveys covered the types of information needs identified by young people and parents and the website features that would be beneficial to support the mental health of young people.
Themes collectively developed from the focus groups and surveys are described within these 2 areas. Data from the focus groups and surveys are integrated throughout this section. Where findings relate only to a specific group (parents or young people) or data collection format (focus group or survey), this is noted in the text.

Types of Information

Up-to-Date Information About Services

Preferences and needs for mental health service information were key topics of discussion in the focus groups and one of the most frequent topics raised in open-ended survey responses. Participants emphasized that it was important for the information on a mental health service navigation website to be regularly updated, with an indication of when updates last occurred, and for no information about listed services to be missing. Content should be relevant to the local region targeted by the website (ACT and surrounding region), as national-level websites can be difficult to navigate and regional content may better cover the full spectrum of services available in that area.

*Anything that is Canberra specific is great - wait times, contacts, prices, explaining which professionals do what. For general advice there are lots of national mh [mental health] services already.* [Young person, survey participant]

*It would need to be regularly updated to match service changes. It would need to be all evidence based.* [Parent, survey participant]

Current and accurate information about service wait times was particularly desirable for all participant groups. Families commonly experienced a lag between identifying that a young person had a problem and being able to access support services. Providing wait time information on a service navigation website could change the way families choose to access services and direct them to services with better availability. Knowing about wait times at the beginning of the help-seeking process would also inform young people and families about likely time frames for receiving support and enable them to plan ahead.

*I think the idea of including information about wait list times is very important - as this is usually critical at the time that you are seeking information and support.* [Parent, survey participant]

*I think most people are primarily looking for immediate reassurance and advice. If they can get an idea on how long it might take to access different services this also gives them a time-frame so they can plan.* [Parent, survey participant]

Young people highlighted the value of a navigation website in providing detailed information about services that would help them make informed choices. Information about accessibility was particularly important for young people. Specifically, cost and parental consent were identified as key barriers to service access, which could be partly addressed by providing detailed cost information (eg, service fees, rebates, and what benefits a child or family may be entitled to), indicating whether parental consent was required to use a service, and noting any relevant legal considerations. Young people also wanted to know if they would be able to physically access a service before they arrived and recommended that the website include information about wheelchair access (eg, presence of ramps and elevators), accessible and gender-neutral toilets, the languages spoken by staff members, whether tailoring was available for people who are vision- or hearing-impaired, and the age range targeted by a service. The content of a service navigation website should also specifically address issues faced by different minority groups, including LGBTIQ+ communities, people with disabilities, and migrant communities.

*Along with a list of mental health services, also ways of accessing them, with or without parental involvement and potential cost.* [Young person, survey participant]

*Information specifically geared towards minority groups (BIPOC, LGBTQIA+, people with disabilities etc.). Having information about different mental health issues is great but it would be a mistake not to factor in the relationship between mental health and other aspects of people’s identities.* [Young person, survey participant]

Parents wanted a navigation website that provided clear information about the kinds of services available in their area, including government and private services and general practitioners who specialize in youth mental health. The ideal website would provide specific information about how to contact services, referral pathways, referral requirements, and whether new referrals were being accepted. Details about service specializations and appointment options (eg, availability of telehealth appointments) were also indicated as helpful across both participant groups.

*Information about accessing public v [versus] private mental health services and explaining the difference.* [Parent, survey participant]

*Make sure info on telehealth is clear on if it’s: via the internet text-based, internet video-call, via the telephone, via text message. Don’t just say “this place offers telehealth services.”* [Young person, survey participant]

How to Seek Help, and What Happens Next?

Parents emphasized that a service navigation website should include practical information about how to navigate the whole help-seeking process—from recognizing signs and providing support for their child through to good questions to ask a general practitioner when seeking a mental health referral and how to advocate for and manage the ongoing care of their child. Real stories of how other families navigated mental health issues, practical step-by-step instructions, and diagrams were suggested as useful tools to facilitate access to appropriate services. Young people also wanted clear step-by-step instructions describing how to access help, including how to access services without parental involvement. They noted that finding and visiting a new location can be scary. Providing extra information about the service location, including a map, pictures of the building and the front door, and pictures of staff members, could make the process easier. Information about different types of therapies included specialist knowledge, service location, contact details, costs, service availability, and relevant legal considerations.
and how they work were also considered helpful for young people.

Lists/help navigating processes - how to get a mental health plan [Mental Health Treatment Plan], how to see a specialist...who to see for gender dysphoria issues etc. [Parent, survey participant]

Maybe some little (short time, a few minutes only) video scenarios with intros to the various services to give a sense of what / who is involved, what to expect...to get a sense of what the service is about...

[Parent, survey participant]

Participants noted that help-seeking resources should foster hope, rather than disappointment, if a service access attempt did not work out. For example, a parent who completed the survey suggested that a service navigation website could illustrate what a good mental health service arrangement looks like and let people know it is okay to try different clinicians and services if the first referral was not a good fit. Parents also suggested that a navigation website should include easily accessible information on how to recognize, respond to, and seek urgent help during a crisis situation. One parent suggested including a function that could directly link people to a crisis service if needed (eg, a crisis telephone service like Lifeline); however, other participants felt that most people would already know about commonly advertised crisis hotlines.

Information on what a good mental health service arrangement should look like - depending on individual need - and it is ok to not just stick with one person/service forever or choose none. [Parent, survey participant]

I think you need information clearly on the homepage about crisis care...and other urgent items that you don’t want to have to sift through a website for. [Parent, survey participant]

Defining Website Scope

In all 4 focus groups and the online surveys, participants raised questions about the ideal scope of a service navigation website. Participants tended to agree that the website’s scope should not be too broad. However, there was uncertainty about whether a navigation website should provide information about mental health in general or only provide information about services. Some participants also expressed a preference for a broader focus on health and well-being, rather than limiting information to mental health services. Young people suggested that broader content could include information about career and employment guidance, coping with current events, mental health at school, and quick references for self-management strategies that could be used while waiting for services (eg, mindfulness, distress tolerance, and coping with panic attacks). Parents were interested in content about mental illnesses (including mood, anxiety, and eating disorders), how to recognize them in specific age groups, and information about common comorbidities and related issues like aggression and self-harm.

This is far too mental illness and mental health service focused than I would be wanting. As a parent it’s helpful to have that information but I would also like resources that are tailor made for the site and have a focus on more on early intervention and mental wellbeing. [Parent, survey participant]

Providing links to different websites or existing online programs was suggested as an acceptable option to prevent the scope of a service navigation website from becoming too broad. For example, a navigation website could provide links to existing early intervention and mental well-being resources to support young people’s and parents’ well-being and assist parents to provide support when issues were first identified. Young people suggested providing links to research papers; stories about other people’s lived experience; and different forms of media that represent mental health in a productive way, such as video games, books, and movies. Participants noted that this approach could also connect a website to resources that fall beyond what they would typically define as a “mental health service,” including information about physical health, disability services, drug and alcohol services, and community programs and events that support and empower young people.

I would like to see it link not just mental health services, but other services to help a child overcome all the problems that may be adding to the mental health issue. For example, if the child is experiencing a lot of pain, if the child needs weight management help, if the child is being bullied or needs to develop resilience, if the child is on the autism spectrum, etc. [Parent, survey participant]

Stories from people who struggle with their mental well-being but have found support and renewed belief in themselves. [Young person, survey participant]

Website Features

Website Design

Participants generally agreed that website design would be an important element of a service navigation website’s success. Elements of website design highlighted by young people included a quality user interface that was easy to use and attractive to the intended audience. Young people described a well-designed website as colorful (but not too colorful or gimmicky), engaging, private, welcoming, local, and informed by what we know about young people and how they think. A level of seriousness in the design was required to ensure that the website was viewed as a reliable resource. Government-branded websites were viewed as a trustworthy source of local information but could be off-putting for young people who had previous negative experiences with government mental health services. A list of organizations that support the website could also signal the trustworthiness of information. Young people were also very aware of accessibility issues, recommending that a navigation website be designed to work across different platforms, for people with slow internet connections, and that it met relevant accessibility standards (eg, for people with low vision or lower literacy levels). A parent suggested that the name of the website was also important and needed to be inviting, explanatory, and nonstigmatizing.

Easy website navigation was another key design issue. When trying to communicate about one’s own mental health in a...
difficult time, participants felt that the most important thing was to access information easily. Participants indicated that they would be more likely to visit a service navigation website for a specific need or to find specific information. The website content should be set out plainly, with clear pathways to the kind of information the user is looking for. Website design should not be overly complicated, avoiding the need to navigate through tabs and the presence of too many distractions (eg, moving images or videos). Young people were described as multitaskers; thus, a service navigation website needed to capture their attention quickly. To achieve this, it would be helpful to present information clearly and concisely, and to avoid walls of text that could be overwhelming. A frequently asked question section and fact sheets were seen as helpful, but only when presented as a dedicated webpage and not solely as a downloadable document.

**Search Engines**

Parents and young people agreed that a service navigation website should systematically connect people to relevant services quickly. A good quality search engine and filtering system was a particularly important aspect of young people’s user experiences; the search bar can be the first port of call for young people trying to find help. A good search engine was described as easy to navigate, with tags and search terms updated as service information changes. In 1 focus group, young people suggested that a service navigation website could be designed like a nice online shopping experience, with tabs and subtabs for different categories of services and filters that allow users to refine their search and locate the most relevant services. However, 1 parent survey participant noted that a filter system would make them feel terrible if it indicated that there were no services matching their child’s needs, indicating that a balance between detail and generalizability may be required. Participants suggested that if there were no services meeting a young person’s search criteria, the website could direct them to resources, fact sheets, or other information they may find helpful.

...a search engine that finds services that are relevant to you. E.g. you could put in the tags “stressed” “self harming” “aged 17” “don’t want to involve parents” and the search engine would suggest; things you could do to help yourself, services you could access, and a helpline. [Young person, survey participant]

The filter would make me feel terrible if meant that my child had no services available so I think that you need to be careful regarding putting too many. [Parent, survey participant]

Focus group participants suggested having a quiz or questionnaire to help young people and parents navigate the website. For example, a pop-up box could appear when a person first accessed the website with some questions about what visitors are looking for. Answers could direct young people and parents to appropriate website sections, services, or self-help strategies. Parents suggested that a navigation website could include a symptom checklist, providing recommendations on whether a person needs to seek help from a health professional and within what time frame. Participants noted that any quizzes or checklists should be accompanied by a disclaimer stating that the website could not provide a diagnosis, and questions should be symptom or problem based, not diagnosis based. The results should be anonymous unless a young person chose to disclose them. However, some participants thought it would be important to determine if a young person was in immediate danger and requiring assistance. To facilitate help-seeking, a symptom checklist tool would ideally lead to an outcome, such as connecting users with a real person who can assist with identifying an appropriate service or next step.

Wouldn’t it be easier to complete a mental health survey upon entering the site that directs you to all the relevant pages? [Young person, survey participant]

Adolescence is a tricky time. Parents don’t know when to worry, when to escalate to professional help, and when to leave kids to muddle through. A quiz that helps navigate that would be super helpful. [Parent, survey participant]

**Supported Navigation**

Participants were enthusiastic about having the option to contact a person, by phone or text-based chat, to help them gauge the seriousness of their issue, navigate the mental health system, connect with appropriate services, and answer questions about what to expect at an appointment. Parents emphasized the importance of creating a sense of trust, confidence, and reliability when a person makes a connection through a navigation website. Finding the right service could take a lot of time, research, and mistakes, particularly during times of stress. Some participants described help seeking as overwhelming, emphasizing the importance of positive experiences that could renew confidence in seeking help and support future service use. An interaction with a real person could be an opportunity to foster hope, positive regard, empathy, reassurance, and a sense of not being alone.

This is a great idea. I found navigating the system to be impossible to start with. I was googling everything, calling all these people, being passed from service to service and getting nowhere. None of the service providers knew what any of the other service providers could do. Someone to help you navigate that would be amazing - especially if you are out of your mind with worry and sleep deprivation like I was! [Parent, survey participant]

When asking questions about mental health problems, some young people reported preferring to talk to a health professional, whereas some parents and young people suggested that this would be a good opportunity for peers to support young people and carers and that young adult peers may be better able to connect with younger website users. However, 1 young person noted that talking to a healthy peer may be intimidating for some young people. Across the surveys and focus groups, participants suggested that the person they contacted should be genuine, engaged, supportive, friendly, empathetic, unhurried, unscripted, and well trained, with appropriate counseling skills to support stressed or distressed callers. Their understanding of
mental health and local health services should be broader than the understanding provided by the caller’s own experiences.

_Having an advisory line (telephone or chat) which is supportive, anonymous if wanted, friendly and unhurried, staffed by a real person who is quietly supportive but knowledgeable would be great to help people navigate the system and get a sense of where they are best placed to use their energies in pursuing or connecting with services._ [Parent, survey participant]

Participants emphasized that the purpose of any phone or text-based contact options and the roles of the people running them need to be very clear. Contact information should be clearly stated and easy to find, and ideally some contact options would be available outside of normal business hours (eg, evenings, nights, and weekends). Participants had concerns around potential privacy issues, particularly related to data collection and storage, and the need to support people who disclose thoughts of suicide and self-harm. Parents recommended that all interactions end with some kind of closure, for example, actions such as making an appointment for the person with an appropriate service or taking a concrete step that progresses the issue, with timely outcomes.

_I’d also be more comfortable in knowing how any conversations via the website were recorded and stored since there is always the chance of personal stuff coming up in conversations, and I wouldn’t want that to be accessible by anyone except those who are directly working to help me._ [Young person, survey participant]

Further, participants discussed the option of receiving a follow-up call or text, after interacting with a person via a service navigation website. Some participants felt that a follow-up call could be comforting for people who were currently on a waitlist, for example, by providing updates on wait times and identifying alternative sources of support. Survey participants were primarily interested in receiving follow-ups related to service access, for example, checking in to see if services had connected with a young person, how effective the service has been, and if the young person’s needs are being met. Although some participants also wanted the opportunity to give feedback about services, some parents felt oversurveyed by mental health services. Other participants felt that a follow-up would not be helpful in all circumstances. For example, I parent felt that receiving a phone call may just be more frustrating if accessing services was not going well. Participants agreed that any follow-up from a service navigation website should be opt-in, the user should have control over how and when they are contacted, young people should decide whether their parents are contacted, and any promises made by a navigation service should be honored (ie, call if you say you will call). Choice and control over contact was seen as particularly important for young people living in high-risk situations, where receiving a phone call or message could potentially be unsafe.

_I think having options is good, especially for kids in potentially dangerous situations. And I do think texting is popular with kids._ [Young person, survey participant]

_I think it is also important to see how well people went with actually accessing the services and whether their child’s needs were met and what negatives there were._ [Parent, survey participant]

_**Forums, Reviews, and User Accounts**_

Website functions that could allow users to share information were met with a mixed reception. The options discussed included forums, service reviews, and user accounts. Forums received the most positive reception, but with important safety considerations for implementation. They were described as a positive tool for young people and parents to connect with peers who have had similar experiences and share coping techniques or to connect with health professionals. However, to be safe and useful, a forum or chat room would require careful moderation. Participants suggested that forums could be provided by a service navigation website itself or the website could instead provide links to external, good quality, moderated mental health social media pages or similar services.

_Particulary when I was younger, online resources were huge! Whether that was headspace’s online counselling, or online chat forums with other people. I think those chats were absolutely fantastic, however they definitely needed expert moderation._ [Young person, survey participant]

_I’m a little concerned about forums and/or chat rooms. They would need to be carefully monitored to make sure there are no trolls responding negatively or people using cyber bullying._ [Parent, survey participant]

User reviews of mental health services were raised as a possibility, but this option had both advantages and disadvantages. Reviews could provide information to help young people choose a suitable service and prepare for their own visit. However, mental health service needs and preferences were seen as highly individual; thus reviews may deter young people from accessing services that would actually suit them. One young person suggested that a government “check mark” (ie, accreditation), indicating that services were legitimate, could be an alternative to reviews, and a parent suggested including a feature where young people and parents could post questions to be answered by a website staff member.

User accounts were the least desirable function of a service navigation website. Young people’s responses to implementing user accounts were overwhelmingly negative, due to concerns around privacy, security, safety, stigma, and limiting access to website features for people without accounts. Young people thought their peers may also associate accounts with costs like subscription fees. A small number of survey participants thought it would be helpful to have a single digital record of the services they had tried and a “wish list” of services they would like to try in the future. However, most parents and young people were uncomfortable with the idea of their mental health information being stored online and believed that this could create a barrier to people using a service navigation website. Young people
emphasized the need to be able to access a service navigation website anonymously, particularly when living in high-risk situations where internet use was monitored, and some felt that an optional user account would overcomplicate a navigation website. Young people suggested a range of other, less invasive, ways to tailor user experiences, including features that made it easy to save pages to favorites in a browser, copy content to the clipboard, email a link to service contact information, and save records of service contact information into another application (eg, into the Notes or Photos app on a phone).

A record of interactions makes me feel insecure, because I know the website is keeping data on me. This is not just “not helpful,” but distinctly unhelpful. [Young person, survey participant]

I would be concerned about a portal where you sign in. While it might be good to have information all in one place, really mental health information belongs in a doctor’s office. If your child is displaying mental health problems, you don’t really want that recorded when you don’t know how that information will be used into the future. [Parent, survey participant]

Discussion

We conducted focus groups and online surveys to inform the design of a mental health services navigation website. Although the research activity was conducted with a specific region in mind, the findings may assist other organizations designing websites or apps to assist young people and parents in navigating mental health systems. Many of the themes represent common issues faced by young people in need of mental health support.

Participants emphasized the need for, and importance of, up-to-date and accurate information about local mental health services (public and private) and guidance on how to access them (including referral pathways). Participants were aware of existing lists and directories of services, but these were described as incomplete, out of date, and difficult to search. Navigation tools were seen to be most helpful if they could provide local, tailored information, including service information that could not be accessed elsewhere. Transparent information about service cost, wait times, and how to access services without parental permission was in particularly high demand. This information could support young people and parents to make informed choices about which services to select and pursue. Future research exploring the specific service information that is needed to adequately meet end-user needs and that translates into actual service contacts would be beneficial.

Similarly to previous research, participants also emphasized the need for information about referral pathways and how to navigate the mental health system [9,19]. Parents and caregivers shared that they often acted like case managers and advocates for their children, and they wanted access to information and resources that could support them. Step-by-step instructions, flow charts, and real-life stories of accessing mental health care, tailored to the local system, could all support young people and their parents on their journeys from first seeking help to accessing specialist services [19].

An effective search engine was an important aspect of the navigation tool’s design. All information within the navigation tool needs to be searchable, and users should be able to refine their search results using relevant filters. Young people and parents felt that they should be able to independently find service information more easily than they could with a web search engine and that a navigation tool should be broadly accessible, functional, easy to navigate, and tailored to its audience in content and appearance. This finding highlights again the importance of the co-design process, and end-user testing, to ensure that the tool developed is fit for purpose and fully meets the needs of those who will use it [15]. Relatedly, digital tools should also be designed in accordance with web accessibility standards to ensure that all users can effectively use them, including those with disabilities [20].

Participants also felt that it would also be helpful for the navigation tool to provide a phone, text, and/or web chat service. Specifically, participants wanted a phone line or web chat option that could help people to identify relevant and appropriate mental health services and support them to decide which service to contact first. Including this feature would reduce the burden on young people and parents to identify, research, and select services alone. Offering an option to receive a follow-up call or text from a phone line or web chat may also be beneficial.

Underlying many of these findings was the need to have control over the help-seeking process. Control over how and when to interact with content is an important concern for young people in the design of online mental health interventions [16,21]. Providing choices was important to participants in our study; both choice in how they could contact a support person through the navigation tool (eg, phone call, web chat, SMS text messaging, or email) and choice in if, how, and when they were contacted by the navigation tool or engaged with a service.

Other potential navigation tool elements, such as being able to create a user account, were not as desirable. Storing records of health information online, particularly mental health information, raised serious concerns around privacy. Generally, participants felt that people would primarily use the navigation tool anonymously and independently. This aligns with previous findings from the development of mental health interventions for young people and adults, which highlighted confidentiality, privacy, and trust in the organization delivering the service as key areas of importance for end users [21-23]. Some people felt that it could be helpful to be able to record their activity (eg, service wish lists) while using the navigation tool and/or service use in a single location, but participants emphasized that user account features should be opt-in. Such features may be off-putting for potential users.

The involvement of end users in the design of the navigation tool was highly valued by the commissioners of this research and resulted in the development of a youth navigation website called MindMap [24], which captures the key elements identified by participants. The findings of this study provided formative information for the development of MindMap, although there was additional development and testing involved to create the final website, which is beyond the scope of this paper. MindMap is an accessible web-based tool that provides a comprehensive
searchable database of local services and provides a clear description of the service, its location, and potential wait times. It is an initiative of the ACT Office of Mental Health and Wellbeing and delivered by a nongovernmental organization with strong connections into the local mental health sector, enabling frequent refreshing of service information. Users of MindMap can use the navigation tool independently or receive navigation support during the week or on weekends from members of the MindMap team via telephone, email, or web chat. Young people and parents or caregivers were involved in the iterative development and testing of MindMap to ensure that it continued to meet their needs.

There are some limitations to this research that should also be considered. First, the participants in the focus groups and survey may not have been representative of all young people and parents or caregivers in the community, and the study may have attracted people with a greater interest in mental health. Preferences for website appearance, content, and features may have varied by age and personal experience of mental health issues [16,25]. Future research would benefit from sampling more young men, and young people and parent or caregivers without mental health service experience, to ensure that the needs and preferences of all targets are adequately captured and met.

The scope of the questions in the focus groups may also have guided the discussion, placing more emphasis on the areas covered by the questions and consequently may have missed other issues. This issue was partly mitigated by providing time within focus groups for participants to identify issues not covered by the questions. The timeline of the project necessitated the use of point-by-point note-taking from focus group recordings, rather than verbatim transcripts, for data analysis. We acknowledge that this approach may have a higher risk of introducing research bias; however, this was mitigated through regular discussion of the analysis with the research team and the inclusion of qualitative survey data in the analysis. Lastly, the research was conducted with a specific region in mind, and thus not all findings may be relevant to other contexts. Overall, this study provides important insights into the navigation needs of young people and their parents or caregivers seeking mental health services and how best to support them in this process. The focus groups and surveys identified the need for tailored local information, the provision of up-to-date service details, and the opportunity for users to navigate the site independently or with support. Ensuring that young people and their parents or caregivers can access mental health services in an efficient and timely manner is essential to the longer-term health and well-being of young people. Future research assessing the effectiveness of navigation tools in meeting this goal should be strongly encouraged.

Acknowledgments
We would like to thank and acknowledge the young people, parents, and carers who participated in this research. This research was funded by the Office for Mental Health and Wellbeing, ACT Health. ALC is supported by a National Health and Medical Research Council (NHMRC) fellowship (1173146). ARM is supported by a Suicide Prevention Australia Post-Doctoral fellowship.

Data Availability
The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions
ALC and PJB led the design of the study, with input from all other authors. ALC, SMM, EM, NJ, and ARM contributed to data collection. ARM and MB conducted the analyses. ALC and ARM drafted the paper. All the authors critically reviewed and approved the final manuscript.

Conflicts of Interest
None declared.

Abstract

Background: Youth who experience traumatic events are at a substantially higher risk of engaging in substance use and sexual risk behaviors and problems (eg, HIV acquisition) than their non–trauma-exposed counterparts. Evidence-based substance use and risky sexual behavior prevention may reduce the risk of these outcomes. Trauma-focused mental health treatment provides a window of opportunity for the implementation of such preventive work with these youth. However, overburdened clinicians face challenges in adding prevention content while implementing evidence-based treatments. Mobile health (mHealth) tools can help reduce this burden in delivering prevention curricula. Trauma-Informed Prevention for Substance Use and Risky Sexual Behavior (TIPS) is an mHealth app that was developed to aid trauma-focused cognitive behavioral therapy (TF-CBT) clinicians in the implementation of an evidence-based risk behavior prevention curriculum.

Objective: The goal of this paper is to describe the rationale for and development of the TIPS app and present the results of a mixed methods approach for the initial evaluation of its usability.

Methods: Participants included clinicians (n=11), adolescents (n=11), and caregivers (n=10) who completed qualitative interviews and an adapted version of the Website Analysis and Measurement Inventory.

Results: In total, 4 overarching themes emerged from the participants’ answers to the qualitative interview questions, demonstrating a generally positive response to the app. The themes were (1) strength of app content, (2) suggestions about app content, (3) esthetics and usability, and (4) benefits to the patient and session implementation. Clinicians, adolescents, and caregivers all agreed that the content was very relevant to adolescents and used examples and language that adolescents could relate to. All 3 groups also discussed that the content was comprehensive and addressed issues often faced by adolescents. All 3 groups of users made suggestions about the esthetics, which mostly comprised suggestions to change the font, color, or pictures within the app. Of all the groups, adolescents were most positive about the esthetics and usability of the app. Results from the Website Analysis and Measurement Inventory further illustrated the users’ favorable reaction to the TIPS app, with 100% (11/11) of clinicians, 100% (10/10) of caregivers, and most adolescents (7/11, 64%) selecting strongly agree or somewhat agree to the following statement: “This app has much that is of interest to me.” Adolescents generally found the app easier to use than did caregivers and clinicians.

Conclusions: The TIPS app shows promise as an mHealth tool for TF-CBT clinicians to integrate evidence-based substance use, risky sexual behavior, and HIV prevention during treatment. Future research, including a randomized controlled trial comparing
TF-CBT implementation with and without the inclusion of the app, is necessary to evaluate the feasibility and efficacy of the app in reducing the risk of substance use and risky sexual behavior among trauma-exposed adolescents.

**Introduction**

**Background**

Children and adolescents who experience traumatic events are at a substantially higher risk of engaging in sexual risk behaviors and substance use than their non-trauma-exposed counterparts [1,2]. Early traumatic experiences also have long-term effects on behaviors as youth exposed to trauma are more likely than their nonexposed peers to develop substance use disorders [3,4] and experience unexpected pregnancy and sexually transmitted infections (STIs) [5,6], including increased risk of HIV acquisition [7,8]. Models addressing the link between trauma exposure and risk behavior have suggested that, although these behaviors are multidetermined, trauma exposure plays an important role by manifesting impairments in affect regulation, impulse control, identity development, and socialization [2,9].

Given the strong relationship between trauma exposure and problematic behavioral health outcomes, preventing morbidity related to substance use and sexual risk behavior may be best addressed from a trauma-informed lens. That is, an important prevention approach may involve addressing risk behavior in the context of trauma-focused assessment and treatment. However, data suggest that clinicians are often reluctant to integrate interventions related to substance use in the context of trauma treatment [10] because of clinical, systemic, and training barriers and limited resources (including limited support) relative to caseload demands [10-13]. Given the need for substance use and risky sexual behavior prevention for trauma-exposed adolescents—and to combat these barriers and demands for time and resources—clinicians may benefit from a structured tool to help efficiently implement evidence-based prevention strategies for risk behaviors common among trauma-exposed youth [14]. Such a tool may be best delivered via a mobile health (mHealth) approach, which can reduce the need for extensive clinician training in multiple new prevention intervention curricula, augment the formal training they do receive, and enhance or extend the effectiveness of the traditional clinical encounter [15,16]. As such, clinicians would be significantly more likely to deliver substance use prevention if a ready-made mHealth tool were available that helped them deliver it efficiently and accurately. This study describes the development and feasibility evaluation of an mHealth app designed to supplement trauma treatment among adolescents, targeting prevention of substance use, sexual risk behavior, and associated health consequences (eg, HIV).

**Adolescent Trauma Treatment as an Opportunity for Prevention**

The gold-standard treatment for addressing adolescent trauma is trauma-focused cognitive behavioral therapy (TF-CBT) [17,18]. With >20 completed randomized controlled trials (RCTs)—including international studies—supporting its effectiveness in addressing a range of mental health problems and improving functioning among trauma-exposed youth, TF-CBT has received the highest ranking for empirical support from professional organizations and federal agencies [19-38]. TF-CBT has achieved widespread dissemination through numerous implementation efforts, including comprehensive training programs (eg, community-based learned collaboratives), educational materials, and collaborations with mental health organizations, ensuring its accessibility and use by therapists and clinicians across various regions and populations. In fact, the widespread utility of TF-CBT is exemplified by the staggering number of clinicians who have accessed TF-CBT Web 1.0 and 2.0 (original and updated versions of the TF-CBT web-based learning course); as of August 31, 2023, a total of 496,061 clinicians worldwide are registered users of the web-based training in the TF-CBT model, and 305,120 clinicians have completed the training [39]. Modules of TF-CBT, including psychoeducation and enhancing safety, may include general psychoeducation about sex and sexual revictimization risk reduction; however, information and skill development specific to HIV and STIs, pregnancy, and healthy dating and sexual decision-making are not detailed in the model manual or training. Similarly, skill development for preventing substance use problems that extends beyond psychoeducation and helps translate this knowledge into skills is not formally or typically incorporated into TF-CBT, limiting the potential impact of these psychoeducation modules. In other words, these clinicians do not systematically receive the training and support needed to feel confident in their delivery of psychoeducation content or in the ways to translate this education into skills (eg, realistic refusal skills) [10].

Although clinicians can informally incorporate risk behavior topics into their implementation, the data suggest that this is uncommon. A national survey of mental health clinicians found that providers feel ill-equipped to address topics of substance use and sexual risk behavior when treating trauma-exposed adolescents even when trained in trauma-informed treatment models [10]. Most clinicians did not report receiving formal training for addressing substance use disorder (54%) or sexual risk behavior (67%), suggesting that this reluctance may be related to deficits in training on these topics [10]. These data reflect a global lack of training in evidence-based practice for adolescent prevention, which results in limited translation and...
accessibility despite the availability of numerous efficacious preventive interventions [40]. In summary, although effective sexual risk and substance use prevention interventions are available, there is a significant gap in the implementation of these interventions even among those at high risk of such behaviors because of trauma exposure.

mHealth as a Viable Approach to Address Prevention

The availability of mobile technology has increased dramatically over the past decade, with 85% of Americans reporting smartphone ownership in 2022 compared with 35% in 2011 [41,42] and 95% of American adolescents reporting smartphone access [43,44]. As mobile technology has rapidly developed, so have health care approaches that leverage mHealth—the use and development of mobile technology, including mobile apps, to improve health care [16,45]. Within mental and behavioral health care, mHealth interventions are diverse, targeting different stages of treatment from education and engagement to the maintenance of treatment gains [16]. mHealth administrations are also diverse and may be stand-alone, client-led interventions or supplements to traditional clinician-facing treatments [16].

Most of the extant mHealth approaches to behavioral health among adolescents are stand-alone interventions rather than supplements to face-to-face treatment [46]. Several stand-alone treatments have shown strong feasibility and efficacy for both primary and secondary prevention of substance use and sexual risk behavior [47-50]. However, most stand-alone behavioral interventions for adolescents lack a theoretical framework in their design and show inconsistent efficacy [46,51]. Furthermore, although data suggest that digital mental health tools delivered in real-world contexts are more likely to be accessed than professional services, they are less likely to be delivered with a sufficient therapeutic dose [52]. These limitations are compounded by clinician- and patient-reported barriers to stand-alone treatments, including the lack of personalization [51,53], lack of privacy and security with regard to sensitive behavioral topics [53,54], limited follow-up [51], and attrition and low completion rates [54,55]. Researchers have suggested that these barriers could be overcome with more support and involvement from clinicians [53]. Accordingly, behavioral health treatments that blend face-to-face and technology-based approaches have been found to save clinician time, demonstrate lower dropout rates, and lead to better treatment outcomes among adolescents and young adults [56,57].

With regard to trauma treatment, 3 popular mHealth apps have emerged for use with adults: Posttraumatic Stress Disorder (PTSD) Coach, Cognitive Processing Therapy Coach, and Prolonged Exposure Coach [58]. The most widely used of these is PTSD Coach, a stand-alone treatment that suffers from limitations similar to those mentioned previously [58], including high attrition and inconsistent efficacy [59]. Conversely, Cognitive Processing Therapy Coach and Prolonged Exposure Coach are supplementary to existing evidence-based treatments for PTSD. Although these apps have not been evaluated for efficacy via RCTs, clinician perceptions of such apps have been favorable, particularly regarding their relative advantage over exclusively face-to-face practices and compatibility with clinicians’ needs [60]. In addition, supplementary mHealth approaches have demonstrated effectiveness in the treatment of comorbid trauma conditions (eg, panic disorder, anxiety, and depression) [61], including comorbid PTSD and substance use [62].

Despite evidence of the feasibility and effectiveness of mHealth interventions in trauma treatment among adults, mHealth approaches to trauma treatment among adolescents are limited. In total, 3 stand-alone prevention approaches for adolescents exposed to acute trauma have demonstrated effectiveness in reducing persistent trauma symptoms, depressive symptoms, and behavioral problems [63-65]. Although no studies have examined the effectiveness of supplementary mHealth approaches for adolescent trauma treatment, the perspectives of trauma-focused clinicians indicate that these approaches would be feasible and useful. For example, Orengo-Aguayo et al [66] found that 96% to 100% of surveyed TF-CBT providers reported that an mHealth supplement would be helpful for enhancing TF-CBT components, extending coping skill development, and improving out-of-session practice among adolescents and families. Clinicians, patients, and families have also responded favorably to pilot versions of a supplemental Apple iPad–based app designed to improve patient engagement and provider fidelity in-session during TF-CBT [67,68]. Thus, mHealth supplements to adolescent trauma treatment may be a feasible and acceptable way to extend and improve behavioral health prevention among adolescents.

This Study

The purpose of this paper is to report on the development and perceived usability of Trauma-Informed Prevention for Substance Use and Risky Sexual Behavior (TIPS), a novel mHealth tablet-based app designed to supplement trauma treatment targeting the prevention of adolescent risk behavior (trial registration: ClinicalTrials.gov NCT03710720). We used a mixed methods approach based on qualitative interviews and quantitative ratings to assess the usability of the TIPS app with clinicians, adolescent patients, and their caregivers engaged in TF-CBT in a community-based outpatient clinic.

Methods

TIPS App Structure

The first author, a national trainer in the TF-CBT model, led a small team of TF-CBT clinicians and trainees in the development of the content of the TIPS mHealth app. This included 7 total topics (Figure 1) designed to be used as psychoeducational tools for TF-CBT clinicians to implement with adolescents and caregivers throughout the TF-CBT treatment process. The tool helps clinicians assess their clients’ and caregivers’ current knowledge and comfortability surrounding topics related to risky sexual behaviors, STIs, drug use, and healthy relationships. Thus, there are 3 intended users of the app: clinicians, adolescents, and caregivers. Each user sets up a unique log-in, and the content displayed on the app is tailored to the user type. For example, Family Check-Up example videos demonstrating parenting skills are displayed for the caregiver but not for the youth, and a sexting decision-making activity is displayed for the youth but not for...
the caregivers; clinicians view both caregiver and youth content but also have unique introduction videos for each app topic tailored to a clinician audience and have additional drop-down menus on the app, such as suggested homework that the clinician can assign.

**Figure 1.** Trauma-Informed Prevention for Substance Use and Risky Sexual Behavior (TIPS) home screen (after log-in) listing the 7 topics and activities.

In particular, the app was designed to map onto the psychoeducation, parenting, and enhancing safety treatment components of TF-CBT. Each topic of the app is introduced by a short video that explains the aims of the section as well as the directions needed to successfully complete the section. After the completion of each component activity (briefly described in this section), users are presented with feedback relevant to their performance on the current activity as well as resources (links to websites) to help further their education on the topic. Specifically, the **What Do You Know?** component is formatted as a multiple-choice trivia game that serves as a psychoeducational tool to educate trauma-exposed teenagers and their caregivers on the effects of drugs and alcohol. The **Myth Busters** component educates users on the common facts and myths about HIV and other STIs. This section was designed as a drag-and-drop game and includes a video that demonstrates how to perform an at-home HIV test kit. The inclusion of the video aimed to reduce negative connotations that may currently exist related to getting tested for HIV (eg, scary, involving needles, and time-consuming). The **Hot or Not** component was designed as a psychoeducational tool to aid adolescents in recognizing unhealthy behaviors within romantic relationships. This section comprises engaging videos, multiple-choice trivia, and feedback that is presented after response submission. A main goal was to highlight warning signs that may precede more obvious unhealthy behavior as trauma-exposed teenagers may be more likely to stay in unhealthy romantic relationships. **Make a Play** helps guide adolescents through tough yet common situations that teenagers may experience. This component consists of 5 activities that educate users on choices involving sending nude pictures, having unprotected sex, consuming alcohol, and being offered different types of drugs. These activities are presented as choose-your-own-adventure screenplays that allow adolescents to make different choices for each situation that is presented and view the results for their different decisions. **Figure 2** illustrates an adolescent presented with the choice to accept or decline the offer of marijuana by a peer. The **Family** topic of the app presents the empirically supported **Family Check-Up** [69] in an engaging way, educating caregivers on the different components involved in positive parenting (eg, communication, encouragement, and supervision). This section consists of videos, text information, and quizzes. **Cyber Life** was created to aid in the education regarding safe web behaviors and choices. This component presents users with possible situations that they may encounter on the web and the choices they can make in a multiple-choice format. Each choice is followed by feedback on its positive aspects and the risks involved. The **Vision 25** topic is to be used as a guide in goal setting. This section helps users think about their current goals, what choices they can make to help them successfully accomplish their goals, and what choices they can make that may result in their goals becoming harder to reach. This section presents users with a road map (**Figure 3**) where they can choose different ages at which to set goals, providing guidance for both short- and long-term goals.
The TIPS platform was developed using AppBuilder, a content management system developed by our institutional’s Clinical and Translational Science Award. AppBuilder includes a wide array of design templates and features to ensure that native iOS and Android apps can be created by researchers, program staff, and other team members who have no formal coding experience. Investigators and innovators use it to wireframe, pilot test, change and add content, and launch and evaluate mHealth apps without the extensive involvement of a technical development team. Mobile app developers often become involved in AppBuilder-based initiatives only on a strategic, limited basis, consistent with our goal of significantly shortening the timeline and costs associated with building mHealth apps.

Usability Testing Overview

Usability testing is incorporated into technology development to improve user experience by measuring whether the user can successfully and effectively use the tool. Usability testing incorporating both qualitative and quantitative methods can also help identify barriers to task completion and examine areas that take the user off topic, create confusion, or decrease satisfaction [70]. The purpose of usability testing in this study was to obtain objective metrics and refine the final TIPS product before formal efficacy testing.

Ethical Considerations

All procedures were approved by the Medical University of South Carolina Institutional Review Board (Pro00041527). Participants (ie, clinicians, caregivers, and teenagers) were given an information sheet that detailed the purpose of the research; procedures; risks, discomforts and benefits; costs and compensation; alternatives; and confidentiality. Participants provided verbal consent in lieu of written consent. Participant data were deidentified to preserve confidentiality. In addition,
participants were compensated for their participation with US $30 in the form of a gift card, cash, or money order.

Participants

Participants included mental health clinicians (11/32, 34%; 26/32, 82% female), trauma-exposed adolescents (11/32, 34%; 26/32, 82% female), and caregivers of adolescents (10/32, 31%; 25/32, 80% female). More specifically, with regard to inclusion criteria, clinicians were master’s or doctoral-level mental health providers in the area local to the study who were fully trained and experienced in TF-CBT and carried active child trauma caseloads. Adolescents were aged between 13 and 18 years, had experienced at least one traumatic event, were in the process of completing or had recently completed TF-CBT, and assented to participate (with caregiver consent). To be included, caregivers needed to have served for at least the previous 2 months in the role of primary caregiver of a teenager in treatment for PTSD who was in the process of completing or had recently completed TF-CBT. Among the clinicians, 72% (8/11) were aged between 25 and 34 years, whereas 27% (3/11) were aged between 35 and 44 years. The adolescents ranged in age from 13 to 18 (mean 15.25, SD 1.90) years, with most (9/11, 82%) falling between the ages of 13 and 17 years. Finally, caregivers ranged in age from 34 to 53 (mean 44.2, SD 6.65) years.

Procedures

Participants (clinicians, adolescents, and caregivers) were recruited from community-based mental health centers that specialized in the treatment of traumatic stress and served multiple counties (including urban and rural areas) in a large city in the Southeast United States. There were 2 primary methods through which participants were recruited: (1) flyers were posted in and around the clinics with contact information for the study project coordinator and (2) potential participants were informed by clinic staff that they may qualify for a study and asked whether they would be interested in learning more. When potential participants responded positively, the study coordinator contacted them and provided a full description of the study, screened them to ensure that the inclusion criteria were met (see the previous section), and consented them to participate in a qualitative interview regarding the TIPS app and completion of the Website Analysis and Measurement Inventory (WAMMI; see the following section).

Measures

The semistructured qualitative interview consisted of a study team member providing the participant with an iPad loaded with the TIPS app and walking the participant through each section. Following each section of the app, the interviewer asked several open-ended questions (eg, “First, tell me, what are you thinking when you look at this page?” “What do you like about this activity?” “What don’t you like about this activity?” and “How can we make this more interesting to teens?”). Follow-up probes were used to clarify the information provided whenever necessary.

The WAMMI [71] is a standardized 20-item assessment measure that captures users’ personal opinions on a given website’s ease of use. The items were slightly revised to refer to the application rather than the website. In the measure, users are asked to rate various aspects of their experience with the app (eg, content, navigation, and design) on a 5-point Likert scale from strongly agree to strongly disagree. Items are then scored to produce 5 subscales measuring the app’s attractiveness (level of visual interest of the app in terms of both function and information provision), control (app navigation ease), learning (users’ ability to easily understand the content of the app and learn what they expect to learn), helpfulness (usefulness and expected content and structure of the app), and efficiency (users’ ability to quickly find and do what interests them on the app). The WAMMI was developed using latent variable analysis, has high reliability, and reports standardized scores (eg, 50=average; 100=perfect) for the 5 aforementioned themes based on a reference database [72].

Data Analysis Plan

Quantitative Approach

All descriptive analyses were performed using Stata (version 17; StataCorp LLC) [73]. The data were screened for outliers and impossible values. Group differences in the WAMMI items were compared using 2-tailed paired t tests.

Qualitative Approach

Data analysis consisted of a qualitative content analysis [74] informed by grounded theory [75], which is used to explore participants’ unique perspectives via the identification of themes and patterns that naturally emerge from the data and the systematic classification of these themes. Specifically, a 3-step inductive approach was used, which involves collecting and analyzing data without preconceived categories or theories. To analyze using this approach, each participant’s interview responses (ie, raw data) were carefully examined to develop a comprehensive codebook to capture all possible themes emerging from the data. The codebook was then used by 2 independent coders to code and analyze each participant’s responses to the interview questions [74,76]. Coders were able to apply more than one code to the participant responses if applicable. The interrater reliability for the double-coded interview responses was 86% and ranged from 82% to 93%. Interrater discrepancies were discussed and resolved by the 2 independent coders. Finally, themes were refined, merged, or divided into subthemes via collaborative discussions in multiple in-person meetings until a comprehensive codebook was developed. The NVivo software (version 11.1; Lumivero) was used for data management and analysis. The interviews were approximately 45 minutes in length and were audio recorded and transcribed.

Results

Technology and App Use Descriptive Information

Clinicians answered some descriptive questions about comfort using smartphones and apps and the benefits and drawbacks of using websites or apps in treatment. All clinicians (10/10, 100%) reported (1) being comfortable using smartphones and tablets and (2) that the primary benefit of using websites and mHealth app tools is that they engage teenagers in treatment and that they are readily accessible. Other benefits reported by clinicians
included that apps are free and that teenagers feel comfortable using them. Drawbacks reported by clinicians included that it is difficult to get teenagers to stop using apps and that not all homes have Wi-Fi access.

Adolescents and caregivers were asked about their use of tablets and cell phones. Most adolescents (8/11, 73%) and caregivers (8/10, 80%) reported personally owning a tablet, and all adolescents (11/11, 100%) and caregivers (10/10, 100%) reported owning a cell phone. The primary uses of tablets by adolescents included accessing social media, playing games, watching television shows or movies, SMS text messaging, and completing schoolwork. Adolescents reported that they primarily used their cell phones for talking to friends, SMS text messaging, accessing social media, playing games, and listening to music. Caregivers reported that they primarily used their tablets for playing games, paying bills, surfing the internet, watching television shows and movies, school and work, accessing social media, and checking email. Caregivers primarily used their cell phones for talking to people, SMS text messaging, accessing social media, and surfing the internet.

Qualitative Results

Overview

Through the individual interviews, valuable information about the usability and perceived effectiveness of TIPS was obtained from clinicians, adolescents, and caregivers. Four overarching themes, each with its own subthemes, emerged from the participants’ answers to the interview questions: (1) strength of app content, (2) suggestions about app content, (3) esthetics and usability, and (4) benefits to the patient and session implementation. Table 1 shows the app themes that emerged. Each is described in greater detail in the following sections, with representative quotes provided throughout for illustrative purposes.

Table 1. Trauma-Informed Prevention for Substance Use and Risky Sexual Behavior (TIPS) app themes and percentages yielded from the qualitative interviews.

aThemes that emerged from the responses of all users during the qualitative interviews (32 participants and 194 responses).

Theme 1: Strengths in the App Content

A total of 62% (20/32) of the participants discussed the strengths of the content of the TIPS app. Most strengths mentioned within this theme included comments about the appropriateness of the content for adolescents (21/32, 66%), the content of the modules (17/32, 53%), pictures or videos (13/32, 41%), or that the content was entertaining and would keep an adolescent’s attention (11/32, 34%). Other comments centered on language content, diversity of content, positive framing of information, or that the content differed by activity. Clinicians, adolescents, and caregivers all agreed that the content was very relevant to adolescents and used examples and language that adolescents could relate to. All 3 groups also discussed that the content was comprehensive and addressed issues often faced by adolescents. For example, clinicians commented the following:

*I really like the feedback sessions when you give the examples. They’re very detailed, but not overly detailed.*

*I think the language is really accessible to most kids.*
Examples of strengths stated by adolescents include the following:

- The videos are funny. I definitely like those.
  - I actually think that the text itself, that was pretty cool how y’all made it like the iPhone with all the emojis and stuff. And it is kind of relatable to people my age, at least, text. And the responses to it were...like sending the cat picture, that’s definitely something people would do if they don’t feel comfortable and they’re trying to make it funny.

Strengths mentioned by caregivers included the following:

- I think the Let’s talk about Sext [video] needs to come as soon as you put the phone in their hand. Plain and simple, right off the rail. It’s not like there’s going to be a certain age, it’s like having the talk about the birds and the bees.
  - Man, I liked the points they’re making. You know, I think they’re absolutely making the right points with, you know, being present, you know, when your kids are around. Knowing your kids’ friends, knowing where they are, surprise phone calls. I like all that stuff.

Theme 2: Changes in or Suggestions for App Content

A total of 59% (19/32) of the participants discussed changes or suggestions regarding the TIPS app content. Most comments within this theme included making content more engaging (22/32, 69%), revising the video or picture content (22/32, 69%), suggestions for content topics to add (17/32, 53%), revising the language to make it more relatable to teenagers (15/32, 47%), and allowing the content to be more individualized (8/32, 25%). Other comments included language suggestions, adding more outside resources, increasing cultural sensitivity, clarifying content, improving instructions, and removing potentially triggering content. Although the specific suggestions differed among the clinicians, adolescents, and caregivers, the feedback overlapped in that adding more interaction and individualizing some of the content would help improve the app.

Some examples of comments made by clinicians include the following:

- I’ve seen a lot of kids get through school that can’t read, so try to look at all factors. Maybe some more visual aids along with the words.

Some statements made by adolescents included the following:

- Add a game or something. I don’t know what type of game, but a game that you can play for the answer.
  - Maybe even include something about rape in a relationship, because a lot of people that I’ve talked to, they don’t think that you can be raped in a relationship.

Comments made by caregivers included the following:

- You know, make it a little bit more interesting. If it could be made more interactive.
  - A lot of kids don’t have parents. They’re already living with a family member, or in foster care. Another line to put in there somewhere is, talk to someone you trust...doesn’t have to be a parent.

Theme 3: Esthetics and Usability

A total of 25% (8/32) of the participants discussed the esthetics and usability of the TIPS app. The most common comments within this theme involved strengths regarding the esthetics of the app (15/32, 47%), suggestions for the esthetics of the app (13/32, 41%), and dislikes regarding the esthetics of the app (9/32, 28%). Participants also made a few comments about usability, including suggestions and strengths regarding the functionality of the app. All 3 of the groups (clinicians, adolescents, and caregivers) made suggestions about the esthetics, which mostly comprised suggestions to change the font, color, or pictures within the app. Of all the groups, adolescents were the most positive about the esthetics and usability of the app.

Some examples of statements made by adolescents include the following:

- Maybe use highlight and change the color or something to make it clear. I think that the progress bar at the bottom is so simple. It stays out of the way, so you’re not sacrificing real estate.
  - [I like] the progress bar on the bottom. It’s a nice touch because then I don’t have to keep wondering how many more questions. I can see that I’m almost done, so that helps me not get frustrated, especially for a teen.

Specific comments made by caregivers included the following:

- I like the subtitles on the bottom, because I feel like you sometimes get lost in the words, so I like that they’re there.
  - I like the bright colors. The bright colors catch my eye.

Theme 4: Benefits to the Patient and Session Implementation

A total of 19% (6/32) of the participants discussed how the TIPS app benefits the patient or made comments about session implementation. Most comments within this theme included that the TIPS app increases the comfort of the adolescent in the session (10/32, 31%) or that clinicians would be more likely to use the TIPS app with particular patients (10/32, 31%), such as female individuals or sexually active teenagers. Other comments in this theme included that the app makes the session more interactive, increases engagement for teenagers, is easy to incorporate into the session, and allows the clinician to modify or select content based on patient needs.

Some examples of comments made by clinicians include the following:

- The activities are very easy to operate.
  - I think it’s a good font size, I wear glasses, and I didn’t have to squinch my eyes to see. I also like how the page is light blue, and it’s dark blue for the words to stick out. So you’ll be able to look at it. That’s one thing I like about it.

Specific comments made by caregivers included the following:

- I like the subtitles on the bottom, because I feel like you sometimes get lost in the words, so I like that they’re there.
  - I like the bright colors. The bright colors catch my eye.

Some examples of statements made by adolescents include the following:

- I like the subtitles on the bottom, because I feel like you sometimes get lost in the words, so I like that they’re there.
  - I like the bright colors. The bright colors catch my eye.
This is good for me, too, the way I’m able to give feedback to the patient, or at least talk about it, cuz once it’s there, okay, I get it, and I can explain it to them, so I really like it.

Comments made by adolescents included the following:

The app makes it easier because it’s just awkward to talk about these things.

Some statements from caregivers included the following:

I think for this exercise as far as getting them to wrap their brain around where they really have established rapport with you, it’s probably a nice way of doing that where they don’t really have to look you in the eye and tell you about what they want.

Quantitative Results

The results of the WAMMI across the 3 groups are shown in Table 2. Responses across the groups indicated that all participant groups viewed the app favorably. In general, clinicians tended to report the most critical responses to the app. Overall, adolescents found the app (relatively) easier to use and understand compared with clinicians and caregivers. Clinicians had a greater propensity to report the app having annoying features compared with caregivers and adolescents. All clinicians (11/11, 100%) and caregivers (10/10, 100%) and 64% (7/11) of adolescents selected somewhat agree or strongly agree for the following statement: “This app has much that is of interest to me.” All adolescents (11/11, 100%) somewhat agreed or strongly agreed with the following statements: “I can quickly find what I want on this app,” “Using this app for the first time is easy,” and “Everything on this app is easy to understand.”

aWAMMI responses among all users interviewed, including clinicians, adolescents, and caregivers. Each item was scored on a Likert scale (1=strongly agree, 2=somewhat agree, 3=neutral, 4=somewhat disagree, and 5=strongly disagree). Lower numbers indicate greater agreement with the statement.

bSignificant differences between the caregiver and adolescent groups (P<.05).

cSignificant differences between the clinician and adolescent groups (P<.05).

dSignificant differences between the clinician and caregiver groups (P<.05).

Discussion
Principal Findings
As of October 2021, a national state of emergency in child mental health has been jointly declared by the American Academy of Pediatrics, American Academy of Child and Adolescent Psychiatry, and Children’s Hospital Association because of the rising rates of behavioral health problems coupled with a limited and overburdened mental health workforce [52]. To address this public mental health crisis, it is critical to enlist a broad and creative range of approaches, including those that leverage mHealth tools, to implement empirically supported content and interventions that target the significant drivers of this state of emergency. Also critical to this crisis is the need for more robust prevention of substance use problems (including opioid overdose and opioid use disorders) and HIV and other STI acquisition (particularly among young people at the highest
risk for new HIV acquisition) [77,78], which is signaled by every public health indicator. The goal of this paper was to describe the development and usability testing of an mHealth app tool that collectively targets the aforementioned problems (ie, high prevalence of trauma-related mental health problems, substance use disorder, and opioid overdose and new HIV acquisition risk, as well as limited resources and opportunities dedicated to implementing substance use prevention and training clinicians in doing so).

The primary overall finding from the usability testing of the app leveraging a mixed methods approach was that the TIPS app was perceived by all 3 user types to be a highly usable mHealth tool to be implemented during the course of TF-CBT. Qualitative data collected from the usability testing of the app yielded positive feedback from clinicians, adolescents, and caregivers, and the quantitative data (ie, responses to the WAMMI) concurred with the qualitative findings (eg, 27/32, 84% of all users agreed or strongly agreed that “The app has much of interest to me”). However, more generally, the results of this study provide valuable insights into the use of technology and apps in adolescent mental health treatment. Clinician responses illustrated that they generally felt comfortable using smartphones and tablets and believed that these mHealth tools yielded benefits of engagement and accessibility for their adolescent clients. Moreover, the fact that all clinicians reported comfort with using these devices suggests a high level of digital readiness among this workforce in need of resources and support, which is a shared sentiment among other clinicians [79]. Despite this positive feedback, clinicians also identified potential drawbacks related to apps and mHealth tools, including the challenge of teenagers potentially overusing or being distracted by apps and issues related to limited wireless internet access in some homes. Indeed, equitable access to technology is essential when developing, evaluating, and implementing mHealth tools as augmentations to mental health interventions.

Specific to the interview responses, 4 overarching themes related to the TIPS app’s usefulness and effectiveness emerged. The first theme, strengths of the app content, highlights the positive aspects of the app, such as content tailored well to an adolescent audience, modules that are viewed as engaging, and relatable language. These strengths are crucial for maintaining adolescent clients’ attention and fostering meaningful interactions during trauma treatment, particularly when talking about what may be perceived as sensitive topics (eg, sexual decision-making). The second theme, changes in or suggestions for app content, points to the need for interactivity, revisions in video and picture content, and the inclusion of important topics such as consent and rape in relationships. Echoing findings of previous studies, these suggestions underscore the importance of user input and continuous improvement and adaptation of app content to meet evolving needs [80]. This also highlights the importance of using tools that allow for efficient and inexpensive minor edits (eg, to language and images) to mHealth apps when possible, as was done using the AppBuilder platform for the TIPS app.

The third theme, esthetics and usability, emphasizes the significance of the app’s design and functionality, with users offering both praise and suggestions for improvement. Beyond further underscoring the importance of having the capacity to revise content within an app as part of the iterative app development process, these praise interview responses also help inform implementation strategies, indicating what end users like most and find most engaging about the app. For example, regarding TIPS, the Make a Play activity emerged as a favorite (eg, the opioid pill activity and Let’s talk about Sext), and it may be an activity to highlight when first explaining the app to a clinician or adolescent client (eg, engaging). Finally, the fourth theme, benefits to the patient and session implementation, highlights the app’s potential to enhance adolescent and caregiver comfort during sessions and improve engagement, particularly for sensitive topics. It also suggests that clinicians are more likely to use the app with specific patient demographics, such as sexually active teenagers.

Regarding one of the clinicians’ comments that it can be difficult to get teenagers to stop using apps, it is important to note that a detailed implementation manual for the TIPS app is provided to clinicians when they are trained in how to use the app. Specifically, they are guided on how to structure the time spent on activities on the app, which occurs in the context of a TF-CBT treatment session. Thus, TF-CBT clinicians are able to contain adolescents’ use of the TIPS app in sessions.

The quantitative results, presented in Table 1, reinforce the positive reception of the TIPS app across all participant groups. Adolescents in particular found the app less difficult to use and more understandable compared with clinicians and caregivers, but clinicians expressed some critical feedback, including minor annoyance with certain features. Notably, all clinicians and caregivers, along with most adolescents, expressed a strong interest in the app’s content. In addition, adolescents found the app easy to navigate and understand, suggesting that user-friendliness is a key factor in their engagement with digital mHealth tools [81]. Overall, these quantitative findings align with the qualitative feedback, highlighting the promising utility of the TIPS app for clinician implementation among adolescents and caregivers receiving TF-CBT while also emphasizing areas for improvement.

A strength of the TIPS tool is that it offers a platform that is telehealth compatible. The past several years have underscored the value of ensuring access to mental health treatment and risk behavior prevention through telehealth strategies. In addition to the benefits of breaking down geographical barriers, the integration of mHealth tools such as TIPS with telehealth helps promote confidential and convenient interactions for patients with mental health clinicians, fostering a sense of privacy and comfort that is crucial for therapy [82,83]. This may be particularly helpful when addressing sensitive topics such as trauma, substance use, and HIV. Ultimately, the synergy between mHealth tools and telehealth in behavioral care represents a transformative shift toward prevention-focused holistic and inclusive mental well-being support.

Limitations

The primary limitation of this study is that it is limited in scope to usability testing with a small sample of clinicians, adolescents, and caregivers. To establish the feasibility and efficacy of the app in reducing the risk of substance use and risky sexual behavior, a fully powered RCT is necessary to compare TF-CBT
implementation with and without the inclusion of the app, including assessment time points that follow youth and their caregivers over time. Although this study informs possible revisions to the app and suggests that clinicians, adolescents, and caregivers will respond positively to its inclusion in trauma-focused treatment, the efficacy trial will ultimately reveal whether indeed the app is able to make a dent in the youth mental health state of emergency and help eliminate some of the burden on clinicians in implementing a prevention curriculum.

Conclusions
In conclusion, this study demonstrates the positive reception of technology—and the TIPS app in particular—in adolescent trauma-focused treatment, with clinicians, adolescents, and caregivers recognizing the benefits of engagement, accessibility, and user-friendliness of this novel mHealth tool. The qualitative themes shed light on the strengths of the app’s content, areas for improvement, esthetics, and usability as well as its potential to enhance adolescents’, caregivers’, and clinicians’ experiences during TF-CBT sessions. These findings underscore the importance of the ongoing development and refinement of digital tools in mental health care—including those that can be integrated into telehealth mental health care delivery—to better meet the evolving needs of trauma-affected adolescents and their caregivers.

Abstract

Background: Science is beginning to establish the benefits of the use of virtual reality (VR) in health care. This therapeutic approach may be an appropriate complementary treatment for some mental illnesses. It could prevent high levels of morbidity and improve the physical health of patients. For many years, the literature has shown the health benefits of physical exercise. Physical exercise in a VR environment may improve the management of mild to moderate mental health conditions. In this context, we developed a virtual environment combined with an ergocycle (the augmented physical training for isolated and confined environments [APTICE] system).

Objective: This study aims to investigate the impact of physical exercise in a VR environment.

Methods: A total of 14 healthy participants (11 men and 3 women; mean age 43.28, SD 10.60 years) undertook 15 minutes of immersive physical exercise using the system. Measures included mindfulness and immersion disposition, subjective perceptions of sensory information, user experience, and VR experience (ie, psychological state, flow, and presence).

Results: First, the APTICE system appears to be a useful tool because the user experience is positive (subscales in the AttrakDiff questionnaire: pragmatic quality=0.99; hedonic quality–stimulation=1.90; hedonic quality–identification=0.67; attractiveness=1.58). Second, the system can induce a positive psychological state (negative emotion, P=.06) and an experience of flow and presence (P values ranging from <.001 to .04). Third, individual immersive and mindful disposition plays a role in the VR experience (P values ranging from <.02 to .04). Finally, our findings suggest that there is a link between the subjective perception of sensory information and the VR experience (P values ranging from <.02 to .04).

Conclusions: These results indicate that the device is well accepted with positive psychological and exteroceptive outcomes. Overall, the APTICE system could be a proof of concept to explore the benefits of virtual physical exercise in clinical medicine.

**Introduction**

The Roman poet Juneval wrote “mens sana in corpore sano” (a healthy mind in a healthy body) [1]. Still relevant today, it has never made as much sense. The body and the mind seem to be indivisible, truly part of a whole [2].

**Virtual Reality**

In recent years, virtual reality (VR) has been recognized as a new approach to health [3-6] that seeks to connect the body and mind [7]. The term was first used by Jaron Lamier in 1986 to refer to an advanced technological interface in which the user interacts with a 3D environment that is generated by a computer to simulate real-world experiences [8,9]. The tool can simulate reality and stimulate the body’s senses in ways that are only limited by our imagination. It creates a new space-time that is halfway between the real and the unreal, pushing back the boundaries of reality and experimenting with new paradigms that we would not otherwise have access to [10,11]. Thus, VR goes beyond a simple simulation of the external world. The modulation of interoceptive, exteroceptive, and vestibular information leads the participant to create a representation of their own body. This conceptualization is described as the body matrix, which refers to the multisensory representation of the body in the brain and the space directly around the body [12]. Through VR, it is possible to induce the illusion of being and moving in a fake body. This interstice allows individuals to perceive, interpret, and interact with their environment through an internal representation of the world [13]. Repeated VR use may stimulate changes in the brain based on neuroplasticity mechanisms [14]. Riva et al [7] noted that the effects may be heightened by immersive VR systems and the induced sense of presence in the surrounding virtual environment.

**Immersion** is a characteristic of VR systems and is created when the virtual environment replaces the user's sensory stimuli with virtual sensory stimuli. Through immersion, it is possible to induce the sense of presence. Multisensory integration generates a feeling of being there and can sometimes lead to the illusion of being in an alternative body [15,16]. Slater [17] defined presence as “the strong illusion of being in a place despite the sure knowledge that you are not there.” Thus, participants have the strong illusion of being in the virtual environment and being able to perceive what is happening in it such as the virtual precipice. However, they consciously know that this is only a perceptual illusion not a reality [18]. Presence is related to flow, which refers to “the holistic sensation that people feel when they act with total involvement” [19]. It is a psychological state corresponding to enjoyment, cognitive absorption, and distortions in time perception. The literature on VR highlights the influence of immersion, induced by VR systems, on both presence and flow in the virtual environment [20,21]. Nevertheless, interindividual differences have been noted regarding both presence and flow. One relevant factor is mindfulness disposition (MD). MD is characterized by the awareness that emerges when paying purposeful attention to the present moment and responding nonjudgmentally to the unfolding experience [22,23]. It is associated with a protective function in both a healthy population and among patients [24,25]. A recent study by Lefranc et al [26] highlighted that high MD is associated with better positive emotions, interoception, and subjective extrasensory acuity. Top-down conceptual representations and bottom-up multisensory inputs contribute to body awareness. Moseley et al [12] suggested that these representations be integrated with exteroceptive data in the body matrix.

Over the years, VR has become increasingly accessible. It has been particularly beneficial in the field of medicine, whether in the context of medical training, surgery, the treatment of certain neurodegenerative diseases, rehabilitation, pain management, or cognitive and psychological disorders [11,27-34]. The literature shows the value of using VR as a therapeutic tool to treat mental disorders such as anxiety, depression, posttraumatic stress disorder, and phobias [8,31,33-38]. Antidepressants, such as selective serotonin-norepinephrine reuptake inhibitors, or benzodiazepines are the first-line treatment for anxiety symptoms in patients while cognitive behavioral therapy has been found to be effective in reducing them [39-41]. VR interventions such as exposure therapy have been shown to be effective as a coadjuvant in mental illness and appear to have the same effects as drug treatments, although the results take longer to become apparent [34]. Used as a complementary therapy, VR may have many advantages, including the ability to recreate a realistic traumatic environment under controlled conditions, which can be complex in vivo [33,42,43]. Most studies show that participants have a high degree of acceptance, and VR use is consistent with postintervention improvements in symptom awareness; a decrease in depressive symptoms; greater motivation to exercise; better enjoyment, engagement, and affect, particularly in clinical populations [35,37]. VR therapy can stimulate emotion (notably fear), as the participant has the feeling of being present in the unreal environment [18,44]. Thus, it appears to be an innovative nondrug supplement to other treatments that can be demanding for the patient and may have side effects. Although the quality of the technology may play a role in positive outcomes [45], it appears to be an interesting new tool that poses no serious threat to participants [46].

**The Potential of Immersive Physical Activity**

In recent years, an increasing body of the literature has investigated the power of immersive physical activity. Physical activity preserves health and protects individuals from many pathologies [47-49]. It can be defined as “any bodily movement produced by skeletal muscles that results in the expenditure of more energy than the resting metabolism” [50]. One of the components of physical activity is physical exercise, understood as “planned, structured, repetitive physical activity whose objective is to improve or maintain one or more components of physical fitness” [50]. For many years, the literature has shown the benefits of physical activity on health, not only physical (ie, reduced mortality, reduced risk of cardiovascular pathologies, reduced incidence of cancer, or weight maintenance) but also cognitive (ie, improved cognitive function, improved sleep, or reduced risk of dementia) and psychological (ie, reduced signs of anxiety and depression or reduced risk of depression), both in the general population (ie, adults, children, and older adults) and in the context of various chronic diseases and health conditions.
conditions [47-49,51]. However, it is only recently that the scientific community has begun to take an interest in the biological and physiological mechanisms underlying these outcomes [52,53]. People with mental illness often exhibit disrupted sensory processing and perception [54]. Thus, physical activity therapy can be both a physical and psychological countermeasure. However, compliance is a key issue as regular practice is necessary for optimal mental illness management.

Few studies have examined the use of VR in this context, although the pioneering work of Plante et al [55-57] seems to indicate real benefits in terms of well-being, particularly in women [56]. The addition of VR has been found to enhance mood, increase enjoyment and energy, reduce tiredness, enhance motivation and confidence, and increase compliance [57,58]. Enjoyment may play an important role in the benefits gained from exercise [58].

In recent years, there has been an increase in the number of studies that encourage the practice of sports to prevent anxiety disorders and protect against anxiety and depression [59,60]. A recent study demonstrated its importance in the context of the COVID-19 pandemic, where it was able to improve well-being through improved physical and cognitive outcomes and limit psychological disorders related to isolation and confinement [61]. Thus, the literature suggests that VR coupled with physical activity may be a useful way to improve the symptomatology of individuals with anxiety disorders, posttraumatic stress disorder, and depression [61]. Furthermore, many studies have highlighted the ability of natural environments to induce positive emotions, promote well-being, reduce anxiety, improve self-esteem, and reduce negative emotions (ie, fatigue, confusion, tension, depression, and anger-hostility) compared with urban or indoor environments [62,63]. The same observation has been made in VR environments [64]. A virtual environment that offers physical activity in a natural setting seems to have the potential to improve the benefits of VR, especially for people with mental illness [65,66].

### Gaps in the Literature and Objectives of the Study

Many of the systematic reviews and meta-analyses that have been carried out have important limitations, notably related to differences in technology. There is also a lack of longitudinal studies on the long-term effects of VR. Most studies are one-shot experiments that evaluate its benefits before and after the intervention. Evaluation itself is problematic as subjective measures (questionnaires) are typically used and few studies have measured physiological effects (ie, heart rate variability, heart rate, and electrodermal activity). As it can be complex to overcome these gaps, caution is advised in interpreting any results or conclusions [33,35,62,65,67,68]. Given these gaps in the literature, there is a need for more rigorous testing. Any evaluation should be based on three assessment criteria: (1) the activity does not duplicate other countermeasures; (2) it must improve the experience of sport and thus increase its attractiveness (especially relevant for patients with depression) [55,56]; and (3) immersion must provide a multimodal sensory input to the user [69-72]. The benefits of multisensory stimulation have been demonstrated in the context of cognitive and sensorimotor rehabilitation [73] and emotion regulation [10,74].

Thus, the aim of this preliminary proof-of-concept study was to investigate the association between VR and physical exercise in a virtual natural environment to improve the psychological state of healthy participants and the underlying processes, before evaluating its benefits in clinical medicine. We measured the user experience (UX) and evaluated 3 hypotheses:

- **Hypothesis 1**: positive changes in psychological state are associated with flow and presence during the session in the VR environment.
- **Hypothesis 2**: both MD and immersion disposition are positively related to change in the participant’s psychological state, flow, and presence.
- **Hypothesis 3**: there is a relation between the subjective evaluation of sensory information, immersive disposition, and mindful disposition and psychological change.

### Methods

#### Ethical Considerations

This study was approved by the Minarm Ethical Committee (N 125 132/MIP/DGA/MINARM). Written consent was obtained from all participants in accordance with the Declaration of Helsinki and subsequent amendments.

#### Participants

In total, 14 volunteers (3 women and 11 men), who were declared medically fit, were recruited during the 3 innovation open days at the French Armed Forces Biomedical Research Institute in 2019. They ranged in age from 22 to 59 (mean 43.28, SD 10.60) years and were either working for the French Armed Forces Biomedical Research Institute (n=9) or the French Football Federation (n=5). See Table 1 for the demographic information. The participants were recruited by email and contacted to determine whether they met the inclusion and exclusion criteria. If eligible, they were assigned an appointment for the laboratory session. All participants were asked to abstain from exercise on the day of their participation to ensure that the results were due to the experiment. The inclusion criteria were based on the following: affiliation to a health care system (social security); age between 18 and 75 years; and no history of neurological or cardiovascular disease, diabetes, or medications that could affect the response. Exclusion criteria included pregnancy, the presence of a contraindication to VR (people who had experienced anxiety or nausea during a VR experience, photosensitive epilepsy, vestibular disorder, or severe myopia >3.5 diopters).

Participants who practiced a physical activity or engaged in video games completed the Addictive Intensity Evaluation Questionnaire (AIEQ). The analysis found that 10 out of 14 (85%) participants engaged in physical activity (mean 31.00, SD 6.20) and 4 (35%) played video games (mean 28.20, SD 14.34). No addictive behaviors were found among the participants in either of these modalities.

Augmented Physical Training for Isolated and Confined Environments

This proof-of-concept study is based on the augmented physical training for isolated and confined environments (APTICE) system. The aim of the system is to use physical exercise in a VR environment to improve the well-being of patients with depression. It is composed of a VR - enabled cycle ergometer (VirZOOM Bike Controller) and a VR-based head-mounted display (Oculus Rift CV1, Oculus VR), which provides visual and auditory inputs. The VR application was developed by GAMIT (Petit-Quevilly) and ran on an Asus A15 TUF566IU-HN326T laptop with an AMD Ryzen 5 4600H 16 GB processor, a 512 GB solid state drive, and an Nvidia GeForce GTX1660 Ti 6 GB graphics card. The VR environment consisted of natural areas of forests and mountain plains (Figure 1). See Multimedia Appendix 1 for further images of the APTICE device.

Figure 1. Natural virtual environment images. (A) Forest with stretches of water. (B) Mountain plain with sheep.
Data Collection

Population Overview
A 7-item sociobiographical questionnaire was developed to collect standard sociodemographic data such as gender, age, hobbies, physical activity, video game use, and VR experience. The AIEQ evaluated addictive practices [75]. Two versions were used: the 14-item AIEQ-g that measures the intensity of video game playing and the risk of its problematic use and the 14-item AIEQ-s that measures sports practice and the risk of its problematic use.

UX of the APTICE Device
The UX of the APTICE device was assessed using the 10-item AttrakDiff questionnaire, which evaluates the hedonic and pragmatic qualities of interactive systems [76]. It is divided into 4 subscales: pragmatic quality, hedonic quality–identity, hedonic quality–stimulation, and attractiveness. Values close to the mean (from 0 to 1) are considered standard values. They indicate that the device meets its objectives with no negative impacts on the user.

Psychological Questionnaires
Two questionnaires were used to evaluate psychological dispositions. The 14-item Freiburg Mindfulness Inventory was used to measure MD [77]. It is divided into 2 subscales: acceptance and presence. Immersion disposition was assessed using the 18-item immersive tendencies questionnaire, which is divided into 4 subscales: focus, involvement, emotions, and games [78]. Two questionnaires were used to evaluate psychological state. First, the 12-item Scale of Positive and Negative Experience (SPANE) questionnaire assessed subjective feelings of well-being [79]. The overall scale is divided into 2 subscales: positive and negative emotions. Second, the 20-item Activation-Deactivation Adjective Checklist (AD-ACL) evaluates the level of awareness and emotional disposition [80]. This is divided into 2 dimensions: energetic arousal (from energy to tiredness) and tense arousal (from tension to calmness). The energetic arousal is further divided into 2 subscales—general activation and deactivation—while the tense arousal is subdivided into general tenseness and calmness.

Subjective Evaluation of the Quality of Sensory Information
We developed the Personal Evaluation of Six Senses questionnaire to assess subjective perceptions of vision, sound, touch, olfaction, taste, and equilibrium. Participants evaluated the accuracy of their perceptions from each of their 6 senses using a ranked scale running from 1 to 6.

The VR Experience
The VR experience was assessed using the 12-item Educational Flow Questionnaire (EduFlow2), which measures flow [81]. It is divided into 4 dimensions: cognitive control, immersion and time transformation, loss of self-consciousness, and autotelic experience. Cognitive absorption (a summary of the first 3 dimensions) was added as the fourth scale. The 24-item Presence Questionnaire assessed presence [82]. It is divided into 7 subscales: realism, possibility of action, quality of interface, possibility of examination, self-evaluation of performance, sounds, and haptic. APTICE device sickness was assessed using the 16-item Simulator Sickness Questionnaire [83]. It is divided into 2 subscales: nausea and oculomotor.

Procedure
The experimental protocol is illustrated in Figure 2. Upon arrival, the participants were asked a few questions to ensure they met the inclusion criteria and signed the consent form. They then completed a series of questionnaires in the following order: sociobiographical questionnaire, AIEQ-g, AIEQ-s, Freiburg Mindfulness Inventory, Personal Evaluation of Six Senses, 18-item immersive tendencies questionnaire, SPANE, and AD-ACL. Then, they engaged in a moderate-intensity bout of exercise in a natural environment for 15 minutes while wearing the VR headset. They could choose their trajectory along various predefined paths and, by turning their head, obtain a 360° view of the virtual environment. At the end of the session, they were asked to complete another series of questionnaires in the following order: SPANE, AD-ACL, EduFlow2, 24-item Presence Questionnaire, AttrakDiff, and Simulator Sickness Questionnaire.
Figure 2. The augmented physical training for isolated and confined environments (APTICE) experimental protocol. AD-ACL: Activation-Deactivation Adjective Checklist; FMI: Freiburg Mindfulness Inventory; ITQ-f: Immersive Tendencies Questionnaire; SPANE: Scale of Positive and Negative Experience; SSQ: Simulator Sickness Questionnaire; VR: Virtual Reality.

Statistical Analysis
Statistical analyses were performed using the RStudio software (version 1.2.5001). Descriptive statistics are expressed as mean (SD). The Shapiro-Wilk test was used to determine whether the data were normally distributed. The effects of the APTICE device experience on emotional and activation-deactivation states were assessed as follows: a t test (2-tailed) for pre-post comparisons and parametric data or the Mann-Whitney U test for nonparametric data. Kendall correlations were run to explore the relationship among virtual exercise, subjective sensory accuracy, and VR experience. For all analyses, significance was set at $P<.05$. Trends were considered when $.05<P<.10$. Deltas were calculated to compare the temporal impact of the experience measured using the SPANE questionnaire and the AD-ACL.

Results

The UX
The APTICE tool was assessed in terms of UX. Participants reported a positive experience measured as pragmatic quality, hedonic quality–stimulation, hedonic quality–identification, and attractiveness (Figure 3). The scores were particularly high for hedonic quality–stimulation and attractiveness. No participant reported any cybersickness.
Figure 3. AttrakDiff’s subscales. Values close to the mean (from 0 to 1) are considered standard and indicate that the device meets its objectives with no negative impacts on the user. However, they also suggest that improvements could be made to the system to obtain high positive values. Values outside this neutral zone are considered positive (1-3) or negative (−1 to −3). X1: pragmatic quality; X2: hedonic quality (stimulation); X3: hedonic quality (identification); X4: attractiveness.

Relationships Between Psychological Assessments, Exteroception, and VR Experience

Overview

Multimedia Appendix 2 summarizes the significant correlations between the tested variables.

Hypothesis 1: The VR Experience (Change in Psychological State, Flow, and Presence)

The analysis of emotional and arousal states only identified a trend for negative emotions. Participants tended to have fewer negative emotions after the APTICE experiment ($t_{12}=2.06, P=.06$).

There were significant positive and negative correlations between flow and presence. Participants who scored high for possibility to examine also scored high for flow cognitive control ($τ=0.45, P<.001$), flow cognitive absorption ($τ=0.67, P=.001$), and flow immersion and time transformation ($τ=0.55, P=.01$). Participants who scored high for possibility to act also scored high for flow cognitive absorption ($τ=0.58, P=.004$), flow cognitive control ($τ=0.76, P<.001$), flow immersion and time transformation ($τ=0.58, P=.006$), and flow-autotelic experience ($τ=0.58, P=.001$). As realism increased, flow cognitive control also increased ($τ=0.52, P=.01$). However, as haptic increased, flow loss of self-consciousness ($τ=0.52, P=.02$) decreased.

Concerning change in psychological states related to flow and presence, our results suggest that there is no correlation between change in emotional state (measured with the SPANE questionnaire) and either flow or presence. However, there were significant negative correlations between flow and changes in activation-deactivation states (measured using the AD-ACL). An increase in tense activation (positive delta) was associated with lower scores for flow immersion and time transformation ($τ=−0.46, P=.04$) and flow-autotelic experience ($τ=−0.52, P=.01$). No correlation was found between presence and flow, and there were no changes in activation-deactivation.

Hypothesis 2: Disposition and the VR Experience (Change in Psychological State, Flow, and Presence)

No relationship was observed between immersive disposition and MD for any subscale.

The analysis found a significant positive correlation between MD and presence. More precisely, higher MD-acceptation was associated with a higher score for possibility to examine ($τ=0.49, P=.02$). There was also a significant positive correlation between MD and flow. High scores for MD-acceptation were associated with high scores for flow cognitive control ($τ=0.45, P=.03$).

Finally, there was a significant positive correlation between immersion and flow. Specifically, high scores for flow loss of self-consciousness were slightly associated with high scores for involvement ($τ=0.54, P=.01$).

Concerning disposition and the VR experience, the analysis found no correlation between change in emotional state and either immersive or mindful disposition. Significant positive and negative correlations were found between immersion and change in activation-deactivation. An increase in tense activation (positive delta) was associated with higher scores for games ($τ=0.45, P=.04$). However, an increase in general activation...
(positive delta) was associated with lower scores for involvement ($\tau=-0.52$, $P=.02$).

**Hypothesis 3: Subjective Exteroceptive Accuracy, Disposition, and the VR Experience**

The analysis found no relation between the subjective exteroceptive evaluation and changes in emotional and activation states, presence, or MD. However, significant positive and negative correlations were observed between immersion and subjective acuity.

Correlation matrices for immersion and subjective acuity variables are shown in Figure 4.

**Figure 4.** Correlation matrices for immersion and subjective acuity variables. Distributions are shown on the diagonal. Trend curves are shown at the bottom of the diagonal scatter plots. The top diagonal shows correlation coefficients and significance levels. A1: olfaction; A3: vision; I1: focus; I2: involvement. *>.99, **.10, ***.05, ****.01.
Increased involvement was associated with higher subjective visual acuity ($\tau=0.48, P=.03$). In contrast, an increase in focus was associated with lower subjective smell acuity ($\tau=-0.43, P=.04$). Low scores for subjective hearing were associated with high scores for flow cognitive absorption ($\tau=-0.43, P=.04$) and flow immersion and time transformation ($\tau=-0.47, P=.03$). Similarly, low scores for subjective taste were associated with high scores for flow cognitive control ($\tau=-0.49, P=.02$).

**Discussion**

**Principal Findings**

The main aim of this proof-of-concept study was to investigate the effect of VR associated with physical activity on the psychological state of healthy participants before further evaluation of patients with depression in a randomized controlled trial. This exploratory study evaluated a new device, named APTICE, which couples physical exercise with a VR headset. This pilot feasibility study proposed variables of interest, which will form the basis for our next randomized controlled trial. The latter will investigate clinical and neurofunctional subtracts in a population affected by depression using VR associated with physical activity. Results from this study provide new insights into the benefits of this type of technology when used in clinical medicine to improve health.

**A Positive UX Experience**

As Hassenzahl et al [84] demonstrated, the evaluation of the hedonic and pragmatic qualities of a system is known to influence overall perceptions of its attractiveness. Understanding the UX is crucial in the design of a new device, which is often ignored. The participants in our study were very positive regarding both the hedonic quality–stimulation and the attractiveness of the device. However, pragmatic quality and hedonic quality–identification scores were lower. Furthermore, the responses were the most disparate for these 2 dimensions. Hedonic quality–stimulation was associated with ideas such as outstanding, impressive, exciting, or interesting. Although the response to the UX appears to be positive, there is room for improvement. The relatively low scores for hedonic quality–identification are not surprising, as this aspect relates to the ability of the system to reflect the user’s identity. Similarly, pragmatic quality needs to be improved with a focus on usability. Both the appropriateness of the functionality and its accessibility need further attention. However, this short 15-minute experiment allowed us to conclude that the APTICE system meets its development and quality objectives—specifically, to design a device that supports physical exercise in VR. In the longer term, we will need to consider how to improve it, particularly in light of the technological development that has taken place since its creation.

**Psychological Changes Induced by the APTICE Device**

Our main hypothesis was that physical exercise in a VR environment could create a positive experience, measured as psychological and sensory feedback from the participants.

Consistent with the literature, our initial results suggest that the APTICE device experience decreases negative emotions [44,85-89]. However, our first hypothesis (that the APTICE device would induce a positive psychological state and an experience of flow and presence) was only partially confirmed. The literature [7,17] notes that presence and flow are usually positively linked, although a negative correlation has been found between haptic presence and loss of self-consciousness in flow experiments. In the absence of a meaningful haptic system, interactions with objects in the VR environment can widen the gap between actual and virtual realities [90]. In our experiment, haptic feedback from the interaction with the ergocycle did not reflect reality, which suggests its key role in inducing flow. For example, there was no body movement when going around the bends and almost no return on effort. The poor quality of the correspondence between the virtual exercise environment and reality could explain the absence of a change in positive emotions.

Our initial results suggest a close relationship between the quality of the technology and the VR experience. This is all the more important as flow (characterized by a deep involvement and absorption in an activity) promotes a state of inner well-being and positive emotions [91,92]. Overall, our results suggest that practicing a physical activity in a VR setting could be used to improve psychological outcomes. According to previous studies [60,61,66], the APTICE device may have potential benefits for patients, especially those with mental illness. The literature also shows that natural scenes support a positive psychological state both in general [65,86] and in the treatment of mental illness [67,93]. This is in line with the reduction in negative emotions in individuals following our study’s APTICE session. Although APTICE needs improvement, both the positive response to the UX and its effect on the user’s psychological state suggest that regular use may have a positive impact on mental health.

**Relationships Between Disposition and VR Experience**

Our results partially confirm our second hypothesis, which focused on the impact of immersive disposition and MD on the VR experience. We found no relationship between immersive disposition and MD in our sample. Immersive disposition is used to evaluate the potential to immerse a subject in a situation, whereas MD is characterized by the ability to be in the here and now. Therefore, it is possible that these 2 dimensions are unrelated. Our experiment showed that the involvement subscale of immersive disposition was associated with a loss of self-consciousness in terms of flow effect. An individual’s interest in a target object [94] or their motivational state in relation to a target object [95] has been described as a condition for flow experience in VR [96]. Furthermore, our experiment found that immersion was unrelated to presence, which conflicts with the literature [15,37]. A key difference compared with earlier work is that our participants were asked to make a physical effort. It is possible that this effort counteracted their immersive disposition. If we turn to the relationship among MD, presence, and flow, acceptance seems to be the most relevant dimension. Acceptance consists of accepting inner events such as emotions, thoughts, or beliefs as they are felt [97]. It does not mean resignation but rather perceiving one’s own experience with an attitude that acknowledges it, rather than judging it as either good or bad. Thus, the ability to accept what is happening now may be a more useful way to examine...
presence and cognitive control than simply being in the here and now. Collectively, these results suggest that physical exercise in VR may be improved by acceptance, which enhances the feeling of presence.

**APTICE Device and Exteroceptive Modulations**

Our final hypothesis concerning the relationship between subjective exteroceptive perceptions of sensory information and physical exercise in the VR experience was exploratory. On the one hand, our results show that there is an assumption that information provided by all 5 senses may help the user to become immersed in the experience of where they are, whom they are with, and what they are doing. The feeling of a real experience gives rise to presence. On the other hand, mindful participants pay more attention to information from their bodies, leading to better adaptation to the environment [98]. Using functional magnetic resonance imaging, Farb et al. [99] identified several brain regions associated with mindfulness. In particular, they found that deactivation of the medial prefrontal cortex and increased activation of parietal areas were associated with proprioception and sensory–motor body experiences. Mehling [100] reported the use of external stimulation when attempting to understand how felt sensations are used internally to regulate stress or attention. Such information is integrated and linked to the person’s emotional state as a function of whether the body is experienced as safe [98,100].

Our results suggest that subjective preferences in exteroception-perception are linked to the experience of physical exercise in the VR environment. Furthermore, they show that immersion is correlated with subjective visual acuity. The participants in our experiment were cycled in a virtual environment based on natural visual information. Unsurprisingly, high scores for subjective visual acuity were associated with flow. Many studies have highlighted the potential of external sensory information to enrich the lived experience [101-104]. Exteroceptive information can generate intense emotional processes [105] and flavor manipulation within VR [101-104]. However, the evidence is weak, and it is also possible that such an environment may inhibit VR experiences because of its limited capacity to provide wider sensory inputs [105]. Another outcome of our study was that individual preferences may play a role in the VR experience. Our findings showed that this experience is negatively associated with all forms of external sensory stimulation (i.e., hearing, taste, and smell) except vision. This suggests that other senses are partially inhibited, and only vision is recruited on a large scale. Vision is an essential component of the APTICE experience.

In this context, Slater and Usoh [106] suggested that an individual’s experience is encoded by visual, auditory, and kinesthetic systems of representation. Depending on the context, the person will naturally tend to favor one system over another. However, the latter authors noted that the visual system predominates in individuals who report a higher sense of presence and those who process information in the first person. Thus, individual characteristics may be a key factor in any experiment. Overall, our study suggests that the APTICE system may alter multisensory representations during physical exercise.

Future studies should address this issue, which remains unexplored.

**Future Clinical Applications**

VR technologies appear to complement established approaches to mental health care. Its association with physical activity makes it an interesting new approach that merits further investigation. Furthermore, the use of VR in health care is expanding rapidly. There are many new opportunities in clinical medicine, including mental illness, where VR may be an alternative treatment [4,5,107,108]. Our findings validated the impact of physical exercise in a VR environment on negative emotions in a healthy population. Although our results should be interpreted with caution, because of the small sample size, they highlight the importance of better understanding the processes involved in healthy participants. Beyond the efficacy of interventions to determine which populations might benefit from VR combined with physical activity, it is important to understand the processes that predispose this state in healthy individuals. Further studies with larger sample sizes are required to evaluate the role of these processes in clinical research. Thus, the next step is to study clinical and neurofunctional subtracts in a population with depression before proposing the tool as a countermeasure (ID-RCB: 2020-A03415-34) for this population and other people in health care. There is an untapped opportunity to use VR as a prevention tool and to target the processes that make an individual poorly adapted to the environment. This is particularly the case for people who work in challenging confined and isolated environments or extreme and unusual environments [65].

**Limitations**

This study has 4 main limitations. The first and most important factor is the small sample size. This study was intended to be a pilot feasibility study that will support a future controlled randomized trial. In this context, it validated the usefulness of the APTICE system and highlighted the interaction between the variables of interest. In the next phase of our work, we will launch a larger clinical study of participants with depression. The second limitation relates to the use of subjective self-report measures. An objective sensory evaluation needs to be developed for healthy participants, which would help researchers to better investigate the human-body relationship. Subjective variables should be combined with physiological measures, such as heart rate variability. Third, our results cannot be generalized because the study population was recruited from among armed forces personnel and footballers, who are usually different from the general population in terms of fitness and psychological state. Finally, the last limitation concerns the VR equipment used in our experiment, which is becoming dated. A new version of the Oculus headset is already available, with a better graphics interface.

**Conclusions**

This exploratory proof-of-concept study investigated some of the processes implicated in physical exercise in a VR environment with the aim of better understanding their relationship with psychological state in a sample of healthy individuals. It represents the first step in a larger randomized
controlled trial that will investigate clinical and neurofunctional substracts in a population with depression. Our results suggest that the APTICE environment can change negative emotional states, consistent with the experiences of flow and presence. Moreover, our findings demonstrate that immersive and mindful disposition play an important role in the VR experience. Finally, they also suggest that the subjective exteroceptive perception of sensory information may be a key aspect and seems to indicate that one sense may prevail over another at the level of the individual. Our study has several implications for clinical medicine: (1) VR can help enhance and reinforce the beneficial actions of physical activity; (2) APTICE is a promising system and may be effective in improving mental health; and (3) APTICE has the potential to be used as an alternative treatment to drugs and to improve quality of life. However, many questions remain unanswered, and further work is needed to exploit the potential of VR associated with physical activity both as prevention and treatment.

Acknowledgments
The authors wish to thank Eric Malbos. The authors thank the French Armed Forces Biomedical Research Institute and French Football Federation for their involvement. They would like to thank Florent Samat and Nicolas Greverie from GAMIT France for the development of the APTICE system. Finally, the authors would like to thank the Centre Nationales des Études Spatiales and the Direction Générale de l’Armement for their support.

This research was funded by the Direction Générale de l’Armement (N 2016/017/S).

Data Availability
The data sets generated and analyzed during this study are not publicly available because they are the property of the French Armed Forces Health Service. Although data are not available to the public, they are available from author MT upon reasonable request.

Authors’ Contributions
BLR, CMK, CP, RR, EM, FB, EG, and MT conceptualized the study and developed the methodology. All authors actively contributed to the experimental process. BLR, CMK, and MT wrote the original manuscript. BLR conducted the formal analysis. All authors have read and approved the final manuscript.

Conflicts of Interest
None declared.

Abstract

Background: Early detection of pulmonary exacerbations (PEX) in patients with cystic fibrosis is important to quickly trigger treatment and reduce respiratory damage. An intervention was designed in the frame of the MucoExocet research study providing patients with cystic fibrosis with connected devices and educating them to detect and react to their early signs of PEX.

Objective: This study aims to identify the contributions and conditions of home monitoring in relation to their care teams from the users’ point of view to detect PEX early and treat it. This study focused on the patients’ experiences as the first and main users of home monitoring.

Methods: A qualitative study was conducted to explore patients’ and professionals’ experiences with the intervention. We interviewed patients who completed the 2-year study using semistructured guides and conducted focus groups with the care teams. All the interviews were recorded and transcribed verbatim. Their educational material was collected. A grounded analysis was conducted by 2 researchers.

Results: A total of 20 patients completed the study. Three main categories emerged from the patients’ verbatim transcripts and were also found in those of the professionals: (1) task technology fit, reflecting reliability, ease of use, accuracy of data, and support of the technology; (2) patient empowerment through technology, grouping patients’ learnings, validation of their perception of exacerbation, assessment of treatment efficacy, awareness of healthy behaviors, and ability to react to PEX signs in relation to their care team; (3) use, reflecting a continuous or intermittent use, the perceived usefulness balanced with cumbersome measurements, routinization and personalization of the measurement process, and the way data are shared with the care team. Furthermore, 3 relationships were highlighted between the categories that reflect the necessary conditions for patient empowerment through the use of technology.

Conclusions: We discuss a theorization of the process of patient empowerment through the use of connected devices and call for further research to verify or amend it in the context of other technologies, illnesses, and care organizations.

Trial Registration: ClinicalTrials.gov NCT03304028; https://clinicaltrials.gov/ct2/show/results/NCT03304028
Introduction

Background
Pulmonary exacerbations (PEx) are the main cause of decline in lung function in patients living with cystic fibrosis (CF), representing the leading cause of death. Recommendations emphasize the importance of diagnosing PEx early to treat patients effectively and for them to have the best chance of regaining their previous baseline lung function after treatment [1]. Identifying warning signs of PEx requires many skills from patients daily—studies have shown that they must be able to monitor a combination of physiological parameters and patient-reported perceptions, such as weight loss, decreased spirometry, increased coughing, or increased sputum production reported daily, to diagnose PEx episodes and put in place the appropriate treatment [2,3]. Nevertheless, patients living with CF do not systematically monitor these warning signs, as few are equipped with devices to monitor variations in their physiological parameters or their perceptions over time, with the exception of patients who have received a lung transplant, who may be equipped with spirometers to detect a decrease in their respiratory function, which is a warning sign of acute rejection. However, patients need to access accurate and reliable measurements to monitor their lung function.

In recent years, a contemporary trend has emerged in health improvement and disease prevention: the “quantified self.” It refers to the quantitative measurement of various parameters linked to the state of one’s health (eg, heart rate and weight) or to lifestyle (eg, diet and physical activity) to monitor a disease or improve well-being. The premise is that one cannot improve what they cannot quantify. This quantification, which was still difficult to achieve a few years ago, has become more accessible through the development of new technologies and connected devices. These devices are connected to the internet and can collect, store, process, and transmit health-related data through sensors [4].

Connected devices can help patients gain a better understanding of disease and treatment and increase their levels of satisfaction and adherence to treatment when combined with patient education interventions [5,6]. Patient education is an empowerment approach for patients with chronic diseases aiming to improve their understanding and adherence to treatment by transferring knowledge from health care providers to patients through educational workshops and also by using patients’ experiential knowledge, which helps them adjust their management of the disease in their daily lives [7]. Patient education is known to have a significant positive impact on bioclinical indicators and on the well-being of patients [8]. Connected devices would act as a learning aid for patients by promoting real-life behavioral experimentation thanks to quick (or even immediate) access to objective data and to the development of knowledge about oneself anchored in one’s memory [9]. The use of connected devices by patients in their daily lives allows them to transfer what they learned during the workshops provided by health care providers to real-life situations, thus expanding on patient education. Experiential and continuous learning is facilitated when it is supported by health care providers to learn to interpret real-life data and compare them with the data collected at the hospital.

This way, connected devices could promote the process of empowerment, a concept that is understood as the development of patients’ ability to identify and meet their own needs, solve their own problems, mobilize the necessary resources to take action, and feel that they are in control of their health and their own lives [10]. According to Funnell and Anderson [11], empowerment is a process that is facilitated by counseling, educational, or psychological techniques to help the individual take control of the day-to-day management of their illness.

Currently, data are scarce on how connected devices are used in real-life situations by patients with chronic diseases and on how they influence knowledge of oneself and of one’s body, health, and disease [12]. However, we know that the dropout rate of connected devices can be high because of how cumbersome their use may be or the fact that they are too pressing a reminder of the person’s disease in their daily life [13,14], whereas adherence is mainly observed in young people and high-income socioprofessional categories who are more familiar with new technologies [15]. People’s experiences of using such connected devices vary depending on the person, the context, and their care environment. Therefore, the assessment of health technology is now moving toward a contextualized, patient-based evidence approach. According to this approach, the evaluation of eHealth devices is based on knowledge that originates directly from patients about their experiences of health, quality of life, and health services [16]. This approach is represented internationally by the work of the Warwick Patient Experiences Framework or the National Institute for Health and Care Excellence Patient Experience Guideline Development Group [17].

Drawing from the humanities and social sciences, it is now recommended for qualitative studies to be centered on patients’ feedback to understand the processes through which connected devices facilitate their acquisition of knowledge (of the body, risks, and diseases), in particular through the intimate and empirical experiences of the quantified body translated into data [18].

Objectives
Therefore, we conducted a qualitative study with patients living with CF and with specialized CF centers in metropolitan France to explore the processes through which connected devices become an essential part of patients’ knowledge to allow them to self-manage their health and to contribute to a theory of individual patient empowerment through technology. The aim...
of the study was to understand how patients and health care providers lived and perceived this new intervention based on connected devices associated with patient education workshops to identify the contributions and conditions of home monitoring. The work is focused on stakeholders’ experience with the intervention. This study is part of an interventional project based on the hypothesis that an intervention that combines the provision of connected devices set up with personalized alert thresholds and a patient education intervention by health care providers can enable patients with CF to detect early signs of PEx and begin managing it themselves in a timely manner. For this self-management process to lead to the implementation of appropriate patient behavior, it is assumed that the educational intervention teaches patients to identify and respond appropriately to alerts.

**Methods**

**Overview**

The MucoExocet (from the French for “Cystic Fibrosis Exacerbation Connected Devices Therapeutic Education”) study, a pilot interventional study, was conducted from 2018 to 2021 and involved 22 adults and 14 adolescents (aged >12 years) with CF to assess whether the use of connected devices was feasible and useful to detect and treat PEx early (trial registration: ClinicalTrials.gov NCT03304028). As part of the overall research project, this qualitative study explored the users’ experiences at the end of the intervention. The intervention and protocol have been extensively described previously [19]. We used the EQUATOR (Enhancing the Quality and Transparency of Health Research) standards for reporting qualitative research elaborated by O’Brien et al [20] to present our study design.

**Summary of the Intervention in Its Context**

Since 2005, a national organization associating health care providers from CF centers and patients and parents in France has been working to define the patient and parent competency framework (in pediatrics) and the associated set of educational tools. A therapeutic education tool named “React to PEx” (“Réagir en cas d’exacerbation”) was used to support patients’ and parents’ self-management of PEx episodes at home (Multimedia Appendix 1).

The intervention designed for the MucoExocet study combined the provision of connected devices with an educational program based on the React to PEx tool. It was renamed “React with CDs” and incorporates measurements from connected devices and personalized alerts (Figure 1). The goal of the intervention was to develop the patients’ (or parents’) ability to take action at the first signs of exacerbation identified through measurement deviations by connected devices. For this study, connected devices were used to collect 13 parameters, including 6 physiological parameters measured by the devices (forced expiratory volume in 1 second [FEV1], cardiac frequency, arterial hemoglobin oxygen saturation, weight, sleep duration [min/night], and physical activity [step count/d]) and 7 patient-reported perceptions described using emoticons in a journal provided by the spirometer application (trouble breathing, need for more airway clearance, increased symptoms at night, difficulty performing usual activities, greater fatigue, loss of appetite, and change in sputum [color or quantity]). At the request of both physicians and patients, the option chosen in the study was to not send the data collected via connected devices to the physician but only to the patient. However, the data could be shared during a consultation at the center or during a phone call or email exchange if the patient (or parent) wished to do so.

![Design of the study intervention. CD: connected device; EW: educational workshop; M0: month 0; M3: month 3; M6: month 6; M9: month 9; M12: month 12; M15: month 15; M18: month 18; M21: month 21; PEx: pulmonary exacerbation.](https://formative.jmir.org/2024/1/e38064/fig1.png)
Thresholds of irregular variation for patients’ parameters were calculated using the cumulative sum control chart method based on the data collected during phase 1 of the implementation of connected devices (3 months); this allowed physicians to set alert thresholds for each parameter and each patient during the first educational workshop with patients. Thus, alerts could be sent by email to the patients or parents throughout the period of routine monitoring using connected devices (12 months). An action plan was agreed upon by the physician and the patient or parent during this educational workshop to respond to alerts.

Development of the Educational Tool and Educational Intervention in the Centers

One of the centers played a leading role in the implementation of the study because of its leading role in therapeutic education for patients with CF in France (the CF center in Nantes). During phase 2, the physician and therapeutic patient education nurse developed the different educational tools for the 3 stages of the program (educational workshops 1-3) based on the statistical analyses of patient data and with the participation of an adult patient expert and tested these tools with a parent and an adolescent patient from their center. The tools and educational program are described in the publication cited previously [19].

Beyond the patient recruitment process, a physician and a health care provider (nurse or physiotherapist) from each investigating center were involved in handing the connected devices to the patients or parents, setting them up with the patients or parents and explaining how to use them, solving technical problems with the patients or parents with the help of the device suppliers, and participating in the interpretation of statistical analysis of the data collected during the implementation phase (3 months) to define personalized alert thresholds for their patients. They were trained in the use of the React with CDs educational tool to agree with their patients on an action plan in the event of PEx; they educated their patients in the 3 sessions provided as part of the educational program (“Your impressions of using connected devices during the implementation phase” and “Your action plan for responding to exacerbation warning signs, and Review of your action plan after 6 months of routine monitoring”). At the end of the study, health care providers participated in a focus group to report on their experience with the study and this monitoring method.

Study Population and Study Centers

The centers were selected by the research group on a voluntary basis among centers who had participated in the quality improvement program. They were familiar with the educational tool “React to an exacerbation.” The 7 CF centers were selected to include patients and their families of various conditions of life, economic statuses, and geographic areas (either urban or rural). Finally, the 7 centers were located in 4 different geographical areas; 3 (43%) were pediatric centers (4 patients per center), and 4 (57%) were adult centers (6 patients per center). None had previous experience with connected devices for their patients at the initiation of the study. In total, 36 patients, adults or adolescents, were included in the MucoExocet study. The sample was defined according to the recruitment capacities of the centers and the possibility of observing a saturation phenomenon in the qualitative study [21].

The recruitment process conducted by physicians in the centers was carried out based on patients’ voluntary participation and their interest in using new technologies. The participant inclusion criteria were as follows: age of ≥12 years, clinically stable condition (no PEx requiring intravenous antibiotics within the previous 4 weeks), at least one PEx within the previous 12 months, current follow-up at a participating CF center (and no plans to change centers during the course of the study), no history of having undergone solid organ transplants, prescription of at least one pulmonary medication (eg, inhaled mucolytic, inhaled or oral antibiotic therapy, or hypertonic saline), ability to speak French, ability to connect a tablet to Wi-Fi, and provision of written informed consent.

The number of individuals to be recruited took into account an estimated dropout rate of 20%. A form was offered to the patients leaving the study to identify the main reasons for their withdrawal (Multimedia Appendix 2).

Data Collected by the Patients Using the Connected Devices

The 13 parameters were collected using 5 different connected devices, and a few of them collected more than one parameter. During the first 3 months, data were to be collected twice a week. During the routine phase, the frequency was agreed upon between the patient and the care team from twice a week to once every 2 weeks depending on the patient’s health outcomes and life conditions. The procedure used to collect the data was explained in a document given to the patients at inclusion (Textbox 1).

Owing to the great variety of measurements taken, the time spent on the measurements was not recorded.

Textbox 1. Procedure to collect the data.

- Data collected without any participation from the patient (sleep, steps, and cardiac frequency): the duration of sleep was measured by the sensor under the mattress, and the step count and cardiac frequency were measured by the watch.
- Clinical data (spirometry and oxygen) required patient participation; at the end of the spirometry measurement, emoticons were presented for each of the 7 perceptions.
- Weight was expected to be measured in the morning (naked) the same day as the clinical data.

Qualitative Data Collection

Patients’ experiences were collected through semistructured interviews using an interview guide with 8 open-ended questions (Textbox 2), derived and adapted from validated protocols for patient narrative elicitation in outpatient care experiences [22]. The experience and workload of the care teams were explored.
in focus groups using an interview guide with 5 open-ended questions (Textbox 3).

Three sources of data were collected: (1) data collected during patient or parent interviews using an interview guide with open-ended questions (Textbox 2), (2) data regarding the educational program with the physician (the documents completed by the patient and the clinician, including the personalized action plan in case of PEx), and (3) data from the focus groups with care teams at the end of the study using a semistructured guide (Textbox 3).

Textbox 2. Guide for the semistructured interviews with patients or parents.

1. For you, what are the most important aspects in the management of your respiratory exacerbations in your daily life?
2. How do you rate the conditions for managing exacerbations during the study (based on what is most important to you)?
3. Can you tell us about a positive experience you had during this study concerning the management of your exacerbations? What happened and how did it make you feel? Did you do anything in particular after this positive experience (eg, change your attitude or behavior)?
4. Can you tell us about an experience that turned out differently than you expected? What happened and how did you feel at the time?
5. Regarding this last experience where you wished things had turned out differently, did you or your doctor do anything to rectify the situation?
6. Did your participation in the study change your outlook on the way you manage your exacerbations?
7. What do you think would be the best way to integrate this type of long-term follow-up so that it addresses the aspects that are most important to you in the management of your exacerbations?
8. Is there anything else you wish to tell us about?

Textbox 3. Guide for the focus groups with care teams.

1. From the point of view of the health care team, what are the most important aspects in the management of patients’ respiratory exacerbations, particularly in their daily lives?
2. In your opinion, how have the proposed monitoring methods, including connected devices and patient education, addressed these priorities or with what limitations?
3. During this research project, what changes have you noticed in the way the team works or in its workload with regard to monitoring patients for the management of their exacerbations? Have you noticed a change in your relationship with the patients’ out-of-hospital physiotherapist?
4. What difficulties or bad experiences have you had in the process of managing patient exacerbations using connected devices?
5. Do you feel that you had positive experiences during this study with the management of patient exacerbations? How would you rate these experiences in relation to the most important aspects of the management of respiratory exacerbations?
6. In your opinion, should this type of long-term patient follow-up be included in the management of exacerbations or in other aspects of their management? If so, what would be the best way to integrate it and for which patients and with which objectives?
7. Is there anything else you wish to tell us about?

Analysis Framework

All the interviews were transcribed verbatim and subjected to a descriptive qualitative analysis. The analysis framework used was grounded theory [23].

Grounded theory is a qualitative research method with an inductive approach aimed at constructing a theory on a cultural, social, or psychological phenomenon by proceeding with the progressive and valid conceptual representation and mapping of qualitative empirical data [24]. In this study, the phenomenon explored was learning and empowerment in health management through the use of connected devices. Grounded theory is relevant as this phenomenon is currently sparsely studied. Studies on connected devices in patients with chronic conditions, and especially in patients with CF, are mostly intended to demonstrate the efficacy of the use of connected devices on various health outcomes. The theories mostly reported in the literature, such as digital behavior change interventions or the theory of reasoned action, are mainly focused on compliance with connected devices. However, the concept of empowerment includes other dimensions, such as understanding, the ability to decide, and self-assessment. Using grounded theory, we aimed to complete the current knowledge by eliciting the various dimensions of empowerment from the patient experiences with the use of connected devices for remote monitoring of their symptoms and by identifying elements that could enrich the theories in the field of remote monitoring.

According to the constructivist grounded theory method by Charmaz [25], which focuses on social processes or actions and the meaning of human actions, we adopted a social psychological approach to explore how and in which context individuals feel that connected devices have an impact on their learning to take care of themselves and on their empowerment.

In grounded theory, verbatim transcripts are analyzed using codes to highlight what was stated by the participants in the study and derive meaning from it. We applied the standard steps of grounded theorizing. In initial coding, we generated as many ideas as possible inductively from the initial data. In focused coding, we relied on the most prevalent and important codes to select the central codes for analysis. In theoretical coding, we refined the final categories of the theory by connecting them to
each other, thus allowing for the integration of the categories into a model and the construction of a theory on the phenomenon studied [26].

The grounded dimensional analysis of patients’ or parents’ and health care providers’ data was conducted by 2 researchers (MM and DPB) using NVivo (QSR International) taking into account their evolution over the course of the study and the various natures and production conditions of the collected material while constantly comparing the data within and across patients or parents and health care providers. A constant comparison between the verbatim transcripts of patients and health care professionals was carried out to bring out the invariant elements as “the essence of the phenomenon,” which elaborate “conceptual categories” remaining as close as possible to the lived realities of patients [27]. The 2 researchers who analyzed the verbatim transcripts were a psychologist and the parent of a child with CF, and both had PhDs in public health and great experience in qualitative research.

Analysis of the Educational Documents

The educational documents filled in by the physician and the patient during the educational session (educational workshop 2) were collected by the research team and reviewed globally but were not analyzed in connection with the patient interview. The aim was to understand which actions had been agreed upon between the patient and the physician when symptoms of a PEx were detected by the patient at home (central column) and whether they could resolve the PEx episode and prevent deterioration through their actions.

Ethical Considerations

The research project was submitted for evaluation by the Committee for the Protection of Persons designated randomly under conditions provided for in the Code of Public Health (Article L. 1123-14). The study was approved by the Committee for the Protection of Persons (CPP North West III) on June 10, 2017 (2017-A00723-50). Free and informed consent was obtained before any act related to research was undertaken.

Results

Population Interviewed and Dropout Rates During the Study

A total of 56% (20/36) of the study participants were interviewed. The population interviewed in relation to the population included in the study and who benefited from the different stages of the educational program (educational workshops 1-3) is listed by center in Table 1. The dropout rate at the end of the first phase of intensive data collection (3 months) was 25% (9/36). In total, 3% (1/36) of the patients died during the study. The death was unrelated to the study. A total of 67% (24/36) of the patients were educated in the first 2 workshops (educational workshops 1 and 2), allowing them to enter the routine monitoring phase using connected devices. Only 39% (14/36) of the patients attended the third educational workshop held at the midpoint of the routine monitoring phase using connected devices. At the end of the study, the nonresponse rate to interview solicitations compared with the number of patients who entered the routine monitoring phase was 25% (6/24). These results differed from one center to another. The gender, age, and geographic area characteristics of the patients interviewed (presented in Table 2) were similar to those of the entire study population. However, the patients interviewed had a higher level of education and employment rate than the entire study population.

A total of 12 health care providers from 7 hospitals participated in focus groups between May 2020 and February 2021 (Table 3).

<sup>a</sup>MD: doctor of medicine.

The forms completed by patients exiting the study reported technical difficulties with certain connected devices, in particular with the tablet computer provided to synchronize data before sending them to the research server. These difficulties were also reported by health care providers in the focus groups, who mentioned that a member of the team (nurse, physiotherapist, or clinical research associate) had spent a significant amount of time solving technical problems with the device suppliers, sometimes unsuccessfully. The reasons for dropping out of the study were multiple and are listed in Multimedia Appendix 3.

Results From the Educational Documents

The educational documents collected after educational workshop 2 show that the first column ("normal state of health, routine activities and treatments actually followed") was filled with detailed information on the treatments and activities of the patient in their daily life, unlike the central column, which contained little information. The agreed upon actions in case of signs of exacerbation were mainly "increase physiotherapy" or "try to do more physical activity" and always "call or send a message to the center team." The actions were aimed more at the diagnosis of the exacerbation by the physician, who then decided what the patient should do, than at the actions that the patients should take by themselves. Most of the physicians added the following comment—"They already know what to do"—meaning that they had not delegated new actions to the patients. One pediatrician decided to give conditional prescriptions of oral antibiotics to the parents after the educational session, thus delegating to them the decision to start the treatment and asking them to inform the team that they had started the treatment.

Descriptive Results From the Interviews

Stage 1: Initial Coding

A total of 12 codes emerged from the patients’ verbatim transcripts. In total, 10 codes emerged from the health care providers’ verbatim transcripts. The analysis allowed for the assignment of a name to each code that identified its area of interest (Table 4).

a PEx: Patient-Exacerbation

b TTP: Telemonitoring

c CDs: Care Devices

d N/A: Not Applicable
During the process of analysis, empowerment was defined as individual empowerment, characterized by the learning achieved during the intervention, the decisions and actions implemented by the patient for their care or health, and their sense of control over their health. Connected devices allow patients to access data on their health status daily to monitor episodes of PEx, prevent them, and adjust the course of action when they happen. They contribute to making some patients more autonomous in the early management of PEx by supporting their decision-making and ability to take action without seeing or contacting primary health care providers:

CDs allow for a better assessment of one’s health status, and to take better care of oneself. It helps to be more autonomous and to avoid waiting until we are very sick to go to the doctor’s. It also helps to complement one’s care with extra physiotherapy, more sports, things like that... [Adult patient]

The use of connected devices in the management of PEx not only allows for the adoption of preventive behaviors or better adherence to medical recommendations. Through their use of connected devices, patients also learn to manage their health with new data about themselves that confront the objective evolution of their health status with the way they feel and the effects of their lifestyle and their attitude toward their care. This process is characterized by the acquisition of new knowledge of one’s state of health, the validation of subjective perceptions, a better understanding of what happens on a physiological level, and focusing more attention on certain monitoring indicators. These learnings can be observed as early as during adolescence:

In the past, I probably used to desaturate without really realizing it. I probably had headaches, but there you go...But now, I’m constantly stressed out, because I check my measurements pretty much all the time. [Adult patient]

Well, no. I can’t see the results of the measurements on the connected devices, and when the nurse called customer services, she was told that it was me who had the data anyway. But I don’t understand the data, and neither does she. So, perhaps we need to be taught how to interpret them better or to get clearer explanations in the alerts we receive. [Adult patient]

Health care providers focused more on the concordance between the perceptions reported by patients and the data collected than on patients learning to manage their PEx. Empowerment was seen by health care providers as patients’ ability to detect PEx and respond to it to limit its effects. Health care providers’ objective was to ensure the effectiveness of the device in
improving patients’ state of health. Some health care providers emphasized the beneficial relational change fostered by the educational intervention that accompanied the implementation of connected devices, owing to which they communicated better with their patients. This allowed them to better understand their living conditions with the disease and how they cared for themselves daily. From their point of view, the data collected using connected devices increased patients’ level of information and of awareness of their condition. This gave the team the feeling of having a new tool to involve patients in the management of PEx and, thus, the capacity to influence the evolution of the disease:

**Behind the word “anticipation,” we mean they should know how to spot the early signs and manage to put things in place and then call us. They should know not to wait for one or two weeks before calling to tell us they haven’t been feeling well for two weeks. So, for me, the study had an aspect of therapeutic education, thanks to the information panel (“React with CDs” Tool) that allowed us to sit down with the patients and have them think a little bit about what exactly they were doing.** [Health care provider]

**Category 2: Adequacy of Technology (Combined With Education) to the Needs of Patients**

Often found in the literature as “task technology fit” (TTF) [28], this category includes aspects related to the reliability of the devices, the accuracy of the data measured (in comparison with a standard), the ease of access to the data, and how adequate the educational program is, all of which shape patients’ perception of how well this “technology” fits their monitoring needs. Patients expressed concern that the devices should accurately reflect their condition. The adequacy of the devices for monitoring purposes can be assessed based on several criteria over time as patients experience the use of connected devices. The first criterion is the perceived reliability of connected devices over time and the accuracy of the measurements compared with measurements taken at the hospital:

**When I took several measurements, I sometimes got very contradictory results. I sometimes wasn’t sure whether it was reliable.** [Adult patient]

The second criterion is the ergonomics and ease of use to connect to the tablet to access data and send them to the research server, which enables the sending of alert notifications:

**But the fact is that the spirometer...it does not save the results. So, I could get a good score at the beginning, but I tried again and because I coughed a little bit the result wasn’t so good, so I started again from the start, but it’s a bit difficult. Results should be saved automatically.** [Teenage patient]

The third criterion is the technical support provided for the implementation of the devices:

**What bothered me was that the curves on the graph—there were two curves—I never knew what they represented. And I even asked the nurse, and the nurse replied: “Indeed, it’s weird, what does it mean?”** Even she searched for an explanation. To

**this day, I don’t actually have the answer...** [Adult patient]

These aspects were supposed to be controlled in the context of interventional research, but some patients had a disappointing experience even though they were aware that they were participating in a pilot study that would sometimes involve “teething problems”:

**We told them that they were the first ones to go through all the steps and that everything was not necessarily perfectly set up for them...I told them that future patients would have fewer difficulties because we would manage to solve some things with them in the study. They tested the tools from beginning to the end and therefore experienced all the computer bugs.** [Health care provider]

The reliability of the devices used to monitor patients was mainly assessed by health care providers in comparison with the measurements taken using standard hospital equipment. This reliability was, from their point of view, guaranteed by the research context. Some patients felt that their health care providers did not have answers to the technical problems they faced:

**I received several emails from the CF centre telling me that they were not getting the data. But I assured them that I was sending the results. I managed to show them that I had uploaded the data...I went onto HealthMate as I was getting an update every Sunday by email for the Withings devices. So, I forwarded it to them, and in fact, they said that the data were loading, but not on the research server.** [Adult patient]

Patients’ interest in technology may vary according to the connected devices proposed, the need they feel to monitor certain health indicators, and the attractiveness of the device. Moreover, patients may not wish to use them for fear of being confronted with poor results on certain critical measurements for the patient (or for the physician):

**So, I found the sleep analysis option rather useful. Because I do sleep well at night, but I cough without realising it. I was either a little tired when I woke up in the morning, or even not at all tired, while it turned out that I had exacerbations at night. So, I could see that from two criteria: the first one was the decibel peak levels at night, and then the second one was when I didn’t have a restful night’s sleep. So, these were two rather useful criteria, I think. And then...yes, there also was a third one...It is my heart rate, which increased as soon as I coughed.** [Adult patient]

The integration of technology and patient education into the care process was seen as an additional workload by health care providers. Although dealing with technical problems took more time than expected for those in charge of the study (nurse or clinical research associate), physicians mainly mentioned the time spent on the patient education workshop (education workshop 2). Patient education undertaken by physicians in the adult patient care pathway is new for some adult centers, and those centers hope to benefit from a “return on investment”
from it in the future. From the point of view of the care team, taking measurements using connected devices adds to the time already spent by patients managing their disease daily:

For us, it takes time, but obviously, for the patients it represents a lot of time too. In patients’ daily lives, it clearly adds minutes to their basic treatment. In terms of the team’s workload, it obviously adds work, and the therapeutic education workshops linked to the protocol were particularly cumbersome. It’s a lot of work at the time, but it clearly is really beneficial for the future. [Health care provider]

Although the educational tool proposed in the study (educational workshop 2) was generally appreciated by adult patients, it may have seemed complicated to the adolescent audience although it was developed by a pediatric team and tested with several teenagers before releasing it to be used for research:

Therapeutic education went well too... The information pane (“React with CDs” tool) was really well done, and it allowed us to look into many habits that we didn’t have, well at least that I didn’t have. [Adult patient]
The dashboard was not bad, but super complicated to use for a teenager. There is too much stuff on it. And clearly, too much information on the same page. You can’t go straight to what you’re looking for… I mean, you really need to look for it. In that sense, I think this table needs to be more legible, because there was a lot of data on it. And reading a lot of data in a table with many columns, it’s…it’s not appealing. [Parent]

Personalized alert thresholds were set for each patient based on data collected during the first phase of the study following the statistical analysis (cumulative sum control chart). However, these alerts were rarely used by patients to manage their exacerbation episodes as reading measurement results alone allowed them to understand their health status or the lack of updates to thresholds rendered the alerts irrelevant:

At the end of the year, my FEV1 had increased by quite a bit, so when I started the new year with a new secondary infection, my FEV1 didn’t drop lower than the year before. As a result, I never received any alerts. So, I think in this case, we need to update the thresholds, because things can really fluctuate. [Adult patient]

Questions emerged among health care providers on the profile or profiles of patients for whom it is more relevant to introduce self-monitoring measures via connected devices. The inclusion criteria of the study targeted patients with good to moderate lung function (FEV1 >50%) so as to limit the risk of patients leaving the study because of lung transplantation, which is considered as soon as FEV1 decreases to <40%. Some physicians who followed adult patients believed that stabilized patients are good candidates for this follow-up through connected devices, whereas others pointed out that very unstable patients could benefit from this reactive warning system to manage decompensation. In such a critical situation, physicians emphasized the importance of systematically transmitting patient data to the center to help monitor the patients using alerts. Although most physician investigators wanted the study not to send patient data to the center as they felt that they did not have the resources to treat them, other physicians considered it not to be viable for patients who were critically ill. The fear of widening existing social inequalities in health was also mentioned by the care teams:

I think it is useful to integrate the use of such devices with severely ill patients who have frequent exacerbations, who are hospitalised… It can really have a positive impact by confirming the patient’s perception that they are not doing so well, and that they may need to begin an intravenous treatment. It can help patients and us, health care providers, for patients who are severely ill, by providing objective data on exacerbations…. But at the same time, we must not delude ourselves. It is with these severely ill patients that it will be more difficult to set up a monitoring process with CDs. Because they often are in complicated situations socially, psychologically, and so on. So, I don’t know whether it will really be possible with these patients. There are biases and inequalities that will remain true with CDs. Whereas patients who are already autonomous and stabilised will more easily appropriate the CDs. [Health care provider]

However, some patients want to maintain control over their data and make decisions themselves as they feared that connected device monitoring would increase the control of the care team:

I don’t need a doctor’s supervision to tell me to be careful and that today’s measurement was not good. Because on the contrary, I find it more worrying than anything else. But then, it depends on the CF centre. For example, some CF centres will use the measurements and overprescribe antibiotics, while others will want to see the patient in consultation…. It should be up to us, it’s our responsibility. [Adult patient]

Category 3: Device Use by Patients (and Health Care Providers)

In the context of this study, device use refers to the ways in which patients used connected devices, whether continuously or intermittently, which may have evolved during the course of the intervention according to factors linked to the patients’ life circumstances, what they experienced during the study, and the conditions of integration of the new monitoring process into the organization of the care team’s work. These uses reflect patients’ perceptions of the benefit-risk balance of the technology and its evolution during the study. Patients adapted the frequency of their connected device use to their need to self-monitor between quarterly visits to the center or, instead, to their need to “let go” slightly on disease management. This need for monitoring increases in periods such as the introduction or cessation of treatment, and it fluctuates depending on life circumstances (work), events related to the environment (high pollen count), or symptoms linked to the disease.
The following is an example of patients’ need for self-monitoring in between consultations at the hospital:

*This allows us to watch the evolution of our data. The problem is that we go to the hospital once a month, or even every three months. So, we don’t have a regular follow-up as such. Whereas with these devices, for example, if I do a spirometry test once a week, I get a score every week, and I will check quite regularly, either it is effective or it is not. It’s complementary to my usual care and it could perhaps help patients be more autonomous.* [Adult patient]

The following is an example of adopting connected device monitoring in specific situations or for particular diagnoses:

*I am planning to get pregnant, and therefore, I think connected devices will be very useful during that time. Indeed, I may not be able to take all the treatments that I can usually take when I am not pregnant. So, I think the devices will be useful then and I also think I’ll be more conscientious in such circumstances.* [Adult female patient]

The use of connected devices also depends on the way measures are integrated into the patient’s personal organization, also known as the routinization process, which, when compatible with their lifestyle, can alleviate the feeling of burden related to the use of devices and contribute to making the collected data more reliable. In the absence of a routine, the use of connected devices can also be taught through therapeutic education sessions and become part of a *self-normative* approach connected to the patient’s perceptions of their health status:

*I do it when I have a quiet moment before leaving in the morning, before physiotherapy, and that’s it. I always tried to do it in the same conditions, so that it wouldn’t skew the data.* [Adult patient]

In the particular case of adolescents monitored using connected devices, their use was *regulated* by the parents, which adds to the burden of preparation and control of certain treatments. The collaboration with an out-of-hospital physiotherapist in this monitoring was seen as a relief for the parent caregiver, and it emphasizes the importance (credibility) of the follow-up for the adolescent patient. The question of maturity related to patients’ age was raised regarding the implementation of monitoring using connected devices in adolescence. Conversely, a parent mentioned the help that these connected devices could bring for the *empowerment of young patients*. Additional notification functionalities inspired by other applications could also support their use of connected devices:

*The greatest thing that could happen for kids would be that the watch sent them a notification if the scores were low and told them what to do. For example, we would set up some instructions onto the app, and as a result, they would receive notifications with the steps to follow on their watch. It would really make them autonomous then. Some apps allow the creation of a schedule and then send out notifications. Youngsters just have to look at their watch and it reminds them they have to bring a check on Monday at 10 AM to the school secretary to pay for the canteen. So, it doesn’t replace the parents, but it would relieve them of the task of always repeating things like a parrot, which causes a lot of conflicts in families.* [Parent]

Sometimes, connected devices reactivated conflicts between parents and adolescents regarding the fear of addiction to the tablet for uses other than health monitoring or because they give parents access to data on the adolescent’s behavior:

*There’s a very intrusive aspect to it. It feels quite overbearing for teenagers to know that they have lost 200 grams and that mum and dad want them to eat more to get the weight back on. Parental monitoring of sleep also creates conflict, and it was the case for almost all teens, with the parents saying: “You’re going to bed too late, that’s why you’re tired, it’s not healthy for you...” Some parents decided not to look at the data for that reason.* [Health care provider]

The use of connected devices by patients is also determined by the interest and attention that health care teams pay to discussions on these data during consultations, phone calls, or teleconsultations with patients, which we will refer to as “patient support”:

*So, I thought it was nice. It was really...I was sending screenshots of the saturation, well you know...and the FEVI. We had real conversations, and I found it interesting. It was more precise, less vague, the explanations I had to give...I had to give numbers, you know...* [Parent]

Conversely, when health care providers fail to take into account information from connected devices in patient monitoring, it can make patients *doubt* the importance and usefulness of such data, which, in addition to the burden of taking measurements, can lead to a lack of interest in these devices:

*We talked about it, but then, we didn’t focus the consultations on it at all...I expected there would be more guidance in terms of therapeutic education...we did it once about the information panel (“React with CDs” Tool), it took a very long time, it lasted almost two and a half hours. But I expected it would be that way during consultations, precisely to teach us to manage it ourselves...Sometimes, I wonder how it would be like if we had a chat every month, just for five minutes, just to ask me if things were going well, if there were any problems, or if I thought something was wrong.* [Adult patient]

Beyond the use of connected devices for monitoring purposes between consultations, some patients suggested that this follow-up could allow them to *space out their visits* to the center, particularly when they lived far from the center or to limit the risk of contamination at the hospital:

*Not on a regular basis, but sometimes when needed, to avoid going to the CF centre, because I live a little over an hour away. So, to avoid the journey, especially if I’m going to the hospital just to do a spirometry test to analyse FEVI, then yes, I might as...*
well do it with the device at home...it allows me to do the measurements myself. At the time of the consultation, we can either have a video call or talk over the phone, and then, we just give the results...in addition, we can extract our data, so we can even send them by email and the doctor can look at them beforehand. [Adult patient]

Stage 3: Theoretical Coding

The comparison of verbatim transcripts in the 3 categories revealed the relationships between them, as shown in Figure 2. These bidirectional relationships can be explained as follows.

First, the TTF–empowerment relationship: this is reflected in patients’ trust in technology as a necessary condition to consolidate their learnings, which in turn strengthens their trust in the support they receive from technology. Second, the empowerment-use relationship: patients’ capacity to take action and their feeling of control over their health condition with the way the technology is used, which in turn strengthens their capacity to act on their health. This relationship is mediated by the support provided by the care team to help patients adjust the use of technology for their daily management of the disease and, therefore, improve the PEx diagnoses and the suitability of the prescription. Third, the TF-use relationship: the adequacy of the technology to patients’ needs influences its use by patients, reflecting the perceived advantage for patients of being monitored using devices compared with their “standard” follow-up at the CF center. Patients use devices more if they seem adapted to their needs and if they are reliable and easy to use. This relationship is mediated by the care team’s appropriation of the technology, which translates to their coordination of the remote monitoring, the use of real-life data in patient education, and their learning to master the use of devices for patient care.

Figure 2. Category modeling and mapping. CD: connected device.

Connecting all the results leads to theorization, the final stage of grounded theory analysis, which can be formulated as follows. The use of connected devices by patients results in an increase in their ability to take action over their health (empowerment) through the continuous adjustment of this use to their degree of autonomy, which influences and is also influenced by the conditions in which the technology is integrated into the organization of the care teams and the patient educational program. The motivation of patients with CF to use connected devices to prevent and manage PEx is dynamic. It depends on the patients’ priorities and specific concerns as well as triggers that will increase the feeling of usefulness related to the connected devices. The data provided by connected devices become a source of new knowledge (eg, about their disease and health) and capacities (eg, to prevent and manage) if a learning process to use them in daily life is implemented. This learning process can be supported by patient education.

This theory accounts for the conditions under which the implementation of connected devices for the management of PEx in patients living with CF can increase their capacity to act on their health.

Discussion

Principal Findings

Our study theorized the conditions that favor individual empowerment in patients living with CF in the management of PEx using connected devices as part of the MucoExocet study. This study took place in the context of a rare disease, proposed by the health care team to patients who could be interested in the technology. This theorization of the individual empowerment of patients through the use of connected devices is provisional, similar to any theory derived from the grounded theory approach, and remains subject to verification.
Our study places the concept of individual empowerment through the use of technology at the center of our research. Indeed, empowerment is an important mechanism of eHealth self-management, but validated assessment tools are rare [29]. In our theorizing, we viewed empowerment as the ability of individuals to identify and meet their own needs, solve their own problems, and mobilize the necessary resources through connected devices and education provided by health care providers to feel in control of the management of PEx [10]. This leads us to consider the success of the implementation of connected devices from the perspective of the patient empowerment outcome, weighted by a typology of the intensity of connected device use by the patient deduced from our results. First, low use: patients doubt the feasibility and usefulness of this continuous monitoring; they are in favor of a “standard” follow-up at the CF center using data collected from the clinical examinations in situ. Second, advanced use: patients know that this monitoring can be useful in case symptoms appear or when a follow-up appointment at the CF center is not easily accessible. The use of connected devices remains optional and selective between the “standard” clinic visits at the center. Third, high use: patients experiment with the use of connected devices when in particular situations or because of particular behaviors, enabling them to consolidate or develop skills in relation to their health and the factors that influence it. This use is connected to their desire to improve their health and control its evolution and to the belief that the use of connected devices can support them in doing so. Depending on the patient’s situation (eg, developmental, emotional, and environmental), the level of motivation to engage in less or more intense connected device use will vary.

We suggest that empowerment, adherence to treatment, and quality of life be favored as primary outcomes of remote digital follow-up. In a recent study using a randomized trial that compared 2 groups of patients (using the tracker device against not using the device), Wildman et al [30] highlighted that the health improvement objectives were not achieved but that the intermediate objective of improving adherence to treatment was exceeded. These findings tend to confirm that, when assessing how effective the implementation of technology is with patients, the improvement of health indicators may not be the first outcome to be expected. This strengthens the case for a patient-based evidence evaluation approach.

In addition, the identification of “opposite cases” encountered in our study, for which patient empowerment was compromised, supports the theory stated—cases in which the devices were unreliable (TTF) or no action plan was defined in response to alerts or variations in measurements or cases of difficulties reaching health care providers (lack of support or difficulty integrating the use of technology into their organization) all led to lower levels of patient empowerment. Our study questions eHealth-backed education models, for which data are currently scarce. Following the work of Greenhalgh et al [31], our results highlight the interaction among the patient, the device, and the organizational and social system as the cornerstone of the learning process in patients. This interdependence underscores the systemic approach to connected device implementation, wherein connected device adoption and use and the positive experience with them cannot be attributed to the patient’s lack of motivation alone. Indeed, connected devices introduce a technopedagogical transformation among health care providers, which pushes them to rethink organizational and educational activities to support a new relationship with patients.

This study shows that connected devices may have enabled health care providers to gain a new understanding of patients thanks to the quality and novelty of the information obtained via connected devices. In this sense, connected devices could help bridge the gap that is sometimes observed between theoretical models based on medicine that is “centered on the person and their family” and the practice of care that lacks understanding of patients’ experiences in daily life [32]. Health care providers are made to understand the daily lives of patients living with a chronic disease in physical, psychological, and social terms, thereby creating a more symmetrical relationship of information sharing [33]. Our study shows that caregiver-patient interactions are modified by the introduction of connected devices. They are enriched by a new outlook on patients’ daily lives mediated by technology, which leads to a new understanding by health care providers.

In addition, this study confirmed that the implementation of connected devices should be considered based on patients’ health goals and not simply focused on education on the device [34]. Patient empowerment depends on the connected devices’ capacity to meet the needs of patients’ health project. Patients then enter a learning process supported by the connected device and with educational support from health care providers structured in 4 phases, as described by Almalki et al [35]: identification of an area of interest (the patient is focused on a specific health goal that requires the collection of data about themselves), personal analysis (analyzing one’s behavior in light of the objective data collected), self-experimentation (structuring a reasoning based on the trends identified in support of the experimentation carried out with the connected device), and activation (confirmation of the hypotheses made during the experimentation phase and development of personal knowledge). This process must be structured and accompanied to unfold properly.

Although a recent review of the literature [36] on the use of mobile devices (phones, patient monitoring devices, digital assistants, and other wireless devices) by patients with CF has shown medical, psychological, and behavioral benefits as well as benefits in terms of level of satisfaction with care, the psychological aspect has thus far received little attention, as is the case with the educational dimension of technological devices. In adolescence, although the disease significantly influences the development of one’s body image and self-concept [37], the integration of new technologies into self-care leads to a new understanding of oneself and, therefore, to a potentially modified relationship with one’s body, health, and illness. This process is an integral part of the use of new technologies. Therefore, it is a potential topic for future research, which is necessary to understand the use of new technologies in care and their effects on people.
Limitations of the Study
This pilot study was based on an interventional research protocol. On the one hand, this protocol was implemented differently depending on the centers and the devices selected for the research—the teams applied the educational program differently, the elaboration of self-management action plans in the event of exacerbations was done differently (educational workshop 2), or the midterm review session of the routine follow-up of the patient was different (educational workshop 3). These differences in the implementation of the protocol were noted when collecting the experience of patients and data from the focus groups; they contributed to enriching the definitions of the categories and the relationships between them. In contrast, within the framework of this research protocol, we could not modify the tools that proved to be unreliable (which had been selected in 2016 via a market analysis while planning for the study), adjust the formatting of the data, or more generally adapt the intervention according to the results collected throughout the early phases of the study. Thus, having a protocol that is too fixed is probably a mistake to avoid in health technology research if we wish to adapt the intervention during its implementation to explore the best way of using health technology. In the context of the intervention, the choice of connected devices and the setup chosen did not allow patients to access a dashboard displaying the data collected by all connected devices. Some more motivated patients created their own dashboards separately. Furthermore, the pulmonologists in charge of patient follow-up were not always involved in the study, and this dichotomy made routine monitoring more complicated for patients. Similarly, when the clinical research associate in charge of the study was not the patient’s coordinating nurse, the latter was unable to answer patients’ questions during consultations or phone calls. Eventually, the study included people interested in technology, which could have biased the results based on the experience of using technology.

If this had been a descriptive pilot study, a quality improvement approach would have allowed for adjustments and improvements to the intervention over the course of the study and would have been directly driven by the care team. This format has been used to introduce connected devices into the patient care process for CF in the United States [38], which enabled patients to be monitored remotely when CF centers were closed during the COVID-19 pandemic by using a connected spirometer coupled with teleconsultation. The quality approach allowed for the evaluation of the results during the course of implementation, and adjustments were made to the intervention to improve its impact. The results were convincing:

In March 2020, the beginning of the pandemic, 37% (49/131) of patients owned a HS (home spirometer) and around 50% (9/20) of patients were connected to home telemedicine performed spirometry at home. By September 2020, 97% (127/131) of adult patients at UVA owned a HS, and by October 2020, 96% (24/25) of patients provided spirometry results during their telemedicine encounters.

Prospects for Transferability
Assessing how transferable the theory could be outside the context of its development would require studying the introduction of connected devices in other circumstances: with patients living with different diseases, using different devices, or with a different organization of care.

Two opposite contexts could be studied in terms of patient empowerment through technology: (1) a context of patient dependence on self-regulated or caregiver-driven technology, whether it is telemonitoring, implantable devices for which the use is predetermined (dependence on technology and on health care providers making the care decision in the event of an alert or emergency), or protocolized treatment with little margin for adaptation or action because of side effects (eg, protocol dependence in cancer treatments); and (2) a context of patient-developed technologies [39] made available to patients living with the same condition in open source, as is the case with type 1 diabetes mellitus (T1DM). T1DM has the highest degree of patient empowerment and has recently led to the publication of an international consensus for the guidance of professionals caring for patients who use such devices. The case of T1DM is also interesting as research was conducted on the transition of patients from devices that allow for the management of glycemia and insulin delivery in a semiautomated way to a closed-loop insulin delivery system, which is designed to “free” the patient from self-management by automating the process of insulin delivery. However, this specific case might also lead patients to feel that they lose control over their glucose levels before they take back control over some other parameters of the automated process.

Contribution to an Extended Theory of Empowerment From Remote Monitoring for Health Symptom Tracking
A recent publication by White et al [40] reports on a systematic review to help define engagement with remote monitoring for health symptom tracking (RMT) and how to measure it. Engagement is seen as a mediating factor that eventually explains the impact of RMT on patient health outcomes. Their analysis is of most interest to our own work and shows that concepts still need to be clarified in the context of RMT. They propose a definition of engagement through a remote monitoring protocol (dropouts), objective engagement, subjective engagement, and interactions between objective and subjective engagement. Although objective engagement (with remote monitoring itself, with symptom tracking compliance, and with app use of statistics) is clearly measurable, subjective engagement appears to gather a wide range of concepts, some of them from the technology acceptance model literature (usability, TTF, satisfaction with the technology, utility for symptom management, ease of use, and intention for future use: Davis [41] revised by Venkatesh et al [28] and Chang et al [42]).

In a further extended theory, we would rather build on certain determinants of the technology acceptance model and distinguish them from the concept of patient engagement. These determinants leading to the “behavioral intention of use” would be the personal characteristics (age and sex, expectations, social influence, hedonic motivations, and previous experiences with technology).
information and communication technologies), the facilitating conditions over time, TTF (over time as technologies are continuously refined), and the mediating factors (perceived ease of use and perceived usefulness). We would propose to include the “engagement with the research protocol” by White et al [40] as a determinant, renamed as “conditions for the RMT introduction/intervention” (either research or routine care or self-care). Our study aimed to add elements to modulate the “behavior use” in the RMT context, which is not explained by the previous theories and not necessarily consistent with the “behavioral intention of use.” From our study, these elements could refer to patient empowerment, such as their learnings about their own body, their trust in the technology, and the relationship and support they receive from their care team. We agree with the conclusion of White et al [40] to explore the RMT field in its own right as separate from Digital Behavior Change Interventions or general eHealth literature.

Conclusions
Our study allowed us to propose a theory on individual patient empowerment through the use of connected devices based on patients’ and health care providers’ experiences in the context of an interventional pilot study. This theory needs to be validated with a larger sample and verified in the context of different diseases, different devices, and a different organization of care. It implies that, if the empowerment of patients with chronic diseases is indeed a desirable goal for all parties involved (patients, health care providers, and the health care system), the necessary conditions for the successful implementation of connected devices cannot be looked at separately for each party (health care providers, patients, and health care system). On the contrary, these conditions must be adjusted to the overall collaboration among these stakeholders, who cooperate toward patient empowerment. Only if all these conditions are met can patient empowerment be the outcome of the use of technology.

Abstract

Background: Informal caregivers of people with dementia are at high risk of developing mental and physical distress because of the intensity of the care provided. iSupport is an evidence-based digital program developed by the World Health Organization to provide education and support for the informal everyday care of people living with dementia.

Objective: Our study aims to describe in detail the cultural adaptation process of iSupport in Switzerland. We specifically focused on the participatory strategies we used to design a culturally adapted, Swiss version of iSupport that informed the development of the desktop version, mobile app, and printed manual.

Methods: We used a mixed methods design, with a community-based participatory approach. The adaptation of iSupport followed the World Health Organization adaptation guidelines and was developed in 4 phases: content translation, linguistic and cultural revision by the members of the community advisory board, validation with formal and informal caregivers, and refinement and final adaptation.

Results: The findings from each phase showed and consolidated the adjustments needed for a culturally adapted, Swiss version of iSupport. We collected feedback and implemented changes related to the following areas: language register and expressions (eg, from “lesson” to “chapter” and from “suffering from” dementia to “affected by” dementia), resources (hyperlinks to local resources for dementia), contents (eg, from general nonfamiliar scenarios to local and verisimilar examples), graphics (eg, from generalized illustrations of objects to human illustrations), and extra features (eg, a glossary, a forum session, and a read-aloud option, as well as a navigation survey).

Conclusions: Our study provides evidence on how to culturally adapt a digital program for informal caregivers of people living with dementia. Our results suggest that adopting a community-based participatory approach and collecting lived experiences from the final users and stakeholders is crucial to meet local needs and to inform the further development, testing, and implementation of digital interventions in a specific cultural context.

Introduction

Background

Approximately 55 million people are currently living with dementia worldwide [1]. Switzerland accounts for >150,000 cases of dementia, with an expected doubling by 2050 [2]. In Switzerland, as in most countries, the majority of people living with dementia live at home assisted by an informal caregiver, who is usually a family member who provides daily support and coordinates care delivery [3]. There are positive outcomes that may be associated with the caring role, such as the perception of a better relationship and closeness with the care recipient [4]. Nonetheless, the increasing complexity of taking care of a person affected by dementia exposes informal caregivers to psychological distress and increases the risk of loneliness and developing symptoms of anxiety and depression [5,6]. Caregivers’ psychological distress is also associated with a lower quality of care provided [7] and with the worsening of behavioral and psychological symptoms in the care recipients [8].

Providing guidance and support to informal caregivers is one of the priority areas identified by the World Health Organization (WHO) to reduce the global impact of dementia and to improve the quality of life of caregivers and their families [9]. In the last 2 decades, digital educational and psychosocial interventions for caregivers have bloomed [10,11]. Internet-based interventions are more easily accessible [12,13] and adaptable to the time and geographic constraints of caregivers [14]. Some reviews suggest that multiple components of digital interventions can contribute to reducing the burden and improving the quality of care and be even more beneficial if tailored to caregivers’ specific needs and contexts [10,15,16]. The active involvement of the final users and relevant stakeholders in the design and local adaptation as well as the testing and piloting of interventions is crucial for need-centered interventions in terms of their uptake, integration, and scalability at the community level [17,18]. However, more evidence is required to understand the most effective methods and strategies needed to involve participants in the design and adaptation of digital interventions [19,20].

iSupport is an evidence-based digital training intervention developed by the WHO to provide support and education to informal caregivers of people with dementia [21]. The original program consists of 22 thematic lessons distributed across 5 modules (Figure 1). Each lesson covers a specific topic associated with care that ranges from the daily assistance of the care recipient (eg, toileting, personal care, and nutrition) to the self-care of the carer (eg, reducing stress and involving others in care duties). All lessons include theoretical and informative sections and case scenarios with interactive multiple-choice questions. The WHO provides guidelines to culturally adapt iSupport contents to the local language, culture, and context before implementation [22]. The reporting of adaptation processes of complex interventions is limited but extremely important [23]. Knowledge exchange of methodologies and approaches as well as evidence on barriers and facilitators to local adaptation are crucial preliminary steps to inform the implementation of interventions and their mid- to long-term uptake and sustainability [24].
Objectives
This study aims to describe in detail the cultural adaptation process of iSupport in Switzerland. We specifically focused on the participatory strategies we used to design a culturally adapted, Swiss version of iSupport that informed the development of the desktop version, mobile app, and printed manual. Our purpose is to inform the implementation of not only iSupport but also other complex health interventions, specifically in the context of the cultural adaptation process.

Methods
Study Setting
The study took place in the Italian-speaking part of southern Switzerland, namely the canton of Ticino.

Ethical Considerations
Before initiating the study, we sought ethics oversight by submitting our project to the cantonal ethics committee, and we obtained a waiver of ethics approval and official authorization to proceed with the study (project ID: 2020-02030 / CE 3731). Specifically, the ethics committee determined that our project did not fall within the scope of the Swiss Federal Human Research Act [25], thereby granting us permission to proceed.

Theoretical Approach
The overall process of culturally adapting iSupport in Switzerland was based on principles from the community-based participatory research (CBPR) framework, which can be defined as “an approach to research that involves collective, reflective and systematic inquiry in which researchers and community stakeholders engage as equal partners in all steps of the research process” [26]. In intervention research, adopting CBPR has the advantage of facilitating knowledge exchange between the community and the researchers, reducing potential power imbalances, and increasing the likelihood of intervention uptake and success [27]. We based the specific phases and procedures of the adaptation process on the WHO iSupport adaptation guidelines [22], which, in turn, are based on the ecological validity framework proposed by Bernal et al [28] that is widely used for developing culturally sensitive interventions and strengthening their ecological validity [29-31].

![Figure 1. iSupport index.](https://formative.jmir.org/2024/1/e46941)
Study Procedure

The Community Advisory Board

At the outset, we established a community advisory board (CAB) comprising community members and organization representatives who shared a common identity, geography, language, culture, and other values and principles [32]. We identified potential members of the CAB through a structured stakeholder analysis and mapping that accounted for the different levels of power, importance, and interest of the stakeholders in the project. We included representatives of the project’s funding agencies and other collaborating partners, caregivers of people with dementia, and members of the IT service in charge of developing the iSupport web platform and app. Once consensus among researchers was reached, we contacted and informed the identified members via email using a brief description of the project, the scope of the CAB, and their expected roles and responsibilities.

In the context of iSupport adaptation, the specific roles of establishing a CAB were to (1) help researchers to identify the needs and legitimate interests as well as the expectations of the different stakeholders and the final users and (2) inform the development of the intervention throughout a purposely co-designed process.

The adaptation process of iSupport consisted of four phases: (1) content translation, (2) linguistic and cultural revision, (3) validation with formal and informal caregivers, and (4) refinement and final adaptation. Each phase was based on, and adapted from, the WHO guidelines. Any change or proposed addition was discussed with, and approved by, the WHO. The members of the CAB were constantly informed and updated on the progress of the study. A flowchart of the phases is summarized in Figure 2.

**Figure 2.** Flowchart of the adaptation process of iSupport in Switzerland. CAB: community advisory board; WHO: World Health Organization.

---

**Phase 1: Content Translation**

The first step in the cultural adaptation of iSupport was the translation of the contents (approximately 60,000 words) from English, the original language of the program, into Italian, the local language in southern Switzerland. The process started in May 2020 and ended in August 2020. According to the WHO guidelines, the translation should be accurate while recognizing the local culture and its people. In line with this, we conducted a preliminary adaptation of culturally sensitive terms, including (1) personal names of the characters used in the case studies, (2) available information materials and local services, and (3) reference to cultural habits and leisure activities in the region [22].

One member of the research team fluent in English, AM, a psychologist with previous expertise in the dementia field, translated the original contents of the iSupport program into Italian. Subsequently, a senior member of the team, MF, with expertise in the field of health communication, checked the translations and proposed changes and modifications. All disagreements or doubts about the translation of sensitive terms
and expressions were documented and discussed within the research team in meetings until a consensus was reached. We sought the support of an external professional translator to resolve some specific language locations and terms.

Throughout the process, translators applied the international standards and available dementia guidelines to avoid stigmatizing expressions and to use language that promotes the inclusion and dignity of people living with dementia and their carers [33]. During this phase, we did not apply any changes to the meanings of the original structure of the iSupport program, including case studies or activities. All translations were copied into secure Microsoft Word files and stored in a dedicated Microsoft Teams workspace to optimize efficiency.

**Phase 2: Linguistic and Cultural Revision**

In September 2020, the first CAB meeting took place with the main goals of introducing the members of the CAB to the iSupport program and the research team and clarifying their roles and involvement throughout the research process. During the meeting, we answered all questions and proposed an interactive activity where participants were asked to provide the translation from English into Italian of a selection of sensitive terms and expressions used in iSupport that were noted by researchers during phase 1. At the end of the introductory meeting, participants were asked to sign a letter of intent that summarized the functioning of the CAB and their role and commitment as members of the local iSupport CAB. We explicitly specified the structure and definition of the CAB; goals, roles, and responsibilities (of both CAB members and the research team); and duration (Multimedia Appendix 1). All 9 invited participants agreed to join the iSupport CAB: 4 (44%) were informal caregivers, and the remaining 5 (56%) included representatives of the government (1/5, 20%), the local Alzheimer association (1/5, 20%), a health care service provider (1/5, 20%), the IT service (1/5, 20%), and the University of Applied Sciences and Arts of Southern Switzerland (1/5, 20%).

In October 2020, we shared the translated contents of iSupport with the members of the CAB and asked them to evaluate, and provide feedback on, each chapter and module of the program by the end of December 2020. On the basis of the work of previous adaptations of iSupport [34], participants were asked to carefully go through the 23 thematic lessons and assess the translation and preliminary adaptation of iSupport considering six main parameters: (1) familiarity, (2) sensitivity, (3) comprehensibility, (4) precision, (5) cultural adequacy, and (6) overall evaluation. In addition, they were asked to assess the extent to which (1) the terms used were familiar to the target group (eg, the use of idioms and figures of speech), (2) the language used respected and promoted the dignity of people living with dementia and their carers (eg, the use of stigmatizing terms), (3) the contents were intelligible and easy to understand (eg, minimal use of technical jargon), (4) the contents were presented in an accurate way (eg, they were in accordance with the facts, and there were no mistakes), (5) the contents were appropriate and reflected the experiences of local people (eg, case studies), and (6) the content of each chapter was overall culturally appropriate. At the end of each chapter, participants were asked to fill out a digital survey via Research Electronic Data Capture (REDCap; Vanderbilt University) [35,36] to evaluate each of the aforementioned parameters using a Likert scale ranging from 1=requiring an extensive revision to 4=no additional revision needed. We also invited participants to provide additional comments about individual chapters through a dedicated open-ended question in the survey or to provide free feedback on the overall program via email. The survey was specifically designed for the purpose of this phase and was based on the work of Teles et al [34] to evaluate the cultural adequacy of the contents, as recommended by the WHO adaptation guidelines [22].

After the data collection period, AM and BB (a research assistant with a degree in psychology and health communication) performed a descriptive analysis of the quantitative data and a thematic analysis of the qualitative data. For the quantitative analysis, we used SPSS statistical software (version 25.0; IBM Corp) [37] for Windows to compute mean scores for each program module and survey parameters. For the qualitative analysis, we performed a thematic content analysis of open comments [38]. The maintenance of scientific rigor was ensured through regular meetings among research team members, particularly involving MF and RA, both experts in qualitative research methods.

In January 2021, the main findings of this phase were summarized in a report shared across, and approved by, all CAB members.

**Phase 3: Validation With Formal and Informal Caregivers**

We adopted a qualitative descriptive design, and we used focus groups (FGs) as a data collection method [39]. Between June 2021 and August 2021, we conducted FGs with formal and informal caregivers to explore their attitudes toward, and impressions of, the adapted version of iSupport. We prompted and collected suggestions for improvement, as also recommended by the WHO guidelines. In addition, we decided to expand our inquiry to caregivers’ attitudes toward support measures and help-seeking behaviors, which we have previously reported in detail elsewhere [40].

From April to May 2021, we crafted an invitation letter and a flyer presenting the project, the main purpose of the FGs, the eligibility criteria, and contact information. We disseminated these materials in a local newspaper, to members of the CAB and their associations and institutions, to daycare centers for people with dementia, and to participants of other ongoing research projects who had consented to be informed about further research activities.

Eligibility criteria for both formal and informal caregivers included (1) having (at present or in the past) experience in caring for a person living with dementia, (2) being fluent in Italian, and (3) living in the canton of Ticino. Caregivers who met the inclusion criteria could contact us via email or telephone. Those who contacted us were given an overview of the iSupport program, with excerpts from the same translated material used in phase 2, and the informed consent form (Multimedia Appendix 2). The FGs, which lasted approximately 2 hours, were audio recorded and took place either digitally via the Zoom.
platform (Zoom Video Communications, Inc) or in person at the Università della Svizzera italiana in Lugano, Ticino. AM moderated all FGs, with the supervision of MF and RA. The discussions were transcribed verbatim and pseudonymized by EB, an independent research assistant. AM, RA, and MF performed a thematic content analysis to identify key themes [38]. Initially, the researchers familiarized themselves with the data through repeated reading of notes and transcripts to get an idea of the overall meaning and begin discerning key themes. Subsequently, each researcher independently identified codes within each FG (vertical analysis) and across the whole data set (horizontal analysis) to uncover variations and patterns within the data. Themes were progressively refined and consolidated through discussion in weekly meetings over 4 months (from November 2021 to February 2022) and until a consensus was reached. Data management and coding processing were facilitated by NVivo 12 software (Lumivero) [41]. Additional methodological details have been previously reported [40].

**Phase 4: Refinement and Final Adaptation**

All data collected during phases 2 and 3 were collated to generate a set of proposed changes and adaptations to the iSupport program. AM and BB familiarized themselves with the data and differentiated the feedback between cross-cutting and general comments and specific chapter–related comments and arranged them across 5 dimensions: language, resources, contents, graphics, and extra features. Each comment was then discussed between AM and BB and categorized as (1) rejected/not applicable, (2) possibly applicable, and (3) applicable. The categorization was based on the number and contents of suggestions received as well as in accordance with the WHO adaptation guidelines [22]. The feedback data that were considered possibly applicable and applicable were then discussed with the other members of the team to agree on their potential implementation.

Subsequently, all specific and applicable comments were charted using the iSupport WHO adaptation spreadsheet (Multimedia Appendix 3). All proposals of change were then supported by a rationale and by the source of the proposal: the research team (preliminary adaptation during phase 1), the members of the CAB (results from the linguistic and cultural adaptation during phase 2), and FG participants (data collected during phase 3). Attached to the adaptation spreadsheets, we also sent a list of general suggestions and feedback. The material was sent for revision to the authors of the WHO iSupport program in October 2021, and the results of their final fidelity check were received in January 2022. Subsequently, the local research team implemented all approved changes and uploaded the new adapted contents on the beta version of the iSupport Swiss web platform.

**Results**

A detailed description of all final adaptations made to the original iSupport program, resulting from the 4 phases of the adaptation process, is presented in Multimedia Appendix 4. The results of phases 2 and 3 are summarized in the subsections that follow.

**Adaptations From Phase 2: Linguistic and Cultural Revision**

**Overview**

All 9 members of the iSupport CAB revised ≥1 modules of iSupport and provided feedback, with each module revised by at least 1 CAB member. Module 5, which dealt with behavior changes, was the most revised and received the most comments (7/9, 78%). Descriptive analysis showed that all modules were generally positively evaluated with an overall mean evaluation score of 3.72 (SD 0.00) out of 4. Mean scores of the parameters across all modules ranged from 3 (SD 0.00) to 3.89 (SD 0.47) for familiarity, from 3 (SD 0.00) to 4 (SD 0.00) for comprehensibility, from 3.93 (SD 0.26) to 4 (SD 0.00) for cultural adequacy (Table 1).

We conducted a qualitative thematic analysis of the open comments and identified 7 potential areas for the improvement of iSupport (for more details, refer to Multimedia Appendix 4).

**Familiarity With Terms and Expressions**

The unfamiliarity with the terms referred especially to some expressions that were largely used throughout the text to designate caregivers and health care workers or dementia health and social care facilities, and the comments by the CAB members allowed us to improve the translations; for instance, “informal carers” and “paid in-home helpers” were newly translated using local terms that were easily identifiable and familiar to participants (eg, “informal carer” was replaced with “familiare curante,” which literally means “family carer”). Importantly, the term is also used at an institutional level [42] to refer to people who take care of a loved one (relative or friend) affected by a chronic disease.
Sensitivity of the Language

Participants also suggested improving the sensitivity of the language by removing expressions potentially stigmatizing such as “suffering from dementia,” which was replaced with “affected by dementia” (affetto da demenza), or “show compassion,” which was replaced with “show comprehension” (mostrare comprensione).

Scientific Accuracy of the Terms

The jargon used was generally perceived as comprehensible and easy to understand. However, some of the participants (2/9, 22%), especially those working in the field of dementia, reported the need to use scientific terms to improve the accuracy of the language and ultimately the users’ literacy. As a result, the expression “memory loss” was, for example, replaced with “memory impairment” (difficoltà di memoria), and “helpful/unhelpful thoughts” was replaced with “functional or dysfunctional thoughts” (pensieri funzionali e disfunzionali).

Educational Approach

The educational approach referred to the use of terms considered scholastic and potentially belittling by participants, such as “lesson” and “learn,” which were replaced with “chapter” (capitolo) and “know more about” (conoscere di più), respectively.

Use of English

Some English terms that were retained during the content translation because they are normally used in spoken Italian were translated into Italian, including “focus” (obiettivo) and “relax” (rilassa).

Use of Numbers

To make the reading smoother, some of the participants (3/9, 30%) suggested replacing numbers with sentences (eg, from “20%-30%” to “approximately one-third”; circa un terzo).

Language Register

Finally, almost all participants (8/9, 89%) found that the tone and prose were at times informal or even childish; therefore, for example, the original sentence at the end of each chapter “you finished the lesson, well done” was replaced with “you finished the chapter, let’s go to the next!” (hai completato il capitolo, passa al successivo!).

Adaptation From Phase 3: Validation With Formal and Informal Caregivers

Overview

Between May 2021 and August 2021, we conducted 6 FGs: 1 (17%) with formal caregivers and 5 (83%) with informal caregivers. Most of the participants (16/19, 84%) were female, and the formal caregivers (6/19, 32%) had longer years of caring experience than the informal caregivers (13/19, 68%). The main characteristics of the caregivers are reported in detail in Tables 2 and 3.

**FG With Formal Caregivers**

Formal caregivers are professionals who are trained, hired, and paid to provide care to a person living with dementia. In our study, all formal caregivers (n=6) actively participated in the digital discussions. All participants were female. Their mean age was 44 (range 28-59) years. All participants had professional experience in taking care of a person living with dementia. Of the 6 participants, 3 (50%) reported having >10 years of experience in dementia care. In addition to the professional caregiving experience, 3 (50%) of the 6 participants also reported taking care, or having taken care in the past, of a relative affected by dementia (Table 2). The main findings of the FG are summarized in the following paragraphs.

Participants agreed that an intervention aiming to support and improve the knowledge of informal caregivers of people with dementia was much needed. A caregiver compared information learning to a safeguard not only for the carer but also for the care recipient:

*I hope that this program will spread because information protects all of us: the carer, and especially the person who is cared for.* [ID 6]

iSupport was generally appreciated and acknowledged by participants as a useful tool. The contents were found appropriate and sufficiently comprehensive. The difficulty regarding accepting the disease and the changes in the relationship with the care recipient were found to be the main challenges and contents to cover in the program:

Relatives finds it extremely difficult to accept the disease and the change...I believe a very strong support is needed...also at a social level because the disease is often associated with shame. [ID 1]

Similarly, a participant also suggested adding to the program specific resources for social and psychological support:

You could mention [the existence or the opportunity for family members] to benefit from psychological support because they need it, always. [ID 2]

This quote underscored the recognition by formal caregivers of the potential emotional and psychological strain on family members as they witness the progression of the disease of their care recipients.

In light of the participants’ perspectives, an important feature to add to the original iSupport format was the inclusion of a platform for caregivers to engage with each other and that facilitated the caregivers’ interactions with each other (this adaptation was also needed to differentiate iSupport from another repository of information or digital available resources on dementia):

There are a billion guides on dementia...I think people need to interact. [ID 4]
Regarding case scenarios, the caregivers generally found that the examples were appropriate and consistent with their experiences. However, the answer options often did not reflect the variety of, and differences in, caregiving situations and experiences, including the age of the person affected by dementia, the severity of dementia, the living situation, or the type of dementia (e.g., Alzheimer disease and frontotemporal dementia). A participant suggested adding general guidelines to the examples to include more answers:

*If the examples aim to increase knowledge, they should give general indications that can apply to different caring situations.* [ID 6]

**FG With Informal Caregivers**

Of the 20 informal caregivers who contacted us, 13 (65%) joined the FGs. Reasons for nonparticipation were lack of time and geographic distance. Most of the caregivers (10/13, 77%) were female; nearly half were spouses (6/13, 46%) of the persons living with dementia, and more than half were children (7/13, 54%; daughter: n=4, 57%; son: n=3, 43%) of the persons living with dementia. Their age ranged from 55 to 82 years. Most of the participants (10/13, 77%) reported a caregiving experience of at least 3 years, and most of them (8/13, 62%) cared for a relative who lived at their own residence. Of the 13 participants, 2 (15%) reported that the person they cared for had passed away. The number of caregivers attending each FG ranged from 2 to 7: of the 13 caregivers, 6 (46%) attended FG 1 on June 14, 2021; a total of 7 (54%) attended FG 2 on July 12, 2021; a total of 2 (15%) attended FG 3 on July 15, 2021; a total of 6 (46%) attended FG 4 on August 18, 2021; and 2 (15%) attended FG 5 on August 24, 2021. Of the 13 participants, 7 (54%) attended >1 FG (Table 3). The main findings of the 5 FGs are summarized in the following paragraphs.

Participants generally believed that iSupport holds the promise to be useful, to increase dementia knowledge, and provide information about available services and support measures for people living with dementia and their families:

*The idea is brilliant because everything can be useful...In my opinion, the most interesting thing is the overview of what is locally available to support caregivers.* [ID 9; daughter]

The need for guidance and orientation to services was felt owing to a perceived lack of support and direction, likely stemming from the uncertainty and confusion that frequently followed the diagnosis. This feeling of bewilderment was echoed by a participant:

*It’s confusing outside, you don’t know where to go, whom to turn to...there are no guidelines, no support.* [ID 2; daughter]

Regarding the contents, participants reported familiarity with most of the case scenarios.

A participant commented as follows on a scenario (module 3, chapter 3) involving a person affected by dementia who cannot find the house keys and does not want the carer to leave him alone at home:

*It happened to me many times, not always with the keys though.* [ID 12; daughter]

However, despite the familiarity reported and the need to obtain information and increase knowledge to cope with difficult situations, the original exercise format was seen as a limitation by some of the participants. A participant reported feeling diminished when choosing between wrong and right answers:

*It’s almost guilt-inducing...There is the best solution and if you guess wrong you are doing your role wrong.* [ID 8; daughter]

In addition, some of the answer options were considered to be so wrong as to be offensive to the carer; for example, in module 5, chapter 9, a case scenario described a situation where the person affected by dementia (Matteo) makes sexual remarks toward a domestic worker, and the user is asked what they would do in this situation. A participant commented on the option “shout at Matteo and shame him for his conduct” as inconceivable:

*Shout?!...We do know what we’re doing!* [ID 9; daughter]

Similar to what formal caregivers reported about case scenarios, participants also highlighted the risk of generalizing solutions that may not be appropriate for all caregiving situations:

*It should be clear that each user has to transpose his or her situation by taking cues from the scenario, but unfortunately it isn’t black and white.* [ID 13; spouse]

Finally, the informal caregivers too suggested adding interactive features to the digital version of iSupport to minimize the risk of the caregivers isolating themselves; for instance, a participant commented as follows:

*For me, the biggest utility is in connecting people...there should be people behind the app.* [ID 5; spouse]

**Discussion**

**Overview**

This study described in detail the main steps taken to culturally adapt the WHO iSupport program for informal caregivers of people living with dementia in Switzerland. Our results demonstrate the complexity as well as the necessity of adapting an evidence-based complex intervention to a specific cultural context and population. We collected feedback and implemented changes, in accordance with the WHO authors of the program, to the original iSupport version in the areas of the language, resources, contents, graphics, and features used in the program. In the following paragraphs, we summarize and comment on the main lessons learned.

**Valuing Experiential Knowledge**

One of the main messages we took away during the adaptation process was the importance placed by informal caregivers on being recognized for their role and expertise. This finding is consistent with the findings of other studies, including the works reporting on iSupport adaptation processes in other countries [31,34,43-45]. Our participants suggested that the learning
approach used in the original iSupport program was too scholastic and recommended the removal of expressions that likely resulted from a top-down approach to content and compilation. Referring to case scenarios, some of the informal caregivers (5/13, 38%) felt that the simplicity of certain answer options was offensive. Informal caregivers claimed to be recognized because of their lived experience as experts in the field who could contribute to not only locally adapting iSupport but also integrating and shaping it. This echoes the inclusive procedures used to develop iSupport in the first place [21] and the work done for the iSupport adaptation process in Portugal and the United Kingdom [34,43]. Informal caregivers can spend on average 170 hours a month providing care to a loved one affected by dementia [46]. In our study, more than half of the caregivers (10/13, 77%) reported a caregiver experience of at least 3 years and up to 10 years. Although one may argue that caregivers acquire and improve their learning by doing, it is undeniable that they can become experts in caring; surely, they provide a unique perspective of the person with dementia and their own needs. However, besides the years of personal experience, caregivers’ knowledge of dementia and caring may also depend on other factors and may be influenced by their educational level and sociocultural background. Similar to any complex health intervention [47], it is important to ensure that the final version of iSupport is adapted to the real user’s experience and preexisting abilities. An early, timely, and active involvement of caregivers is needed [48,49]. The adoption of a language register and skills training techniques that promote preexisting abilities, rather than replace them, may enhance the acceptance and use of the intervention.

Enhancing Social Contacts

According to participants, iSupport could benefit from the inclusion of interactive features (eg, chat and forum) that allow the user to communicate with other caregivers and share experiences and problem-solving strategies. This finding is consistent with a recent study [50] that found that peer support can be complementary to professional support and beneficial in reducing social isolation, as well as in connecting patients and caregivers to others with similar issues. Similarly, Greenwood et al [51] found that, besides providing psychosocial support, peer support interactions for caregivers of people with dementia can offer practical information and guidance in managing difficult situations and gaining new perspectives on their caring role.

The adoption of peer support programs for informal caregivers of people with chronic diseases and disabilities is well established in the literature [52]. A recent scoping review [53] found that peer support was often part of multicomponent interventions that also addressed information sharing, skills development, personal coping skills, and self-management. Despite the difficulty in identifying what component may or may not be beneficial for the carers, the authors concluded that peer support, particularly if delivered digitally, could represent a cost-effective medium and opportunity to meet caregivers’ needs and preferences.

Importantly, digital meets among peers seem more promising, usable, and potentially effective for caregivers when embedded in digital interventions [10] such as iSupport.

Facilitating Access to, and Navigation of Local Services

Another suggested feature to implement in the program was the inclusion of contacts of local resources for dementia, such as health care services and facilities, charities, or other relevant organizations. Consistent with what our participants reported, informal caregivers often experience a lack of information and support, especially at the beginning of the caregiver journey, when it is best to establish fruitful contacts and interactions with local health and social care services and offers in general [1]. According to the latest World Alzheimer Report [3], <50% of informal caregivers are advised to contact the local Alzheimer association or receive postdiagnostic support information. The navigation of the services and various offers for both people living with dementia and informal caregivers is taxing, often ineffective, and can be frustrating. The lack of information about existing services and support is associated with caregiver burden and distress [54]. A recent review on the needs of family caregivers revealed that information provided on available support services and measures was one of the main needs reported by caregivers after their loved one was diagnosed with dementia [55]. Caregivers may seek support autonomously, mainly digitally. However, the variety of information and sources available on the internet about dementia may contribute to creating feelings of bewilderment and difficulties in finding relevant and reliable information [56]. Hence, digital interventions that also include contacts with external and local resources may help users to access and navigate the health care system and find the most appropriate service or information for their situation.

Limitations

We acknowledge that our study has limitations. First, we included only a few participants for each phase of the adaptation process. Because of their pressing needs and duties, informal caregivers are a challenging population to reach and involve in research [57]. However, the number of caregivers and experts that we included in our study was adequate for the qualitative methods used and is higher than the minimum recommended by the WHO guidelines to adapt iSupport to local contexts [22]. In addition, we set up a CAB that included both stakeholders and caregivers who worked continually and with great dedication through the adaptation process of iSupport. Second, the discrepancy in FG size between formal and informal caregivers and the attendance of informal caregivers in >1 FG may have contributed to reaching data saturation, but this may have reduced social desirability bias, thanks to both the progressive cementing of positive small group dynamics among participants and the variety of the contents discussed. Third, our study was conducted in Switzerland, a high-income country, equipped with a National Dementia Strategy that aims to improve the quality of life of people affected by dementia and to promote awareness and education on dementia [58]. Therefore, the feedback and experiences that we collected may not be easily generalized to all contexts. However, the adaptation strategies and phases described in our study may be useful for...
all countries interested in adapting digital interventions for caregivers of people with dementia, not only iSupport. Our findings suggest that digital interventions benefit from a community-based participatory approach and the involvement of caregivers to ensure that the final program meets the needs and preferences of users [17].

Future Research
The recommendations and feedback that we collected during this study allowed us to adapt the original contents of the iSupport program to the Swiss context and to inform the development of the iSupport desktop version, mobile app, and printed manual. Following the Medical Research Council guidelines for the development of complex health interventions [59], we will proceed to assess the usability and feasibility of iSupport before its implementation. Evidence not only on the effectiveness but also on the ease of implementation and scalability of caregivers’ interventions is still rare in our country. We are determined to design and conduct good-quality studies to address these gaps and to promptly disseminate our findings and experience widely through peer-reviewed publications, the WHO knowledge exchange platform [60], and the global WHO iSupport network coordinated by the Brain Health Unit at the WHO.

Finally, the iSupport original program was developed by the WHO based on evidence related to carer training and support interventions and in collaboration with experts and caregivers [21]. Therefore, the program can be adapted to the extent that it maintains the original aims and structure [22]. During the study, we collected recommendations and feedback that would have required a consistent change in terms of resources and digital infrastructure to be implemented. These included, for instance, contents based on the type of dementia and stage of the disease, a comprehensive map of all digital and local resources available, and consultation from professionals as well as legal and financial assistance. Therefore, further development of iSupport could focus on supporting specific groups of caregivers, such as young carers or caregivers of people with rare dementia, and on providing personalized support tailored to the stage of the caregiver journey and the care needs of the care recipient.

Conclusions
Despite the recognized importance of culturally adapting interventions to implement them in real-world settings, the evidence on how to conduct this process is still limited. Our study enriches this landscape by underscoring that an active engagement of the final users and stakeholders allows to adapt an intervention to their culture, values, and needs. In addition, this study provides examples of concrete strategies and methods to involve community members and stakeholders across different phases of the intervention. Indeed, despite the emerging importance of coconstructing research together with people as collaborators, rather than as simply subjects of traditional research, there is limited evidence regarding the modalities of this practice.

Our experience confirms that the adoption of a CBPR approach is necessary to identify and address criticisms and potential barriers to the use and acceptance of a digital educational intervention before its implementation. In conclusion, we envision this study as a potential driver for enhancing a more robust dialogue between researchers and communities. We firmly believe that CBPR represents a transformative research opportunity where the needs of academics and community members can be met and where both groups can find opportunity for mutual knowledge exchange and growth.

Acknowledgments
The authors thank all informal and formal caregivers of people with dementia for their time and precious contribution to this work. The authors also wish to acknowledge the support provided by the members of the community advisory board, the funders, and collaborators for the realization of this project.

Abstract

Background: This study assesses the accuracy of a Bluetooth-enabled prototype activity tracker called the Sedentary behaviOR Detector (SORD) device in identifying sedentary, standing, and walking behaviors in a group of adult participants.

Objective: The primary objective of this study was to determine the criterion and convergent validity of SORD against direct observation and activPAL.

Methods: A total of 15 healthy adults wore SORD and activPAL devices on their thighs while engaging in activities (lying, reclining, sitting, standing, and walking). Direct observation was facilitated with cameras. Algorithms were developed using the Python programming language. The Bland-Altman method was used to assess the level of agreement.

Results: Overall, 1 model generated a low level of bias and high precision for SORD. In this model, accuracy, sensitivity, and specificity were all above 0.95 for detecting sitting, reclining, standing, and walking. Bland-Altman results showed that mean biases between SORD and direct observation were 0.3% for sitting and reclining (limits of agreement [LoA]=–0.3% to 0.9%), 1.19% for standing (LoA=–1.5% to 3.42%), and –4.71% for walking (LoA=–9.26% to –0.16%). The mean biases between SORD and activPAL were –3.45% for sitting and reclining (LoA=–11.59% to 4.68%), 7.45% for standing (LoA=–5.04% to 19.95%), and –5.40% for walking (LoA=–11.44% to 0.64%).

Conclusions: Results suggest that SORD is a valid device for detecting sitting, standing, and walking, which was demonstrated by excellent accuracy compared to direct observation. SORD offers promise for future inclusion in theory-based, real-time, and adaptive interventions to encourage physical activity and reduce sedentary behavior.

Introduction

Sedentary behavior (SB) is defined as “any waking behavior characterized by an energy expenditure of less than 1.5 metabolic equivalents while in a sitting, reclining, or lying posture” [1,2]. SB is an independent risk factor for many noncommunicable diseases, with the risk being most pronounced in those who are also physically inactive (ie, not meeting physical activity [PA] guidelines) [3-5]. Reducing SB for all...
people, including those who are physically active, can assist in producing health benefits [6]. Interrupting SB with standing or light or moderate intensity PA can improve chronic risk factors including glucose homeostasis, insulin sensitivity, blood lipid concentrations, and diastolic blood pressure [7-10]. Recent World Health Organization guidelines on PA and SB explicitly state the importance of reducing sedentary time in addition to promoting PA for adults and older adults, including those with chronic conditions [11]. This has subsequently led to the development of interventions targeting SB reduction, although interventions to date have been compromised by the lack of a tool that can capture SB accurately and in real time. Accurate measurement of sitting, standing, and walking in real time will enable the design of interventions that can adapt to changes in the activity state and can be delivered at times when an individual is most responsive to the intervention, therefore maximizing the potential opportunity for reducing SB and increasing PA [12].

To date, the majority of interventions to reduce SB and promote PA have relied on subjective measurement of these behaviors, which are subject to self-report bias [13,14] and may underestimate daily sitting time by up to 2 hours compared with objective measurement [15]. Few activity trackers, including research-grade (eg, activPAL) and commercial (eg, GENEactive and Fitbit One), measure sedentary time with reasonable precision [16-22], but they are not optimal for SB change interventions [23]. The 2 main issues involve technical difficulty in using support software for real-time interventions and concerns about device accuracy in distinguishing postural states (sitting, standing, etc) [24,25]. Most activity trackers use similar technologies, including accelerometers, magnetometers, and gyroscopes, to detect posture and activity [26]. However, the placement of devices on the body can considerably influence accuracy [27]. Commercial wrist-worn devices such as the Garmin Vivofit are unable to detect sit-to-stand transition [23,28]. Other thigh-worn devices, such as activPAL and FitFIT, are capable of detecting sitting and standing due to their horizontal placement [23]. In terms of behavioral intervention, activPAL does not offer any real-time prompts or feedback to participants [29]. The FitFIT device provides real-time feedback to the user, and its accuracy, although acceptable, was lower when compared to the activPAL, which is considered the preferred device for research purposes [30]. However, FitFIT is pocket-worn, which limits its use for those not wearing suitable clothing (eg, trousers) or garments without pockets (eg, dresses) [30]. More importantly, SitFIT does not distinguish standing from walking [31] and therefore cannot be used to assess standing as a unique outcome both for real-time and adaptive interventions. It should be noted that these devices (SitFIT and Fitbit One) are no longer available on the market and were included in our discussion to provide historical context and illustrate the evolution of activity-tracking technology. Evidence on the positive impact that standing may have on health outcomes in different population groups is emerging from short-term and small-scale studies [32,33], although real-time assessment and behavior change interventions are missing. This, in turn, suggests a need for a platform to momentarily evaluate both sedentary and standing outcomes to study their exclusive health effects and intervene accordingly.

In summary, despite the presence of activity tracker devices, few have included evidence- and theory-based interventions or strategies to promote PA and reduce SB (eg, self-monitoring and goal setting), and the use of some other devices is restricted due to a lack of real-time assessment of outcomes (eg, standing). In response, we designed and developed a new wearable platform called “Sedentary behaviOR Detector” (SORD), which collects real-time sedentary data, including lying, reclining, sitting, and standing, as well as walking activity time. Therefore, this study aimed to assess the validity of the SORD device in detecting sedentary and walking activities among adult participants.

**Methods**

**Overview**

A cross-sectional, laboratory-based study was conducted to assess the criterion validity (SORD vs direct observation) and convergent validity (SORD vs activPAL). Adults were recruited to take part in this laboratory-based study through print and email advertisements at a university campus. Adults aged 18 years or older, without gait abnormalities, able to walk on a treadmill easily, with no skin sensitivity to plasters or tapes, and able to communicate in English were included.

Upon arrival, participants completed a demographic questionnaire including age, sex, ethnicity, job status, marital status, education, and the Physical Activity Readiness Questionnaire [34] for safe exercise. Anthropometric measures, including height to the nearest 0.1 cm and weight to the nearest 0.1 kg, were taken using a stadiometer (Seca 213) and Tanita scale (Tanita Innerscan 50), respectively.

Participants were given a printed activity protocol to help familiarize them with the required activities and the order in which they were to be performed. *Textbox 1* presents a range of different states of activities included in the study protocol to mimic typical postures that may be encountered during everyday life.

Hypoallergenic retention dressing tape (Hypafix) was used to attach the SORD and activPAL devices on the midline of the right thigh. Participants were then instructed to engage in a combination of activities in the order of sitting, reclining, sitting, standing, walking, standing, sitting, lying, and walking on a treadmill. Each activity variation lasted for a minimum of 2 minutes and a maximum of 3 minutes and 30 seconds, except walking, which involved participants walking at their regular walking pace along a 10-m-long path. Participants had 2 minutes of optional resting to break up the activities if needed. Ground truth, or the true time spent on each of the activities, was measured by a researcher with the help of a video camera for direct observation.

Sedentary behaviOR Detector

Overview
The SORD is a wearable electronic device (Figure 1A) that collects and provides real-time data associated with sitting, reclining, lying, and PA. Data provided by the device can be used to separate sitting versus standing versus ambulation. To separate sitting time from lying time, 2 same devices will be attached to 2 different locations of the body.

The SORD device includes a number of internal components (Figure 1B): a low-power processor and transceiver, inertial measurement unit, voltage regulator, battery charger, battery, antenna, micro-USB connector, LEDs, motherboard, and an enclosure. These components have been described below.

Figure 1. (A) Sedentary behaviOR Detector (SORD). (B) Internal components of the SORD device. The SORD is a small device with the following dimensions: 0.9 mm (height), 37 mm (width), and 68 mm (length). It is also lightweight, with a weight of 23.5 g. The device can operate for about 45 hours on a single charge. The SORD device measures 3-axis orientation using the accelerometer that gives acceleration signals for 3 axes, the gyroscope that provides rotation along 3 axes, and the magnetometer that gives motion in the magnetic field in 3 axes. It hosts an embedded C firmware that continuously reads from the sensors, records their data at 25-Hz frequency, preprocesses the data, and transmits the data wirelessly. No initialization is required for the SORD device, as the data are captured and transmitted through the 2.4-GHz Bluetooth Low Energy 5.0 transceiver in real time.

Processor and Transceiver
The ATSAMB11-ZR210CA is used that includes a low-power ARM Cortex M0 32-bit processor, 128 KB of RAM, 128 KB of stacked flash memory, a 2.4 GHz Bluetooth Low Energy 5.0 transceiver and modem, a power management unit, a ceramic high-gain antenna, and a printed circuit board with a small footprint.

Inertial Measurement Unit
The BNO055 is used that includes a single-chip integrated circuit incorporating an intelligent inertial measurement unit with a triaxial 14-bit accelerometer, a triaxial 14-bit gyroscope, a triaxial geomagnetic sensor, an I2C communication interface, and an ARM Cortex M0+ 32-bit processor executing a sensors data fusion algorithm.

Voltage Regulator
The XC9264B755MR-G is used which includes a synchronously step-down DC/DC voltage regulator. It operates within the voltage range of 3-18 V and provides a 500 mA output current. It has a selectable switching frequency of 500 kHz, 1.2 MHz, or 2.2 MHz. It also features overcurrent protection as well as thermal shutdown.
Battery Charger
The BQ25101YFPR is used which includes a linear Li-Ion and Li-Pol battery charger with a very small footprint. It has a single power output that charges a battery in 3 steps: conditioning, constant current, and constant voltage. The junction temperature of the device is monitored to control the charge current.

Micro-USB Connector
A micro-USB connector is used for programming the processor and also for establishing serial communications as well as charging the onboard battery.

LEDs
A total of 2 multicolor LEDs are used to illuminate different functional states of the device to the user.

Battery
A 3.7-V, 700-mAh, 303759 Lithium Polymer rechargeable battery is used. Its height, width, and length are 3 mm, 37 mm, and 59 mm, respectively, and its weight is 14 g.

Antenna
A Freedom 2.4-GHz flex circuit PCB antenna is used.

Motherboard
A printed circuit motherboard is designed and fabricated to host all the electronic components of the SORD device.

Enclosure
A small enclosure for the SORD device is designed and 3D printed. It hosts all the components of the device.

ActivPAL
ActivPAL is a thigh-worn triaxial accelerometer that classifies an individual’s activity into periods of time spent sedentary (lying or sitting), standing, and walking, as well as the number of steps and stepping speed [29,35]. ActivPAL devices were initialized before the data collection and date-time stamped 1-second epoch files were used for comparative analysis.

Direct Observation
True time spent engaging in activities was logged by a trained researcher (RDK). This was assisted by a video camera positioned in the room and checked by another researcher (JM). If there was any discrepancy, RDK and JM reviewed the camera data together to achieve consensus. No formal intra- or interrater reliability was conducted.

Data Handling and Analysis
SORD data were transmitted to a computer through Bluetooth Low Energy. A program was developed in MATLAB (MathWorks) and run on a Microsoft Windows (Microsoft Corp.)–based computer to receive data from the SORD devices in real time and store it into a Microsoft Excel (Microsoft Corp.) file. The program starts by initializing relevant variables and a communications port, creates a file name based on the current date and time, continuously receives data from the SORD devices, and stores the incoming data in the Microsoft Excel file in real time. Each data packet received from the SORD devices includes values obtained from the onboard sensors at the current time. For a data packet, the following information is then stored in the file in real time: date, time, angle, accelX, accelY, accelZ, gyroX, gyroY, gyroZ, magX, magY, magZ, and battery voltage. To avoid potential Bluetooth transmission package loss, this study used the time-stamp data from the SORD device instead of the computer receiver (ie, the sending time stamp rather than the receiving time stamp). Thus, we had computer receiver and accelerometer data, along with their timestamps. Based on the real sampling rate, the computer calculated the time stamp difference between each data point (ΔT). In this research, the number of missing data points was defined by missing = ΔT/(1/25Hz) – 1. The values of these data points were filled by the average of the 2 data points before and after the missing data points (eg, Vi[missing] = [Vi – 1 + Vi + 1]/2). Before sending data to the server for inference, the phone app waits until all required data have been received (processing buffer length). Using the VANE (standard) classification algorithms, activPAL data were processed and collected using proprietary software (activPAL Professional Research Edition, PAL Technologies). The software-generated event file was used. This file contains a chronological list of all episodes of sedentary, standing, and stepping (ie, walking) activities recorded at 1-second intervals. The frequency of the recorded signals from SORD was subsequently reduced to 1 Hz (ie, 1-second epochs) for comparative analysis. This reduction in frequency simplifies data processing and facilitates direct comparison with activPAL, which was also sampled at 1 Hz. Furthermore, outliers or irregular data points were identified and removed. Once individual data sets were cleaned, they were combined for subsequent comparative analysis. The combining process involved aligning the data sets temporally so that corresponding data points from both devices were synchronized for direct comparison.

Due to multiple limitations, we did not use the available open-source activity recognition algorithms. These limitations include (1) inconsistency in the data format and ranges, (2) differences in the frequency of raw data assumed by these algorithms compared to SORD (which is 28 measurements per second), and (3) the variations of activities considered by these algorithms were not exactly the same as the ones we wanted to address in this research at this stage and in the future. Thus, we developed the data engineering and activity recognition models. Although ensemble learning techniques outperform deep learning, they demand higher computation resources and have longer processing latency [36,37]. Therefore, for practical reasons and real-world applications of SORD, this study used deep neural network models—a combination of convolutional neural network and recurrent neural network—to develop algorithms. Deep neural network can learn features automatically from the raw data, therefore performing better than statistical and basic machine learning methods, and they are suitable for recognizing complex activities [38].

A data scientist developed deep learning algorithms to classify activity type and postural states from preprocessed motion sensor data using the Python programming language [39]. First, machine learning classifiers were developed, trained, and tested for the SORD device. A dynamic sliding window approach was used for machine learning [40], where each window was related
to a particular activity and multiple variables were examined within each window to identify patterns. When a particular activity was detected in the sensor readings, features were extracted to classify activities between the previous one and the current one (further details are provided below). Then, criterion validity (against direct observation) and convergent validity (against activPAL micro) were evaluated. Using Python, the Bland–Altman method was used to assess the level of agreement between SORD and each reference measure (criterion agreement=directly observed time and convergent agreement=activPAL). Mean difference represents the systematic bias, and the limits of agreement (LoA) show the range of agreement between SORD and reference methods, where a positive value indicates underestimation and a negative value indicates overestimation by SORD. For all activity states, we predefined the acceptable LoA between ±10%.

**Classification Algorithms**

A single data set included SORD, activPAL, and direct observation data for 1 participant. Deep learning was used to randomly select 6 data sets for training, 1 for validation, and 7 for testing. In the training set, similar patterns were identified for the previous 35 data points to specify an activity. Confusion matrices were used to visualize the model’s performance. In a confusion matrix, each row represents the instances in the predicted activity, and each column represents the instances in the actual activity.

**Ethical Considerations**

Ethics approval was granted by the Deakin University Human Research Ethics Committee’s Human Ethics Advisory Group (HEAG-H 109_2019). All participants provided written informed consent. All research data were anonymized before cleaning and analysis. Participants were remunerated with an Aus $20 (US $14) gift voucher.

**Results**

**Overview**

In total, 15 adults (12 female adults) aged between 20 and 62 years completed the experimental study. Table 1 presents the demographic characteristics of the participants.

**Deep Learning Results**

A total of 4 models were presented for SORD. Model 1 classified 3 activities, including sedentary (lying, reclining, or sitting), standing, and walking separately. As illustrated in Figure 2, model accuracy, sensitivity, and specificity for detecting sedentary time were 0.92, 0.99, and 0.87; for standing, they were 0.95, 1.00, and 0.91; and for walking, they were 0.96, 0.92, and 1.00, respectively. Model 2 included 4 activities: sitting, reclining, standing, and walking; lying was excluded (ie, lying moments observed by video camera were omitted from the data set). As illustrated in Figure 3, model accuracy, sensitivity, and specificity for detecting sitting and reclining were 1.00, 1.00, and 1.00; for standing, they were 0.99, 0.99, and 1.00; and for walking, they were 0.98, 1.00, and 0.95, respectively.

Model 3 included 3 activities: sitting, standing, and walking; reclining and lying were excluded. Respectively, model accuracy, sensitivity, and specificity for detecting sitting were...
0.97, 1.00, and 0.94; for detecting standing, they were 0.95, 0.91, and 1.00; and for walking, they were 0.98, 1.00, and 0.97 (Multimedia Appendix 1).

Model 4 included all 5 activities: lying, sitting, reclining, standing, and walking. Respectively, model accuracy, sensitivity, and specificity for detecting lying were 0.70, 0.54, and 1.00; for sitting and reclining, they were 0.85, 1.00, and 0.75; for standing, they were 0.75, 0.63, and 0.93; and for walking, they were 0.99, 1.00, and 0.98 (Multimedia Appendix 2).

**Figure 2.** Confusion matrix for model 1 classification algorithms. Sedentary (lying, sitting, and reclining), standing, and walking were included in the model.

**Figure 3.** Confusion matrix for model 2 classification algorithms. “Sitting and reclining,” standing, and walking were included in the model.
Agreement

For models 1 and 2, results of the Bland-Altman analysis comparing second-by-second data on sedentary, standing, and walking time between direct observation versus SORD and activPAL versus SORD are presented in Figures 4 and 5. Multimedia Appendices 3 and 4 illustrate Bland-Altman for the other models. Percentage values are presented in the text (see Figures 4 and 5 and Multimedia Appendices 3 and 4 for true values).

Figure 4. Bland-Altman plot comparing seconds of sedentary behavior, standing, and walking between direct observation and activPAL against the Sedentary behaviOR Detector (SORD) activity tracker (model 1).
Mean differences (biases) between SORD model 1 and direct observation were 6.4% for sedentary (LoA=–4.3% to 17.1%), –8.7% for standing (LoA=−23.5% to 6.1%), and –8.9% for walking (LoA=−22.2% to 4.4%). Results of model 1 show wide limits, although the mean biases were below 10% for all activities. Relative to total activity durations, mean biases between SORD model 1 and activPAL were –2.5% for sedentary (LoA=−15.0% to 9.9%), 1.7% for standing (LoA=−23.3% to 26.9%), and 7.4% for walking (LoA=−2.3% to 17.1%). Results of model 1 comparing SORD to activPAL show wide limits.

Mean biases between SORD model 2 and direct observation were 0.3% for sitting and reclining (LoA=–0.3% to 0.9%), 1.19% for standing (LoA=–1.05% to 3.42%), and –4.71% for walking (LoA=–9.26% to –0.16%). Model 2 showed the narrowest LoA for “sitting and reclining,” standing, and walking, denoting excellent agreement with direct observation. All the mean biases were within ±10%. Relative to total activity durations, mean biases between SORD Model 2 and activPAL were –3.45% for sitting and reclining (LoA=−11.59% to 4.68%), 7.45% for standing (LoA=−5.04% to 19.95%), and –5.40% for walking (LoA=−11.44% to 0.64%). Results of model 2 comparing SORD to activPAL show a wider LoA, although mean biases are relatively low for “sitting and reclining” and walking.

Mean biases between SORD model 3 and direct observation were –6.4% for sitting (LoA=–18.6% to 5.7%), 12.4% for standing (LoA=–6.6% to 31.5%), and –4.9% for walking (LoA=−12.5% to 2.5%). Therefore, sitting and walking were...
overestimated, while standing was underestimated. The mean bias was acceptable for sitting and walking but not standing. A narrow LoA were observed for walking.

Mean biases between SORD model 4 and direct observation were 52.2% for lying (LoA=−6.9% to 111.4%), −32.0% for sitting and reclining (LoA=−78.2% to 14.1%), 48.8% for standing (LoA=−13.7% to 111.4%), and −2.2% for walking (LoA=−6.7% to 2.2%). Therefore, “sitting and reclining” and walking were underestimated while lying and standing were overestimated. Model 4 shows the broadest LoA for “sitting and reclining” and standing, while the narrowest LoA were observed for walking in this model.

### Discussion

This laboratory-based study assessed the criterion and convergent validity of a prototype activity tracker (ie, SORD). A high level of accuracy in detecting sitting, standing, and walking for the SORD device among adults was confirmed. Based on the Bland-Altman plots, high levels of agreement with direct observation demonstrated high criterion validity.

ActivPal is a triaxial accelerometer that has been validated for detecting sitting, standing, and walking activity [29,41,42] and has been widely used in previous intervention studies [43-47]. However, a recent review found that activPal has lower accuracy during fidgeting [48]. In this study, the agreement between SORD and activPal was not ideal. The discrepancy observed might result from the inclusion of various fidgeting states. In addition, since activPal does not enable real-time transmission of data to external devices or networks [29], it cannot be used for real-time or adaptive interventions. SitFit [30] is among the few devices that provide real-time feedback on SB. SitFit (PAL Technologies Ltd) is a pocket-worn device that requires appropriate clothing (eg, trousers with a front pocket), which is a barrier to its usability [30]. SitFit has an embedded screen to provide visual feedback to users and is also Bluetooth-enabled for connectivity to smartphones, tablets, and PCs. However, outputs generated by SitFit include sedentary time (sitting or lying), upright time, and step count [30]. The upright time includes both quiet standing and stepping [30], meaning that SitFit alone is not suitable for measuring standing as an outcome. Measuring standing and its variations (eg, fidgeting while standing) in real time will enable future intervention studies to identify distinct behavioral determinants of standing and to study its long-term clinical implications. As described in this study, SORD accurately measures sedentary (sitting and reclining), standing, and walking time. Other deep learning models (eg, model 4) examined whether the algorithms could distinguish lying from other sedentary states. A lower accuracy was observed for SORD in distinguishing lying from other sedentary activity states. Since the thigh is horizontal during lying posture, distinguishing sitting and lying postures with thigh-worn devices would be difficult. Methods that include rotational angle thresholds to determine the orientation of the thigh have been able to distinguish lying from sitting [49], even though these techniques require validation against direct observation to produce robust evidence.

A strength of this study is the inclusion of several variations of activity states (eg, sitting with outstretched legs, sitting while ankle-on-knee, and standing while shoulder on the wall), allowing more robust testing of the device accuracy and improving the generalizability of findings. For example, detecting standing as it appears in real-life situations and distinguishing from walking will enable the design of interventions measuring standing as a behavioral or clinical outcome. There are also limitations with this study, including the laboratory-based nature of the study. As with any laboratory-based experiment, it is possible that participants behave differently (eg, sit tall and neat and not as they would do normally). Moreover, a comparison between devices in terms of walking intensities was not conducted. This work is the first step in the validation of SORD, and longer-term studies in free-living environments would be necessary future steps to assess its practicality and accuracy under diverse conditions. The majority of participants in this study were female, and that might be considered a source of bias, that is, sex bias. However, evidence suggests that there are no significant differences between female individuals and male individuals in terms of posture, including sitting, standing, and walking [50]. Most participants were younger adults, and therefore the findings may not be generalizable to older adults. Investigating the usability of SORD in populations beyond young adults can help determine its broader applicability. Finally, we observed errors in the raw data from 2 participants for SORD and 3 others for activPAL.

In this study, we did not intend to compare or advance the activity recognition models; rather, the goal was to use the best approach for real-world applications of SORD for real-time intervention. The future development of SORD will include exploring other models (eg, ensemble learning).

In conclusion, SORD accurately detected sitting, standing, and walking activities among healthy young adults, and measurement accuracy was excellent compared to direct observation. While the current iteration of SORD displays promising levels of accuracy, it requires more work and real-world testing in an intervention to assess its applicability. Therefore, SORD holds potential for future integration into evidence- and theory-driven, real-time adaptive interventions to promote activity and reduce sedentary time.

Abstract

Background: During the COVID-19 outbreak, video appointments became a popular method for health care delivery, particularly in the early stages of the pandemic. Although Mayo Clinic aimed to reduce face-to-face (F2F) appointments to prevent the spread of the virus, some patients continued seeing their health care providers in person. In the later stages of the pandemic, many patients became comfortable with video appointments, even if they were initially hesitant. However, a subset of patients continued to avoid video appointments. It is not yet clear what sociodemographic factors may be associated with this group of patients.

Objective: This cross-sectional study aimed to examine demographic and social determinant of health (SDoH) factors associated with persistent nonusers of video appointments among a sample of patients within a multisite health care organization. We also explored patient beliefs about the use of video for health care appointments.

Methods: We conducted a 1-time cross-sectional paper survey, mailed between July and December 2022, of patients matching the eligibility criteria: (1) aged ≥18 years as of April 2020, (2) Mayo Clinic Midwest, Florida, or Arizona patient, (3) did not use video appointment services during April-December 2020 but attended F2F appointments in the departments of primary care and psychiatry/psychology. The survey asked patients, “Have you ever had a video appointment with a healthcare provider?” “Yes” respondents were defined as “users” (adapted to video appointments), and “no” respondents were defined as “persistent nonusers” of video appointments. We analyzed demographics, SDoH, and patient beliefs toward video appointments in 2 groups: persistent nonusers of video appointments and users. We used chi-square and 2-tailed t tests for analysis.

Results: Our findings indicate that patients who were older, lived in rural areas, sought care at Mayo Clinic Midwest, and did not have access to the patient portal system were likely to be persistent nonusers of video appointments. Only 1 SDoH factor (not having a disability, handicap, or chronic disease) was associated with persistent nonuse of video appointments. Persistent nonusers of video appointments held personal beliefs such as discomfort with video communication, difficulty interpreting nonverbal cues, and personal preference for F2F appointments over video.

Conclusions: Our study identified demographic (older age and rural residence), sociodemographic factors (not having a disability, handicap, or chronic disease), and personal beliefs associated with persistent nonusers of video appointments. Health care institutions should assess patients’ negative attitudes toward technology prior to introducing them to digital health care services. Failing to do so may result in its restricted usage, negative patient experience,
Introduction

Since the COVID-19 pandemic, video appointments have been widely implemented for remotely delivered health care [1,2]. Both prepandemic and pandemic literature suggest that video visits improve provider access to patients, reduce patient travel and wait times, and provide health care quality comparable to face-to-face (F2F) appointments [3-6]. Despite these positive associations with telemedicine, video appointments for nonemergent care have not been as widely used by patients as expected. Studies show that individuals who could not adapt to digital health care delivery have faced significant health care access barriers during and since the pandemic [7]. In the current post-COVID-19 era, digital health care services are a new standard of care [8], and patients who need to be connected to the health care system digitally but are struggling to adapt to telemedicine may experience suboptimal health care [9]. Therefore, factors associated with nonengagement with video visits, especially in patients who have persistently not engaged in video appointments, require further exploration. While patients’ attitudes to telemedicine, especially in the COVID-19 era [10-12], have been explored, gaps remain in understanding social and individual characteristics associated with the persistent nonuse of video appointments for health care.

A large body of evidence suggests that older age, low education, poor digital access (broadband [BB] internet and smart devices), [13] and personal preferences [14] are independently and interactively associated with lower engagement with digital health care [14-17]. This is ironic, given that a critical reason behind the embarkation of digital health care technology was to provide uninterrupted health care access to those who live in remote areas where access to health care providers is limited, those who experience low socioeconomic status and associated transportation challenges and those with poor mobility due to old age and other constraints [18,19]. Evidence also shows that if the individual digital barriers are addressed [20-22], people are willing to engage in technology and participate in telemedicine programs. Preliminary public and institutional efforts to mitigate patient-related barriers to telemedicine are in their infancy but may include brief verbal and printed technology instructions, digital navigation programs for those who have poor digital literacy (comfort and ease of using technology), use of public Wi-Fi and “to-go kits” (smart devices with written instructions on connecting for a visit) [18,23]. Despite nationwide initiatives that accelerated after COVID-19 to encourage patients to use digital health care, many still chose to engage in F2F appointments [14,24]. This phenomenon was observed with and without social distancing associated with the COVID-19 pandemic.

Social determinants of health (SDoH) such as economic stability, access to quality education and health care, neighborhood safety and housing, community and social contexts, and experiences of racism and discrimination [25] significantly impact people’s well-being. The adverse outcomes associated with SDoH inequitably impact marginalized groups and prevent them from accessing quality health care. SDoH not only impact how easily and efficiently people can access health care, but also how they will access it (video vs F2F vs both).

For example, evidence shows that patients who identified as Black, indigenous, or people of color, and were non-English speaking patients and lived in neighborhoods with low socioeconomic status were less likely to engage in digital health care [17,26]. However, it has not been investigated yet which SDoH factor is linked to the persistent use and nonuse of video technology for health care appointments.

This cross-sectional study aimed to examine demographic and SDoH factors associated with no video use (self-reported persistent nonusers of video appointments) among a sample of patients within a large multistate health care organization. We also explored patient beliefs about the use of video for health care appointments. We hypothesized that certain demographic factors, including older age, being a woman, low education, rural residence, and SDoH, such as financial constraints and limited transportation options, may be associated with the persistent nonuse of video appointments.

Methods

Setting

Mayo Clinic consists of a large academic medical center and associated health system spanning the United States in 5 states (Minnesota, Wisconsin, Iowa, Florida, and Arizona). Mayo Clinic’s main campuses are located in Rochester, Minnesota; Phoenix, Arizona; and Jacksonville, Florida. Mayo Clinic Health System (MCHS) consists of clinics, hospitals, and other health care facilities in 4 regions in southern Minnesota, western Wisconsin, and northern Iowa. The Mayo Clinic Midwest (MN, WI, and IA) serves patients that are predominantly White, older people, and living in rural areas. In contrast, Mayo Clinic in Florida and Arizona serve a more diverse patient population.

Ethics Approval

This study was approved by the Mayo Clinic Institutional Review Board (21-004523).

Study Overview and Design

During earlier phases of COVID-19, in early 2020, the US government and the Centers for Disease Control and Prevention

digital health; telemedicine; telehealth; video visits; appointments; SDoH, social determinants of health; social determinants; appointment; users; sociodemographic; prevention; discomfort; video communication; communication; willingness; mobile phone

and wasted resources. For patients who hold negative beliefs about technology but are willing to learn, a “digital health coordinator” could be assigned to assist with various digital health solutions.
recommended social distancing measures, including stay-at-home orders and video appointments with health care providers [27]. Despite Mayo Clinic’s attempts to minimize F2F appointments to prevent the spread of the virus, many patients requested F2F appointments with their health providers. We were therefore interested in examining whether demographic and SDoH, including area-based metrics (where patients live), were associated with F2F visits. This study used a cross-sectional design with data collected from a 1-time survey administered to Mayo Clinic and MCHS patients.

Survey Instrument and Measures
The survey was designed using results from a prior qualitative study detailed elsewhere [14]. Guided by the qualitative results and informed by a scoping literature review, the survey items were developed to address existing gaps in the literature. The finalized paper survey was pretested with study staff with an estimated 10–15 minutes to complete. The survey included 21 items querying patient’s digital access such as BB internet connection and smart devices, digital literacy (the ease and comfort of using digital technology), use of the patient portal (Mayo Clinic patient online messaging system), use of video appointments, attitudes, and beliefs toward F2F versus video appointments and barriers to engaging in video appointments. The SDoH-related questions included in our survey were adapted from the Social Needs Screening Tool [28] (Multimedia Appendix 1).

Demographic characteristics (age, gender, and race or ethnicity), education status (highest during this study’s period), patient portal status (yes or no), and residence zip codes were extracted from the electronic health record (EHR). Rurality was ascertained from patient zip codes to identify corresponding rural-urban commuting area (RUCA) codes based on the University of Washington classification C method classification [29].

The dependent (outcome) variable was a dichotomous response (yes or no) to the question, “Have you ever had a video appointment with a healthcare provider?”

Data Collection or Procedure
We extracted data from the EHR of adult patients with this study’s eligibility of (1) being aged ≥18 years as of April 2020, (2) being a Mayo Clinic Midwest (Rochester or MCHS), Florida or Arizona patient, (3) not using video appointment services during the time frame of April-December 2020 but attending F2F appointments for nonemergent outpatient clinical care in the departments of primary care and psychiatry/psychology.

The Mayo Clinic Survey Research Center mailed eligible patients a survey in a prelabeled return envelope in early July 2022. By that time, a significant number of patients were oriented and made aware of video appointment procedures through self-learning and efforts by our health care institutions. Thus, the following survey item: “Have you ever had a video appointment with a healthcare provider?” with dichotomous responses “Yes/No,” provided valuable cross-sectional information distinguishing patients in this cohort in terms of their ability to adapt or not to evolving remote health care delivery appointments through video appointments for nonemergent care after April 2020. The respondents who marked “no” were defined as “persistent nonusers.” In contrast, those who responded “yes” were defined as “users” who, despite not having used video appointments between April and December 2020, adapted to the changing digital landscape, using them later.

Surveys were mailed to eligible patients stratified by departmental visit type (psychiatry/psychology versus primary care), demographic characteristics (gender, race, and Mayo Clinic location), and if the patient has an active patient portal account. The Survey Research Center mailed reminder letters to nonresponders in August 2022 and then conducted phone call reminders to nonresponders in October-December 2022. Survey participation was closed in January 2023. Survey respondents received a sheet of forever stamps valued at US $5.

Statistical Analysis
Demographics, SDoH, and patient beliefs about video encounters were compared across groups, persistent nonusers of video appointments, and users groups, using the chi-square (exact) test for categorical variables and the 2-sample t test (rank sum) for continuous variables. In all cases, P values <.05 were considered statistically significant.

Results

Overview
Respondent sociodemographic characteristics (N=321) are described in Table 1 overall and by use of video appointments. The survey response rate was 11% (321/3000). In the total respondent sample, 172 (54%) were women, 217 (68%) were White, 169 (53%) had bachelor’s or higher education degrees (persistent nonusers vs users; 84, 52.5% vs 85, 52.8%), and 282 (88%) were urban dwelling (persistent nonusers vs users; 133, 83.1% vs 149, 92.5%; P=.01). In addition, 266 (83%) had access to an online patient portal account (persistent nonusers vs users; 122, 76.2% vs 144, 89.4%; P=.002).

Demographic Correlates to Persistent Nonuse of Video Appointments
Persistent nonusers of video appointments were older than users ($P=.001$). In addition, patients living in rural residences ($P=.01$) were more likely to be persistent nonusers of video appointments. Other demographic factors, such as gender, education, and race, were not significantly different between persistent nonusers and users of video appointments (Table 1).

Institution Site Correlates to Persistent Nonuse of Video Appointments
Patients who sought care at Mayo Clinic Midwest, comprising Mayo Clinic, Rochester, and MCHS, were more likely to be persistent nonusers of video appointments ($P=.02$; Table 1).

Social Correlates to Persistent Nonuse of Video Appointments
Patients without any disability, handicap, or chronic disease were more likely to be persistent nonusers of video appointments than users ($P=.01$; Table 2). Other SDoH-related factors were not statistically significant.
Table 2. Social determinant of health factors associated with using and not using video appointments.

Video Encounter-Related Beliefs Correlate to Persistent Nonusers of Video Appointments

Scenario 1: “Imagine you are having a video appointment with a Mayo Clinic doctor for a general medicine health check-up that does not require any procedures or exams. Further, imagine you have seen this doctor before for a face-to-face or in-person visit.” A significantly lower proportion of persistent nonusers responded “agree,” while a significantly higher proportion of persistent nonusers of video appointments responded “somewhat disagree” or “disagree,” respectively, to the following statements in response to this scenario: “I am confident my doctor would be able to address any medical concerns effectively” ($P=0.047$), “I am confident I would be able to express all my concerns clearly” ($P=0.04$) and “I am confident I would feel comfortable enough to talk openly” ($P<0.001$) compared to users (Table 3). No other responses were statistically significantly associated with the comparison groups.
Table 3. Patients’ beliefs about video encounters and their association with the use of video appointments.

residences, those who sought care at Mayo Clinic Midwest and observed that patients of older age, those living in rural video appointments in our institution (April 2020). We further persistently have not engaged with video appointments for health care in a multisite medical institution. We observed that about 50% (161 of 321) of respondents appointments for nonemergent primary and psychiatric care since the start of video appointments held beliefs that included being potentially uncomfortable communicating with their doctor through video, difficulty reading their doctor’s facial expressions or nonverbal cues, struggle to hear the doctor clearly, and overall better comfort with F2F appointments over video appointments. Much evidence has demonstrated that older patients have limited engagement with telemedicine, including using video appointments for their health care needs [30-32]. Our study observed an analogous association with older age correlated with persistent nonuse of video appointments for health care. Given that few individuals in our sample experienced substantial limitations in SDoH (Table 2) and that most respondents lived in urban dwellings and had access to the online patient portal (which requires smart devices and internet BB connection), we speculate that factors other than just digital access barriers should be considered when approaching older patients for increasing digital engagement. One possible factor is limited interest in digital health care due to negative personal beliefs toward video appointments. Given that older adulthood is a period when many individuals experience a decline in physical and cognitive health and could lose interest in exploring newer concepts (technology in this case), it is essential for health care providers and health care systems to take a patient-centered approach to understand the reasoning behind an older adult patient’s preference for in-person versus video appointment and provide the appropriate support and develop barrier mitigating strategies tailored to age to engage these individuals with needed care. This study found that patients who lived in rural areas were more likely to be persistent nonvideo users. This finding has been established by many studies. A key reason for the rural-urban digital health disparity is unequal access to BB connections. Additionally, individuals living in rural areas tend to be older, have limited education, and lack the financial resources to invest in BB connections and smartphones. Overall, our research effectively collected information on demographic

Scenario 2: “Imagine you are having an appointment with a Mayo Clinic Psychiatrist or Psychologist that does not require any procedures or exams. Further, imagine you have seen this doctor before for a face-to-face or in-person visit.” A significantly lower proportion of persistent nonusers of video appointments responded “agree,” while a significantly higher proportion of persistent nonusers of video appointments responded “somewhat disagree” or “disagree,” respectively, to the following statements in response to this scenario: “I am confident I would be able to express all my concerns clearly” (P=.03), and “I am confident I would feel comfortable enough to talk openly” (P=.001) compared to users. No other responses were statistically significantly associated with the comparison groups.

Video Encounter-Related Beliefs as a Correlate to Persistent Nonuse of Video Appointments

A significantly lower proportion of persistent nonusers of video appointments responded “agree,” while a significantly higher proportion of persistent nonusers of video appointments responded “somewhat disagree” or “disagree” to the following statements: “I am confident I would be able to read my doctor’s facial expressions or non-verbal cues” (P=.046), “I am confident I would be able to express my symptoms/health” (P=.046), “I am confident I would be able to read my doctor’s facial expressions or non-verbal cues” (P=.05), “I am confident I would be able to hear my doctor clearly” (P=.046), “I would enjoy connecting with my doctor as much as if the appointment were face-to-face” (P=.009), and “I would feel comfortable talking with a doctor I have never met before in-person” (P=.01) compared to users. No other responses were statistically significantly associated with the comparison groups.

Discussion

Principal Findings

This cross-sectional study demonstrated demographic and SDoH factors associated with persistent nonusers of video appointments for health care in a multisite medical institution. We observed that about 50% (161 of 321) of respondents persistently have not engaged with video appointments for nonemergent primary and psychiatric care since the start of video appointments in our institution (April 2020). We further observed that patients of older age, those living in rural residences, those who sought care at Mayo Clinic Midwest and those who did not have access to the patient portal system were more likely to be persistent nonusers of video appointments. Only a single SDoH-related factor (not having a disability, handicap, or chronic disease) was associated with persistent nonuse of video appointments. We also observed that individuals held certain personal beliefs about video appointments that were associated with their decision to use versus not use video appointments for health care. The persistent nonusers of video appointments held beliefs that included being potentially uncomfortable communicating with their doctor through video, difficulty reading their doctor’s facial expressions or nonverbal cues, struggle to hear the doctor clearly, and overall better comfort with F2F appointments or video appointments.
indicators associated with not using video appointments that parallels the geographic demographics of Mayo Clinic, Rochester and various MCHS locations in rural areas with mostly older White residents.

As part of this study, we also aimed to evaluate the social factors or SDoH-related concerns that contributed to the persistent nonusers of video appointments. In our sample, the only factor associated with not using video appointments was not having a disability, handicap, or chronic disease. It is possible that their mobility or health allowed for greater flexibility in choosing an F2F visit or that they simply had fewer visits overall and were, therefore, less likely to choose video visits as an alternative. On the other hand, video appointments could be specifically beneficial for patients with disabilities or chronic illnesses who may have challenges with physical energy or mobility, be at higher risk for contracting illness when in public or have more health care appointments to attend overall. Given that there was limited variation in SDoH within our sample, this may have limited our ability to identify potential correlations between SDoH factors and selecting video or F2F appointments. Large-scale studies with socially diverse patients are required to fully understand the extent to which SDoH factors play in patients’ decision-making in choosing health care delivery methods. This understanding will further enhance patient outreach efforts and strengthen high-impact population health and research initiatives.

Since the pandemic, a significant public effort has been made to increase patients’ digital access at state, federal, and institutional levels [33]. Still, some patients may be unenthusiastic about attending video appointments [14,34]. We found that persistent nonusers of video appointments feel that they may not be able to “express” their concerns and are not able to “feel comfortable enough to talk openly” when having video appointments with primary care and psychiatry practicing physicians. Enjoying F2F encounters better than video appointments and potentially being unable to hear doctors clearly during a video appointment were 2 other beliefs that persistent nonusers of video appointments cited in high proportion. These patients conveyed these beliefs despite evidence of never engaging in video appointments in our institution. It is possible that individuals who consistently do not use video appointments have formed their opinions based on information obtained from sources other than their personal experience. These sources may include internet forums or the opinions of their peers. Another potential explanation could be poor digital experience when they attempted to engage in video appointments due to limited digital access (low-speed internet), language barrier, and low digital and health literacy [35]. It has been widely understood that poor digital experience could trigger patients’ anxiety regarding existing and emerging technology used in health care and may lead to its avoidance. This problem could be solved by appointing a “digital health coordinator” at the institutional level whose sole responsibility should be assisting patients with digital health solutions. This could overcome the perceived reluctance of patients to use digital services for health consultations. In addition, health care institutions should take into account the strong negative attitudes of this group toward video appointments when introducing them to digital technology for health care delivery.

Overall, our study results may inspire researchers to initiate a conversation about video adoption that goes beyond digital access and literacy. Our research examined the impact of SDoH and confidence or belief in video appointments adoption. Previous studies have not investigated which SDoH is most closely associated with video use. Furthermore, individuals with digital access and digital literacy may still choose to refrain from using video appointments. Therefore, objective measures should consider patient beliefs. Health care institutions should assess and evaluate patient preferences when implementing digital health care, especially those with digital competencies. We have yet to identify any digital literacy (validated) scales that have assessed an individual’s digital belief as one of the variables (negative vs positive) to assess overall digital literacy. From the perspective of behavior change theories [36], it is widely accepted that targeting one’s beliefs is essential for behavior change (digital adoption in this case). Therefore, our study adds novelty to the literature by informing researchers about understanding digital beliefs as a confounder in digital literacy and adoption. We suggest that through the community-based participatory research (CBPR) approach, researchers should attempt to identify facilitators to expedite behavior change. In a subsequent study with a larger sample size, it would be worth exploring if patients with limited interest in video appointments have sufficient digital access and literacy.

Limitations
Our study has several limitations, including the low survey response rate, which may have led to selection bias, resulting in a study population that does not accurately represent the target population, and respondents may differ systematically from nonrespondents. We used the self-reported data and the possibility of recall bias. To help alleviate such a concern, we did verify eligibility and the existence of an F2F appointment via EHR. Additionally, though we tried to enroll participants from diverse backgrounds, the majority of patients in our sample were White, lived in urban areas, and did not experience major social challenges, limiting the generalizability of our findings. Our demographic variables were not extensive due to lack of availability or missing values in the data extracted from EHR. In addition, the survey did not include factors related to the health care system, such as whether patients requested a video appointment, if video appointments were encouraged and offered to patients, or if video appointments were offered but declined by the patient. The results of our study may also lack generalizability because the sample was derived from Mayo Clinic patients and there was no feasible way to assess if patients sought care outside Mayo Clinic and used video visits. However, we enrolled patients who have their primary care providers (PCPs) at Mayo Clinic (ie, paneled patients), reducing the likelihood of video visits being done outside of our health care system. According to FAIR Health [37], a national database of private and Medicare claims data, only 0.1% of all claims nationally in 2019 were related to telehealth. This percentage was even lower in rural areas. Based on these data, it is highly unlikely for patients with a PCP at Mayo Clinic to seek outside video-based care. It’s important to note that FAIR Health data
include not just video visits, but also other telehealth technologies such as mobile health, remote patient monitoring, and store and forward technologies. We aimed to gather diverse data by including Mayo Clinic, Arizona, and Mayo Clinic, Florida. Despite a larger number of responses from Florida, the participants who responded were not from a diverse population. The studies show that there are differences in participation rates based on race, including lower rates of completing consent forms and responding to surveys, with Blacks and Hispanics being the most underrepresented [38]. Future work should explore the patterns of video use in more diverse patient populations, especially those who may be more likely to face barriers to health care (eg, patients living in rural areas and patients experiencing challenges with transportation). Our study also had several strengths, including that our sample was drawn from a multistate institution spanning rural and urban settings, the use of a validated measure of SDoH and the inclusion of scenario-based questions to better understand patients’ beliefs about video encounters.

**Conclusions**

Our study identified sociodemographic factors and personal beliefs about video appointments that influenced patients’ decisions to choose between video versus F2F appointments for health care delivery. The patients who were older, lived in rural residences, sought care at Mayo Clinic Midwest, and who did not have access to the patient portal were more likely to be persistent nonusers of video appointments. We observed a single SDoH factor, that is not having a disability, handicap, or chronic diseases associated with persistent nonusers of video appointments. Not being able to adequately “express” their medical concerns and not “feel comfortable enough to talk openly” and adequately listen to their provider were notable beliefs held by persistent nonusers of video appointments. We recommend that health care institutions consider and evaluate patients’ strong negative beliefs toward video appointments when introducing them to digital technology for health care delivery. Conducting large-scale studies that encompass a diverse range of social and demographic backgrounds is imperative to comprehend why patients prefer video or in-person appointments. Only through such research can we identify the factors that influence their decision-making process.

Abstract

Background: Given the re-emergence of coal workers’ pneumoconiosis in Appalachia and Mountain West United States, there is a tremendous need to train rural professionals in its multidisciplinary management. Since 2016, the Miners’ Wellness TeleECHO (Extension for Community Health Outcomes) Program held by the University of New Mexico, Albuquerque, and Miners’ Colfax Medical Center, Raton, New Mexico, provides structured longitudinal multidisciplinary telementoring to diverse professionals taking care of miners by creating a digital community of practice. Program sessions emphasize active learning through discussion, rather than didactic training. Professional stakeholder groups include respiratory therapists, home health professionals, benefits counselors, lawyers or attorneys, clinicians, and others. Rural-urban differences in knowledge transfer in such a community of practice, however, remain unknown.

Objective: We aim to evaluate the role of the rurality of the patient or client base in the transfer of knowledge to professionals caring for miners using the digital community of practice approach.

Methods: This is a cross-sectional study of 70 professionals participating in the Miners’ Wellness TeleECHO Program between 2018 and 2019. Drawing insights from social network analysis, we examined the association between the rurality of participants’ patient or client base and their self-reported receipt of knowledge. Our focal independent variable was the respondent’s self-reported percentage of patients or clients who reside in rural areas. We measured knowledge transfer sources by asking participants if they received knowledge regarding the care of miners by creating a digital community of practice. Program sessions emphasize active learning through discussion, rather than didactic training. Professional stakeholder groups include respiratory therapists, home health professionals, benefits counselors, lawyers or attorneys, clinicians, and others. Rural-urban differences in knowledge transfer in such a community of practice, however, remain unknown.

Objective: We aim to evaluate the role of the rurality of the patient or client base in the transfer of knowledge to professionals caring for miners using the digital community of practice approach.

Methods: This is a cross-sectional study of 70 professionals participating in the Miners’ Wellness TeleECHO Program between 2018 and 2019. Drawing insights from social network analysis, we examined the association between the rurality of participants’ patient or client base and their self-reported receipt of knowledge. Our focal independent variable was the respondent’s self-reported percentage of patients or clients who reside in rural areas. We measured knowledge transfer sources by asking participants if they received knowledge regarding the care of miners by creating a digital community of practice. Program sessions emphasize active learning through discussion, rather than didactic training. Professional stakeholder groups include respiratory therapists, home health professionals, benefits counselors, lawyers or attorneys, clinicians, and others. Rural-urban differences in knowledge transfer in such a community of practice, however, remain unknown.

Results: Respondents, on average, identified 4.46 (SD 3.16) unique knowledge sources within the community, with a greater number of cross-stakeholder knowledge sources (2.80) than same stakeholder knowledge sources (1.72). The mean knowledge source range was 2.50 (SD 1.29), indicating that, on average, respondents received knowledge sources from roughly half of the 5 stakeholder groups. Finally, the mean heterogeneity of knowledge sources, which can range between 0 and 0.80, was near the midpoint of the scale at 0.44 (SD 0.30). Multivariable analyses revealed that as the rurality of patient or client bases increased, participants reported more knowledge sources overall, more knowledge sources from outside of their stakeholder groups, a higher knowledge source range, and greater heterogeneity of knowledge sources (P<.05 for all comparisons).

Conclusions: Our findings suggest that participants who serve rural areas especially benefit from knowledge transfer within the TeleECHO community of practice. Additionally, the knowledge they receive comes from diverse information sources,
emphasizing its multidisciplinary nature. Our results underscore the capacity of the TeleECHO model to leverage technology to promote rural health equity for miners.

Introduction

Recent studies reveal an increasing prevalence and severity of pneumoconiosis (ie, dust-related lung diseases) among US coal workers since the late 1990s [1-7]. Data from the US Coal Workers Health Surveillance Program indicated that the 2017 prevalence of radiographic pneumoconiosis for coal miners with over 25 years of underground mining experience was greater than 10%, which was double the prevalence from the late 1990s. Similarly, the 2014 rate of complicated pneumoconiosis (a particularly deadly form) among long-tenured underground coal miners was 1.1%, compared to 0.3% at its lowest point in the late 1990s [7,8].

This re-emergence of pneumoconiosis presents unique challenges for rural communities. US counties with the highest mortality rates for pneumoconiosis are concentrated in rural contexts with long histories of mining, such as the Rocky Mountain states and central Appalachia [9]. The prevalence of radiographic pneumoconiosis and complicated pneumoconiosis in rural central Appalachian miners, in particular, is much higher than the national average [6]. While the number of miners requiring specialized care has increased, multidisciplinary expertise and access to complex care for pneumoconiosis have decreased in rural areas [10]. Compared with urban residents, residents of rural areas have less access to outpatient pulmonary rehabilitation [11] or pulmonologist services [12]. Rural practitioners also face unique challenges, including professional isolation and complex patient profiles [13], and describe multiple barriers to knowledge acquisition, such as resources and personal costs, physical distance, and time [14]. Such challenges amplify health inequities and mandate innovative approaches to enhance the health and well-being of rural miners, who constitute an underserved, geographically isolated, medically vulnerable, and often underinsured population [10].

Increasing access to education and mentoring of rural professionals involved in the multidisciplinary care of miners can ameliorate the current dearth of skilled expertise in mining-related diseases in rural areas. The multidisciplinary skills required include medicolegal, clinical, and “soft” skills, the latter including the interpersonal and communication skills needed to navigate highly collaborative work in the care of miners. Insufficient expertise among rural providers in these diverse skills demands innovative education and mentoring solutions.

The Miners’ Wellness TeleECHO (Extension for Community Health Outcomes) Program was established in 2016 to provide structured longitudinal multidisciplinary telementoring to members of professional groups caring for miners who reside in pneumoconiosis mortality hotspots in the United States [9]. Professional stakeholder groups include respiratory therapists, home health professionals, benefits counselors, lawyers or attorneys, clinicians, and others. These members from various stakeholder groups constitute a digital community of practice, or a group of people who “share a concern or a passion for something they do and learn how to do better as they interact regularly” [15]. This approach facilitates knowledge transfer and translation among participants. Knowledge transfer refers to the transmission of information and insights between people or groups [16,17], and knowledge translation involves enhancing users’ awareness of multidisciplinary knowledge and its use in day-to-day work and decision-making in the “real world” [16-18]. Importantly, little is known about how digital communities of practice transfer knowledge across professional stakeholder groups that tend to be geographically isolated, such as rural home health care workers and clinicians or specialists. Thus, examining the patterns of knowledge transfer in such communities of practice can provide insight into how technology can be leveraged to enhance care of complex disease in rural settings and how to promote shared objectives within communities of practice.

Preliminary studies indicate a favorable impact of the ECHO telementoring strategies on providers’ self-efficacy in the care of miners [19], adding to the knowledge base about how the ECHO model can enhance the management of other chronic diseases [20-22].

The rurality of the patient bases for those serving miners limits professionals’ capacity to seek and obtain specialized knowledge concerning the care of pneumoconiosis. This specialized knowledge tends to be concentrated within groups from urban areas, where academic health centers are located. Conversely, urban and suburban practitioners may have limited knowledge concerning the day-to-day challenges of rural patients undergoing treatment for complex diseases. The complexity and interdisciplinary nature of care for pneumoconiosis, coupled with the decline of multidisciplinary knowledge sources within rural areas, underscores the need for specialized knowledge transfer to underserved rural areas. Digital communities of practice are well-equipped to transfer multiple kinds of knowledge [23] across stakeholder groups. First, digital meetings help counteract large geographic distances, thereby providing opportunities for transmitting knowledge concerning facts (eg, know-what) and practical knowledge, skills, and expertise (eg, know-how) among otherwise isolated community members. Perhaps equally important, digital communities of practice help members make social connections and leverage their social
networks to gain more access to practical skills and best practices and to adapt to the evolving needs of patients [23]. Understanding knowledge transfer between the community of practice participants from urban and rural patient or client bases is, therefore, essential but has not been fully evaluated—in turn, constituting a critical gap in knowledge. Addressing this knowledge gap can inform evidence-based interventions to enhance future efforts aimed at providing interdisciplinary care for rural miners.

This study evaluates the transfer of knowledge to professionals caring for miners using the digital community of practice approach. We integrate methods from social network analysis to examine patterns of knowledge transfer within and across stakeholder groups within a digital community of practice. We consider the association between the rurality of professionals’ patient or client base and (1) the number of knowledge sources from within the community of practice, (2) the number of knowledge sources outside one’s stakeholder group, (3) the number of knowledge sources within one’s stakeholder group, and (4) the range and heterogeneity in knowledge sources across stakeholder groups. Our study represents a crucial step in assessing the potential to reduce health inequity through greater investment in workforce diversity and interprofessional telementoring efforts that promote collaborative health care in medically underserved mining communities. Our study thus has important implications for understanding how technology fused with specialized expertise can be used to address complex health issues within rural, remote, and medically underserved communities and begin to address health inequities rooted in unequal access to medical care, more broadly. This approach may help rural communities counter the re-emergence of the pneumoconiosis epidemic.

Methods

Study Design

This is a cross-sectional study of professionals participating in the Miners’ Wellness TeleECHO Program, a community-university partnership between a small rural hospital—Miners’ Colfax Medical Center—and its academic partner—University of New Mexico School of Medicine, together constituting the “hub” site of experts. Stakeholder groups include clinical professional groups (clinicians, respiratory therapists, and home health professionals) and nonclinical professional groups (ie, benefits counselors, lawyers or attorneys, and others, including policymakers, administrators, and mine safety officers), constituting the “spoke” sites located across the United States. The hub and spoke partners regularly engage in telementoring and together form a digital community of practice.

Recruitment

This study was based on a convenience sample of 70 participants who volunteered to complete this study’s survey, among all program attendees invited, during the 1-year study duration from September 12, 2018, to September 18, 2019. Core program faculty did not participate in the survey.

Program Description

As detailed in a previous publication [19], TeleECHO sessions have a uniform format and are held at the same time twice every month, lasting 75 minutes. Program sessions begin with 10-minutes of introductions and announcements, followed by a 15-minute didactic delivered by an invited expert and a 20-minute facilitated question-answer session. Next, the program director facilitates a 30-minute interactive case discussion. Program sessions emphasize active learning through discussion, rather than didactic training. Participants earn continuing medical education (CME) credits without charge, upon completing a CME survey. A multidisciplinary curriculum committee follows a structured curriculum that is continually adapted based on the needs of the learning community, which are identified through review of the CME feedback reports. Attendance at ECHO sessions is open and voluntary, which allows those not presenting a case to view the didactic, partake in case discussions, contribute insight from professional experiences, and learn from the expert panel. Participants can also access experts at hub or spoke sites for urgent consultation outside of program sessions through telephone or electronic correspondence. Recorded didactic sessions are made available through a web-based archive.

Program Development

Since July 2016, our program has used the ECHO model to provide long-term and structured telementoring in the care of miners. This approach deviates from traditional telemedicine where providers assume short-term direct care of individual patients [24]. Further, unlike webinars or traditional didactic lectures, the ECHO model provides an interactive discussion of cases with expert panels in real-time that is highly contextualized and adheres to key learning theory principles. As detailed in a previous publication [19], the ECHO model is based on the following five key principles. (1) The model uses internet-based technology for multipoint videoconferencing, to leverage scarce resources. (2) It uses an established disease-management model associated with best evidence for that disease that has been demonstrated to improve outcomes by reducing variation in processes of care and sharing best practices [21,22,25,26]. (3) It uses the principle of case-based learning for participants to learn with guidance from mentors, based on discussion, questions, and investigation of patient cases under their care. Over time, with iterative practice and feedback, participants gain knowledge and skills and progressively become more independent. (4) It creates a digital community of practice, which emphasizes reciprocity in the sharing of skills and information, and acknowledges that all participants bring useful expertise in the care of miners. Through regular interaction, community members increase their own expertise and that of other participants. As a result, the program aims to increase the ability of individual participants to (a) refer miners appropriately to other experts, (b) accept miner referrals from other experts, and (c) to serve as local experts for less experienced community professionals, thereby improving the care of miners. (5) Finally, it uses an internet-based database (ie, iECHO software) to monitor participant outcomes.
Outcomes

We conceptualized knowledge transfer as the transmission of “facts, experiences, and insights” between people or groups [16,17]. We used a social network approach to examine knowledge transfer among community members by measuring respondents’ number of unique knowledge sources. We also considered the stakeholder group where knowledge originates, which allows us to examine the extent to which participants receive interdisciplinary knowledge from others outside of their own stakeholder groups as well as the overall distribution of knowledge sources across stakeholder groups.

We measured knowledge transfer sources by asking participants if they received new and important knowledge regarding the care of miners during and outside of TeleECHO sessions from each of the other participants. To measure knowledge transfer, respondents were given rosters that included names of all registered participants, with the option of providing additional names not on the roster. Rosters were arranged by stakeholder groups to reduce respondent burden and assist recall. We used these nominations to measure our dependent variables that capture unique dimensions of knowledge transfer. Our first dependent variable, number of knowledge sources, is the count of other participants from whom respondents received new and important knowledge (regardless of the source’s stakeholder group).

Apart from the number of knowledge sources, we tested whether rural participants report greater numbers of knowledge sources from outside of their primary stakeholder group. We thus measured the number of cross-stakeholder knowledge sources, which captures the number of participants from whom respondents received knowledge who were outside of respondents’ stakeholder group. We also analyzed the number of same stakeholder knowledge sources, with a measure capturing the number of participants from whom respondents received knowledge that were in the same stakeholder group as the focal respondent.

We also consider 2 dimensions of diversity in the sources of knowledge transfer among respondents. Range captures the extent to which individuals are connected to others from different social systems or interpersonal environments (eg, employers, associations, and schools) [27,28]. Importantly, a higher range level translates to greater access to nonredundant information [29]. We measure knowledge source range by calculating the number of unique stakeholder groups from which respondents reported receiving knowledge. This variable ranges from 0 to 5, with 0 indicating respondents reported no knowledge sources to 5 indicating respondents received knowledge from at least one member from each of the 5-stakeholder groups.

Our second measure capturing the diversity of knowledge sources is heterogeneity of knowledge sources. Our measure of heterogeneity of knowledge sources taps the distribution of knowledge sources across stakeholder groups for each respondent and is calculated as follows [30]:

Here, $A_j$ is the number of knowledge sources that belong to a stakeholder group $j$, $k_s$ is the number of knowledge sources, and $n$ is the total number of stakeholder groups from which the focal respondent reported receiving knowledge (ie, knowledge source range). Heterogeneity increases when respondents receive knowledge from a larger number of different stakeholder groups (ie, have high knowledge source range) and the knowledge sources are equally distributed across the stakeholder groups. In our study, this measure potentially ranges from 0 to 0.8, with higher values indicating greater heterogeneity in knowledge sources. Note, heterogeneity is undefined for respondents reporting 0 knowledge sources, which was the case for 2 of our respondents, who were excluded for analyses of heterogeneity.

Independent Variables

Our focal independent variable captures the level of rurality among a respondent’s patient or client base. The measure is based on the percent of patients or clients who reside in rural areas, as self-reported by the participant. Initial responses were ordinal and included five categories: 1 (0% to 20%), 2 (21% to 40%), 3 (41% to 60%), 4 (61% to 80%), and 5 (81% to 100%). For this study, we collapsed the ordinal variable into a binary variable indicating rural patient or client base, which equals 1 if 41% to 100% of a respondent’s patient or client base resided in rural areas, and 0 if only 0% to 40% of their patients or clients lived in rural areas. We collapsed the categories for 2 reasons. First, exploratory analyses revealed that only 5 respondents reported serving a 21% to 40% rural patient or client base. Second, comparisons of the means of the knowledge source variables across levels of patient or client rurality suggested a threshold effect, with only minimal differences in the outcomes for those serving 0% to 20% versus 21% to 40% rural patient or client base but large differences between these combined categories and those serving a 41% or greater rural patient or client base. The results based on the original 5-category ordinal variable were similar to those presented in this study.

Covariates

Multivariable models include control variables to account for potential confounding between the association between patient or client rurality and our outcomes. Experienced versus fresh participant: fresh participants were defined as those who first attended the community of practice in or after the summer of 2018 (defined as from May 9, 2018, onwards) versus experienced participants (defined by those who had first attended any time between July 1, 2016, and May 8, 2018). Experienced participants had greater cumulative participation and therefore, experience with the TeleECHO Program than fresh participants (11.4, SD 9.8 vs 4.6, SD 4.6 total sessions attended before or during this study’s timeframe; $P = .03$). This cutoff date was chosen based on the date of funding by the sponsor, which allowed the frequency of the TeleECHO Program to be raised from monthly to twice a month. Respondents’ length of care for miners taps the number of years each participant reported having served miners. Initial responses were measured in years. To aid in the interpretation of our regression results, we divide the reported number of years cared for miners by 10, so that the variable captures the number of decades respondents reported having cared for miners.
We also control for participant demographics. We control for age with 2 dummy variables indicating 51 to 60 years old and older than 60 years (1=yes, 0=no) with younger than 50 years old serving as the reference category. Male sex is binary and indicates the respondent reported a male sex identity (1=yes, 0=no). Respondents reported their race and Hispanic ethnicity status. Based on the responses from these questions, respondents were initially categorized as either Asian, non-Hispanic-Black or African American, Hispanic, multiracial or some other race, or non-Hispanic White. We report the percentages of respondents in each race or ethnic category but collapsed categories into a binary variable indicating non-White (1=yes, non-Hispanic White is the reference) in our regression analyses due to the small sizes of non-White racial or ethnic groups in the sample. Alternative methods of collapsing race or ethnic categories resulted in similar findings as those presented here.

Data Collection
The program monitored the number of sessions, learners, unique learners, geographical sites of learners, and patient cases presented (using the iECHO software). Survey data were collected using the REDCap (Research Electronic Data Capture; Vanderbilt University), a secure web app for building and managing online surveys and databases.

Analytic Strategy
All analyses were conducted in Stata/MP (version 16.0; StataCorp LLC). We used negative binomial regressions to analyze the total number of knowledge sources, number of cross-stakeholder knowledge sources, and number of same stakeholder knowledge sources, which were discrete counts and were over dispersed. Ordinary least squares regression was used to analyze knowledge source diversity and knowledge source heterogeneity. Model coefficients (b) and SE were used to summarize effect sizes. Data missingness due to nonresponse was minimal, with 2 respondents declining to report their age, 1 respondent declining to report on length of care for miners, and 1 respondent declining to report on rurality (for a total of 3 respondents having missing data on at least 1 variable). Missing values on these measures were imputed using the Stata ice procedure [31], and models were estimated with 10 imputed data sets using the mi command suite in Stata 16. The results based on unimputed data using listwise deletion were nearly identical to those presented here.

Ethics Considerations
Approval was obtained from the institutional review board, Human Research Protections Office, at the University of New Mexico Health Sciences Center (18-386). Anonymized consent was obtained from all participants. Study data were deidentified for analysis to maintain confidentiality. All participants were provided an electronic merchandise card of US $50 upon survey completion.

Results
Table 1 shows the descriptive characteristics of the 70 ECHO participants caring for pneumoconiosis in a cross-sectional study during the timeframe of 2018-2019.

**Knowledge Source Variables Among all Participants**

Respondents, on average, identified 4.46 (SD 3.16) unique knowledge sources within the community. Respondents, on average, reported greater numbers of cross-stakeholder knowledge sources (2.80, SD 2.63) than same stakeholder knowledge sources (1.72, SD 1.46). The mean knowledge source range was 2.50 (SD 1.29), indicating that, on average, respondents received knowledge sources from roughly half of the 5 stakeholder groups. Finally, the mean heterogeneity of knowledge sources, which can range between 0 and 0.80, was near the midpoint of the scale at 0.44 (SD 0.30).

**Knowledge Source Variables Among Participants Serving Rural Versus Nonrural Bases**

We explain the means of the knowledge source measures among those serving rural versus nonrural patient or client bases. Those serving rural patient or client bases, on average, reported 5.00 (SD 3.13) unique knowledge sources compared to 3.00 (SD 2.88) among those primarily serving nonrural patients or clients. There was only a minor difference in the mean number of same
stakeholder knowledge sources for those serving rural (1.68, SD 1.42) versus nonrural (1.86, SD 1.66) patients or clients. However, rural providers, on average, identified 3.30 (SD 2.61) cross-stakeholder knowledge sources, whereas nonrural providers, on average, identified 1.14 (SD 1.99) cross-stakeholder knowledge sources. Finally, comparing the measures of diversity of knowledge sources, those serving rural patients or clients had a higher mean knowledge source range 2.78 (SD 1.22) versus 1.74 (SD 1.19) and mean knowledge source heterogeneity 0.52 (SD 0.25) versus 0.23 (SD 0.31) than those serving primarily nonrural patients or clients.

**Multivariable Results**

Table 2 presents results from multivariable regression models of the different dimensions of knowledge transfer.

*a P values obtained from 2-tailed tests.
*b In these models, our dependent variables are knowledge sources, that is, other participants from whom respondents (ie, targets) received new and important knowledge (within and outside the source’s stakeholder group).
*c Not available.

**Number of Knowledge Sources**

Model 1 examines the number of knowledge sources using a negative binomial regression. The results indicate that rural patient or client base is positively associated with the number of knowledge sources (b=0.50; P=.02). This finding suggests that providers serving rural clients or patients identify greater numbers of knowledge sources within the community of practice than participants whose patients or clients reside in nonrural areas, even after accounting for key confounders. Compared with fresh participants, experienced participants report greater numbers of knowledge sources (b=0.37; P=.03). No other participant characteristics were significantly associated with the number of knowledge sources (all P>.05).

**Number of Same Stakeholder and Cross-Stakeholder Knowledge Sources**

Models 2 and 3 examine the number of same stakeholder and cross-stakeholder knowledge sources, respectively. These models provide insight into whether participants tend to identify
knowledge sources from within or outside of their primary stakeholder groups. Note, participants from “Other” stakeholder groups were dropped from Models 2 and 3, as they by definition have all different stakeholder ties and 0 same stakeholder ties. The results from Model 2 indicate that rural patient or client base has a nonsignificant association with the number of same stakeholder knowledge sources ($b=0.04; P=.89$). Compared with those aged 50 years or younger, participants between the ages of 51 and 60 years report more ties to members of the same stakeholder group ($b=0.67; P=.03$). Turning to Model 3, which examines the number of cross-stakeholder knowledge sources, the rurality of the patient or client base was positively associated with the number of cross-stakeholder ties ($b=0.91; P=.01$). This indicates that participants serving larger proportions of rural patients or clients reported larger numbers of cross-stakeholder knowledge sources than those serving smaller proportions of rural patients or clients. Additionally, experienced participants report larger numbers of cross-stakeholder knowledge sources than fresh participants ($b=0.74; P=.003$) and benefits counselors report larger numbers of cross-stakeholder knowledge sources than clinicians ($b=0.84; P=.03$).

**Range and Heterogeneity of Knowledge Sources**

The final models in Table 2 examine the range and heterogeneity of participants’ knowledge sources. These models provide insight into the number of different stakeholder groups from which participants received knowledge, and the extent to which participants’ knowledge sources are equally dispersed across different stakeholder groups. Turning to Model 4, which is a linear regression of knowledge source range, we found that a rural patient or client base has a positive and significant coefficient ($b=0.92; P=.01$). Model 4 also indicates that experienced participants reported higher knowledge source range than fresh and new participants ($b=0.70; P=.03$).

Finally, Model 5 examines the association between rurality and participants’ knowledge source heterogeneity. Whereas range is the count of the number of unique stakeholder groups from which participants receive knowledge, knowledge source heterogeneity also assesses whether stakeholders from which participants receive knowledge tend to be concentrated in 1 stakeholder group (low heterogeneity) versus equally distributed across multiple groups (high heterogeneity). Note, that because knowledge source heterogeneity can only be measured among participants with at least one knowledge source, Model 5 excludes 2 respondents who reported 0 knowledge sources. Patient or client rurality was positively associated with participants’ heterogeneity of knowledge sources ($b=0.25; P=.003$), indicating knowledge sources are more equally distributed across stakeholder groups as the rurality of their patient and client bases increased.

**Discussion**

**Principal Findings**

Community of practice participants with higher proportions of rural patient or client base, on average, report more knowledge sources overall, more knowledge sources from outside of their stakeholder groups, a higher knowledge source range, and greater heterogeneity of knowledge sources than those with a lower proportion of rural patient or client base. These findings were confirmed after adjustment for potential confounders in regression analyses. More broadly, these findings suggest participants who serve rural areas especially benefit from knowledge transfer within the TeleECHO community of practice. Additionally, the knowledge they receive comes from diverse information sources, emphasizing its multidisciplinary nature.

Further, 1 primary objective of Project ECHO is to decentralize knowledge for the care of patients through exchanging insights and information. Knowledge transfer is key to enhancing the care of complex disease by timely, evidence-based information shared by experts who have used, amplified, and applied this knowledge with interested professionals who (1) are seeking knowledge to assist their patients or clients and (2) through its application, increase access to complex disease care for patients in rural and underserved communities. Project ECHO supports knowledge transfer within the community of practice, through experts sharing and discussing evidence in association with challenging questions with which professionals at program spoke sites are wrestling. Our study suggests this knowledge transfer may be particularly effective among professionals with longer experience with the program.

Professionals in rural mining communities often lack access to traditional knowledge sources. This disparity results from professional isolation; challenges with continuing professional education that requires travel to a distant site for participation with resultant closure of their practices, often without adequate coverage available; and unavailability of specialists with more in-depth knowledge about the clinical, medicolegal, and interpersonal aspects of care of miners. The need to increase access to information for rural professionals is, therefore, obvious. To this end, information technology has come to the fore. However, research suggests that even when electronic information services are provided to rural practitioners, they may not be well used [32]. The lack of information handling skills, lack of time, and perceived peripherality to the job are all seen as major constraints [33,34]. However, our study challenges this belief by demonstrating that professionals serving rural areas especially benefit from access to knowledge through the innovative TeleECHO model, which would otherwise remain siloed within stakeholder groups. Further, the knowledge source range and heterogeneity that the TeleECHO model promotes may allow greater access to thought-provoking ideas that foster learning and other growth-enhancing actions [27,35]. To the best of our knowledge, our approach of studying patterns of knowledge transfer, using social network analysis tools, has never been used previously.

**Strengths**

Our study has multiple strengths. It involves an innovative intervention that addresses the barriers to the care of miners by using the TeleECHO model, which provides a multidisciplinary community of practice approach, using internet-based technology, an approach that has been well studied in other diseases [21,22,25,26]. This study is topical and significant because it addresses a critical gap related to the emerging pneumoconiosis epidemic in the rural United States. Since the
ECHO model has been adopted nationally and globally to improve rural access to care for patients with numerous chronic diseases, there already exists infrastructure to allow for rapid scaling of the Miners’ Wellness TeleECHO Program nationally and globally.

**Limitations**

There are also limitations to this study. We are unable to correlate knowledge transfer to patient outcomes or changes in provider behavior. We have, however, previously published a listing of qualitative changes that our ECHO participants reported they were going to make in their practice, obtained as part of a CME survey requested at the end of each TeleECHO session [36]. Although a small sample size raises the possibility of a type I error, individual professionals and teams of professionals trained in the ECHO model can reach a large number of miners, with the potential for creating exponential change. High-risk individuals who did not volunteer to participate in this study would not have provided information in the estimation of the program effects, thus introducing an element of potential participation bias. The knowledge transfer instrument was not validated in this study. Program participants had variable competencies, with varying levels of sophistication, commitment, expertise, experience, and historic levels of collaboration within the TeleECHO Program. However, adjustment for participant experience with the TeleECHO Program or length of care for miners in the multivariable models did not change our study findings. Intergenerational, interinstitutional, and rural-urban disparities in ability to leverage technology by participating professionals may challenge empirical examinations of knowledge transfer. Finally, data limitations, including survey nonparticipation by the core program faculty and survey nonresponse among the TeleECHO Program participants, preclude the use of complex social network analysis methods (eg, exponential random graph models) commonly used to examine network selection processes in our study. Although our methods are adequate for examining associations between participating characteristics and the number, range, and heterogeneity of knowledge sources, we are unable to examine how network processes such as reciprocal knowledge transfer operate within the learning community.

**Conclusions**

Despite these limitations, our findings suggest participants who serve rural areas especially benefit from knowledge transfer within the TeleECHO community of practice. Additionally, the knowledge they receive comes from diverse information sources, emphasizing its multidisciplinary nature. Our results underscore the capacity of the Project ECHO model to leverage technology and workforce diversity to facilitate knowledge transfer to rural professionals and ultimately promote health equity among rural and medically underserved mining communities. Although this approach addresses a critical gap related to the emerging pneumoconiosis epidemic in rural United States, future research will evaluate whether this translates into improved patient outcomes in rural mining communities.

Abstract

Background: Medical photography plays a pivotal role in modern health care, serving multiple purposes ranging from patient care to medical documentation and education. Specifically, it aids in wound management, surgical planning, and medical training. While digital cameras have traditionally been used, smartphones equipped with specialized apps present an intriguing alternative. Smartphones offer several advantages, including increased usability and efficiency and the capability to uphold medicolegal standards more effectively and consistently.

Objective: This study aims to assess whether implementing a specialized smartphone app could lead to more frequent and efficient use of medical photography.

Methods: We carried out this study as a comprehensive single-center panel investigation at a level 1 trauma center, encompassing various settings including the emergency department, operating theaters, and surgical wards, over a 6-month period from June to November 2020. Using weekly questionnaires, health care providers were asked about their experiences and preferences with using both digital cameras and smartphones equipped with a specialized medical photography app. Parameters such as the frequency of use, time taken for image upload, and general usability were assessed.

Results: A total of 65 questionnaires were assessed for digital camera use and 68 for smartphone use. Usage increased significantly by 5.4 (SD 1.9) times per week (95% CI 1.7-9.2; P=.005) when the smartphone was used. The time it took to upload pictures to the clinical picture and archiving system was significantly shorter for the app (mean 1.8, SD 1.2 min) than for the camera (mean 14.9, SD 24.0 h; P<.001). Smartphone usage also outperformed the digital camera in terms of technical failure (4.4% vs 9.7%; P=.04) and for the technical process of archiving (P<.001) pictures to the picture archiving and communication system (PACS) and display images (P<.001) from it. No difference was found in regard to the photographer’s intent (P=.31) or reasoning (P=.94) behind the pictures. Additionally, the study highlighted that potential concerns regarding data security and patient confidentiality were also better addressed through the smartphone app, given its encryption capabilities and password protection.

Conclusions: Specialized smartphone apps provide a secure, rapid, and user-friendly platform for medical photography, showing significant advantages over traditional digital cameras. This study supports the notion that these apps not only have the potential to improve patient care, particularly in the realm of wound management, but also offer substantial medicolegal and economic benefits. Future research should focus on additional aspects such as patient comfort and preference, image resolution, and the quality of photographs, as well as seek to corroborate these findings through a larger sample size.
Introduction

Medical photography serves 3 primary purposes: documentation of diseases and procedures, education of patients and medical personnel, and publications in various forms [1-3].

The potential of medical photography lies in its ability to objectify conditions that cannot be properly illustrated by laboratory results or medical imaging. This mitigates the risk of biased descriptions or inconsistent measurements across clinicians, particularly those from different specialties [4]. Additionally, unlike written diagnoses, photos can also be proof of missed diagnoses or negative findings, as they are not limited to the perception and experience of the examiner [5].

Additionally, medical photography provides several key advantages, including supporting medical diagnoses in legal cases, enhancing diagnostic accuracy and therapeutic outcomes, improving the quality of consultations, and offering documentation for billing purposes [6-10].

The digital era and the technological revolution with digital imaging and smart devices have further lowered the threshold of medical photography [11-13]. Now, every adequately instructed person can produce medical photos anywhere at any time, repealing restrictions such as the availability of a trained medical photographer, time pressure in an emergency setting, or missing equipment. An exemption from this are specialized photographs for scientific or educational purposes, or in certain kinds of fields, that is, aesthetic surgeries, in which higher resolution and quality necessitate the use of more professional equipment.

However, data security and patient confidentiality need to be upheld. Thus, current guidelines, such as Recital 26 of the European Directive (EU) 2016/679, demand informed consent of the patient; a defined medical need for this photography; correct documentation; and safe, restricted, and password-protected storage with an access log [14].

Nonetheless, in a recent systematic review analyzing ethical aspects of medical photography, the consent process was found to be insufficient or inadequate in 95% of all cases [15].

Digital cameras are mainly used for medical photography in the clinical setting, and most patients seem to prefer these over smartphones [1,11,16]. This is because it is not clear how the data are stored and protected on either a clinically owned or private device. In both cases, people tend to estimate a higher risk of data-protection infringement in smartphones than in cameras, impairing their general acceptance as a reliable tool for medical photography [17-19]. Additionally, patients’ will to approve is influenced not only by individual consent depending on the reasoning, particularly concerning web-based publication, but also by situational preferences, such as the difference between emergency departments and aesthetic surgeries [15]. In high-paced emergency settings such as trauma units, obtaining immediate verbal consent, witnessed by another health care provider, can often be the most practical approach. This should be followed up with written consent as soon as the patient is stabilized or conscious. In contrast, nonemergency cases allow for a more thorough process where the patient can take the time to understand the implications before giving written consent. Across both scenarios, the ethical principles of autonomy, beneficence, and confidentiality remain paramount, ensuring that patient data are secure and used only for medical purposes.

Inherently, both devices bear the same risk of data infringement. Digital cameras cannot be password protected, do not encode their data, and are not usually stored as would be required: either under supervision or locked away. The last aspect is not a problem with smartphones since they are usually kept within reach all the time. Yet if the phone is not password protected or the pictures are saved in the photo app, they can be accessed by people close to the owner or may accidentally be transferred to cloud storage that is not properly protected and where access is not documented [17].

However, if the photos are taken with a password-protected app and are not stored on the device but directly in the picture archiving and communication system (PACS), data protection would be secured. Moreover, this would diminish the risk of false identification of the photo, and so all legislative demands would be met. The use of smartphones with apps that fulfill the data-protection requirements in medical photography is being increasingly examined. Yet an extensive literature search revealed that no study has compared the use of such an app with digital cameras in terms of the quantity and efficiency of medical photography [1,3,16-18,20-22]. The following hypothesis was tested: using an app for medical photography would increase the quantity of pictures taken and the efficiency of this process.

Methods

Study Design

A prospective panel study design with 3 stages was chosen. This was realized in the period from June to November 2020 at a level 1 trauma center. No restrictions were made on where and how pictures should be taken, as the usage in clinical routine was to be evaluated. Pictures could be taken in the emergency department, as well as during surgical procedures, in the surgical ward, or in the outpatient clinic. The study focused on general usage patterns and did not collect data on the specific clinical situations in which the photographs were taken or the type of photographs captured. As a first step, the use of digital cameras was assessed using a printed questionnaire, which was handed out to emergency department and aesthetic personnel.
out to trauma and orthopedic residents of different years of training with the instruction to fill one out at the end of every week. As a second step, this process was repeated after the installation of a specialized medical imaging app on the clinically owned smartphones, using the same questions adapted to smartphone use. At the end of this second stage, a separate web-based questionnaire about the experiences with the app and its usability and interface could be filled out by all members of the medical staff, not just the residents participating in steps 1 and 2. Since the questionnaire was designed to assess what opportunities and benefits could result from the implementation of the smartphone app in comparison to the digital camera, no respective questionnaire for the usage of the camera was deemed necessary. Both questionnaires were specifically designed for this study; an example of each is included as Multimedia Appendices 1-3.

We used a Likert scale (ranging from –2 to +2) to express experiences with smartphone usage, with –2 representing “strongly nonbeneficial,” +2 as “highly beneficial,” and 0 resembling indifference or no benefit, allowing an intuitive interpretation of the results.

**Digital Camera**

Every resident who entered employment received a digital camera (Lumix DMC-FT30, 16 megapixels; Panasonic Corporation) to be used for medical photography. After taking a photo, the resident had to use 1 of 3 workstations in the clinic that offer the capability to upload the photos to the clinical PACS with certain predefined keywords, that is, preoperative or surgical site, to categorize what kind of image had been taken. After uploading, the images had to be deleted from the secure digital card. The digital camera has a 28-mm² sensor with a pixel pitch of 1.3 µm and a resolution of 16 megapixels.

**Specialized Smartphone Application**

For clinical communication, each resident received a smartphone (Galaxy xCover 4; Samsung) that only allowed phone calls and viewing of radiological images through mRay (version 6.0.3; mbits imaging GmbH), which is a certified app for medical imaging and processing. The smartphone camera has a 20-mm² sensor with a pixel pitch of 1.1 µm and a resolution of 16 megapixels.

In this study, the fully digitalized photo documentation of mRay was used. This is divided into 3 main steps (Figure 1). First, an existing wound is photographed using the smartphone camera (Figure 1A and B). More than 1 picture can be taken if necessary for the patient’s case. In the next step, the wound image can be assigned to the respective body area (Figure 1C). Using a barcode scan or direct search in the clinical PACS, the images can be keyworded and assigned directly to the associated patient’s data (Figure 1D).

**Patient Confidentiality and Data Protection**

In accordance with the hospital’s standard operating procedures (Multimedia Appendix 4), each patient is informed upon admission that, in addition to radiological images, clinical photographs necessary for their treatment may also be taken during their course of stay, and a written consent is signed. Additionally, as soon as a photo is to be taken, the patient is educated again about what kind of picture will be taken, where it will be stored, and why it is necessary, and verbal consent is obtained. In emergency situations, another staff member acts as a witness during the process of taking the photograph. Patient consent is subsequently obtained as soon as the individual regains responsiveness.

For digital cameras, data protection protocols require staff to promptly upload images to the clinical PACS, associating them with the respective patient’s file. Once uploaded, images must be deleted from the secure digital card. When not monitored, the camera should be securely stored. Regarding smartphones,
they are designated solely for clinical use and feature password protection. Additionally, photographs are exclusively taken through a specialized app, which is also password protected, ensuring direct storage of clinical photographs in the PACS.

Statistics
Primary end points were effective usage of a camera or smartphone in times per week and the time taken from capturing to uploading the taken pictures in minutes. Secondary end points were the estimated time necessary to archive and display images from the PACS, as well as the intention and reasoning behind the photographs. Additionally, it evaluated how users experienced the introduction and usage of the app, but this was not statistically analyzed. The continuous variables, usage and time to upload, were expressed using mean (SD), and time to archive photos and display them from the PACS were expressed using median (IQR). Evaluations were conducted using the Mann-Whitney U test, as these variables were considered estimations despite being interval-scaled as an International System of Units variable. The other categorical variables were analyzed using the chi-square test. The level for statistical significance was set at \( P < .05 \). Statistics were made using Prism (version 8.2.1; GraphPad Software).

Ethical Considerations
All procedures performed in this study involving human participants were in accordance with the ethical standards of the Ethics Committee of the State Medical Association of the Rhineland-Palatinate and with the 1964 Declaration of Helsinki and its later amendments or comparable ethical standards. Since the actual photographs taken were acquired as part of the daily clinical routine and were not part of this study, neither informed nor written consent from the patients was necessary. Informed consent was obtained from all individual participants included in the study, and all data were deidentified. No financial compensation was provided to any of the study participants. Data collection, coding, routing, and analysis were in accordance with the legal data protection policy.

Results
A total of 65 questionnaires regarding digital camera use were collected from June to July 2020, and 68 questionnaires regarding the smartphone app were collected from September to November 2020. The questionnaires were filled out by 5 orthopedic residents. Additionally, 19 fully completed web-based questionnaires were received.

A comparison of the usage of both devices revealed no significant differences. Cameras were used 16.4 (SD 7.7) times per week for taking pictures and 11.2 (SD 9.7) times per week for showing pictures for consultation, whereas for smartphones, these values were 18.8 (SD 5.9; \( P = .10 \)) times per week and 9.8 (SD 4.4; \( P = .47 \)) times per week, respectively. In 17.5% (SD 16.1%) of cases for taking pictures and 18.6% (SD 22.6%) for showing pictures, a missing digital camera was mentioned; however, this issue never arose with smartphones. Technical failure occurred significantly less if the smartphone was used, with a rate of 9.7% (SD 18.2%) of cases with the digital camera and 4.4% (SD 9.1%) with the smartphone (\( P = .04 \)). If the total amount of usage (taking photos and demonstrating them) is adjusted for the cases of missing devices and technical failure, then the corrected usage for the digital camera is 20.8 (SD 11.4) times per week and for the smartphone, 26.2 (SD 10.1) times per week. This difference was statistically significant (\( P = .005 \); Table 1).

Table 1. Primary end points. Values are presented as mean (SD), and \( P \) values were calculated using the Mann-Whitney U test.

aPercentages exceed 100% because multiple selections were allowed, and the P value was calculated using the chi-square test.

However, both groups did differ in the reasons as to why there had been a delay (P<.001). The main reasons mentioned with the digital camera were the distance to one of the workstations and organizational reasons, that is, being preoccupied in the operating theater. With the smartphone, there were mostly no reasons for a delay, yet in a quarter (12/68, 24% and 17/68, 25%) of cases, a time lag or app crashes were mentioned (Table 3).

No difference was found in the intention behind the photo, which was mostly documentation of soft tissue conditions (74% and 78%, respectively) and wounds (both 82%; P=.31), nor in the reasoning why the photo had been taken (legal requirements, improving therapy, and consultation; P=.94).

The smartphone app’s high acceptance and approval could be deduced from the web-based questionnaire, especially in terms of time savings and an easier workflow (Table 4), with a mostly positive rating on the applied Likert scale (ranging from −2 to 2; Figure 2). There were 2 indifferent evaluations regarding higher usage and improved communication. Only the responsiveness of the app was evaluated negatively with a median of −1, which concurs with the written answers about the occurring time lag and crashes of the app (Table 3 and Figure 2).
### Usage and usability

#### Discussion

#### Overview

This prospective study highlighted the advantages of workflow and data security for medical photography by integrating a smartphone app. One key indication is the reduced time taken from capturing the photo to its storage in the PACS: almost instantaneous with smartphones, in contrast to an average 12-hour duration using digital cameras. While viewing photos is feasible at all workstations, uploading is confined to specific stations due to network security concerns. Especially in a time-critical specialty such as traumatology and emergency medicine, such a tool could be particularly beneficial. By lowering the threshold and simplifying the cumbersome workflows of medical photography, the photography process and the number of photos taken could be increased to the benefit of the patient. This would take away the argument that there is no structured assessment or procedure for documentation of acute wounds because the required effort is considered too high and time-consuming [13,23,24].

Such reasoning might originate from studies such as Bronsard et al [23], which tried to establish a pathway for the secure handling of patient data. In their workflow, the photo was sent to a coordinator after it had been taken. This person assessed it and converted it to a DICOM file, which was then cropped by a secretary and finally uploaded. Each week, it took 3 individuals 1-2 hours to generate 1 image from 3-5 photos. It is therefore hardly surprising that they only managed to produce 300 images in 2 years.

Furthermore, previous studies showed that adequate medical photography can improve the care for and decision-making about complex injuries, especially when soft tissues are at risk [7-9,25]. In the case of traumatology, this would mainly be open...
fractures. Inaccuracies in the description and extent of the concomitant soft tissue injury could affect the planning of the surgical approach and, in the worst case, necessitate the recurrent removal of the dressings to reassess the wound, facilitating a rise in infection risk [26].

The need for an easier and safer way to perform medical photography in traumatology is also enhanced by the argument of Friesen et al [27]. With the rising incidence of older patients in trauma wards, they estimated that 25% of in-house patients could exhibit chronic wounds requiring structured care and documentation [27].

The key aspect that needs to be addressed is the medicolegal aspect and risk of data infringement, which have been shown to be insufficiently addressed in most studies focusing on the adequacy of protocols for patient consent and publication in current practice [15]. First, because the workflow must uphold data security and patient confidentiality, and second, because the acceptance of photography performed with smartphones still needs to be increased, particularly among older patients [18,20].

Anonymous interviews from O’Farrell and Ferreira [1] showed that in 74% of cases, photos taken using a smartphone were not deleted. Furthermore, 58% were stored on a laptop and 26% on a flash drive, while 16% admitted that the device in question was not password protected, and in 21% of cases, third parties could have accessed the pictures. The distribution methods further raise concerns: 58% of the photos were sent for consultation through WhatsApp and 80% through email. Given European Union regulations, these findings underscore a pressing need to address security and privacy challenges in medical photography [1,14].

On the contrary, although the acceptance of clinically owned cameras is fairly high, ranging from 75% to 95%, they also pose a considerable data breach risk. They cannot be password protected, the data are not encoded, and they are mostly not stored safely when not in use [1,17,18,20]. Using an app akin to the one examined in this study, these concerns can be dismissed. Furthermore, the study of Accetta et al [20] showed that in such cases, smartphone photography, under the premise of special information, could reach a comparable acceptance rate of 88%.

Requirements for performing medical photography are an easy and fast appliance, secure storage of data, and prevention of data infringement. This can be achieved using specialized smartphone apps [28].

In addition to the medical value, efficient and extensive medical imaging can also provide economic benefits. If the pictures taken lead to a new diagnosis or therapeutic purpose, then this could be a billable service [2,21,29]. In a study examining smartphone-based medical photography, Jordan et al [21] demonstrated that in 20% of medical audit cases where photos were used, they helped confirm a diagnosis or procedure. This resulted in additional revenue of US $330 per case, amounting to a total of approximately US $70,000 annually.

Besides the possible benefits for acute fracture care and inpatient management, the third benefit could lie in the effect on medical certificates [2,30-33]. These aim to offer an objective assessment of medical outcomes after injuries and rely, therefore, on measurable findings and reliable tools to avoid bias and achieve interrater agreement. Using goniometry to clinically examine the range of motion is important in this regard, but the interrater reliability and agreement for this are not remarkably high. However, Naylor et al [32] could prove that measuring the range of motion from photos taken could achieve an agreement rate of >0.983.

Finally, a key aspect of modern medicine is the informed consent of patients and patient education, as patient compliance and outcomes could be beneficially affected by this [1,34]. Nair et al [22] showed that over two-thirds of patients stated that after being shown images of their condition, their understanding of their condition increased, they believed that this had improved their therapy, and they would therefore recommend this approach to other patients.

In the future, additional applications, such as automatic measurement and categorization of wounds, could be possible if standardized acquisition of these photos can be achieved [35-38]. This could be further simplified if technology such as light detection and ranging scanners becomes widely available on smartphones. Then maintaining specific distances or including measurement references would no longer be necessary for accurate measurements, especially in depth [38-40].

Limitations

This study has some limitations. Despite its prospective design, the sample size is quite small, and so the evidence base is limited. Additionally, the study was restricted to a single study site. As the data were acquired using questionnaires, a certain amount of bias cannot be excluded. This is especially true for the outcome parameter “time to upload or view,” which is only a subjective estimation but has been treated as a categorical variable. That is the main limitation of this study. For digital camera usage, in particular, an electronic measurement of these parameters was not feasible, and neither were such analyses incorporated in the app. However, any bias should influence both the data acquired from the digital camera and the smartphone app similarly, and we only aimed to analyze any differences found between them. Therefore, the evidence should not be relevantly impaired by these limitations. Another limitation is that smartphone photography can compete with digital cameras in regard to the standards and quality of small versions meant for small everyday tasks but not for scientific, educational, or other more challenging purposes requiring higher resolution and quality. Especially in light of this, another limitation is that usage in general was assessed, not the situations, the content, or the quality of the photographs. In this study, however, the sensor and resolution of the cameras were comparable on both devices.

Finally, no questioning or evaluation of the patients’ comfort and preference with both devices has been conducted.

Conclusions

Specialized smartphone apps offer a secure, fast, and easy way to acquire medical photos and could possibly improve patient education and care in terms of wound management, in particular,
while also offering medicolegal and economic benefits. Future studies should focus on a more objective assessment of differences and take factors such as patient comfort and preference, image resolution, and picture quality into consideration, as well as a larger sample size.

Acknowledgments
The authors would like to thank the IT department of the trauma center for supporting this study by implementing the infrastructural environment.

Data Availability
The data sets used and analyzed during this study are available from the corresponding author on request.

Authors' Contributions
SYV designed and supervised the study. The study was conducted and analyzed by JSEB, who wrote the first draft of the manuscript. MM and HS provided the software used, and HS wrote the technical part of the methods. All authors commented on previous versions of the manuscript and approved the final version.

Conflicts of Interest
The authors declare the following potential conflicts of interest concerning the research, authorship, and publication of this article: the BG Trauma Center Ludwigshafen and mbits imaging GmbH (Heidelberg, Germany) cooperate in the research field of medical digitalization without economic ties. This cooperation influenced neither the outcome of the study nor the manuscript. MM and HS are employees of mbits imaging GmbH. They provided the software "mRay".

Abstract

Background: Degenerative cervical myelopathy (DCM), a progressive spinal cord injury caused by spinal cord compression from degenerative pathology, often presents with neck pain, sensorimotor dysfunction in the upper or lower limbs, gait disturbance, and bladder or bowel dysfunction. Its symptomatology is very heterogeneous, making early detection as well as the measurement or understanding of the underlying factors and their consequences challenging. Increasingly, evidence suggests that DCM may consist of subgroups of the disease, which are yet to be defined.

Objective: This study aimed to explore whether machine learning can identify clinically meaningful groups of patients based solely on clinical features.

Methods: A survey was conducted wherein participants were asked to specify the clinical features they had experienced, their principal presenting complaint, and time to diagnosis as well as demographic information, including disease severity, age, and sex. K-means clustering was used to divide respondents into clusters according to their clinical features using the Euclidean distance measure and the Hartigan-Wong algorithm. The clinical significance of groups was subsequently explored by comparing their time to presentation, time with disease severity, and other demographics.

Results: After a review of both ancillary and cluster data, it was determined by consensus that the optimal number of DCM response groups was 3. In Cluster 1, there were 40 respondents, and the ratio of male to female participants was 13:21. In Cluster 2, there were 92 respondents, with a male to female participant ratio of 27:65. Cluster 3 had 57 respondents, with a male to female participant ratio of 9:48. A total of 6 people did not report biological sex in Cluster 1. The mean age in this Cluster was 56.2 (SD 10.5) years; in Cluster 2, it was 54.7 (SD 9.63) years; and in Cluster 3, it was 51.8 (SD 8.4) years. Patients across clusters significantly differed in the total number of clinical features reported, with more clinical features in Cluster 3 and the least clinical features in Cluster 1 (Kruskal-Wallis rank sum test: $\chi^2_2=159.46; P<.001$). There was no relationship between the pattern of clinical features and severity. There were also no differences between clusters regarding time since diagnosis and time with DCM.

Conclusions: Using machine learning and patient-reported experience, 3 groups of patients with DCM were defined, which were different in the number of clinical features but not in the severity of DCM or time with DCM. Although a clearer biological basis for the clusters may have been missed, the findings are consistent with the emerging observation that DCM is a heterogeneous disease, difficult to diagnose or stratify. There is a place for machine learning methods to efficiently assist with pattern recognition. However, the challenge lies in creating quality data sets necessary to derive benefit from such approaches.

Introduction

Degenerative cervical myelopathy (DCM) is a progressive spinal cord injury caused by spinal cord compression from degenerative pathology and consists of various subcategories of pathology, including cervical spondylotic myelopathy, ossification of the posterior longitudinal ligament, ossification of the ligamentum flavum, and degenerative disc disease [1-4]. It is estimated to affect 2% of adults, although fewer than 10% are currently diagnosed [5,6]. Surgery is the mainstay of treatment for DCM, aiming to decompress the spinal cord [2,7-9].

DCM often presents with neck pain, sensorimotor dysfunction in the upper or lower limbs, gait disturbance, and bladder or bowel dysfunction [2,10-14]. Examination findings include upper motor neuron signs in the limbs, such as positive Babinski sign, positive Hoffman sign, hyperreflexia, and increased tone [2,10-13]. Its symptomatology is very heterogeneous, making early detection difficult. This heterogeneity makes it difficult to measure or understand what drives consequences. For instance, the heterogeneity has made it harder to understand health-related quality of life [15]. This has also hindered comparisons between studies and the development of clinical practice guidelines and recommendations for DCM [16,17]. Additionally, once detected, DCM is unpredictable due to a lack of reliable methods to determine prognosis.

Increasingly, evidence suggests that DCM may consist of subgroups of the disease, which still need to be defined [18-20]. Machine learning can help in finding them. In fact, machine learning has shown potential in predicting health-related quality of life after surgery for mild DCM and outcome after surgery, although external validation and prospective analysis are still needed [21,22]. The use of machine learning in identifying these subgroups is dependent on the data set. Munro et al [23] (2023) provided a unique and comprehensive description of the effects of DCM from the perspective of people living with DCM [24,25]. This is a data set that could lend itself to machine learning analysis due to its comprehensiveness.

The objective of this study was to explore whether machine learning can identify clinically meaningful groups of patients based on solely clinical features.

Methods

Data Set

A mixed methods cross-sectional study was conducted by a team from the University of Cambridge through Myelopathy.org [26], a global charity dedicated to DCM. A focus group session of people with DCM and their supporters was used to inform the development of a web-based survey to explore the consequences of living with DCM. The survey was advertised using the Myelopathy.org website, an international nonprofit organization dedicated to promoting understanding and awareness of DCM. Survey participants were asked to specify the clinical features they had experienced, their principal presenting complaint, and time to diagnosis as well as demographic information, including disease severity, age, and sex. The data consist of 189 yes or no responses to a list of 76 clinical features. This was published in a paper, titled “Targeting earlier diagnosis: what symptoms come first in degenerative cervical myelopathy?” [23], wherein the full methodology is detailed.

Analysis

Patients were grouped into subsets with similar characteristics using k-means clustering. K-means clustering is a method that groups data into “k” nonoverlapping, distinct subsets by finding centroids in the data representing each cluster’s center and allocating data points to each cluster by minimizing within-cluster variance around centroids. K-means clustering was used due to its efficiency for small data sets and explainability, aiming to group respondents into clusters based on their clinical features, using the Euclidean distance measure and the Hartigan-Wong algorithm [27]. The optimal number of clusters (k) was determined through the inspection of 3 ancillary methods, namely, the elbow, silhouette, and gap statistic methods [28]. The clinical significance of groups was subsequently explored by comparing their time to presentation, time with disease severity, and other demographics. DCM severity was assessed using total Modified Japanese Orthopaedic Association scores [29]. Noncomplete records were not excluded, and missing data were not imputed. All analyses were conducted in R (version 4.1.0; R Foundation for Statistical Computing) [30].

Ethical Considerations

This study was conducted with ethical approval from the University of Cambridge (HBREC.2019.14). At the start of the survey, participants were provided with an overview of the study and definition of DCM, and by continuing into the survey, participants were confirming their diagnosis of DCM and providing informed consent to participate. All data collected were anonymous. No incentives were offered for the completion of the surveys.

Results

Cohort Demographics

Of the 189 participants, 134 were female and 49 were male (6 did not report biological sex). Respondents were on average 54.1 years of age. A total of 29 of them had mild DCM, 68 had moderate DCM, and 92 had severe DCM. The majority (131/189, 69%) reported having had surgery for DCM.

Cluster Analysis

Ancillary methods suggested different optimal numbers of clusters (k). Elbow, silhouette, and gap statistic methods identified k=3, k=2, and k=5, respectively (Figure 1A). The
data were hence clustered into multiple values of k and inspected (Figure 1B). After a review of both ancillary and cluster data, it was determined by consensus between AYT and BD that the optimal number of DCM response groups was 3. The reasoning behind this was that the ancillary curves in 2 out of 3 ancillary methods plateaued from k≥3 (Figure 1A), but clusters above k≥4 overlapped (Figure 1B).

**Figure 1.** (A) Determining the optimal number of clusters; (B) k-means clustering (euclidean).

**Characterization Analysis**
In Cluster 1, there were 40 respondents, and the ratio of male to female participants was 13:21. In Cluster 2, there were 92 respondents, with a male to female participant ratio of 27:65. Cluster 3 had 57 respondents, with a male to female participant ratio of 9:48. A total of 6 people did not report biological sex in Cluster 1. The mean age was 56.2 (SD 10.5) years in this cluster; in Cluster 2, it was 54.7 (SD 9.63) years; and in Cluster 3, it was 51.8 (SD 8.4) years.

A spider chart was subsequently generated to explore the clinical significance of the clusters, wherein the curves did not cross (Figure 2A; Multimedia Appendix 1).

It was also checked if patients in the different groups experienced differing numbers of features (Figure 2B). Patients across clusters significantly differed in the total number of clinical features reported, with more clinical features in Cluster 3 and the least clinical features in Cluster 1 (Kruskal-Wallis rank sum test: \( \chi^2 = 159.46; P < .001 \)).
To check whether patients with more clinical features had a more severe form of DCM, patterns of clinical features against severity were compared. The results showed no relationship between the pattern of clinical features and severity (Figure 2C).

Patterns of clinical features against both time since diagnosis and time with DCM were also analyzed. As shown in Figures 2D and 2E, there did not seem to be any differences between clusters in these distributions.

Figure 2. (A) Spider charts showing survey responses across clusters (the abbreviations along the circumference are detailed in the table in the Multimedia Appendix 1); the radius represents relative frequency, normalized to 1; (B) total number of clinical features reported across clusters; (C) proportions of degenerative cervical myelopathy (DCM) severity across clusters (based on the Modified Japanese Orthopaedic Association scores); (D) distribution of time taken to be diagnosed with DCM in each cluster; (E) distribution of time with DCM in each cluster.
Discussion

Principal Findings
Cluster analysis suggested 3 optimal subgroups based on clinical features. When exploring why these groups differed in terms of cohort demographics, only the number of reported symptoms differed significantly. The pattern of clinical features within each of the 3 groups was similar. Notably, the 3 curves in the spider chart appear to peak and trough in a similar pattern, suggesting that there was no difference in the pattern of clinical features. The concentricity of curves, however, suggested that clustering may be due to the total number of features experienced. This possibility was statistically significant (Kruskal-Wallis rank sum test). Finally, there was no link between the groups and disease severity, time with DCM, and time since diagnosis.

Limitations
This study has several limitations. The data represent a single time point cross-sectional survey of an internet-recruited cohort of patients, which could limit the generalizability of the findings. Additionally, information on disease characteristics, used for exploring the clinical significance of clusters, was limited to time with symptoms and a self-reported modified Japanese Orthopaedic Association score [31]. A more diverse data set would be more insightful, especially in DCM, wherein the nuances of symptom presentation and progression are critical. The sample size is also relatively small by machine learning standards. Finally, only 1 analysis method (K-means clustering) was performed, which may prevent us from capturing the full complexity of DCM symptomatology, especially with the increasing prominence of personalized approaches [32].

That being said, this is a unique data set, formed from the unrestricted perspectives of almost 200 patients; it was formed without any preconceptions regarding what symptoms were considered related to DCM. The result is also not unexpected. Standard analytical approaches, using more traditional data sets, have failed to stratify patients by symptoms [33]. Consequently, although a clearer biological basis for the clusters may have been missed, the findings are consistent with the emerging observation that DCM is a heterogeneous disease, difficult to diagnose or stratify [15-17]. This has been highlighted by the work of Cook et al [34] (2022) and is perhaps reflected in our inability to explain the variability in the quality of life in DCM [15].

This study shows that there is certainly a role for machine learning methods to efficiently assist with pattern recognition, but data sets must be large, valid, and comprehensive. In DCM, the challenge and priority appear to be less focused on data set size and more focused on the type of data [35]. For example, our redefinition of DCM in terms of time, mechanical stress, and vulnerability to sustain a spinal cord injury has highlighted the potential significance of various disease factors; these factors range from frailty and genetics to the type of pathology causing compression, encompassing the likely heterogeneous mechanical loading they induce [20]. Further, there are few valid and reliable outcome measures available, with most relying on face-to-face presentations to measure changes over the course of months, exhibiting low statistical power. The work of Cook et al [34] (2022) has highlighted that the experience of DCM is driven by social determinants—features such as ethnicity as well as educational, and economic status [34]. This means subjectivity in outcomes will drive current variability. Novel biomarkers, including imaging, blood, and digital biomarkers, are likely to hold value in this context, offering more disease-specific and sensitive disease indicators [36]. The need for more comprehensive and improved measurement is a firm priority in DCM [16]. Therefore, artificial intelligence undoubtedly has an important role in the future of DCM research and care. To our knowledge, such measures do not currently exist. Analysis of one of the most detailed cohorts also failed to identify biologically significant strata [22,37]. Therefore, the short-term challenge for our community lies in creating quality data sets necessary to derive benefit from these emerging analytical approaches.

Conclusions
Using machine learning and patient-reported experience, 3 groups of patients with DCM were defined. These groups differed in the number of clinical features reported but not in the severity of DCM, time since diagnosis, or time with DCM. The significance and generalization of this study remain uncertain. Overall, this study confirms the role of machine learning in DCM research, but more pressing, it confirms the need to curate the right data sets.

Abstract

Background: Depression during pregnancy is increasingly recognized as a worldwide public health problem. If untreated, there can be detrimental outcomes for the mother and child. Anxiety is also often comorbid with depression. Although effective treatments exist, most women do not receive treatment. Technology is a mechanism to increase access to and engagement in mental health services.

Objective: The Guardians is a mobile app, grounded in behavioral activation principles, which seeks to leverage mobile game mechanics and in-game rewards to encourage user engagement. This study seeks to assess app satisfaction and engagement and to explore changes in clinical symptoms of depression and anxiety among a sample of pregnant women with elevated depressive symptoms.

Methods: This multimethod pilot test consisted of a single-arm, proof-of-concept trial to examine the feasibility and acceptability of The Guardians among a pregnant sample with depression (N=18). Participation included two web-based study visits: (1) a baseline assessment to collect demographic and obstetric information and to assess clinical symptoms and (2) an exit interview to administer follow-up measures and explore user experience. Participants completed biweekly questionnaires (ie, Patient Health Questionnaire-9 and Generalized Anxiety Disorder-7) during the trial to assess depression and anxiety symptom severity. App satisfaction was measured using 2 self-report scales (ie, Mobile Application Rating Scale and Player Experience of Needs Satisfaction scale). Engagement with The Guardians was captured using game interaction metric data. We used backward-eliminated mixed effects longitudinal models to examine the effects of app engagement and satisfaction and length of time in the study on symptoms of depression and anxiety. Content analysis was conducted on qualitative data from exit interviews.

Results: The 15-day and 30-day overall app retention rates were 26.6% and 15.1%, respectively. Mixed effects models found significant negative main effects of week in study (β=−.35; t(61)=−3.05; P=.003), number of activities completed (β=−.12; t(61)=−2.05; P=.04), days played (β=−.12; t(58)=−2.9; P=.005), and satisfaction, according to the Mobile Application Rating Scale (β=−3.05; t(58)=−2.19; P=.03) on depressive symptoms. We have reported about similar analyses for anxiety. There is preliminary evidence suggesting harder activities are associated with greater mood improvement than easier activities. Qualitative content analysis resulted in feedback falling under the following themes: activities, app design, engagement, fit of the app with lifestyle, perceived impact of the app on mood, and suggestions for app modifications.
Conclusions: Preliminary results from this multimethod study of *The Guardians* indicate feasibility and acceptability among pregnant women with depression. Retention and engagement levels were more than double those of previous public mental health apps, and use of the app was associated with significant decrease in depressive symptom scores over the 10-week trial. *The Guardians* shows promise as an effective and scalable digital intervention to support women experiencing depression.

perinatal depression; pregnancy; behavioral activation; mobile app; digital intervention; mobile phone

**Introduction**

**Background**

There is growing recognition of the burden of depression during the perinatal period (i.e., pregnancy and postpartum periods). Prevalence estimates of perinatal depression (PD) range between 10% and 15% in high-income countries and are even higher in low- and middle-income countries [1,2]. If left untreated, there can be significant and detrimental consequences for both the mother and infant [3,4]. In response to this public health problem, the US Preventive Services Task Force recently recommended that clinicians provide or refer pregnant and postpartum individuals who are at increased risk of PD to counseling interventions [5]. Pharmacologic and nonpharmacologic treatments to manage symptoms of depression during pregnancy are available, yet most women do not receive the treatment they need [6]. Furthermore, targeting depression specifically during pregnancy is critical in addressing PD, as depression during pregnancy is a key risk factor for postpartum depression [7], and thus, reducing depression during pregnancy can reduce the risk for postpartum depression. Given the number of individuals affected by PD and significant barriers to care [8,9], strategies that provide increased access to evidence-based treatment approaches are needed.

There is evidence suggesting that women may prefer psychotherapeutic approaches over antidepressant medications during pregnancy [10]. Behavioral activation (BA) is one such psychotherapeutic approach based on the theory that, as individuals become depressed, they tend to engage in avoidance and isolation, which then maintains or worsens their depressive symptoms. BA encourages the individual to gradually increase engagement in activities that serve as “behavioral antidepressants” and decrease their avoidance and isolation [11]. Several meta-analyses support the effectiveness of BA [12,13], and it has been found to be comparable in efficacy with antidepressant medications among adults with major depression [14]. BA has been considered to be advantageous compared with other treatments given the simplicity of the intervention, strong retention rates, and enduring effects over a 2-year follow-up, without the concern of side effects associated with some medications [15,16]. There is emerging evidence supporting BA, specifically among pregnant individuals, with findings that BA can offer significant depression-related, anxiety-related, and stress-related benefits for this population [17].

There is support for scalability and even global dissemination of BA given how it can be delivered by nonspecialists, is cost-effective, and has demonstrated cross-cultural fit and adaptability [18]. Furthermore, BA has been identified as being suitable for “computer-based interventions that would involve no therapist input beyond an initial assessment,” which could dramatically improve the accessibility of effective treatments for depression [15]. Digital technology, including mobile health apps, has been cited as a promising strategy for increasing access to evidence-based interventions for mental health for several reasons, including constant availability, equity of availability, immediate support, low costs, lack of geographic barriers, and reduced need for direct mental health service provision (particularly given the shortage of clinicians in certain locations) [19]. A systematic review of the effectiveness of mobile apps for monitoring and managing mental health symptoms or disorders concluded that there is support for the potential of mobile apps to effectively reduce the burden of mental health symptoms; yet, further robust studies are needed to develop and test evidence-based apps [20]. Therefore, a digital BA app could be a promising way to increase access to support for depression among vulnerable or underrepresented populations.

It is, thus, not surprising that there have been recent efforts to develop BA apps, including a self-help brief BA app focused on activity scheduling for the general population called Moodivate. A preliminary randomized controlled trial (RCT) recruited adults with elevated depression from primary care practices (N=52) and randomized them to receive (1) Moodivate, (2) an active control cognitive behavioral therapy–based mobile app (MoodKit), or (3) treatment as usual (no app) [21]. Study retention was relatively high, with approximately 70% of Moodivate participants continuing to use the app 1 month after trial enrollment and 50% at the end of the 8-week study period. Compared with treatment as usual, participants in both app conditions experienced significant reductions in depressive symptoms over time, and these treatment gains were sustained throughout the trial period. These preliminary results support the potential feasibility of a BA app, such as Moodivate, as a treatment for depression. Other preliminary studies have exhibited promising findings regarding the BA apps’ abilities to provide motivation for adults with depression to plan enjoyable activities [22] and acquire insight into their own behavior and impact on mood [23]. However, these BA apps are not widely and freely available to the public, and more rigorous studies are needed regarding their impact on depressive symptoms and among certain populations.

A recent meta-analysis provides support for the efficacy and acceptability of internet-delivered interventions for pregnant women and highlights the opportunity to leverage technology for interventions targeting this population, including for mental health symptoms during pregnancy [24]. Given the challenges
of engaging pregnant people in treatment, preferences for depression treatment in nonspecialty settings, and limited availability of services targeting depression during pregnancy [25], a widely available and engaging BA app could be a highly impactful service for individuals with PD. Although a variety of apps designed to improve health and well-being have been developed, most are not grounded in evidence-based principles, and most struggle to keep users engaged [26-28]. Many such apps used typical “gamification” techniques (ie, awarding users with badges or points for using the app), which are designed to increase adherence but often fail to give the user reasons to care about those rewards. Thus, long-term retention and engagement in the app may be affected [29]. A different approach used by a mobile game called The Guardians: Unite the Realms provides immediate rewards for using BA therapeutic techniques as part of the app and gives those rewards inherent value and meaning through their use within the game’s mechanics [30,31].

The Guardians: Unite the Realms is a novel gaming BA app that is free to be downloaded by the general public with iPhone Operating System and Android. The app was developed by an author of this paper (CF) with input from experts in digitizing therapies to ensure that it maintains the core qualities and effectiveness of BA. The Guardians was designed to increase adherence to app-delivered BA by embedding BA techniques into the unique context of a mobile game, giving intrinsic incentives for users to continue using the app [30]. Since its launch in April 2020, The Guardians has collected anonymized gameplay data from about >12,500 users and saved them to its secure backend database for research and gameplay recovery purposes, as specified in the app’s privacy policy [29]. The 15-day and 30-day overall retention rates of 10% and 6.6%, respectively, are more than double the average retention rates for mental health apps of 3.9% (IQR 10.3%) and 3.3% (IQR 6.2%), as reported by Baumel et al [27] and Ferguson et al [30]. Furthermore, the 1-day and 28-day observed retentions of 37.9% and 7.3%, respectively, suggest that The Guardians has retention rates that are comparable with those of the top 15% of mobile games. Although there has not yet been a formal study of how the use of The Guardians app may influence depressive symptoms, >80% of the BA activities completed as part of the app resulted in the user feeling at least “a little bit better” [30]. The Guardians is a widely available BA gaming app with a novel approach to engage users, and preliminary data show a positive impact on mood among its users.

This Study

To the best of our knowledge, there are no gaming BA apps that have been developed specifically for a pregnant population with elevated depressive symptoms. Given the promising preliminary data about The Guardians in terms of engagement metrics and user-reported improvement in mood from app-related activities, along with the need for more novel approaches to address depressive symptoms during pregnancy, this pilot study sought to assess app engagement and to explore the potential resulting changes in mental health symptoms among a pregnant sample with elevated depressive symptoms. As anxiety is often comorbid with depression during pregnancy [32] and there is some preliminary evidence suggesting that BA may also be beneficial for anxiety symptoms, we also sought to explore the changes in anxiety symptoms among users of The Guardians app [33,34].

Furthermore, we sought to capture feedback from study participants about how a future version of The Guardians could be specifically tailored for a pregnant population, as we used the publicly available app geared for a general population in this pilot study. Incorporating a user-centered design into app development is linked to high usability, low risk of failure, reduced costs, and high overall quality [35] and can help inform app design and implementation according to feedback about the target users’ needs [36,37]. Thus, the aims of this pilot study were to explore engagement with and impact of The Guardians among pregnant individuals with elevated depressive symptoms, while also qualitatively exploring user experience and gathering suggestions for a future iteration of the app that could be tailored specifically for the context of pregnancy.

**Methods**

Participants and Recruitment

Consistent with a pragmatic trial, the inclusion criteria for this single-arm pilot study were minimal. Women were eligible to participate if they were pregnant, aged >18 years, and English speaking; had access to a smartphone; and had a Patient Health Questionnaire-9 (PHQ-9) score of at least 10 (indicative of a possible depressive episode). Exclusion criteria included a diagnosis of bipolar or psychotic disorder, active mania, psychosis, substance abuse, or immediate risk of self-harm based on PHQ-9 responses and clinician judgment. For this initial pilot study, we focused on pregnancy and excluded women in the postpartum period as there are other complicating factors in the postpartum period (eg, sleep disruption and demands of caring for a newborn) that can affect the ability to engage in the app and completion of app activities. As this was a completely web-based study, participants could be located anywhere in the United States. Participants were recruited through social media advertising, clinician referrals, and the Massachusetts General Hospital Center for Women’s Mental Health website [38]. Individuals interested in participating were instructed to reach out via mobile phone or email to the study’s research assistant using the contact information provided in the study advertisements.

Procedures

Following an eligibility screening via mobile phone, participants provided verbal informed consent and completed a baseline assessment with a trained research assistant. During the baseline interview, demographic variables, pregnancy characteristics, and psychiatric history (ie, diagnosis and treatment) were collected. At the conclusion of the baseline assessment, the research assistant instructed the eligible participants about how to download The Guardians app onto their personal smartphone. To approximate real-world mobile app use, there were no further app-related engagement prompts from study staff after the baseline assessment.

During the 10-week study period, participants were invited to complete web-based biweekly surveys via REDCap (Research Electronic Data Capture; Vanderbilt University) [39,40] to...
assess their depressive and anxiety symptoms (refer to details in the Measures section). If participants did not complete these biweekly assessments, a research assistant contacted the participant to remind them to complete the survey. A final assessment was conducted over mobile phone at the end of the 10-week trial to administer follow-up measures and conduct a brief qualitative exit interview. In addition to assessments via REDCap surveys, app analytics (eg, days played and activities completed) were captured through The Guardians via the game’s cloud save and gameplay recovery functionality. The participant data were compared with the anonymized gameplay data gathered from the app’s public users. All data gathered by The Guardians were anonymized and collected for research purposes, as stated in the app’s privacy policy [30].

Ethical Considerations

All the study procedures were approved by the Mass General Brigham institutional review board (protocol number 2021P001400). All participants provided informed consent, and all study data were deidentified before analysis. Participants were not provided compensation for their participation in the study.

Overview of The Guardians: Unite the Realm App

As noted previously, The Guardians: Unite the Realms is a mobile game designed to increase adherence to a modified BA therapy. A detailed description of the game has been published previously [30]. In brief, The Guardians is divided into 3 realms, each of which unlocks automatically after 28 days, regardless of game progression. In each realm, the user is asked to defeat an enemy character by collecting pets and sending them on missions. The pets automatically complete each mission after 10 to 60 seconds in real time. Once the pets complete a mission, they are given experience points and other rewards that can be used to further the in-game progress. Players are given a limited amount of regenerable “stamina,” which they must spend to send pets on missions. Thus, the challenge comes from carefully managing which pets should go on which missions based on the resources and stamina currently available. Players cannot lose the game or undo any progress. Every day, the player is prompted through the app to complete activities that will reward them with more pets. Players are notified to complete their daily activity in the game and via mobile phone notifications.

The player is prompted to either pick from a list of 75 suggested real-world activities or to choose their own activity. The preselected activities are divided into 3 effort levels (low, medium, and high) and into 5 categories (basics, arts and crafts, social, fitness, and fun); in-game rewards are the same regardless of effort level and category. Once the player chooses their activity for the day, the game instructs the participant to log the activity in the app once it is complete. Players cannot log the activity until sufficient time to complete their activity has passed. After logging an activity, players are prompted to reflect about how they feel after completing it, rating their post activity mood improvement on a scale of “1: Much worse” to “5: Much better.” Reflecting about how an activity affects mood is a key ingredient from BA therapy that has been integrated into The Guardians.

Measures

Diagnostic Assessment

In addition to collecting demographic information, the Mini International Neuropsychiatric Interview [41] was administered at the baseline assessment to evaluate the diagnostic criteria for a current major depressive episode (MDE) and to assess comorbid psychiatric illnesses. It is a structured diagnostic assessment that evaluates the current existence of a variety of psychiatric disorders based on the Diagnostic and Statistical Manual of Mental Disorders (Fifth Edition) criteria. To meet the MDE criteria, participants must report having had a depressed mood most of the day or markedly diminished interest or pleasure in activities for a period of at least 2 weeks. They must also endorse at least 5 of the following symptoms: significant unintentional weight or appetite change, insomnia or hypersomnia, psychomotor agitation or retardation, fatigue, feelings of worthlessness or inappropriate or excessive guilt, decreased ability to concentrate or make decisions, and recurrent thoughts of death or suicidal ideation.

Primary Outcome: App Satisfaction and Engagement

Overall, 2 self-report measures were used to assess satisfaction with The Guardians among this sample at the end of the 10-week trial using the Mobile Application Rating Scale (MARS) and the Player Experience of Needs Satisfaction scale (PENS). MARS is a 23-item self-report survey that contains 4 objective quality scales (engagement, functionality, esthetics, and information quality) and 1 subjective quality scale to classify and assess the quality of mobile health apps [42]. All items are rated on a scale of 1 to 5, and the participants’ score is averaged across all items. High MARS ratings indicate a more usable and high-quality app. PENS is a 6-item survey measuring participants’ play experiences: 3 items measuring competence (eg, “I feel competent at the game”) and 3 items measuring autonomy (eg, “The game lets you do interesting things”) [43,44]. This self-report scale is based on the theory that video games have the potential to satisfy the basic psychological needs for competence, autonomy, and relatedness. Items are rated on a scale of 1 (do not agree) to 5 (strongly agree), and high PENS ratings indicate that the player felt the game met more of their otherwise unmet needs and are associated with high long-term retention [43].

Metrics of engagement captured in the app included Day-N user retention, defined as the proportion of users who interact with the game or complete an activity on the Nth day since they installed the game, where day 1 is the first day after installation, and the denominator is the number of users who install the game on day 0 [30,45]. To compare retention rates among participants in this study with those of public users of The Guardians, we used data collected from public users (as per the privacy policy [30] and stored them in The Guardians database. Other engagement metrics and data collected in the app included days played (ie, the number of days a participant logged into the app) and activities completed (ie, the total number of activities that a participant completed in the game). The exit interview, described further in the following sections, additionally captured qualitative feedback about app acceptability, quality, and overall satisfaction.
Secondary Outcomes: Changes in Depression and Anxiety Symptom Severity

Depressive symptom severity was assessed using PHQ-9 on a biweekly basis during the 10-week trial using a REDCap survey. PHQ-9 is a well-validated self-report measure consisting of 9 Likert-style items assessing various depressive symptoms [46]. If a participant endorsed suicidality at any point during the trial or via the PHQ-9 suicidality item, further assessment of suicidal ideation and behaviors was performed using the Columbia Suicide Severity Rating Scale [47]. A safety protocol was triggered if the participant endorsed item 9 of PHQ-9 (thoughts of being better off dead) or if the participant endorsed suicidal intent or plan upon completion of the Columbia Suicide Severity Rating Scale. Following a safety protocol trigger, a study clinician would contact the participant as soon as possible and, according to clinical judgment, call the participant’s emergency contact. Participants were also provided with safety resources, including the National Suicide Prevention Hotline, and the safety protocol was modeled after that used in a large federally funded study (Preventing Depressive Relapse in Pregnant Women with Recurrent Depression; National Institute of Mental Health; NCT03623620), where participants (N=500) were assessed for depression across the pregnancy and postpartum periods [48].

Participants also completed the Generalized Anxiety Disorder-7 (GAD-7) scale, a 7-item scale assessing symptoms of anxiety biweekly [49]. As noted in the description of The Guardians previously, an additional assessment of post activity mood improvement was captured in the app by prompting users to rate how they felt after completing an app-based activity on a scale of “1: Much worse” to “5: Much better.”

Qualitative Inquiry: Exit Interview

Participants were invited to complete a brief, 30-minute, web-based exit interview with a research assistant at the end of the 10-week trial. During this interview, participants were asked about perceptions regarding their level of engagement with the app, approach to selecting activities, motivation levels, and aspects of the game that they liked or disliked. Participants were also invited to share their experiences with using the app, perceptions about its impact on their mood, and any recommendations regarding how to best tailor the app for pregnant individuals. Refer to Multimedia Appendix 1 for the exit interview questions.

Data Analysis

Quantitative data were analyzed using SAS software (version 9.4; SAS Institute). Demographics, user engagement, ratings of satisfaction with the app (eg, activities completed, days played, MARS, and PENS), average post activity mood improvement, and depression and anxiety symptoms were analyzed using descriptive statistics. Pearson correlation analyses were conducted to explore the correlation between metrics of app satisfaction (ie, MARS and PENS) and engagement metrics (ie, activities completed and days played). A best-fit curve for the participant app user data was created by assuming an exponential decay in app retention. The user retention must have a day-0 retention of 1 by definition and can be assumed to have an eventual plateau of long-term dedicated users, resulting in the formula, $y=(1-\alpha)e^{-\lambda \cdot x} + \alpha$ [50]. A series of independent group 2-tailed $t$ tests explored the differences in baseline measures of depression (PHQ-9) and anxiety (GAD-7) among participants who completed the final 10-week assessment and those who did not complete this final study assessment. A mixed effects General Linear Model was run with a dependent variable of post activity mood improvement rating versus the fixed effect of effort level (ie, easy, medium, and hard). The random term was the participants.

We also conducted analyses to explore how app engagement metrics (ie, activities completed and days played) were associated with symptoms of depression (PHQ-9) and anxiety (GAD-7) over the 10-week trial. To examine the effects of the intervention, as predicted by number of activities completed and days played, in separate analyses, on symptoms of depression and anxiety, we used backward-eliminated mixed effects longitudinal models for the dependent variables of PHQ-9 and GAD-7, also in separate analyses. The fixed predictors in these models were the numeric variable week in study (both linear and quadratic components) and either number of activities completed or number of days played and their interactions with week in study. We included baseline age and gestational age as additional covariates in the models. The random term was participants interacting with linear week in study. For all models, model residuals were checked for conformance to model assumptions of normality.

We also used backward-eliminated mixed effects longitudinal models to examine the effect of the overall app satisfaction rating (MARS), needs met through the app (PENS), and a binary predictor indicating whether treatment (ie, psychotropic medication or psychotherapy) was started midstudy for symptoms of depression (PHQ-9) and anxiety (GAD-7), in separate analyses. The random term was participants interacting with time, week in study. For all models, we calculated the proportion of variance in the dependent variable accounted for by the fixed effects and by fixed and random variables combined.

Content analysis [51] of the transcribed exit interviews was conducted to identify key themes regarding design features that participants reported as important for the usability and acceptability of the app. A team of 2 coders (LAK and HD) first familiarized themselves with the transcripts, making notes about the themes observed in the qualitative data. Key concepts from the transcripts were used to develop a codebook; codes were developed inductively from the data and deductively from interview topic areas, in addition to exploring the study participants’ perceptions about the design and usability of the app, the app’s impact on mood, and recommendations for the app’s improvement. The coders met to review the codebook and organize codes into broad categories, with guidance from the first author of this paper, who has experience in qualitative methods (RCV). Deidentified transcripts were coded and analyzed using Dedoose (version 9.0.17), a qualitative analysis software program [52].
Results

Overview

During the study enrollment period from September 2021 to April 2022, a total of 96 women indicated interest in participating in this pilot study. Refer to Figure 1 for the flow of participants, including reasons for ineligibility. Ultimately, 24% (23/96) women screened eligible for participation, and 19% (18/96) women enrolled in the study. Of the 18 participants, 10 (56%) completed the final assessment at the end of the 10-week study; we only have data on this 56% (10/18) of the participants for certain measures captured only at the end of the study (e.g., PENS, MARS, and exit interview). Table 1 describes the baseline characteristics and demographics of the enrolled sample.

\[c\]Mini International Neuropsychiatric Interview.

App Satisfaction and Engagement

The average number of activities completed in The Guardians by participants (N=18) was 11.07 (SD 13.65), and the average number of days played was 16.67 (SD 17.52). The average activity completion rate (ie, rate at which a participant, on average, would complete an activity on any given day that they opened the gaming app) was 68.2% (SD 0.33). Of all the activities that study participants completed across the study period, 43.6% (65/149) were classified as easy, 27.5% (41/149) as medium, and 13.4% (20/149) as hard in effort level (the remaining were classified as other for effort level). Among the 56% (10/18) of the participants who completed MARS and PENS ratings at the final 10-week assessment, the average MARS rating was 3.49 (SD 0.76), and the average PENS rating was 4.13 (SD 1.66). All the correlations between engagement metrics (ie, days played and activities completed) and satisfaction measures (ie, MARS and PENS) were moderately positive (r=0.44-0.50) but not significant (with P values ranging from .13 to .20). Day-N study participant retention curves mapped on to those of the public The Guardians users are displayed in Figure 2. The optimal fit with all study data included is \(\alpha=0.13\) and \(\lambda=0.12\) with \(R^2=0.93\).

Figure 2. Day-N user retention. Day-N user retention rates from day 1 to day 50 for public users of The Guardians: Unite the Realms and the study participants, with both raw data and its best-fit line.

Change in Clinical Symptoms

Overview

A series of independent 2-tailed \(t\) tests indicated no baseline differences in depression or anxiety scores between study completers (10/18, 56%) and noncompleters (8/18, 44%; \(P>.05\)). Table 2 summarizes the change in PHQ-9 and GAD-7 scores across the 10-week study.

Regarding postactivity mood improvement ratings, participants reported feeling at least “a little better” 76% (113/149) of the time after completing an activity as part of The Guardians app. On average, participants reported having a greater improved mood after completing hard activities (mean 4.47, SD 0.21) compared with after completing activities identified as medium (mean 4.17, SD 0.16) or easy (mean 3.89, SD 0.14) in effort level. There was a significant (\(P=.05\)) relation between activity effort level and post activity mood improvement, with a gradually increasing mean post activity mood improvement rating from Easy to Medium to Hard effort levels of activities, as shown in Figure 3.

Table 2. Average scores on the 9-item Patient Health Questionnaire (PHQ-9) and Generalized Anxiety Disorder Scale-7 (GAD-7) across study assessment time points.

**Figure 3.** Means for postactivity mood improvement for various categories of activity effort level. Means are estimated via least squares (LS) regression and thus conventionally termed as “LS Means.”

**Change in PHQ-9 Score According to Time (Week in Study) and Activities Completed**

For all the mixed effects models in the following sections, baseline age and gestational age were removed from the model as nonsignificant. For the first mixed effects model where the dependent variable was the PHQ-9 score, there was a significant negative main effect of linear *week in study* (unstandardized partial regression coefficient $\beta = -0.35; t_{61} = -3.05; P = .003; 95\% CI = -0.59$ to $-0.12$) and number of *activities completed* ($\beta = -0.12; t_{61} = -2.05; P = .04; 95\% CI = -0.25$ to $-0.003$). Overall, these fixed effect predictors accounted for 20.8% of the variance in the PHQ-9 score.

**Change in PHQ-9 Score According to Time and Days Played**

The same model as described previously was run except that number of *days played* replaced the number of *activities completed*. Results were analogous to those mentioned previously. There was a significant negative main effect of *days played* ($\beta = -0.12; t_{58} = -2.9; P = .005; 95\% CI = -0.21$ to $-0.04$) and linear *week in study* ($\beta = -0.34; t_{58} = -2.86; P = .006; 95\% CI = -0.57$ to $-0.10$). Overall, fixed effects accounted for 29.31% of the variance in the PHQ-9 score.

**Change in GAD-7 Score According to Time and Activities Completed**

The same model with the independent variables, *activities completed* and *week in study*, was rerun with GAD-7 score as the dependent variable. There were no significant effects of *activities completed* and only a marginally significant quadratic relation for *week in study* ($\beta$ for linear term = 0.3; $P = .38$; $\beta$ for quadratic term = 0.06; $t_{45} = -1.89; P = .07; 95\% CI = -0.125$ to 0.004). Overall, fixed effects accounted for only 4.2% of the variance in the GAD-7 score, whereas combined fixed and random effects accounted for 77.96% of the variance. Figure 4 displays the predicted values for this model and essentially indicates an accelerating decline in GAD-7 score across time, beginning at approximately week 4.
Mean values for Generalized Anxiety Disorder Scale-7 (GAD-7; with 95% CI) predicted by significant fixed effects in the fitted longitudinal model of GAD-7 versus week in study and activities completed. For fixed effects, a quadratic function for week in study was retained (marginally significant; \( P=0.07 \)), whereby the model–predicted GAD-7 values remained essentially stable up to approximately week 4.

**Change in GAD-7 Score According to Days Played**

The same model as described previously was run with days played as a fixed effect substituted for activities completed. Although the main effect terms for linear week in study and for days played were not significant, there was a marginally significant interaction effect of linear week in study and days played (\( \beta=-0.01; t_{55}=-1.97; P=0.05; 95\% \text{ CI } -0.02 \text{ to } 0.0002 \)), whereby GAD-7 score was predicted as essentially stable across time for participants with low numbers of days played but showed increasingly steep declines across time for those with increasingly high numbers of days played (Figure 5). Fixed effects accounted for 11.31% of the variance in the GAD-7 score.
**Figure 5.** Mean values for Generalized Anxiety Disorder Scale-7 (GAD-7; with 95% CI) predicted by significant fixed effects in the fitted longitudinal model of GAD-7 versus week in study and days played. For fixed effects, only an interaction of days played × linear week in study was retained as significant \((P=.05)\), whereby GAD-7 values were predicted by the model to remain essentially stable across time when the number of days played was relatively low (below 10) but showed an increasingly steep linear decline across time when the numbers of days played was increasingly high. Predicted values for GAD-7 are shown at selected illustrative strata of number of days played ranging from the minimum observed value of 2 up to the maximum observed value of 57 and at equally spaced intervals in between.

**Change in PHQ-9 Score Over Time According to MARS, PENS, and Treatment Started**

In the model with MARS, PENS, week in study, and whether medication was started midstudy as independent variables and PHQ-9 score as the dependent variable, we found a significant negative main effect for linear week in study \((\beta=-.35; t_{45}=-2.74; P=.009\); 95% CI -5.86 to -0.24) and MARS \((\beta=-3.05; t_{45}=-2.19; P=.03; \text{ Figure 6})\). The PENS variable was nonsignificant and was removed in the backward elimination. Additive to these effects, there was a marginally significant effect of treatment initiation \((\beta=-3.25; t_{45}=-1.84; P=.07)\), with the treatment started group (ie, medication or therapy started during the study period) estimated to have an adjusted mean of 11.45 (SD 1.2588), whereas the no treatment started group had a low adjusted mean of 8.20 (SD 1.2393). Overall, fixed effects accounted for 35.01% of the variance in the PHQ-9 score. There was no interaction effect between treatment started and reduction in PHQ-9 score across time; therefore, there was no significant difference in the slopes of change across time between the 2 medication groups.
Figure 6. Mean values for Patient Health Questionnaire-9 (PHQ-9; with 95% CI) predicted by significant fixed effects in the fitted longitudinal model of PHQ-9 versus week in study, Mobile Application Rating Scale (MARS), Player Experience of Needs Satisfaction Scale, and treatment initiation (ie, whether medication or therapy was started or not started during the study). For fixed effects, only negative main effects for linear week in study ($p=.009$), MARS ($p=.03$), and treatment initiation (marginal; $p=.07$) were retained. Predicted values for PHQ-9 are shown in the respective panels for those who started or did not start treatment, across time within each panel and at selected illustrative strata of MARS ranging from the minimum observed value of 2.256 up to the maximum observed value of 4.283 and at equally spaced intervals in between.

Change in GAD-7 Score Over Time According to MARS, PENS, and Treatment Started

For the backward-eliminated mixed effects model for total GAD-7 score, there was a significant interaction between MARS and weeks in study ($\beta=-.64; t_{43}=-3.27; P=.002$), reflecting the fact that as MARS ratings increased, GAD-7 score was predicted to decline more across time (Figure 7). PENS and treatment started variables were nonsignificant and removed in the backward elimination. Overall, fixed effects accounted for 18.07% of the variance in the GAD-7 score.
Figure 7. Mean values for Generalized Anxiety Disorder Scale-7 (GAD-7; with 95% CI) predicted by significant fixed effects in the fitted longitudinal model of GAD-7 versus week in study, Mobile Application Rating Scale (MARS), Player Experience of Needs Satisfaction Scale, and treatment initiation. For fixed effects, only an interaction of MARS $\times$ linear week in study was retained as significant ($P=.002$), whereby GAD-7 values were predicted by the model to vary from rising linearly across time among individuals with relatively lower MARS ratings to declining linearly across time for those with relatively higher MARS ratings. Selected illustrative strata of MARS in the figure were chosen to range from the minimum observed value of 2.256 up to the maximum observed value of 4.283 and at equally spaced intervals in between. The slight crossover of lines before approximately week 3 is likely just an artifact of the linear constraint for the lines and probably should not be interpreted with substantive meaning.

Qualitative Feedback

Overview
Themes from the exit interviews fell into the following major categories: app activities, app design, app engagement, fit of The Guardians with lifestyle, and perceived impact of The Guardians on mood. Positive and negative feedback were identified in each of these categories. Participants also provided suggestions for app modifications, some of which were general recommendations and others were specific to pregnant app users.

App Activities
Participants reported that The Guardians encouraged completion of activities outside the game, as described in the following quote:

So, I would try to do daily house tasks...Like there was one, “clean-up a junk drawer,” and another one, like, “clean a room in your house.” So, I would try to pick those activities because, let’s face it, nobody ever wants to do those kinds of things. And that, I think, was kind of helpful for me, especially because I knew we were going to be moving, and it helped me declutter some stuff before we moved, so that was really awesome.

Participants also reported appreciating the variety of activities available. A participant shared the following:

I enjoyed the activities that were offered...there’s a wide variety of activities that would suit a lot of different people.

Some participants, however, had difficulty in completing certain activities (eg, “Doing longer [activities] was harder because at the time I was having some health issues myself...”). Others felt that it was easy to select activities that they were already doing in their daily lives, as described by a participant:

I mean, most of [the activities] were things that I was kind of doing already, like taking a shower, or I think, like, doing dishes...So honestly, I kind of picked the easy ones I was automatically doing.

App Design
Overall, participants appreciated the design of The Guardians’ characters (eg, “The aesthetics were adorable; they’re really cute.”). A participant noted that the characters in the game motivated her to continue engaging with the app:

I think within the game itself, my biggest motivator was probably getting new pets. As someone who really likes arts and things like that, the designs of the creatures were really interesting. Being able to get a new creature each day was great.
Participants also appreciated the design of The Guardians itself, in terms of its aesthetics (eg, “I did enjoy that the different levels had different world feels.”) and mechanics (eg, “…It’s one of the only apps that never crashed on me.”). Some participants also had more critical feedback regarding the app’s design. For instance, a person felt that the app was difficult to navigate (eg, “If I didn’t feel like I was…fumbling my way through it, I could have maybe engaged faster and more.”). Others were frustrated that they had to wait before the next level unlocked (eg, “At one point, I think I had to wait, like, thirty days or something in order for the next level to open up, and I was like, ‘Oh, my goodness—what do I do now?’”). Similarly, some participants were frustrated by the length of the game’s introduction and overall complexity, as summarized by a woman:

I would say that the learning curve was just too much...like the mental state I’m in, plus, like, the amount that I’m trying to juggle. It was just a lot to try and add the additional learning of a game...

**App Engagement**

Participants shared that The Guardians allowed them to develop a sense of routine (eg, “When I was trying to get myself out of bed and stuff like that, [the app] just gave me another reason to get out of bed…”). They also enjoyed the gamification of daily household activities that may otherwise be difficult to complete while pregnant or experiencing elevated depressive symptoms (eg, “I definitely liked the aspect of…little challenges of doing laundry and cleaning and stuff like that, because it kind of gamified doing that type of stuff.”). Furthermore, engagement with the app even helped a participant to start and maintain a healthy coping behavior beyond the end of the trial:

I think having that structure, having that reward to engage in a very common coping mechanism for me, really helped to motivate and get me in a pattern of reading that has continued, even if I’m not actively engaging with the app right now.

Not all participants, however, found The Guardians to be motivating or engaging (eg, “I didn’t really feel like [the app] was pushing me to come back in any way.”). Some found the app to be very complex, as previously described, whereas others felt that it was very simple (eg, “I think if it was a little bit more complex, it would have been more engaging for a longer period of time.”).

**Fit of The Guardians Into Lifestyle**

Some participants found that using The Guardians was an easy fit into their existing lifestyle (eg, “I would use [the app]…on the way to work.”). Furthermore, a participant felt that the game helped them return to a previous routine:

Once I started using the app in the mornings, I was able to get out of bed and do the things that I [had previously] been doing. So, it kind of snapped me back into my regular routine...

In terms of negative feedback, some participants felt that their busy schedules and lifestyles were not compatible with using The Guardians consistently. A participant stated the following:

I already have three kids, so I needed something to kind of be easy and mindless, and this was like…you had to be focused in on what you’re doing to even learn the game. So, for me, it was just too much.

**Perceived Impact of The Guardians On Mood**

Some participants reported that The Guardians positively influenced their mood (eg, “I think that the reward [was] my mood improving.”). Other participants did not find the app effective in influencing their mood (eg, when a participant was asked whether The Guardians affected their mood, the participant responded, “No, not really.”).

**Suggestions for App Modifications**

Participants had various recommendations for future improvements to The Guardians. Broadly, participants recommended simplifying the introduction to the app (eg, “Make it a little bit easier so it’s not so much upfront…to make sense of it.”). In addition, participants suggested a way to track activities in the game to monitor progress (eg, “I think if…it tracked [the activities], that would be really helpful, too.”).

Recommendations also centered around ideas for making The Guardians more relevant and engaging for pregnant individuals. Participants suggested adding more pregnancy-specific activities, as described in the following quote:

I think maybe for pregnant women specifically...if you made one of those activities, like, do your kick counts, or something...just a reminder to some people, especially first-time moms, because they might not know to do those kinds of things...

Furthermore, some participants recognized that potential activities could differ based on gestational age. A participant shared the following:

For pregnant women, even having, like, a first trimester versus second trimester versus third trimester...There are different goals in there too, if you look at, like, pregnancy guidelines. Like, maybe, “Pick out something for the nursery today.” I think it could be interesting...to even look at how you can engage at different points of your trimesters.

Others recommended that The Guardians incorporate educational content related to pregnancy, as described in the following quote:

I think there are elements too, where there's pregnancy education that could be added into a gamification setting, where you are educating people at the same time as encouraging...healthy habits and things like that.

**Discussion**

**Principal Findings**

Our findings from this pilot study provide preliminary support for The Guardians as a potentially desirable intervention to engage and improve mood among some pregnant women. All enrolled participants met the criteria for a current MDE and the average baseline depressive symptoms fell into the moderate...
symptom severity level according to PHQ-9 [53], suggesting that The Guardians may be of interest to and able to engage pregnant individuals with moderate depressive symptom levels. Without providing any compensation for participation in the study, we enrolled 18 pregnant women within a brief, 8-month recruitment period, indicating that a gaming app such as The Guardians may be of interest to some individuals in the target pregnant population. Furthermore, one-third of the sample (6/18, 33.3%) identified as non-White, which is encouraging in that the app may be acceptable to a diverse population. However, we recognize that this was a small and relatively highly educated and employed sample; further studies are needed to assess the ability to engage a diverse perinatal population with elevated depressive symptoms using The Guardians.

Our user engagement data aligned with previous studies suggesting that The Guardians may be effective in improving long-term engagement relative to other digital mental health interventions [30]. The 15-day and 30-day overall app retention rates of 26.6% and 15.1%, respectively, compare favorably with the median retention rates of 3.9% (IQR 10.3%) and 3.3% (IQR 6.2%) for mental health apps, as reported by Baumel et al [27]. Furthermore, our retention rates suggest that The Guardians is favorably consistent with rates observed in the top 15% of entertainment-only mobile games that include engagement rates [54]. Such retention and engagement metrics are particularly encouraging, as there were no external (ie, outside the app) reminders for participants to use The Guardians, unlike other digital mental health interventions (eg, use of a therapist or coach to check in and encourage engagement). Although not statistically significant (likely owing to the small sample size in this study), it is not surprising that there were positive, moderate correlations between ratings of satisfaction with the app (as assessed using PENS and MARS) and engagement with the app (as assessed using days played and activities completed).

This was the first study to explore the change in depressive and anxiety symptoms among users of The Guardians. Our findings demonstrated reduction in both depressive and anxiety symptoms over the course of the 10-week study on average among study participants. Although we cannot attribute the decrease in clinical symptoms to the app owing to the lack of control group and this being an underpowered pilot study focused on feasibility, our analyses indicated statistically significant relationships between depression improvement and app engagement when there were less depression symptoms (according to PHQ-9), more activities were completed, and more days played. This offers some preliminary support that there may be improvement in depression when pregnant women engage more with The Guardians. Furthermore, low depressive symptoms were associated with high MARS rating of app satisfaction, indicating that there may be great improvement in depressive symptoms when a user is more satisfied with The Guardians. Overall, of the 2 app satisfaction ratings (ie, MARS and PENS), our mixed effects models found MARS to be a better predictor of change in clinical symptoms (main effect for decrease in PHQ-9 score; interaction with time for decrease in GAD-7 score) relative to PENS, which was removed in backward elimination for all of our analyses.

Our findings also suggest that there may be great improvement in mood after completing activities that require more effort. However, the effort level of app activities was assigned by the app developers, and activities determined to be easy or hard may not align with how a user would rate the effort for these activities. Further studies are needed to explore the relationship between the types and effort levels of activities completed and impact on mood. In addition, this study focused on individuals only during pregnancy and not during the postpartum period, as it seems there are unique aspects of the postpartum period (eg, sleep deprivation and demands of a newborn) that may influence the ability to engage with the app or complete certain activities. Future studies could assess the impact of this app in the postpartum period and further explore how certain activities in the postpartum period are perceived in terms of effort level and impact on mood.

Our findings regarding change in anxiety symptoms revealed an interaction between days played and time, indicating that there were relatively stable anxiety levels on average among participants who used the app less, but there was great improvement in anxiety scores for those who used the app more (ie, great number of days played). This provides some support for the potential benefit of using The Guardians among this sample of pregnant individuals with anxiety and elevated depression, yet only for those who used the app more often. Not surprisingly, given the nonsignificant but positive correlation between app satisfaction (ie, MARS) and days played, there was great improvement in anxiety symptoms when the MARS ratings were high (ie, high acceptability). Again, further studies are needed with a powered RCT to explore these changes in clinical symptoms among users of The Guardians, including assessment of other factors that may be contributing to change in clinical symptoms (eg, specifics about treatment changes during the study and major life events). Our findings indicate that participants who started treatment (medication or psychotherapy) during the course of the trial had great depressive symptoms both at baseline and at the end of the 10-week trial; however, the rate of change in depressive symptoms between these groups over the course of the study period was similar.

The qualitative feedback provided by participants indicated that there were contrasting opinions about certain aspects of the app. Participants tended to positively assess the activities on the app if they were novel to the participant or suited their individual lifestyles and abilities. Participants tended to negatively assess the activities if they felt that they were very difficult or did not have a significant or positive effect on their mood. There were also some contrasting views about the nature of the app; some felt that it was “mindless” and fun, whereas others felt that it was very demanding and time consuming. Future studies could explore ways to tailor the app to make it more or less challenging, depending on a person’s preferences or needs. On the basis of participants’ recommendations, other features could be added in future iterations of the app, such as an activity tracking module to help monitor activity completion and impact on mood over time. Other feedback from participants will be critical in informing the adaptation of The Guardians to a perinatal population to include pregnancy-specific activities.
and educational content. It is possible that a more tailored version of the app for perinatal individuals with depression may be even more feasible, acceptable, and effective in reducing depressive symptoms for this population.

**Limitations**

This study has several limitations. As indicated previously, the study sample was small and relatively highly educated and employed. Thus, we do not know how generalizable these findings are to a broad population. As this pilot study did not have a control condition, we cannot make any causal claims regarding the impact of the app on clinical symptoms. Furthermore, future studies should assess how access to smartphones or comfort with technology may influence who would engage with an app such as *The Guardians*. A large RCT is needed to further explore how *The Guardians* may be used among pregnant individuals across socioeconomic levels and to rigorously assess the app’s effectiveness in treating PD.

**Conclusions**

*The Guardians* is a widely available and highly engaging gaming app that incorporates BA principles. In this study, we sought to explore the usability, acceptability, and preliminary effectiveness of this app among a small sample of pregnant individuals with elevated depressive symptoms. Findings from this small pilot study provide initial support for *The Guardians* as an acceptable and engaging app, and there may be some improvement in mood and anxiety among certain users in the target population. This was one of the first longitudinal pilot studies to explore the effectiveness of a BA gaming app on PD. Further studies, including a powered RCT, is needed to follow-up on these preliminary findings.

Telephone-Based Training Intervention for Using Digital Communication Technologies for Social Housing Residents During the COVID-19 Pandemic: Mixed Methods Feasibility and Acceptability Evaluation

Abstract

Background: In an era in which digital communication technologies play a pivotal role in everyday life, social housing residents remain highly susceptible to digital exclusion.

Objective: This study aims to evaluate the feasibility and acceptability of a telephone-based training intervention designed to empower people to confidently use digital communication technologies (ie, video calls and web-based messaging).

Methods: Conducted in collaboration with a UK social housing association, the intervention was facilitated by a unitary authority’s Digital Inclusion Team during the COVID-19 pandemic. A mixed methods approach was used, encompassing quantitative and qualitative data collection on demand, reach, implementation, and potential outcomes. Demographic and qualitative data on the reasons for undertaking or not undertaking the training were collected via telephone interviews during the recruitment process. Digital competency and well-being data were collected via a self-reported survey before and after the intervention.

Results: Among the 4485 residents who were offered training, 67 (1.49%) expressed interest, of whom 12 (18%) of the 67 completed the training. The findings indicate a demand for basic digital training among social housing residents. The key findings revolve around the substantial dropout rate among those who were interested in undertaking the training. Barriers were strongly influenced by socioeconomic and health circumstances, reflecting the sociodigital inequalities commonly found in this group. For the training participants, the intervention was acceptable and achieved its goals, demonstrating the potential of tailored, persistent training efforts in overcoming barriers. There were no changes in self-reported well-being or digital competency outcomes (but this was limited by the small sample size).

Conclusions: Sociodigital inequalities impact the reach, implementation, and acceptability of telephone-based digital training for social housing residents. Barriers to reaching and training digitally excluded groups can be overcome through the use of trusted intermediaries, personalized recruitment approaches, the minimization of administrative barriers, and tailored and agile training programs. Recognizing the resource-intensive nature of such initiatives, this study calls for enhanced recognition of intermediary efforts in national digital inclusion policies.

Introduction

Background
Facilitated by near-ubiquitous digital connectivity in the global north, digital technologies are increasingly used across all areas of life and bestow significant benefits upon those who use them [1,2]. In response, many organizations, not least public service providers, proceed as if access to the internet and digital technology is already universal [3]. However, although connectivity has increased, access to digital technologies and the competencies to use them are not yet universal [4,5]. In the United Kingdom, the 2021 Consumer Digital Index found that approximately 10 million people (14% of the population) do not have the basic digital competencies needed for use of everyday digital technologies [6]. Digital exclusion can no longer be seen as a product of rural or remote living, place-based infrastructural and connectivity issues, or older age. Instead, digital exclusion is currently most likely a product of wider social and economic inequalities. Sociodigital inequalities [7] refer to the interplay between traditional (ie, social, economic, and health) and digital inequalities and have led to systematic differences in the ability and opportunity of different groups to beneficially use digital technology and participate in society. These differences, in turn, contribute to deeper social inequalities, which lead to greater digital inequalities over time [8].

A growing body of literature has begun to document the extent of digital inequalities and highlight the specific barriers to digital use in different social contexts [8]. In the United Kingdom, the Digital Inclusion Strategy sets out how the government and partners from the public, private, and voluntary sectors will increase digital inclusion [9] by targeting the following 4 interconnected barriers to digital inclusion: digital access, skills, confidence, and motivation [10]. However, although national policies are imperative to improve inclusion from an infrastructure and digital connectivity [1] perspective, localized interventions are much better placed to address digital skills, confidence, and motivation across previously excluded groups [11]. In the United Kingdom, localized digital training interventions are typically delivered by intermediaries, such as voluntary and community sector organizations and public libraries, and include formalized group programs, one-to-one digital buddy programs [12], and peer support [13]. Specifically, the United Kingdom’s Local Government Association’s Digital Inclusion Programme is funding councils to reach residents and provide personalized digital training programs for those who do not have access to or confidence in using digital communication platforms [14]. However, there is limited evidence on whether these digital training interventions are effective in increasing “digital readiness,” the competency and increased motivation to use digital technologies [15-17]. However, evidence does suggest that individuals who participate in these digital interventions have a higher socioeconomic status, higher education, higher social participation, and a greater experience with technology [18,19]. Conversely, those who are already experiencing sociodigital inequalities remain the hardest to reach [20-22] owing to reported barriers, including physical health issues, a negative attitude toward technology, caring for a sick spouse, a lack of energy, and a lack of time [23,24].

This Study
Within the context of the digital needs of hard-to-reach populations, this study focused on social housing residents in Southwest England. In the United Kingdom, social housing associations (HAs) are not-for-profit organizations that provide rental properties at 50% to 60% of market rates to those whose circumstances exclude them from the private market [25]. Overall, 3.9 million people live in social housing for various socioeconomic reasons [25]. Studies have shown that the demographic and socioeconomic profile of social housing residents means that they are significantly more likely to be digitally excluded and harder to reach than other groups in the United Kingdom [10,26-28]. This is because the factors that are known to increase digital exclusion are found at higher incidences among social housing residents than among those outside the social housing system [29,30]. These factors include lower incomes, fewer qualifications, older age, physical and mental health issues, disabilities, and living in more deprived areas [31,32].

The Smartline project [33] worked with 200 social housing households in one of the most deprived areas of England [34] to understand the potential of everyday digital technology to address health and well-being challenges. A qualitative scoping study on the feasibility and acceptability of digital technology among Smartline participants found that although the participants had positive perceptions of technology and were keen to try new technologies, digital readiness and the desired digital destination (goals) varied greatly among the community [28]. Several concerns surrounding technology use were identified, including data security and privacy concerns and the fear of “making a mistake” or “pressing the wrong button.” Many participants expressed a strong desire for further training and support.

Following this research, a training intervention was conducted to help Smartline participants get on the web and use digital communication technologies, such as web-based video calls and messaging, with confidence. The Getting Connected (GO:SC) intervention was originally planned as a face-to-face intervention with peer-to-peer support on how to use video calling technology. However, as with many research interventions during this time [35], the outbreak of the COVID-19 pandemic in March 2020 meant that the study had to be redesigned as a smaller-scale telephone-based training intervention for social housing residents delivered in conjunction with the Cornwall Council’s Digital Inclusion Team (DIT). The aim of this study was to evaluate the feasibility of the telephone-based training intervention. Specifically, informed by the feasibility framework of Bowen et al [36] and RE-AIM...
(Reach, Effectiveness, Adoption, Implementation, and Maintenance) model of Glasgow et al. [37], this study aimed to evaluate the (1) reach and demand, (2) implementation, (3) acceptability, and (4) potential efficacy of the telephone-based digital training intervention for social housing residents [36,37]. These are established frameworks for evaluating digital health interventions [38,39] and are suitable and credible for testing an unexamined intervention in a real-life setting where constraints exist over conditions [36,38,39].

**Methods**

**Overview of the Study Design**

This was a mixed methods feasibility study. The protocol and ethics application were informed by best practices for the process evaluation of public health interventions [40]. An overview of the study procedure, including recruitment and data collection, is provided in Figure 1 and Table 1 and detailed throughout the subsequent subsections.

**Figure 1.** Feasibility study process map for the digital training program covering recruitment, data collection, and intervention delivery.
Residents who expressed an interest in the digital training either via telephone or email were posted the study information sheet, the consent form, and a baseline survey assessing well-being and digital competency (Multimedia Appendices 2-4). Participants returned the completed forms via a Freepost envelope to the research team, who forwarded the participants’ phone numbers and digital training interests to the Cornwall Council’s DIT via email. The DIT then directly telephoned each participant to arrange the provision of the training.

The inclusion criteria were adult (aged >18 y) social housing residents in Cornwall who defined themselves as lacking either the competency or confidence to use digital communication apps. These included existing participants in the Smartline project and residents of the wider Coastline HA. Participants were excluded if they did not have access to an internet connection or at least 1 internet-enabled device. Training was provided free of charge to participants (in line with the DIT’s protocol).

The Intervention
The intervention is described in line with the TIDieR (Template for Intervention Description and Replication) standards for intervention reporting [42]. The training intervention was based on a 4-week, face-to-face, and basic digital skills course that was established by the DIT and delivered in libraries and community venues across Cornwall before the COVID-19 pandemic. The course structure adhered to the UK government’s Essential Digital Skills Framework [43], encompassing fundamental computer skills, problem-solving skills, communication skills, transactional skills, and skills for handling...
digital information and content, as detailed in Multimedia Appendix 5.

In response to the social distancing measures in place during the COVID-19 pandemic, the DIT adapted the training to be delivered over telephone. This adaptation was informed by best practices in digital inclusion initiatives [44] and participant preferences identified in our prior qualitative scoping work [28]. The adapted training approach emphasized informality; flexibility; person-centeredness; and task-specific, on-demand delivery, diverging from traditional, predetermined, and technically focused programs imposed by training organizations [44]. This informal model aligns with research indicating that training success factors encompass participant autonomy, personalized learning, practice opportunities, and individualized support [13,45]. Informal learning, in particular, enhances self-efficacy and proves highly effective for digitally marginalized groups [46].

The overall purpose of the training intervention was to support participants in achieving active and continued use of digital devices and communication apps of their choice (eg, WhatsApp [Meta Platforms, Inc], Zoom [Zoom Video Communications, Inc], and Facebook). The training was delivered through one-on-one phone calls facilitated by a digital inclusion officer from the DIT, all of whom possessed a background in education. To provide course content guidance and ensure consistent and best-practice training delivery, the DIT used a bank of task-specific instructions (ie, step-by-step guide to installing WhatsApp), which could be printed and posted to participants on demand (Multimedia Appendix 6). Training sessions varied in duration (between 5 min and 2.5 h) according to each participant’s individual learning needs, often including follow-up calls as necessary.

Ethical Considerations

Overarching ethics approval to conduct research with Coastline Housing (a social HA in Cornwall) residents was granted by the University of Exeter Business School Research Ethics Committee as part of the Smartline project (eUEBS002996 v4.0). Specific approval for the GO:SC project was granted by the College of Life and Environmental Science Penryn Research Ethics Committee (eCORNS002229). Written informed consent was obtained from all participants involved in the study (Multimedia Appendices 3 and 4). Data were anonymized using pseudonyms. Participants who completed the follow-up survey received a £10 (US $12.7) shopping voucher as compensation for their time.

Data Overview

The following 4 qualitative and quantitative data sources were used to assess the feasibility and acceptability of the intervention: a recruitment log, recruitment survey, well-being and digital competency survey (administered at baseline and 6-month follow-up), and digital training call log (Table 1). Previously piloted by the Smartline participants, the well-being and digital competency survey (Multimedia Appendix 2) used quantitative rating scales and was completed at baseline (immediately before training commencement) and 6 months following the training, with the aim of assessing potential outcomes. This survey (disseminated via post) was based on a validated survey, the “Happiness Pulse” [47], and included 4 domains of psychological well-being (general, emotional, behavioral, and social). A bespoke module on digital attitudes, behaviors, and competence was developed by the research team for the wider Smartline project. This digital module was informed by behavior change and technology acceptance theories [48-51] and included questions adapted from existing sources, including the UK government’s Digital Inclusion Evaluation Toolkit [52]. The module contained specific questions on video calls and messaging in addition to questions on technology in general. The theoretical basis of this module is provided in Multimedia Appendix 7 [47,49-63].

Data Analysis

To determine the reach of and demand for the intervention, as well as participants’ levels of engagement with the training, descriptive statistics (frequencies and percentages) from the recruitment log, recruitment survey (n=168), and training call log (n=12) were calculated. A probit model was used with the recruitment survey data to identify the socioeconomic factors associated with initial interest in participating in the digital training program. The analysis was performed in Stata (version 17; StataCorp) [64].

For well-being and digital competency survey, the scoring protocol for the Happiness Pulse was followed [53], with means and SDs calculated from summary scores to describe each of the 4 well-being domains. As digital competency outcomes were measured on interval scales, medians and IQRs were calculated for these outcomes.

The COREQ (Consolidated Criteria for Reporting Qualitative Research) criteria [65] for reporting qualitative research were adhered to throughout the analyses. Qualitative data analysis used data from the recruitment log, recruitment survey, and digital training call log. To manage the qualitative data analysis process with transparency and traceability [66], NVivo (QSR International) [67] was used. In line with best practices [68], 3 rounds of inductive coding were conducted using a constant comparative method [69,70]. The first round of coding was open and focused on identifying and labeling discrete incidents. For example, “I have a smartphone, but I struggle to use it” contains 2 incidents: an object (smartphone) and a construct (competency). The second round of coding was axial, where open codes were compared (via contradiction, expansion, and support) and integrated into themes, and the third round of coding was selective, where connections between themes were compared and refined to build the grounded theory. The lead researcher (TW) conducted the initial coding, and the themes identified were discussed with a second researcher (SAB). To further improve rigor and reliability [71,72], a third researcher (KM) was consulted, and minor discrepancies were resolved through discussion. Pseudonyms were applied to protect participants’ identities.

The quantitative and qualitative data were integrated within the selected feasibility criteria of reach, demand, acceptability, implementation, and potential outcomes [36] to provide a complete picture of the feasibility, acceptability, and potential impact of the intervention. This use of mixed methods enabled
triangulation to strengthen the validity of the findings and complementarity to explore different facets of a phenomenon [73].

**Results**

**Reach and Demand of the GO:SC Digital Training Intervention**

**Recruitment and Reach**

Digitally excluded groups within social housing are known to be difficult to reach [20,26]. In total, 4485 social housing residents were offered the training either via email (n=4365, 97.32%) or phone call (n=120, 2.68%; Table 2). The total number of responses to the recruitment survey (conducted via phone and email) was 168. A much higher proportion of phone survey respondents (37/120, 30.8%) were interested in the training, compared with the proportion of email survey respondents who were interested (30/4365, 0.69%). Although the HA actively promoted the intervention via its various web-based and printed communication channels over several months, none of the residents responded to these advertisements.

**Table 2.** Demand for and uptake of the digital training in and demographic characteristics of each group.

aThe percentage values in columns 3 to 13 were calculated using the corresponding n value in column 2.

bThe percentage value was calculated with 67 as the denominator.

Phone calls were the most successful means for recruiting older and more digitally excluded groups. This success can be attributed to their familiarity as a channel for communication and the person-centered approach they enable [44]. Phone conversations also facilitated a further understanding of personal circumstances (eg, social, financial, or health needs) and desired outcomes (eg, connecting with friends or family or accessing health services), making it easier to adapt the conversations to include relevant training benefits. Furthermore, a previous study [74] found that women tend to be more receptive to recruitment contact via phone, which may explain the gender bias found.

Overall, 39.9% (67/168) of the recruitment survey respondents were interested in potentially undertaking the intervention. Among those initially contacted via email and phone, older women residents and those contacted by the HA were more interested in the intervention (probit model; Table 3). None of the interested participants who responded to the email survey completed the training. Our results affirm the substantial challenge of reaching and recruiting individuals interested in foundational digital training using conventional communication channels.
Digital Training and Reach

Of the 37 potential participants who indicated interest via phone, 12 (32%) completed the training. Of these 12 participants, 9 (75%) were women. Only respondents aged ≥55 years undertook the training, of whom 42% (5/12) were aged 55 to 64 years, 42% (5/12) were aged 65 to 74 years, and 17% (2/12) were aged ≥75 years (Table 2). Overall, 50% (6/12) of the participants reported a disability, 42% (5/12) of the participants reported no disability, and 8% (1/12) of the participants were missing data on disability. The majority of the participants racially identified as White (9/12, 75%) and culturally identified as British (5/12, 42%) or British Cornish (4/12, 33%). The demographic, disability, racial identity, and cultural identity profiles of participants who completed the training were proportionally similar to those who did not complete the training.

The small sample size recruited for digital training is consistent with the small sample sizes recruited to other feasibility studies on interventions for digitally excluded populations. For example, Barbosa Neves et al [39] recruited only 12 participants in residential care to a feasibility study concerning the use of digital communication for social connectedness. Nonetheless, given their research objectives focused on uncovering feasibility, this sample size was appropriate and useful [36,75]. Similarly, we argue that our findings are useful for interpreting the feasibility of this digital intervention among social housing residents.

Training Demand

The most salient factors influencing the demand for the intervention were digital competency, preference for nondigital communication, and social networks. These multifaceted factors underscore the intricate dynamics surrounding digital training interventions and highlight the need for tailored strategies to address diverse participant needs and circumstances.

Among those interested in undertaking the intervention, demand was highest for training on video calling, primarily using Zoom; setting up and using devices, primarily a tablet; and improving digital skills, knowledge, and confidence in general, with most participants (37/67, 55%) who indicated interest in the recruitment survey noting multiple training needs across the 3 areas. In line with the initial scoping study conducted by Buckingham et al [28], it was a lack of competency in using digital devices, rather than device ownership and internet connectivity, that hindered digital technology use: “I am not able to use it [device] properly” (James, a man resident aged 55 to 64 years) and “I am interested in video calling, I have a smartphone, laptop, tablet, and mini-iPad, but I struggle to connect to the internet” (Mary, a woman resident aged 55 to 64 years).

The primary reason people were not interested in accessing the training was because they were already competent in using web-based video calling and messaging tools (57/101, 56.4%). However, those who were already competent were supportive of the intervention, reporting a need for digital training in general. Further reasons for the lack of demand included preferences for nondigital communication technology (“I prefer to just pick the phone up and call people” [Thomas, a man resident of unknown age]) and a feeling that the training was not personally necessary (“No, don’t think I need to learn things like this at my age, manage just fine thanks” [Deborah, a woman resident aged 65 to 74 years]).

Social networks played a key role in demand among participants who replied to the initial recruitment survey about the intervention. The lack of a digitally engaged social network was commonplace among those contacted, as was a small social network in general: “I don’t know anyone who I would call. I only have my sister and she doesn’t use internet stuff” (John, a man resident aged 55 to 64 years). Unsurprisingly, living farther away from family and friends was a key reason for engaging with digital communication technology: “My family live a distance away, so keeping in touch is important” (Sharon, a woman resident aged 86 years). However, for us, a key finding

*Not available.*
was that people remain happy to rely on their broader support group, particularly younger family members. Having family and friends that could be relied on for help was a disincentive to undertake the training: “No help necessary, grandchildren able to help” (Rebecca, a woman resident aged 65 to 74 years).

Regarding the overall reach of the intervention, although initial recruitment calls found a moderate level of demand for this training, this interest did not translate into the same level of reach, with only 18% (12/67) of the interested participants completing the training. A key reported factor contributing to the lack of reach was health status, either personal health status (12/67, 18%) or the health status of family members (9/67, 13%); however, long-term disability (23/67, 34%) or impairments also affected the capacity to use technology and communicate, particularly among participants with visual, speech, or hearing difficulties (4/67, 6%). Caring responsibilities also acted as an impediment to uptake, particularly among older women:

I am interested [in the training], but my head is just full of decisions about my husband who will be in a nursing home for the rest of his life. I need to focus on what is important to me now. [Martha, a woman resident aged 55 to 64 years]

**Implementation of the GO:SC Digital Training Intervention**

The main implementation finding relates to the reduction in the number of participants between those who expressed initial interest in the training and those who completed the training. The study found that key facilitators included the HA's established relationship with a digitally susceptible population and the flexible, informal approach of the DIT. Barriers involved issues with written consent, internet access, and device functionality. Here, we discuss each of these in turn.

The tangible and intangible positive roles that the HA played as an intermediary [76,77] in the implementation of the intervention cannot be overstated. In the United Kingdom, the role of HAs has evolved over recent decades to include supporting the health and well-being of their residents [78]. As a result, many HAs have built meaningful, trust-based relationships with their residents, and this factor played an important role in this project. From a practical perspective, this meant that the collaboration of Smartline with the HA enabled a wider reach in advertising the training offer. For example, the HA was able to use its customer relationship management system with phone numbers and email addresses to contact over 4000 residents. Indeed, examining the socioeconomic factors associated with initial interest in participating in the digital training program revealed that respondents who were contacted by the HA were more likely to be interested in the training program (P<.001; Table 3).

Another factor important for reach was customer liaisons by the HA with known susceptible residents who they felt would be interested in and would benefit from the training. Although recruitment remained difficult and the uptake of the intervention was low, the implementation of the recruitment survey and associated data collection would not have been possible without the help of the HA.

Participant dropout at the recruitment stage negatively affected implementation; only a small proportion of those who expressed an initial interest went on to complete the training. Among those (n=67) who were initially interested in the training, many (n=37, 55%) required multiple callbacks (up to 4) before they could be reached again; for reasons discussed next, many (55/67, 82%) dropped out. Making multiple callbacks was an administratively complex task that required many hours and email exchanges within the recruitment team. The need for written consent was a key factor for recruitment dropout, as was the need for a working digital device and an internet connection. Completing and returning the necessary consent forms was found to be a particular challenge for some participants. Participants noted that “filling in forms is a worry” (Julia, a woman resident aged 65 to 74 years) and that making time for the task was difficult: “I have the forms but have a lot on at the moment” (Jess, a woman resident aged >75 years). The possession of an internet-enabled device and internet connection was a requirement for participation in the training. Although we found high rates of digital technology ownership and internet connection possession among the participants contacted, 17.3% (29/168) of the respondents to the recruitment survey did not have a tablet, 5.9% (10/168) of the residents did not have a smartphone, and 7.1% (12/168) of the residents did not have an internet connection. Financial constraints, in particular, were a key reason for the lack of internet:

If I could get internet I would be interested [in the training], but not at the moment due to affordability issues. [Thomas, a man resident of unknown age]

I live in poverty so am scared I will incur charges using the tablet and smartphone. [James, a man resident aged 55 to 64 years]

For other interested participants, the working condition of the device was also a barrier to participation in the training:

I need to learn how to adjust settings so my old PC can cope. [David, a man resident aged 55 to 64 years]

I am not sure if my phone is smart enough. [Grace, a woman resident aged 55 to 64 years]

In addition, it is important to reflect on the implementation of the training itself. In practice, 3 different digital inclusion officers delivered the telephone-based training to 12 participants. The calls lasted between 5 minutes and 2.5 hours. To fit around participants’ caring responsibilities and day-to-day lives, all participants required multiple calls to arrange and rearrange training times. Training sessions lasted as long as required for the participant to learn to use the digital application, and follow-up support calls (up to 5) with the digital inclusion officer were arranged to ensure that the training objectives were achieved (Table 4). Successful delivery of the training required flexibility and persistence from the DIT. This indicates that there is a wide range of digital needs that are best served by informal and one-to-one support directed by individual needs [13,46].

Acceptability of the GO:SC Digital Training Intervention

Similar to the key findings on implementation, the study’s key findings on acceptability revolve around the substantial dropout rate, highlighting the challenges of translating training interest to training participation. Participants dropped out because of competing priorities, including health issues, caregiving responsibilities, and time constraints. However, all the 12 participants who started the training completed it; this suggests high acceptability of the intervention itself.

As with all research conducted during this period, the COVID-19 pandemic impacted all aspects of the intervention. We found the lockdown to have both a positive and negative impact on acceptability. For some, it was a driver for learning how to use video calls to access health services, social groups and classes, and resident groups, which had transitioned to function on the web:

*I need help to connect to video appointments with the health professionals helping me.* [Katy, a woman resident aged 25 to 34 years]

*I would really like to join the online Coastline meetings [HA residents’ group] but don’t know how to use Zoom. It’s a priority for me to get online now.* [Lily, a woman resident aged >75 years]

The lockdown also had a negative impact on the acceptability of the training intervention, with potential participants noting a need to attend to everyday tasks and self-care, rather than learning new skills: “I have been unwell with COVID for months, I just need to focus on the day-to-day things at the moment” (Judith, a woman resident aged 45 to 54 years). Importantly, we found that the pandemic compounded and increased several preexisting barriers to undertaking digital training for our participants. For example, we found that preexisting health conditions arose as a key barrier to participation:

*I am apprehensive about if a phone conversation would be enough to get online, would prefer one-to-one and face-to-face. I learn best by doing.* [Michael, a man resident aged 65 to 74 years]

*I need baby steps with the learning as I am not confident with technology, AKA a technophobe.* [Gill, a woman resident aged 65 to 74 years]

The timing of the training was an important factor for participants, particularly for those who were working or had chronic health issues: “I have ME [myalgic encephalomyelitis or chronic fatigue], so afternoon is better for me” (Susan, a woman resident aged 55 to 64 years). Therefore, despite the increased need for digital communication at this time [79], the already complex social and health needs of the Smartline participants [80] meant that the recruitment and retention of interested participants was time intensive and a major challenge for the acceptability of the intervention.

Outcomes of the GO:SC Digital Training Intervention

Of the 12 people who participated in the training, 9 (75%) completed the baseline and follow-up well-being and digital competency surveys (Multimedia Appendix 2). Table 5 provides the summary well-being scores for participants who undertook the digital training intervention; there were no changes in the mean general, emotional, or social well-being between baseline and follow-up.

Counter to the overall aim of the intervention, we found a small reduction in behavioral well-being for participants who had undertaken the intervention [53]. The behavioral well-being measures included a question asking whether participants were attending courses and a further question on whether respondents were learning a new skill. As such, respondents would have indicated “yes” to these questions at baseline; however, at follow-up, participants were unlikely to be undergoing any other training given the ongoing COVID-19 restrictions. As such, this decrease could be explained by a confounding reduction in training levels from before to after the intervention, rather than an actual decrease in behavioral well-being.

Table 6 provides the summary digital competency scores of the intervention participants (n=9) at baseline and follow-up. From...
Table 6, it can be inferred that there were no clear changes over time in any of these scores.

*Higher scores indicate higher perceived competence, greater frequency of use, and more positive attitudes toward technology.

Reverse-coded responses were used for these questions.

Scores range from 1 to 6 for the frequency of use questions; scores range from 1 to 5 for all other questions.

n=7 (data are missing; therefore, the number of responses is indicated).

n=6 (data are missing; therefore, the number of responses is indicated).

n=5 (data are missing; therefore, the number of responses is indicated).

Although conclusions on potential efficacy based on the survey data are limited owing to the small sample size, the qualitative data indicated that participants had achieved their original training objectives. Table 4 provides a summary of the training objectives, training needs, and the level to which they were met.

From Table 4, it can be inferred that increased competency in using video calling apps, particularly help with the installation and setting up of these apps, were key training needs. Participants’ training needs were motivated by both social and personal goals, such as contacting family members and becoming more competent with digital technology in general. Although advertised as training on video calling and messaging, participants received a diverse range of training, from training on how to order prescriptions on the web to training on more
complex tasks such as recording and mixing music using web-based platforms. The flexibility to deliver such diverse and tailored training was not initially planned as part of the intervention yet proved a successful strategy. Overall, from the qualitative data, we found that participants achieved their training objectives and social and personal goals and have the potential to use other digital technologies in the future.

Discussion

Principal Findings

The findings indicate a demand for basic digital training among social housing residents, and the intervention was acceptable for those who received it. However, recruitment and implementation were challenging, with potential participants experiencing barriers that reflected the sociodigital inequalities commonly found in this group [10,26-28]. Barriers were strongly influenced by socioeconomic and health circumstances, which were closely related to preexisting digital readiness (eg, preexisting skills, confidence, motivation, and access) and further compounded by the COVID-19 pandemic. Our results confirm that the factors known to increase digital exclusion are particularly high among social housing populations [29,30] and highlight the interplay between traditional inequalities (ie, social, economic, and health) and digital inequalities [7]. However, social and personal goals were achieved by the participants who received the intervention. This demonstrates that tailored, flexible, and persistent training efforts can overcome barriers.

Implications for Policy and Recommendations for Practice

Regarding policy, the UK’s Digital Inclusion Strategy aims to “equip the whole country with the skills, motivation and trust to go on the internet, be digitally capable and to make the most of the internet” [81].

Although national policies are imperative to improve infrastructure, access, and digital connectivity [1,9,10], the implications of this study are that an effective policy also needs to focus on strategies for reaching digitally excluded groups [20-22]. The essential strategies and recommendations for practice derived from our findings are listed in Textbox 1.

Textbox 1. Essential strategies and recommendations for practice.

1. Partnerships with trusted intermediaries: forge partnerships with trusted local intermediaries, such as housing associations (HAs), community organizations, councils, and public libraries [76,77]. Prioritize intermediaries with established relationships and direct contact with the target group for effective reach.

2. Personalized recruitment approaches: use personalized recruitment methods, such as personal phone calls or face-to-face conversations. Understand individuals’ social, economic, health, and digital circumstances and align training benefits with their specific goals [7].

3. Minimize administrative barriers: reduce administrative burdens by minimizing form-filling processes, which negatively impact recruitment efforts. Be mindful of research monitoring procedures that may affect recruitment numbers, aiming for a streamlined approach.

4. Tailored and agile training programs: offer a flexible combination of device provision and internet access tailored to individual needs. Implement agile, person-centered training programs that adapt to participants’ personal goals and requirements.

5. Resource allocation and recognition: recognize the resource-intensive nature of initiatives targeting digitally excluded groups. Advocate for a stronger recognition of the efforts and resources required by intermediaries in national digital inclusion policies.

By implementing these strategies, policy makers, organizations, and communities can address sociodigital inequalities. However, in making these recommendations, we recognize that this places a considerable burden on individuals delivering such interventions. Future feasibility research of this nature could investigate the burden on intervention deliverers and the associated economic costs, which were not examined here.

Limitations

A strength of this study is its focus on social housing residents, an understudied population with associated socioeconomic inequalities that can present particular barriers to digital technology use. Another strength of this study is the collection of quantitative and qualitative data from various sources to enable rich insights into feasibility, acceptability, and potential impact, including the capture of data on those who initially expressed an interest in participating but did not go on to receive the intervention.

A limitation of the study is the small sample size for quantitative evaluation; however, as this is a feasibility study, quantitative outcomes (well-being and digital competency) were only intended to be indicative of the potential impact and were supplemented by qualitative findings on the achievement of training objectives. Owing to the unexpected difficulties in recruiting participants to the intervention, follow-up interviews were not possible within the time frame of the project.

We measured psychological constructs with individual items to balance theory alignment with reducing participant burden. However, we suggest that future feasibility and acceptability studies use established multiitem measures to assess such constructs. The final limitations to note are those with regard to intervention delivery fidelity and economic costs. The study did not assess how the DIT delivered the intervention, other than following the “standard operating procedure.” It is possible that variations occurred in training delivery with regard to relationships with participants. Future studies should consider structured approaches to assessing intervention fidelity [82].

Finally, the intervention’s cost could not be specified, as it was provided through a county council’s DIT. Despite their personalized nature, similar personalized digital training programs are common in UK councils [14]. Therefore, the results of this study are valuable for providers facing challenges in engaging specific resident groups.
Conclusions
This study contributes to the contemporary literature, theory of “sociodigital inequalities” [7], and need to redefine digital inequalities in terms of their relation to other forms of socioeconomic and health inequalities. To address sociodigital inequalities, this study highlights that future policies need to be more proactive in reaching excluded groups, and such initiatives need to be considerable of people’s everyday lives, which will be conditioned by social and health circumstances. To achieve this, initiatives need to be appropriately resourced and include a flexible combination of digital provision with an agile person-centered approach to training based on personal needs and goals.

Acknowledgments
The authors would like to thank Karen Spooner (Volunteer Cornwall), Phil Gilbert (Coastline Housing), and Adrian Ankers (Coastline Housing) for their help and support with recruitment. They thank the University of Exeter’s Smartline team, namely Belinda Broughton, Chloe Bines, and Claire Wilcox, for support in managing survey administration. They thank the Cornwall Council’s Digital Inclusion Team, namely Dawn Stoddom (Digital Inclusion Team lead), Simon Gooding (digital inclusion officer), Kym Ley (digital inclusion officer), and Peter Finlay (digital inclusion officer), for delivering the digital training. They thank the rest of the Smartline team, particularly Emma Bland, for their feedback on the manuscript. They are grateful to all of the Smartline participants who gave their time to be involved in this study.

The Smartline project (05R16P00305) received £3,740,920 (US $4,752,989) and the Smartline Extension project (05R18P02819) received up to £3,307,703 (US $4,203,172) of funding from the England European Regional Development Fund as part of the European Structural and Investment Funds Growth Programme 2014-2020. The Ministry of Housing, Communities and Local Government (and in London, the intermediate body Greater London Authority) is the Managing Authority for the European Regional Development Fund. Established by the European Union, the European Regional Development Fund helps local areas stimulate their economic development by investing in projects that support innovation, businesses, job creation, and local community regeneration. The study received additional funding of £25,000 (US $31,768) from the Southwest Academic Health Science Network and £200,000 (US $254,162) from the Cornwall Council.

Data Availability
The anonymized quantitative data sets analyzed during this study are available from the University of Exeter Open Research Exeter repository. Qualitative data cannot be shared because they contain sensitive participant information, identifying information, and information whose dissemination would violate the agreement to which the participants consented.

Abstract

Background: Individuals who have committed sexual offenses against children often have difficulties finding treatment, despite its potential effectiveness. Although the development of web-based interventions could enhance therapeutic supply, up to now the acceptance thereof among this target group is unknown.

Objective: For the first time, this study assesses the acceptance of a web-based intervention among individuals who committed sexual offenses against children and analyzes variables that predict acceptance. Following the Unified Theory of Acceptance and Use of Technology (UTAUT), it is assumed that acceptance of web-based interventions in individuals who have committed sexual offenses against children follows the same mechanisms as for individuals in general psychiatry.

Methods: This cross-sectional study is based on the data from an ongoing clinical trial (@myTabu) evaluating the effectiveness of a web-based intervention in individuals who committed sexual offenses against children (N=113). Acceptance level was measured using a questionnaire based on the UTAUT and modified for the target group. Furthermore, predictors of acceptance from the UTAUT (performance expectancy, effort expectancy, and social influence [SI]), attitudes toward web-based interventions, and internet anxiety were assessed at baseline.

Results: Most participants (61.1%, 69/113), reported high acceptance, while 36.3% (41/113) of them indicated moderate acceptance, and 2.7% (3/113) of them expressed low acceptance. In a linear regression model, the predictors explained 41.2% of the variance ($F_{11,101}=9.055; P=.01$). Attitudes toward web-based interventions ($B=0.398$, 95% CI 0.16-0.64; $P=.001$) and SI ($B=0.183$, 95% CI 0.03-0.38; $P=.04$) significantly predicted acceptance. Post hoc explorative analysis showed that the participants’ belief that people close to them would recommend the use of a web-based intervention is a predictor of acceptance. In contrast, the belief that their community supervisor would recommend the use thereof was not predictive in this respect.

Conclusions: For the participants of this study, we identified high acceptance of web-based interventions for the majority of participants. SI and the participants’ attitudes toward web-based interventions were important in predicting acceptance.

Introduction

Background

Sexual abuse during childhood has disruptive short and long-term effects for children who are victims of such an offense [1,2] and the treatment of individuals who committed sexual offenses against children should be a major part of efforts to reduce the risk of recidivism. Despite findings that therapy can reduce the risk of recidivism [3], many individuals who committed sexual offenses against children struggle to find a therapist. Therapists often express a low willingness to work with individuals who are convicted of a sexual offense—especially with those who have a pedophilic disorder [4]. The result, at least in Germany, is that only limited therapeutic treatment is available [5]. Web-based interventions represent a possible enhancement in the therapeutic supply [6].

Web-based interventions can be advantageous in comparison to face-to-face (f2f) therapy for the users, as they can be anonymous, flexible in time and space, and can be cost-effective [6,7]. Anonymity could be especially advantageous, as individuals who committed sexual offenses against children can feel ashamed and guilty which may hinder the willingness to find a therapist. To date, only a few web-based interventions exist for individuals who have committed sexual offenses against children and the majority of them have not yet been evaluated [8]. In a placebo-controlled trial, Läth et al [9], showed for the first time that a guided web-based intervention for individuals who consume child exploitation material can reduce the amount of time thus spent. In addition, the study showed that, as is the case in web-based interventions in general psychiatry [10], many persons who signed up for a web-based intervention did not participate by logging in or completing the therapeutic content [9]. Also, in f2f therapy for individuals who have committed offenses, roughly one-third of individuals do not complete therapy [11,12]. Up to now the variables that predict why and for how long individuals who have committed sexual offenses against children use web-based interventions are unknown. In general, a factor that is expected to predict whether someone uses web-based interventions in general psychiatry is acceptance [13,14]. Thus, this predictor might also be important in the treatment of individuals who committed sexual offenses against children.

To study acceptance and its predictors, research on web-based interventions for general mental health often uses the Unified Theory of Acceptance and Use of Technology (UTAUT) as a theoretical framework [15,16]. The UTAUT states that the use of a technology can be predicted by acceptance. Acceptance is thereby defined as the behavioral intention to use a technology. Further, 4 core predictors are assumed, which are performance expectancy (PE), effort expectancy (EE), social influence (SI), and facilitating conditions (FC). PE is related to whether or not the person believes that the web-based intervention can help him or her; EE is related to the perceived ease of use of the web-based intervention; SI is the perception of whether people close to him or her would recommend the use of the web-based intervention; and FC is related to the belief that there is an organizational and technical infrastructure that would help him or her in case of problems with the web-based intervention. According to the UTAUT, FC together with acceptance predict the use of technology. The other 3 variables, PE, EE, and SI, predict acceptance.

Although the UTAUT was first conceptualized to explain the use of technology in organizational settings, it has been generalized to many different fields including the use of technology for treatment in general psychiatry [16]. Philippi et al [16] conducted a secondary analysis in which they integrated the data of 1588 participants from 10 UTAUT studies. The original studies analyzed the participants’ acceptance and its predictors based on the UTAUT for web-based interventions, for example, for treating depression, chronic pain, or aftercare for inpatients. In the study by Philippi et al [16], the basic structure of the UTAUT with PE, EE, and SI predicting acceptance was replicated. PE was found to be the strongest predictor, in accordance with results from prior studies [15,17,18].

Gender, age, degree of voluntary use of technology, and experience with the technology were included next to predictors in the UTAUT as moderators [15]. The authors showed that the effect of PE was stronger for younger and male individuals; the effects of EE was stronger for older female, and less experienced individuals; and the effect of SI was stronger for older, female, and less experienced individuals as well as under conditions of mandatory use [15]. In web-based interventions in general psychiatry, however, Philippi et al [16] could not replicate a moderating effect of age, gender, or experience on any predictor. Next to moderating effects, a direct effect on acceptance of participant age was analyzed. In some studies on web-based interventions in general psychiatry, it was found that a lower age predicted higher acceptance [19-21] whereas other studies found no effect [16,22].

In the field of web-based interventions in general psychiatry, the variables attitudes toward web-based interventions and internet anxiety were also integrated into the UTAUT to predict acceptance. Attitudes refers to the evaluative judgment of a web-based intervention, which can be expressed in attributes ranging for example, from pleasant to unpleasant or likable to dislikable [20,23]. Internet anxiety is the fear, distrust, or apprehension that is experienced when using the internet [16,24]. Attitudes and computer anxiety were removed from the final UTAUT model because the explorative power of the variable was captured by EE [15]. In recent studies, however, attitudes was found to be a strong predictor for acceptance [20,25,26]. Similarly, internet anxiety studies have shown that persons with lower internet anxiety have a higher acceptance for web-based interventions in general psychiatry [16,22,26].

Objective

The goal of this study is to address the following research questions for individuals who committed sexual offenses against children, either by contact or noncontact offense (ie, child sexual exploitation material offenses): (1) how high is the acceptance of web-based interventions? (2) Which variables predict acceptance of web-based interventions?
As shown above, no data exist for the specific target group of this study. Therefore, we assume that acceptance of web-based interventions for individuals who have committed sexual offenses against children follows the same mechanisms as for individuals who use web-based interventions in general psychiatry (Figure 1). As a consequence, it is expected that higher scores in PE, EE, SI, attitudes toward web-based interventions, and lower scores in internet anxiety predict higher scores in acceptance. In addition, we will examine whether age has a moderating and direct effect on acceptance.

Figure 1. Conceptual study model with the UTAUT predictors [15] and additional variables as well as age as moderator. UTAUT: Unified Theory of Acceptance and Use of Technology. *Age as a moderator variable.

**Methods**

**Study Design and Data Collection**

This cross-sectional study used data collected between March 1, 2021, and March 1, 2022, of an ongoing clinical trial to evaluate the effectiveness of the web-based intervention @myTabu [27,28]. Participants were individuals convicted of child abuse, of child sexual exploitation material use, or of both under the German Penal Code and were under community supervision. Further eligibility requirements were adulthood (18 years of age or older), a community supervision period of at least 6 months at study inclusion, internet access, no severe acute psychiatric disorder, no severe cerebro-organic disorder, and no severe cognitive impairment. For the recruiting process, research staff informed community supervisors of the clinical trial and asked them to inform eligible clients. When an eligible client was interested in the clinical trial, he or she was informed about the study by research staff in a personal interview. During the recruitment period, 118 interviews were conducted and 113 individuals agreed on taking part in the study.

**Measures**

**Sociodemographic and Criminological Data**

For each participant, 1 research staff member (out of a total of 3 research staff members) collected sociodemographic and criminological data using a standardized data collection form. The written court judgment and records of the Federal Central Criminal Register were used as the primary source of information. If information was missing from these documents, corresponding information was obtained from participants. The modified Static-99, which is a version of the original Static-99 that omits victim-related variables, was assessed [29]. The Static-99 includes variables that have been found to be predictive of sexual reoffending among individuals who have previously committed a sexual offense. A higher score represents a higher risk [30]. Scores of the modified Static-99 range from 0 to 9. Information on the additional data that were coded during that process can be found in the study protocol of the @myTabu clinical trial [28].

**Acceptance and Predictors**

To measure acceptance and its predictors, the German adaptations of the UTAUT questionnaire by Baumeister et al
modified to the context of a web-based intervention for individuals who committed sexual offenses against children based on face validity (Textbox 1, see Multimedia Appendix 1 for original German questionnaire).

**Textbox 1.** Items of the questionnaire for acceptance of technology with references to original studies; the sections that have been adapted for this study are italicized.

</table>

According to the UTAUT, acceptance was operationalized as behavioral intention and was measured using 4 items. The UTAUT predictors PE and EE were measured using 3 items each and SI was measured using 2 items. Attitudes toward web-based interventions and internet anxiety were measured using 4 and 2 items, respectively. Responses were made on a 5-point Likert scale ranging from 1 (does not apply at all) to 5 (applies absolutely). McDonald $\omega_{\text{total}}$ [35,36] were 0.59 for acceptance, 0.80 for PE, 0.81 for EE, and 0.83 for attitudes toward web-based interventions, showing good reliability for PE, EE, and attitudes toward using web-based interventions and a poor reliability for acceptance [37]. For scales with 2 items, Spearman-Brown coefficient was calculated [38]. Spearman-Brown coefficient of SI was 0.21 and of internet anxiety was 0.65, showing a questionable reliability of internet anxiety and an unacceptable reliability for SI [37].

In addition to the above named scales, scales were measured on FC [31], planning behavior [39], and study compensation for hypotheses that were not part of this study.

**Statistical Analyses**

**Research Questions 1 and 2: Acceptance and its Predictors**

Data analysis was performed using the software R (version 4.2.1; R Core Team) [40]. The mean acceptance score was
calculated and its distribution was assessed. The acceptance mean score was categorized as low (1-2.34), moderate (2.35-3.67), and high (3.68-5), in accordance with previous studies [41,42].

To test for predictors of acceptance, a multiple linear regression with acceptance as the criterion was conducted. The variables PE, EE, SI, attitudes toward web-based interventions, internet anxiety, and age were included along with a moderation of age on all variables (age x variable). The predetermined α level was .05. Variables were included simultaneously in the model. For meaningful interpretation of the coefficients of the first-order terms in the presence of interactions, we mean-centered the variables prior to computation [43]. For missing items responses, the mean across the available items of each scale was calculated. There were missing items for 5 participants with a maximum of 6 missing items (mean 2.2, SD 2.17). There was no missing scale, as every participant answered at least 1 item on every scale [44]. To test for outliers, Cook distance, leverage value, and studentized deleted residuals were calculated. After correcting for coding errors, there were 23 participants who were considered outliers by the above named criteria. To test the model assumptions, we looked at linear relationships between the variables and acceptance, normality of residuals [45], homoscedasticity [46], and multicollinearity [47-49]. There were signs of nonnormality of residuals; the other analyses showed no assumption violation. Because of the outliers and the nonnormality of residuals, a bootstrap procedure was used with the number of bootstrap samples of 1000. By using bootstrapping, results are less sensitive to extreme values and thus no participant had to be excluded from the analysis [49,50].

Explorative Analysis
Because of the low internal consistency of SI, a multiple linear regression was conducted with acceptance as the criterion and the items of the SI scale as factors with the lowest value as reference. In addition, the predictors PE, EE, internet anxiety, attitudes toward web-based interventions, and age were included. For the SI item (asking whether the community supervisor recommends the use of a web-based intervention), values 1 and 2 were too infrequent for a statistical analysis and were thus combined into 1 category with 3. Because of missing values on SI items, 2 participants were excluded from the analysis. There were 9 outliers according to Cook distance, leverage value, and studentized deleted residuals. There were signs of nonnormality of residuals [45]; the other analyses showed no assumption violation. Therefore, a bootstrap procedure with the number of bootstrap samples of 1000 was used [49].

Ethical Considerations
This study was conducted in accordance with the Declaration of Helsinki, was approved by the medical ethical board of the Human Medical Center Göttingen, Göttingen, Germany (16/2/20), and was preregistered on AsPredicted (107090). During study enrollment, informed consent was obtained from all participants. In the informed consent, participants agreed on the study conditions and data protection and processing. Study data were saved and deidentified by using pseudonyms for each participant. During participation, identification of each individual was only possible by the respective community supervisor. After participation, identification lists were stored separately from the study data in paper form in a safe. Individuals received monetary compensation for their participation; the compensation level was dependent on the number of sessions completed in the web-based intervention. A maximum of €120 (US $131.06; €1 is approximately US $1.2 at the start of the clinical trial) could be obtained.

Results

Demographic and Criminological Data
All 113 participants were male and had a median age of 38 years with a range of 20-72 (mean 40.67, SD 12.75 years). The participants had on average 1.25 previous convictions (SD 2.47). For 57.1% (64/112; 1 missing) of the participants, the present conviction was their first. For their present conviction, 38.9% (44/113) of the participants were convicted for sexual abuse of children (German Penal Code section 176 in the version in effect before July 01, 2021), 14.3% (16/113) for aggravated sexual abuse of children (German Penal Code section 176a in the version in effect before July 01, 2021), and 74.3% (84/113) for dissemination, procurement, and possession of child pornographic content (German Penal Code section 184b). Note that 28 participants had more than 1 present conviction. The mean score for the modified Static-99 was 1.87 (SD 1.19; range 0-6).

Descriptive Data of Acceptance and Predictors
The mean (SD) acceptance level in this study was 3.78 (SD 0.66). The distribution of acceptance is negatively skewed with 2.7% (3/113) of the participants indicating low, 36.3% (41/113) moderate, and 61.1% (69/113) high acceptance. The mean score of PE was 4.08 (SD 0.77), of EE was 4.10 (SD 0.67), of SI was 3.88 (SD 0.81), of attitudes toward web-based interventions was 4.15 (SD 0.63), and of internet anxiety was 2.02 (SD 0.93). The mean (SD) PE, EE, Internet Anxiety and Age were 4.08 (SD 0.77), 4.10 (SD 0.67), 2.02 (SD 0.93) and 38.9 years (SD 12.75), respectively.

Prediction of Acceptance
According to the F test (F11,101=9.055), the variables in the regression model explained 41.2% of the variance of acceptance (R²=0.412; P<.001; Table 1). With a regression coefficient of B=0.398 (95% CI 0.16-0.64; P=.04) for attitudes toward web-based interventions and B=0.184 (95% CI 0.03-0.38; P=.04) for SI, there were significant linear effects of both variables on acceptance. The other variables did not predict acceptance above the effects of attitudes toward web-based interventions and SI (all P>.05). There was no moderating effect of age on any variables (all P>.05).
Table 1. Regression results using bootstrapping with acceptance as the criterion (N=113).

Explorative Analysis

The mean (SD) score for the item of the SI scale asking whether people close to the participant recommend the use of a web-based intervention was 3.24 (SD 1.20). The mean (SD) score for the item of the SI scale asking whether the community supervisor recommends the use of a web-based intervention was 4.49 (SD 0.80).

The variables in the regression model explained 35.95% of the variance of acceptance (F\(_{11,99}\)=6.273; R\(^2\)=0.3595; P<.001). Attitudes toward web-based intervention (B=0.331; 95% CI 0.09-0.55; P=.01) and the perceived opinion of people close to the participant significantly predicted acceptance. Participants who indicated a score of 5 (B=0.455; 95% CI 0.07-0.96; P=.04) or 4 (B=0.502; 95% CI 0.17-0.89; P=.01) had significantly higher acceptance than participants who indicated a score of 1. There was no significant effect for participants who indicated a score of 3 (B=0.340; 95% CI 0.01-0.72; P=.07) or 2 (B=0.182; 95% CI -0.31 to 0.60; P=.42) in comparison to participants who indicated a score of 1. PE (B=0.108; 95% CI –0.08 to 0.28; P=.24), EE (B=0.106; 95% CI –0.12 to 0.29; P=.30), internet anxiety (B=-0.06; 95% CI –0.22 to 0.09; P=.46), age (B=0.006; 95% CI –0.005 to 0.01; P=.22), and perceived opinion of the community supervisor, when scored 4 (B=-0.05; 95% CI –0.47 to 0.25; P=.79) or 5 (B=0.094; 95% CI –0.18 to 0.42; P=.55) in comparison to lower or equal to 3, did not significantly predict acceptance.

Discussion

Principal Results

This study examined for the first time the acceptance of web-based interventions and variables predicting it among individuals who committed sexual offenses against children. For the majority of participants, the acceptance of web-based interventions was high. Persons with higher scores in SI and attitudes toward web-based interventions showed significantly higher acceptance. In contrast to expectations, the other predictors of the UTAUT, PE and EE, as well as internet anxiety and age did not predict acceptance. An explorative analysis of the 2 items comprising the SI scale revealed that the belief that people close to the participant would recommend the use of a web-based intervention predicts acceptance but the same is not true for the belief that the community supervisors would recommend the use thereof.

Comparison With Prior Work

In comparison to prior work from general psychiatry, the average acceptance was higher in this study with a smaller variance. In the secondary analysis from Philippi et al [16], in which results from 10 original studies were included, the mean acceptance for male participants was low to moderate (mean 2.68, SD 1.12). One explanation for the high acceptance scores in this study may be that it is difficult for individuals who committed sexual offenses against children to find face-to-face therapy [5]. Another explanation for the divergent acceptance levels may be differences in the sample selection. A common recruiting method to contact specific target groups in the studies incorporated in the secondary analysis by Philippi et al [16] was.
to contact patients directly in clinics [31,32,41], for example by recruiting in the waiting rooms [14]. To protect the identity of clients, recruitment in this study involved collaboration with community supervisors. Thus, the research staff did not contact eligible clients directly but instead asked the community supervisors to inform eligible clients of the study. Through this approach, it is likely that some clients were never informed about the study because they were considered unsuitable by the community supervisor. In addition, clients who declined after first being informed by the community supervisor never met with research staff. Further, the participants in this study all agreed to participate in an evaluation study for a web-based intervention. The aim of most of the studies incorporated in the secondary analysis by Philipp et al [16] was to test acceptance-facilitating interventions and participants were not given access to a web-based intervention. Thus, it is likely that the results are based on a selected group of individuals in community supervision, which may not be representative of individuals who committed sexual offenses against children in general. This explanation is in line with the study by Lin et al [22], who recruited participants by sending invitations to individuals who had earlier expressed interest in participating in an evaluation study on a web-based intervention and (thus) assessed comparatively high acceptance (mean 3.44, SD 0.89; values were divided by 4 to match the scale used in this study). Despite this potential bias, the results of this study show that there exists a group of individuals who committed sexual offenses against children in community supervision that has high acceptance of web-based interventions.

Participants in this study rated web-based interventions as more helpful (PE), easier to use (EE), more enjoyable (attitudes toward web-based interventions), and perceived that their social surroundings would recommend the use of web-based interventions more (SI) than did participants in studies of web-based interventions in general psychiatry. All of these predictors are positively correlated with acceptance [16,25]. As mentioned above, this positive view of web-based interventions can be partly explained by the selection of the sample. In comparison, internet anxiety, which has a negative correlation with acceptance, was found to be slightly lower in studies from general psychiatry [16]. For individuals who were not convicted for a crime using the internet, this result could be understood when considering that internet anxiety is negatively correlated with internet use [51] and convicted individuals often lack the skills and resources to use the internet or specific technologies [52]. Although the internet anxiety levels in this study cannot be considered as high, a lack of experience with the internet could be a more important issue for individuals who committed sexual offenses against children compared to individuals who have not been convicted of a crime.

The proportion of explained variance of 41.2% in the regression model can be considered as high according to the Cohen criteria [53]. However, this proportion is lower than in other UTAUT studies, where UTAUT predictors explained for example 57% to 63% of the variance of acceptance [21,54,55]. This could mean that, for individuals who have committed a crime, further predictors are relevant that have to be investigated in order to fully understand the acceptance of web-based interventions. In this study, to test our hypotheses, only selected variables that were replicated in previous studies on web-based interventions in general psychiatry were examined for their prediction on acceptance [16,20,25]. In studies on web-based interventions in general psychiatry, further variables that have been investigated include, among others, perceived reliability [56] and perceived privacy risks [54]. Next to these variables, those that predict the treatment motivation for f2f therapy in individuals who committed sexual offenses against children, for example, antisocial personality disorder, might also be relevant for web-based interventions [57]. In addition, web-based interventions are becoming more common in general mental health care [58] and are increasingly being developed for individuals who committed sexual offenses against children [8]. Therefore, it is likely that an increasing number of individuals have some experience with web-based interventions which could have a direct or moderating effect on acceptance [15]. These and other variables could be important when explaining the variance of acceptance of web-based interventions in individuals who committed sexual offenses against children.

In previous studies, it has been repeatedly shown that the original UTAUT predictors PE, EE, and SI are predictive of acceptance [16,59]. In this study, against our expectations, the predictive effect of PE and EE could not be replicated for individuals who had committed sexual crimes against children. In contrast, SI and attitudes toward web-based interventions were significant predictors of acceptance. Attitudes toward web-based interventions was also found to be a strong predictor of acceptance in other subject groups and was equally as strong as PE [20,25]. The importance of attitudes for acceptance may be related to the fact that the participants in this study most likely had no specific knowledge or experience with web-based interventions at the time they answered the UTAUT items. In this state of indecision, positive attitudes might be more important than cognitive beliefs about the web-based intervention. That could be a reason why the hypothesis that PE and EE are predictive for acceptance was refuted in this study [25].

The significant prediction by SI of acceptance could be explained by the fact that participants are influenced by how other people, especially their community supervisors, evaluate their community supervision time. However, in the exploratory analysis, it was found that the perceived higher opinion of people close to the participant but not the perceived lower or higher opinion of the community supervisor significantly predicted higher acceptance. A reason why the perceived opinion of the community supervisor was not predictive could be that most participants rated the opinion of their community supervisor as high. This may be because community supervisors who did not support web-based interventions may have not informed their clients. Thus, the results of this explorative analysis could imply that especially in a situation where the community supervisors support a web-based intervention, the opinion of people close to the participant predicts acceptance.

In previous studies, it was found that lower age predicted higher acceptance [19-21] and that the effect of PE, EE, and SI was moderated by age [15]. In this study, however, no direct or moderating effect of age could be observed in individuals who...
committed sexual offenses against children. This is in line with studies by Philippi et al [16] and Lin et al [22], who also could not replicate a direct or moderating effect of age.

Limitations
The first limitation arises from the sample selection. As mentioned above, participants were preselected by community supervisors and the participants were persons who already agreed to take part in a web-based intervention study. Because of that, it is not clear if and how representative the sample is of individuals who committed sexual offenses against children and who are presently in community supervision and thus how generalizable the results of this study are.

The second limitation could have resulted from the preselection. The variances in this study are low, which could be an indicator that the sample variance is lower than the actual population variance. Because of that restriction of variance, the statistical power to detect interactions is reduced [43].

The third limitation is that the scales acceptance, SI and internet anxiety show low reliability. For this study, we used the well-established UTAUT questionnaire [15] and adaptations used in the field of general psychiatry [17,32-34]. The questionnaire for this study was based as closely as possible on this format. However, some aspects of general psychiatry may not be transferable to the context of this study. For example, the acceptance scale includes an item asking whether participants would recommend a web-based intervention to a friend. For individuals convicted of a crime, shame and the need to hide the conviction from those close to them could be relevant aspects that might influence the answer to this item [60].

The fourth limitation is that the questionnaire was completed in the presence of the research staff. Therefore, the participants might have answered in a socially desirable manner, for example, to appear cooperative toward the study.

Future Directions and Clinical Implications
Future research should examine the predictive power of further variables that go beyond the UTAUT model. Variables that are possibly relevant are described in the previous section (eg, perceived reliability, antisocial personality disorder, and experience with web-based interventions). To increase acceptance, it should be tested whether acceptance-facilitating interventions, that highlight the positive aspects of using a web-based intervention (attitudes toward web-based interventions) and address reasons why the potential users assume that people close to them may not be in favor of them (SI) are especially effective. To that end, it should be investigated whether there are differences in acceptance depending on the characteristics of the potential users (eg, conviction type and the number of previous convictions). By doing that, acceptance-facilitating intervention could be tailored to the specific needs of the potential participants and may be more effective [31]. Further, research should look at the actual use of web-based interventions and test whether acceptance, as hypothesized by UTAUT, can predict factors like satisfaction or need fulfillment [61] and the actual use of a web-based intervention.

Conclusions
This study is the first to analyze the acceptance of web-based intervention in individuals who committed sexual offenses against children. In this study the acceptance levels of the majority of participants were high. The perceived opinion of the social contacts, as well as, the attitudes toward web-based interventions, that highlight the positive aspects of using a web-based intervention (attitudes toward web-based interventions) and who are presently in community supervision and thus how generalizable the results of this study are.

Acknowledgments
This study was funded by the German Federal Ministry of Education and Research (Bundesministerium für Bildung und Forschung, 01KR1807A). The funder has not, and will not, participate in the study design, data collection, management, analysis, and interpretation of data, or writing of reports. They do not have the authority over the decision to submit reports for publication or the conclusions herein. The publication was created as part of the @myTabu research-consortium. We acknowledge support by the Open Access Publication Funds of the Göttingen University. We thank Bruno Siegel, for his help in data collection. He was not compensated for his contributions beyond his established salary. Further, we thank all Departments of Justice, community supervisors, and participants for their contribution to this research project.

Data Availability
The data sets analyzed during this study are not publicly available due to their high sensitivity (eg, conviction of sexual abuse of children), the lack of possibility for complete anonymization, and the fact that the @myTabu clinical trial is ongoing but are available from the corresponding author on reasonable request.

Authors' Contributions
CB, JLM, and PF contributed to the conceptualization of the clinical trial the data are derived from. SS, CB, LN, JLM, and PF contributed to the methodology of the clinical trial. PF coded the web-based interventions within the clinical trial. SS initiated and conceptualized this study, conducted the statistical analyses, interpreted the data, and wrote the first draft of the paper. SS and LN performed the data collection. CB supported the statistical analyses. CB, JLM, and PF contributed to the data interpretation of this study. CB, LN, JLM, and PF critically revised the initial paper. All authors approved the final paper.

Abstract

Background: Despite an increase in hospital-based deliveries, neonatal mortality remains high in low-resource settings. Due to limited laboratory diagnostics, there is significant reliance on clinical findings to inform diagnoses. Accurate, evidence-based identification and management of neonatal conditions could improve outcomes by standardizing care. This could be achieved through digital clinical decision support (CDS) tools. Neotree is a digital, quality improvement platform that incorporates CDS, aiming to improve neonatal care in low-resource health care facilities. Before this study, first-phase CDS development included developing and implementing neonatal resuscitation algorithms, creating initial versions of CDS to address a range of neonatal conditions, and a Delphi study to review key algorithms.

Objective: This second-phase study aims to codevelop and implement neonatal digital CDS algorithms in Malawi and Zimbabwe.

Methods: Overall, 11 diagnosis-specific web-based workshops with Zimbabwean, Malawian, and UK neonatal experts were conducted (August 2021 to April 2022) encompassing the following: (1) review of available evidence, (2) review of country-specific guidelines (Essential Medicines List and Standard Treatment Guidelines for Zimbabwe and Care of the Infant and Newborn, Malawi), and (3) identification of uncertainties within the literature for future studies. After agreement of clinical content, the algorithms were programmed into a test script, tested with the respective hospital’s health care professionals (HCPs), and refined according to their feedback. Once finalized, the algorithms were programmed into the Neotree software and implemented at the tertiary-level implementation sites: Sally Mugabe Central Hospital in Zimbabwe and Kamuzu Central Hospital in Malawi, in
December 2021 and May 2022, respectively. In Zimbabwe, usability was evaluated through 2 usability workshops and usability questionnaires: Post-Study System Usability Questionnaire (PSSUQ) and System Usability Scale (SUS).

**Results:** Overall, 11 evidence-based diagnostic and management algorithms were tailored to local resource availability. These refined algorithms were then integrated into Neotree. Where national management guidelines differed, country-specific guidelines were created. In total, 9 HCPs attended the usability workshops and completed the SUS, among whom 8 (89%) completed the PSSUQ. Both usability scores (SUS mean score 75.8 out of 100 [higher score is better]; PSSUQ overall score 2.28 out of 7 [lower score is better]) demonstrated high usability of the CDS function but highlighted issues around technical complexity, which continue to be addressed iteratively.

**Conclusions:** This study describes the successful development and implementation of the only known neonatal CDS system, incorporated within a bedside data capture system with the ability to deliver up-to-date management guidelines, tailored to local resource availability. This study highlighted the importance of collaborative participatory design. Further implementation evaluation is planned to guide and inform the development of health system and program strategies to support newborn HCPs, with the ultimate goal of reducing preventable neonatal morbidity and mortality in low-resource settings.

**Introduction**

**Background**

In 2021, overall, 2.3 million children died in their first month of life, and the proportion of deaths below the age of 5 years attributed to neonates has risen from 40% in 1990 to 47% in 2021 [1]. The main causes of neonatal death include intrapartum-related complications and prematurity. Accurate, evidence-based identification and management of neonatal conditions could improve outcomes by standardizing care. It has been demonstrated in the literature that poor-quality care delivered by undertrained and overstretched health care professionals (HCPs) in low-resource settings can be attributed to approximately 60% of deaths from treatable conditions [2].

Clinical decision support (CDS) tools aim to standardize the assessment process and provide evidence-based guidance at the bedside, improving HCPs’ knowledge and competence. Previous studies have demonstrated that, owing to limited laboratory diagnostic capabilities, within these low-resource settings, there is significant reliance on clinical findings to make a diagnosis [2-4]. The implementation of diagnostic pathways could improve outcomes for this vulnerable neonatal population [4]. In addition, the development of management pathways adaptable and modifiable to resource availability is paramount [3]. There is potential for digital CDS tools to support HCPs to deliver improved neonatal care despite resource limitations and hence optimize outcomes.

The use of decision support tools has been well established and supported in health systems globally [6]. In this digital age, mobile phone coverage and digital uptake in low-resource settings has surged. Together with the low-dose, high-frequency education strategies [7,8] to improve newborn care, digital interventions appear to present a promising approach to improving newborn care [9,10].

Digital CDS tools are designed to aid directly in clinical decision-making and can use individualized patient data to guide management to implement evidence-based clinical guidelines at the bedside [11]. Paper-based guidelines are established resources, but these often get lost, are placed on shelves, and become easily outdated and therefore redundant. The systematic review of CDS systems by Kawamoto et al [12] identified four features for improved clinical practice:

1. Automatic provision of decision support as part of clinician workflow
2. Provision of recommendations rather than just assessments
3. Provision of decision support at the time and location of decision-making
4. Computer-based decision support

To date, most digital tools have implemented CDS as stand-alone tools to provide additional support to clinicians [9,13]. Consequently, the use of these tools can be limited as their use is voluntary and assumes clinician readiness and preparedness to adopt digital tools for which they may not have preexisting training or knowledge [14]. There is a growing evidence base for newborn digital interventions in low-resource settings ranging from patient level (NeMo tool trialed in Uganda, designed to support mothers in identifying newborns who are sick [15]) to system level (such as the World Health Organization standards-based, machine-readable, adaptive, requirements-based, and testable guidelines) for systematic pathways for the development and implementation of localized digital systems [16]. Digital interventions have the potential to both improve neonatal quality of care in low-resource settings and, in turn, improve neonatal outcomes, but there is a growing need for these interventions to be rigorously evaluated and to move from pilot or small-scale projects to scale [17]. Key elements to optimize the generalizability and scalability of such interventions are the vital importance of software sharing and the ability to have the intervention open source, which offers lower costs; greater transparency; faster iterations; and importantly, for the low-resource setting, local ownership in comparison with proprietary and, often siloed, digital interventions.
Neotree

Neotree was developed as an integrated, open-source, digital, quality improvement system for hospital-based sick and vulnerable newborns [18-20]. The evidence suggests that up to 70% of newborn deaths could be prevented by the implementation of evidence-based interventions [21]. The system guides HCPs through the admission and clinical care of newborns. It combines evidence-based clinical guidelines with real-time newborn data collection, data visualization, data export, and newborn education on a single platform [22]. This tablet-based digital system is for use at the hospital bedside by HCPs with a range of skills and competencies supporting the care and treatment of newborns. It is currently implemented in the neonatal units at Sally Mugabe Central Hospital (SMCH) and Chinhoyi Provincial Hospital in Zimbabwe and at Kamuzu Central Hospital (KCH) in Malawi. SMCH’s neonatal unit is a physician-led unit with mainly junior physicians (1-2 years after graduating) using Neotree and providing neonatal care, with consultant oversight; Chinhoyi Provincial Hospital and KCH are both nurse-led or midwife-led units with consultant oversight. Neotree offers a solution that integrates directly into everyday care for all admitted newborns. Crucially, the CDS functionality is not dependent on nurses or clinicians having any specialist knowledge about the care of the newborn. This integration and development process is consistent with the suggestions by Kawamoto et al [12]. An overview of the development and implementation experience so far can be found elsewhere [18,22]. To date, Neotree has aided in the care of approximately 35,000 newborns and the education and training of >1000 HCPs at the implementation sites in Malawi and Zimbabwe and has demonstrated high acceptability, feasibility, and usability with perceived and observed improvements in newborn care [18,22].

The CDS Function Development

The aim of the CDS function was to ultimately provide a personalized, integrated, evidence-based management plan (with embedded educational messaging around newborn care), tailored to the health care facility’s workflow and resource availability. In addition, a list of potential clinical problems was provided to facilitate pattern recognition and for education purposes. Evidence-based algorithms were preceded into Neotree management guidelines for the programmed conditions. Therefore, the entered data instantaneously provide a list of potential clinical problems and associated clinical management actions at the bedside.

The algorithms fell into four categories:

1. **Simple condition-based decision trees based on good evidence** (eg, prematurity or low birth weight or resuscitation)
2. **Simple conditional expressions based on weak evidence** and best clinical judgment (eg, jaundice)—these require additional refinement with evidence review and clinical consensus
3. **Complex conditional expressions based on good evidence** (eg, Thompson score for neonatal encephalopathy)
4. **Complex conditional expressions with weak evidence base** (eg, sepsis)—these require analytical refinement of the algorithm and testing

Phase 1

First-phase CDS development in Zomba Central Hospital, Malawi, included developing and implementing neonatal resuscitation and stabilization algorithms, conducting a Delphi study to review key algorithms (neonatal sepsis, hypoxic ischemic encephalopathy, respiratory distress of the newborn, and hypothermia) [23], and developing the initial versions of CDS to address a range of neonatal conditions [20]. The resuscitation and stabilization algorithms were configured in 2016 based on the World Health Organization guidelines and Helping Babies Breathe and have been activated throughout implementation, so that, for example, if a baby is not breathing, Neotree will advise how to resuscitate [20]. Clinical management support pages were also configured for several potential diagnoses. These appeared in Neotree at the end of the admission process according to the HCPs’ chosen diagnosis and included hypoxic ischemic encephalopathy or birth asphyxia, prematurity, neonatal sepsis, gastrochisis, and transient tachypnoea of the newborn. The development of these clinical management support pages continued through 2018 and 2019. Neotree uses a web-based editor function using “variable expressions” to describe the condition, which is coding depicted by a “$” and brackets (“”). The paper by Khan et al [22] describing the software development of Neotree describes the web editor function in detail; an example can be found in Multimedia Appendix 1.

Evaluating solutions such as CDS is important for both improvement and assessment of the effectiveness of the app [24]. For Neotree, evaluation and user feedback has been collected in three distinct ways: (1) on an ongoing basis, (2) during usability workshops, and (3) through questionnaire evaluation [20,25].

Phase 2

This study aimed to conduct the second phase of the algorithm development. In addition, we aimed to understand the user experience of the CDS functionality. As integrating such tools in routine care is not part of standard practice, we hoped to understand the strengths and weaknesses of these solutions and how we can optimize the implementation of such solutions in the future.

**Methods**

**Overview**

The second phase of CDS development was to integrate the clinical data entered during admission to trigger evidence-based diagnostic algorithms alongside personalized management guidelines, tailored to health care facility’s resource availability. On the basis of the clinical data entered by the HCP using Neotree, nested algorithms would determine whether a diagnosis should be triggered and, if so, would provide a suggested diagnosis, as shown in Figure 1.
First, it allows the HCPs to select their own diagnoses from a list of differentials. It then provides all the algorithmic diagnoses generated from clinical data (but not selected by the HCP) as “suggested diagnoses.” Phase-2 development of the CDS algorithms was planned in 3 stages (Figure 2).

**Figure 1.** Overview of the clinical decision support (CDS) pipeline in Neotree. HCP: health care professional.
Stage 1

To develop the algorithms required to implement CDS, a team of subject matter experts was formed and comprised of neonatal clinicians based in Zimbabwe, Malawi, and the United Kingdom. The experts were selected based on their extensive experience in and knowledge about delivering newborn care within the settings and the limitations within their environment and context; the UK-based experts had both neonatal experience and detailed knowledge about the Neotree system. Importantly, the Zimbabwean and Malawian experts had detailed knowledge of resource and equipment availability within each setting, which ensured the development of actionable management guidance. Web-based workshops were conducted to discuss each clinical diagnosis. All clinical problems and potential diagnoses were described clearly under the following headings:

1. **Measurement** (how and when)
2. **Categorization** (with reference to evidence)
3. **Variable expression** (how the diagnosis is or will be coded within Neotree)
4. **Clinical management advice** (with reference to evidence)
5. **Needs for further refinement** (next steps required)

The algorithm triggers were clearly defined and agreed upon, and subsequent clinical management was based on local, national, and international clinical guidelines and adapted based on local resource availability. Textbox 1 shows an example of the discussions, and “$” denotes the variable being described. The national guidelines used were the *Essential Medicines List and Standard Treatment Guidelines for Zimbabwe* [26] and *Care of the Infant and Newborn, Malawi*.

Mock clinical test cases were created by the expert team and were used for active testing in Neotree to ensure that the algorithms were triggered in the correct circumstances and were intuitive to use, leading to further refinement. This testing was performed by Neotree team members and then a cohort of HCPs who had been trained and used Neotree in their everyday clinical practice.

</tr>
</tbody>
</table>

Stage 2
Following the finalization of the individual algorithm pathways, the CDS functionality was deployed in 2 cycles (December 2021 and May 2022). The first cycle included the first set of clinical diagnoses (update to resuscitation and stabilization, thermoregulation, convulsions, low birth weight, prematurity, hypoglycemia, HIV, and respiratory distress), and the second cycle comprised clinical diagnoses that required more extensive review and definition by the expert team (neonatal encephalopathy; sepsis; jaundice; and congenital abnormalities, which include cleft lip or palate, congenital dislocation of the hip, talipes, gastrochisis, omphalocele, and spina bifida). These were to be deployed only in the 2 central hospitals (SMCH in Zimbabwe and KCH in Malawi), as both centers have senior neonatal clinical oversight.

Stage 3
Usability evaluation was planned to include usability workshops and usability questionnaires.

The usability workshops were conducted to understand the user experience and to provide specific information about the steps and items that require improvement in CDS design and development. The workshops were conducted using a think-aloud approach [27]. The HCPs, familiar with Neotree, were provided with a specific medical scenario (designed by the expert team) and asked to complete a Neotree admission in real time. These workshops were conducted in a nonneonatal environment to allow users to focus on their experience and understanding of the app instead of having to focus on neonatal clinical care. The provided scenario simulated a typical admission. Interviews were conducted by the interviewer in English (the clinical working language of both Zimbabwe and Malawi). The interview was recorded and later transcribed by the interviewer. While the user thought out loud and provided feedback about the app, the interviewer took short notes to prompt further questioning, especially about the CDS functionality.

Usability questionnaires such as the System Usability Scale (SUS) and the Post-Study System Usability Questionnaire (PSSUQ) provide additional quantifiable insights and metrics into the user experience of CDS [28]. PSSUQ assesses 3 categories: system usefulness, information quality, and interface quality. These 3 domains cover 16 questions, rated on a Likert scale ranging from 1 (strongly agree) to 7 (strongly disagree). Participants could also indicate if the question was not applicable to them. The SUS is a 10-item Likert scale questionnaire with options ranging from 1 (strongly agree) to 5 (strongly disagree). The SUS score was compared with an internationally recognized measure of acceptable usability of 68 out of 100. Both survey questionnaires were chosen because of their popularity in assessing mobile health solutions in low-resource settings. For the quantitative measurements (SUS and PSSUQ), means and SDs were calculated using Stata (version 17.1).

Ethical Considerations
The Neotree study, including the wider implementation evaluation of Neotree and the CDS functionality development, received approval from SMCH Research ethics committee (reference HCHEC070618/SS), University College London ethics committee (5019/004), Biomedical Research and Training Institute (AP148/18), Medical Research Council of Zimbabwe (MRCZ/A/2570), and Electronic Health Records Department of the Zimbabwe Ministry of Health and Child Care. The collection of qualitative data from HCPs using Neotree to assess the usability of all functionalities was also approved. Written informed consent was obtained from all usability evaluation participants, and their results were deidentified and stored anonymously. Attendance at the workshops was compensated through reimbursement of travel costs and refreshments. Participants were reimbursed US $10 for their time and travel costs as per the Zimbabwean Medical Research Council policy.
Results

Algorithm Development

Overall, 11 diagnosis-specific web-based workshops with Zimbabwean and Malawian neonatal experts were conducted between August 2021 and April 2022, encompassing the following:

1. Review of available evidence
2. Review of country-specific guidelines (Essential Medicines List and Standard Treatment Guidelines for Zimbabwe and Care of the Infant and Newborn for Malawi)
3. Identification of uncertainties within the literature for future studies

Table 1 shows the diagnoses discussed and the phase they were introduced in.

Detailed discussions and clinical triggers, documented in the A to E format (discussed previously), alongside the country-specific management plans and the coding used for Neotree can be found in Multimedia Appendix 2 [23,26,29-35]. Where national management guidelines differed, for example, birth weight thresholds for admissions to the neonatal unit, country-specific guidelines were created. Management guidelines were created based on resource and equipment availability in each setting. These international meetings also facilitated cross-site learning and quality improvement discussions. The clinical content and Neotree algorithm coding for each developed algorithm can be found in Multimedia Appendix 2.

The first-cycle algorithms developed, including low birth weight, convulsions, and hypoglycemia, had internationally defined descriptions and management guidelines, with minimal variation between nationally agreed management pathways. These diagnoses were relatively straightforward to discuss among the experts and gain unanimous agreement on the clinical content. The more complex diagnoses proved to be more challenging and required multiple meetings with the experts to be clearly defined. As a result, neonatal encephalopathy and neonatal sepsis were assigned to ongoing international working groups for continuing research. The respiratory distress algorithm was split into term (defined as ≥37 weeks of gestation) respiratory distress and preterm (defined as <37 weeks of gestation) respiratory distress, and we identified the need for a more formal review of the literature within the global health context.

After agreement of clinical content, the algorithms were programmed into a test script, tested with the respective hospital’s HCPs, and refined according to their feedback. Figure 3 shows how the algorithm-derived diagnoses are presented within Neotree.
Figure 3. Algorithm-derived diagnosis page in Neotree. HCP: health care professional.

Usability Workshop Results

Overview

In total, 2 workshops were conducted in both Zimbabwe and Malawi after the release of each CDS—in January 2022 and in June 2022. An example of the recorded feedback is shown in Figure 4. In Zimbabwe, the workshops were attended by 5 HCPs—2 (40%) female participants and 3 (60%) male participants. In Malawi, the workshops were attended by 4 HCPs—3 (75%) female participants and 1 (25%) male participant, and feedback was recorded.

From the usability workshops that were conducted, three main themes emerged, two of which related directly to CDS, and the last one related to the Neotree tablet:

1. Education
2. Streamlining of processes
3. Technical challenges

Figure 4. Excerpt of records from a usability workshop conducted after the release of the second set of clinical decision support, in May 2022. EDLIZ: Essential Medicines List and Standard Treatment Guidelines for Zimbabwe. SRMO: senior resident medical officer.

Education

The main theme prevailing across interviews was the positive feedback toward the availability of information and clinical guidance provided through Neotree and CDS. As most of the clinicians using Neotree are junior physicians, especially at SMCH, they have limited experience in the management of neonates:

This might seem obvious but on your first day it is not. [Participant 2]

Streamlining of Processes

HCPs highlighted that CDS in Neotree was found to streamline and systematize clinical diagnosis and management at the hospital, resulting in better and more effective care. This was done by implementing diagnostic algorithms that provide
data-driven results and by providing management for the clinical diagnoses that are based on the most up-to-date guidelines. By providing the management pages for each diagnosis (and a repertoire of all management pages) in a centralized location, Neotree provides streamlined care for newborns as clinicians do not resort to a multitude of different resources that may not agree in management:

*These are the nevirapine doses? You have outdone yourself. I like this very much because we learn about HIV guidelines but sometimes you just forget so this is nice.* [Participant 5]

Despite the ability of Neotree to provide data capture, CDS, and clinical management, this proved to extend the admission process. Clinicians highlighted the duration of admission completion to be a problem, especially in an already overstretched and understaffed hospital:

*Sometimes when you’re on call you don’t have time to go through it.* [Participant 2]

*Takes a lot of time when you have 6 babies screaming.* [Participant 4]

*Admitting a patient really does take 15-20 minutes.* [Participant 1]

### Technical Challenges

During the workshops, the tablets had issues with general degradation as they had just reached 3 years of use in the hospitals. These challenges resulted in the app crashing or not reacting to user input. The users, however, did not show frustration and mentioned that because it happens in the ward, they have grown used to it and have adapted to the challenges. Despite the clinicians adapting to these issues, this is severely affecting their experience of using the tablets and CDS, which may provide explanation for the relatively low scores in the SUS and PSSUQ questionnaires with respect to technical capability:

*Can we have better tablets.* [Participant 2]

*Just delete the ones that clicked themselves here.* [Participant 4]

*I guess I’ll wait for it.* [Participant 4]

### Usability Questionnaire Results

In this study, usability of the Neotree CDS was also assessed using the PSSUQ (8/9, 89%) and SUS (9/9, 100%) questionnaire at SMCH.

The same group of HCPs was asked to complete 2 questionnaires (SUS and PSSUQ). One person failed to complete the PSSUQ due to time constraints on the neonatal ward. The SUS results are shown in Table 2, and the PSSUQ results are shown in Table 3. SUS showed generally high usability of the CDS system in Neotree, especially relating to aspects such as desire to use the system (questions 1, 7, and 9) and ease of use (questions 3 and 7). In contrast, the CDS system scored low on questions relating to technical complexity and difficulties (questions 2, 4, 6, 8, and 10).

The PSSUQ showed results similar to those of the SUS, where the technical complexities of the system (question 8) was highlighted as an issue.

Overall, both usability scores (SUS mean score 73.8 out of 100 [higher score is better]; PSSUQ overall score 2.28 out of 7 [lower score is better]) demonstrated high usability of the CDS function (comparable with previous SUS scores assessing the usability of Neotree data capture and dashboard functionalities in Malawi [mean score 88.1 out of 100] [25]) but highlighted issues around technical complexity, which have been subsequently addressed.

Discussion

Principal Findings

This study describes the successful development and pilot implementation of the only known neonatal CDS system incorporated within a bedside data capture system with the ability to deliver up-to-date management guidelines, tailored to local resource availability. Bucher et al [9], Mitchell et al [36], and Long et al [17], as examples, describe CDS digital tools generally designed for the pediatric population, not specifically neonatal, and without incorporated digital data capture. To date and to the best of the authors knowledge, there is no other neonatal digital intervention designed to improve neonatal care using these methods. As a significant proportion of the global mortality below the age of 5 years is attributed to neonatal deaths in low-resource settings, the development of sustainable interventions targeting this vulnerable group are vital. The incorporated real-time usability evaluation demonstrated high usability from HCPs actively using Neotree in their everyday practice, within 2 low-resource settings—Zimbabwe and Malawi. The adaptability of the Neotree system allowed for real-time changes to the app to improve the processing times and algorithm function. This enabled changing the surfacing format of the algorithm-selected diagnoses to improve the usability of the CDS function.

It has been well documented in the literature that improving adherence to evidence-based clinical guidelines can improve the quality of care and, in turn, patient outcomes. However, this has been challenging to effectively implement, particularly in low-resource settings [37,38]. A multifaceted approach is required, and a system with the ability to adapt is therefore essential, both to resource availability and guideline updates. With the plethora of digital health interventions implemented in low-resource settings, centralizing information for HCPs instead of relying on memory, wall charts, or printed guidelines has been demonstrated to improve adherence [36]. The target product profile developed by Pelle et al [37], for electronic CDS algorithms in low-resource settings, sets out specific guidance about the development of such interventions. The algorithms need to be based on evidenced clinical guidelines and be customizable to the context. This has been heavily incorporated into the design and methodology of the development of the Neotree CDS functionality.

Comparison can be made with studies within the pediatric population. Several studies have reviewed the feasibility of the implementation of electronic, user-friendly Integrated Management of Childhood Illness tools, for example, in both Tanzania and South Africa [36,39]. In the Tanzanian setting, adherence to guidelines was demonstrated to improve the use of electronic versus paper-based systems [36]. In comparison, the South African study demonstrated the challenges with technical issues and workload implications [39]. Technical challenges and workload implications were also highlighted in the usability workshops for Neotree; however, despite these challenges, the system scored well on the usability questionnaires. The HCPs stated that they had adapted to these challenges.

Detailed understanding of the context and setting within which the digital intervention has been implemented is an essential component for sustainability. Many of the comments from the
interviewed HCPs described the understaffed, demanding, and poorly resourced environment they work within, which has been described in the literature and is common across many health institutions in low-resource settings [40]. Understanding this context and the complexities of adding a digital intervention, such as power failures within degrading infrastructures or additional workload, is key in successful implementation [17]. Alongside this aspect is the importance of collaborative participatory design. Many health care interventions have been developed from the high income–setting perspective with minimal attention to the real-life adaptation within low-resource health care settings. Collaborative participatory design and research can help to close the gap between research, policy, and practice [41]. The contextual reality that many low-resource settings face with frequent crises or shocks, such as economic crises, natural disasters, or health crises, inevitably has an impact on how well the interventions are implemented. Damschroder et al [42] have stated that “Many intervention studies have been found to be effective in health services research but fail to translate into meaningful patient care outcomes across multiple contexts.” The Neotree algorithm workshops including Zimbabwean and Malawian experts demonstrated the key importance of these international relationships for the CDS algorithms to be usable within their intended context. The customizability of the CDS algorithms to resource availability and the perceived streamlining of processes from diagnosis to management increased the usability of Neotree by incorporating the detailed knowledge about the working environment.

Limitations
The introduction of the algorithms had a perceived impact on the duration of the admission process. In an already overburdened neonatal unit, the increased time of use could have implications on both its acceptability and use. However, the time-use analysis and cost analysis (paper in progress) by Haghparast-Bidgoli et al [43] found that admission times were similar when comparing Neotree with paper-based systems. Implementation in low-resource settings is always going to be influenced by the environment and context it is used in. In Zimbabwe, a degrading health care system [40] poses challenges to any digital tool to be implemented in this setting. The usability questionnaires were only performed in SMCH in Zimbabwe. As SMCH is a predominantly physician-led unit, comparative Malawian and Zimbabwean CDS functionality qualitative data are needed to ensure that usability evaluation across all HCP cadres is reviewed; more comprehensive usability data are required and therefore planned to be collected.

Next Steps
Further usability evaluation is planned 1 year after implementation as part of the wider sustainability program of Neotree. This will again include the usability workshops and questionnaires with real-world observation, similar to previous usability testing of the data capture functionality. Approvals from the Pediatric Associations of Zimbabwe and Malawi are pending. The assigned international working groups for continuing research are ongoing. The Neonatal Sepsis Working Group is currently in the process of an in-depth review of neonatal sepsis guideline use within low-resource settings [44], conducting a scoping review [45], and developing a robust clinical prediction model with integrated machine learning technology to be implemented within Neotree. The Neonatal Encephalopathy Working Group published their study of risk factors for mortality [46], is evaluating the use of the Thompson score and its applicability in the low-resource setting, and is developing a neurodevelopmental follow-up pathway to be implemented in Zimbabwe and Malawi. Ongoing studies from the respiratory distress workshop include an in-depth scoping review of the literature about clinical features and risk factors for neonatal respiratory distress in low-resource settings to be incorporated into the respiratory distress algorithm and evaluation of the uptake of the TRY (T: Tone is good, R: Respiratory distress, and Y: Yes) continuous positive airway pressure algorithm [47] and associated outcomes in Malawi. A similar project is underway for neonatal jaundice. A mixed methods, large-scale evaluation of impact on neonatal quality of care and survival is planned. A key gap within the Neotree system is the potential to link with point-of-care diagnostic technology that is low cost, suitable and adaptable to the low-resource setting; early discussions have been made with potential collaborators.

Conclusions
This study describes the successful development and implementation of the only known neonatal CDS system incorporated within a bedside data capture system with the ability to deliver up-to-date management guidelines, tailored to local resource availability. The methods used in this study highlighted the importance of collaborative participatory design and South to South learning. Real-world usability testing could further enhance effective implementation. Detailed understanding of the context and setting within which the digital intervention has been implemented is an essential component for sustainability. Effective, motivated local and international partnerships are key to the success of CDS integration into routine practice. Further review of newborn CDS functionality impact and implementation evaluation is planned to guide and inform the development of health system and program strategies to support HCPs, who are overstretched and underresourced, with the ultimate goal of reducing preventable neonatal morbidity and mortality in low-resource settings.

Abstract

Background: Atopic dermatitis (AD) is a chronic skin condition that millions of people around the world live with each day. Performing research into identifying the causes and treatment for this disease has great potential to provide benefits for these individuals. However, AD clinical trial recruitment is not a trivial task due to the variance in diagnostic precision and phenotypic definitions leveraged by different clinicians, as well as the time spent finding, recruiting, and enrolling patients by clinicians to become study participants. Thus, there is a need for automatic and effective patient phenotyping for cohort recruitment.

Objective: This study aims to present an approach for identifying patients whose electronic health records suggest that they may have AD.

Methods: We created a vectorized representation of each patient and trained various supervised machine learning methods to classify when a patient has AD. Each patient is represented by a vector of either probabilities or binary values, where each value indicates whether they meet a different criteria for AD diagnosis.

Results: The most accurate AD classifier performed with a class-balanced accuracy of 0.8036, a precision of 0.8400, and a recall of 0.7500 when using XGBoost (Extreme Gradient Boosting).

Conclusions: Creating an automated approach for identifying patient cohorts has the potential to accelerate, standardize, and automate the process of patient recruitment for AD studies; therefore, reducing clinician burden and informing the discovery of better treatment options for AD.

Introduction

Background

Atopic dermatitis (AD) is a common skin disease with a population prevalence of approximately 30% [1]. It is often diagnosed in early childhood, but onset can occur at any age [2-5]. Symptoms of AD include inflamed, red, irritated, and itchy skin and can cause significant physical and emotional distress. AD is often associated with other allergic illnesses, including asthma, seasonal allergies, and food allergies [2,3,5-7]. AD is thought to be associated with skin barrier dysfunction and immune dysregulation [5]. AD has also been associated with genetic variation as well as environmental factors [5]. Classic treatment for AD has included the use of moisturizers, topical steroids, and other topical anti-inflammatory agents [8]. However, in the past few years, there have been significant
treatment advances, which include systemic agents that alter immune function, such as dupilumab. Therefore, due to the widespread nature of AD, the need for improved knowledge of the natural history of AD, the need to understand the efficacy of new treatments, and the need to develop new treatments, there is an urgent need to understand the clinical course of individuals with AD. However, identifying appropriate cohorts of patients for medical studies can be difficult and time-consuming. Because AD is so common as well as being diagnosed and managed by many different clinicians in varying health care settings, a potential source population would be patients from a health system’s electronic health records (EHRs) [9]. Investigators often ascertain a patient’s illness using International Classification of Disease (ICD) hospital billing codes as recorded during routine office visits. However, it has been previously demonstrated that reliance on ICD codes is not an accurate method for the ascertainment of study cohorts with AD [9,10]. Furthermore, epidemiologic studies have used different methods and algorithms, including the UK Working Party (UKWP) diagnostic criteria and the Hanifin and Rajka (HR) criteria [11,12]. Investigators attempting to conduct clinical trials and observational studies have also relied on manual, large-scale chart review, a process that is inefficient, slow, and tedious [9]. This motivates the need for a standard method to accurately, automatically, and efficiently identify potential patient cohorts from their text medical records by using natural language processing (NLP) and machine learning (ML) techniques.

Previous Work

Previously, researchers aimed to phenotype patients with AD using EHR data. In particular, Gustafson et al [10] trained a logistic regression model with lasso regularization to identify cases of AD from the Northwestern Medical Enterprise Data Warehouse, which contained both structured data (ICD Ninth and Tenth Revision codes, medication prescriptions, and laboratory results) as well as unstructured data (clinician notes from patient encounters). A gold standard diagnosis was assigned to each patient in their data set by 2 rheumatologists following a chart review when using the UKWP criteria and (alternatively) when using the HR criteria.

Although similar, this study differs in the following ways: (1) we survey a wide range of supervised ML algorithms as opposed to only using lasso regularized logistic regression, (2) we use transformer embeddings of sentences to represent information in each patient’s records and aggregate these embeddings with multilayer perceptron (MLP) networks to create a patient vector representation for patient phenotyping, and (3) we performed an ablation study of processing methods to compare the impact on performance in using a probability-based versus binary label of whether each patient meets various AD diagnostic criteria when creating a vector to represent each patient for input to our final patient phenotyping algorithms.

Contributions

The primary contributions of this study are as follows:

- We introduce and validate a rules-based approach for aggregating information from patient EHR data to generate binary-valued patient vectors that are used with standard ML algorithms for patient phenotyping.
- We introduce and validate a transformer-based approach for aggregating information and patient phenotyping by using “Bidirectional Encoder Representations from Transformers” (BERT) models (ie, BERT Base Uncased and BioClinical BERT) to generate patient vectors of probabilities, which are used with standard ML algorithms for patient phenotyping.
- We compare the aforementioned approaches to (1) discern whether a transformer model pretrained on clinical text can provide performance benefits over a transformer model not pretrained on clinical text, and (2) discern whether a transformer-based approach for aggregating information could outperform a rules-based approach for aggregating information.
- We demonstrate that MLP networks can be used with BERT sentence embeddings to identify which sentences in patient records are relevant to the diagnosis of AD. These MLP networks can then be used during clinician chart review to highlight sentences that are relevant to diagnosis and therefore accelerate the process of chart review during clinical trial recruitment.

Methods

Overview

To predict whether a patient may qualify as a participant for an AD study based on their EHR, we first assigned patients in our data set to either the training or testing sets. Then, for each patient, we aggregated the text from their EHR and constructed a vector representation of clinical features indicative of AD according to the UKWP criteria. Lastly, we leveraged our vectorized patient representations to train several ML classifiers to predict whether each patient has AD. In the following sections, we detail this process.

Data Set Creation

We initially sampled 2000 patients and their clinical records from Epic Clarity, Penn Medicine’s EHR database. We selected Penn Medicine patients who were diagnosed with a subset of AD-related ICD codes [9]. As shown in Figure 1, of the 2000 sampled patients, we identified 1926 patients who had clinical notes for processing. We then deidentified these patient records according to the Safe Harbor method using the “Protected Health Information filter” (Philter) [13]. Each patient in the data set was also manually reviewed and labeled according to the UKWP diagnostic criteria for AD. According to the UKWP criteria, in order to qualify as having AD, a patient must have an itchy skin condition along with 3 or more of the following: a history of flexural involvement, a history of asthma or hay fever, a history of dry skin, an onset of rash when aged 2 years or younger, or a visible flexural dermatitis. Our data set was validated by 2 clinicians (a board-certified dermatologist [DM] and a medical fellow [RF]), resulting in 137 patients with AD and 1789 patients without AD.
Training and Testing Split

We first created our training set. Due to the heavy class imbalance in our data set, we decided to create a balanced training set to prevent biasing the model toward either patients with AD or patients without AD. In particular, we created the training set by assigning 80% (109/137) of the 137 patients with AD to our training set and undersampling the patients without AD to match the number of patients with AD. The remaining 20% (28/137) of the 137 patients were assigned to both of our testing sets. This resulted in a training set that had 109 patients with AD and 109 patients without AD.

Next, we created 2 testing sets. The first testing set was class-balanced and was intended to show how our patient classification model can generalize to unseen samples if the class distribution is kept the same. The second testing set was class-imbalanced (28/91, 30% of patients with AD and 63/91, 70% of patients without AD) and was intended to show how our patient classification model can perform when the class-distribution of the data set matches the prevalence of AD in the United States.

We chose not to create a separate hyperparameter tuning set and instead applied cross-validation for hyperparameter tuning on the training set due to the data-scarce setting of our experiments.

Vector Representation for AD Classification

Next, we created a vector representation for each patient. We performed 3 experiments to compare different methods of creating each patient’s vector representation (Figure 2).

![Figure 2](https://formative.jmir.org/2024/1/e52200)

**Figure 2.** Atopic dermatitis (AD) phenotyping pipeline across all 3 experiments. BERT: Bidirectional Encoder Representations from Transformers; MLP: multilayer perceptron.
Description of Patient Vector Representation

Each patient’s vector representation is 8 elements long, where each element of the vector is representative of whether the patient fulfills a different AD diagnosis criteria based on the UKWP criteria as well as clinician feedback (Table 1). Across all 3 experiments, each element in the patient vector corresponds to a distinct classification task; however, in experiments 1 and 2, each element is a probability, and in experiment 3, each element is a binary value.

In experiments 1 and 2, elements 1-8 of each patient’s vector represent the highest probability that any sentence in the patient’s EHR mentions (1) AD or synonyms of AD, (2) keywords that suggest hay fever allergies, (3) keywords that suggest atopic allergies, (4) keywords that suggest eczema or rashes, (5) keywords that indicate dry or itchy skin, (6) keywords denoting nonasthma medications, (7) keywords suggesting the presence of asthma, and (8) keywords indicating the use of asthma medications.

In experiment 3, instead of each element representing a probability, each element represents a binary value of whether there was at least 1 sentence in the corresponding patient record suggesting the presence of the corresponding AD indicator.

In the first 2 experiments, each patient’s vector elements represent probabilities (ranging from 0 to 1). Each probability value is derived from a distinct MLP classifier. Experiments 1 and 2 were performed to compare the use of 2 BERT models (BERT Base Uncased [14,15] in experiment 1 and BioClinical BERT [16,17] in experiment 2) for creating sentence embeddings used to train MLP networks (or alternatively, sentence classifiers). A separate MLP network is trained for each element of the patient vector. Each MLP network is trained to distinguish sentences in 1 of the 8 AD indicator categories from sentences in all other categories. Furthermore, medSpacy (Eyre et al [18]) was used to split documents into sentences and label each sentence with different categories. After each sentence classifier is trained, embeddings of all sentences in each patient’s full EHR are passed through each sentence classifier, and an aggregation function (max operator) is used to assign a value to each element of each patient’s vector. Our goal in experiments 1 and 2 was to test the hypothesis that a BERT model pretrained on clinical text (BioClinical BERT) could outperform a BERT model trained on nonclinical text (BERT Base Uncased).

In experiment 3, each patient’s vector elements are binary (either 0 or 1). Each element corresponds to a diagnostic criterion and represents whether medSpacy was able to identify at least 1 sentence in the patient’s record with a keyword and affirming context that suggests the patient meets the corresponding diagnostic criteria. Our goal was to conduct an ablation study to test the hypothesis that an AD phenotyping classifier leveraging BERT embeddings to create the patient vector representation will better discern whether a patient has AD than an AD Phenotyping Classifier without BERT embeddings.

Preprocessing for Experiments 1-3

Before each experiment, we applied the same preprocessing steps to assign 1 or more labels to each sentence in our corpus of documents in both our training and testing sets. Each sentence can be labeled as applying to 1, multiple, or none of the 8 AD indicators previously defined.

For each of the 8 diagnostic criteria, we first created a list of keywords and phrases (for each vector element) that suggested the presence of the corresponding diagnostic criteria. Next, we used medSpacy with the ConText (Harkema et al [20]) algorithm to split each document into sentences and categorize each sentence [18]. Using medSpacy allows us to obtain sentences that suggest the presence of each of the 8 diagnostic criteria due to medSpacy’s use of regex and rules-based keyword matching. Furthermore, medSpacy’s implementation of the ConText algorithm allows us to discern between sentences that affirm from negated assertions. We define negated sentences for each AD indicator as sentences where the indicator is ruled out, sentences where the indicator is experienced by someone other than the patient, and sentences where the existence of the indicator is hypothetical [19-22].

After assigning 1 or more categorical labels to each sentence with medSpacy, we then performed 3 different experiments to create a vectorized representation of each patient.

In Tables 2 and 3, we include some statistics on the data set obtained after preprocessing.
As shown in Table 2, patients with AD have approximately twice as many sentences as patients without AD. The average number of documents and sentences is the same (within patients with AD and similarly within patients without AD) between BERT Base Uncased and BioClinical BERT experiments because these values are only dependent on medSpacy’s preprocessing of documents. Furthermore, using BioClinical BERT to tokenize sentences tends to yield more tokens (on average) per patient and per document. We hypothesize this is because the BioClinical BERT tokenizer is able to recognize more clinical terms and therefore yields more tokens for the same sentence than using the tokenizer from BERT Base Uncased.

aBERT: Bidirectional Encoder Representations from Transformers.

As shown in Table 3, sentences in category 5 (relating to dry or itchy skin) tend to have the most tokens, whereas sentences in category 6 (relating to the use of non-asthma medications related to treating AD) tend to have the least number of tokens. We hypothesize that this is because categories where the average number of tokens per sentence is greater tend to correspond to more general categories where many terms and sentences could apply, whereas categories where the average number of tokens per sentence is lower tend to correspond to more specific categories, thus yielding a lower average number of tokens per sentence. Additionally, similarly to before, we can see that using BioClinical BERT tends to result in a greater number of tokens per sentence than using BERT Base Uncased for the same sentence.

aBERT: Bidirectional Encoder Representations from Transformers.

**Experiments 1 and 2: Patient Vector Construction With BERT Embeddings**

In experiments 1 and 2, we first used the sentences medSpacy identified in each category to create class-balanced training and testing sets for each MLP network classifier, as shown in Table 4. The same training and testing set was used for both experiment 1 (BioClinical BERT) and experiment 2 (BERT Base Uncased).

Next, we used pretrained BERT models to generate embeddings of the sentences in each classifier’s training and testing set. We incorporated pretrained BERT models because these models have been trained on a much larger corpus than our existing data set, and BERT provides a context-sensitive embedding of text that other techniques, such as bag of words, do not provide. Furthermore, we used BERT Base Uncased in experiment 1 and Alsentzer et al’s [16] BioClinical BERT in experiment 2 because we wanted to quantify how much of a difference in performance using a model pretrained on clinical text can provide over a model that has not been pretrained on clinical text.

Using these embeddings, we trained a MLP network to distinguish sentence embeddings in each category from sentence embeddings that are not in the corresponding category. Each of our MLPs was trained with the following architecture: a fully connected input layer of shape $768 \times 100$, followed by a Rectified Linear Unit (ReLU) activation, further followed by a fully connected output layer of shape $100 \times 2$. We trained each...
of our MLPs for 10 epochs with the cross-entropy loss function, the stochastic gradient descent (SGD) optimizer, a learning rate of 0.001, and a momentum value of 0.9. The final layer of each MLP can then be used to obtain the probability that any given sentence embedding comes from the category for which the MLP is being trained by passing the logits of the final layer to the softmax function.

We used the ReLU activation function as defined below, where $x$ is the input to the ReLU function:

$$f(x) = \max(0, x)$$

We also used the softmax function as defined below, where $e$ is the standard exponential function and $s_i$ is element at index $i$ of the $K$ element long input vector.

$$\text{softmax}(x) = \frac{e^{x_i}}{\sum_{j=1}^{K} e^{x_j}}$$

We chose to embed our sentences once with pretrained BERT models and then feed these saved embeddings to our MLP networks as opposed to adding a classification head (a linear layer) to the end of our pretrained BERT models. Although doing so only allows us to fine-tune the weights in our MLP network (as opposed to also fine-tuning the weights BERT uses to embed the sentences), doing so allows us to iterate over different experiments more quickly and with less computational power. In particular, we are able to (1) avoid the large computational expense of gradient calculations during backpropagation for all 12 layers of transformers used by BERT when fine-tuning the model, (2) avoid the computational expense of repeatedly generating the same embeddings from BERT multiple times (if we choose to freeze the weights of BERT and only fine-tune an added classification head or linear layer), and (3) iterate more efficiently over different hyperparameter combinations across different experiments with our MLP networks.

After training a separate MLP network for each of the 8 categories, we generated a vector representation for each patient, where each of the 8 vector elements represents the highest probability that any given sentence in the patient record affirms the presence of the corresponding AD indicator (Figure 3). We accomplished this by iterating through all sentences in each patient’s full EHR and passing the sentence embedding through each of our 8 trained MLP networks to obtain 8 probabilities for each sentence corresponding to the probability that the sentence affirms each of the 8 AD indicators we previously selected. Then, for each patient and for each AD indicator, we kept the highest probability that any given sentence in the patient’s record affirms the presence of the AD indicator.

Figure 3. Patient vector representations of atopic dermatitis indicators in experiments 1 and 2. BERT: Bidirectional Encoder Representations from Transformers; MLP: multilayer perceptron.

Experiment 3: Patient Vector Construction Without BERT Embeddings

In experiment 3, we generated each patient’s vector representation by assigning a 1 to each element of the patient vector if medSpacy with the ConText algorithm identified at least 1 sentence in the patient’s record that affirms or suggests the presence of the AD indicator for which the vector element corresponds (Figure 4). Experiment 3 was conducted as an
ablation study to quantify the performance benefit (if at all) of using contextual BERT text embeddings to generate probability scores that the patient meets various AD indicators.

**AD Phenotyping With Vector Representations**

In all 3 experiments, after generating a vector representation for each patient, we collated each patient’s vector representation with the corresponding label our clinicians assigned the patient when validating the data set. Then, we fed the vector patient representation corresponding patient label through a variety of classification algorithms. These include logistic regression, support vector machines (SVM), decision trees, random forests, k-nearest neighbor (KNN), Extreme Gradient Boosting (XGBoost), and Adaptive Boosting (AdaBoost). During training for each of the previously mentioned classifiers, we used 5-fold cross validation to determine the best set of hyperparameters to use (as opposed to creating a separate validation set) due to the data-scarce setting of our experiments. We then used the selected hyperparameters to train each algorithm on the entire training set and evaluated performance on the unbalanced and balanced testing sets. In addition to using the previously mentioned classifiers, we also used the stacking algorithm provided by scikit-learn to obtain an ensemble prediction from the different classifiers [23]. To quantify performance, we calculated the accuracy, precision, recall, $F_1$-score, negative predictive value (NPV), and specificity of each algorithm on both testing sets.

We define accuracy, precision, and recall as follows, where TP is the number of true positives, TN is the number of true negatives, FP is the number of false positives, and FN is the number of false negatives:

$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$

$\text{Precision} = \frac{TP}{TP + FP}$

$\text{Recall} = \frac{TP}{TP + FN}$

$F_1 = \frac{2 \cdot \text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}}$

$NPV = \frac{TN}{TN + FN}$

$\text{Specificity} = \frac{TN}{TN + FP}$

Additionally, we define the $F_1$-score, NPV, and specificity as follows:

**Ethical Considerations**

This research protocol was reviewed and approved by the University of Pennsylvania Institute Review Board and determined to be exempt (IRB#843922).

**Results**

**Performance of MLP Networks**

In this section, we compare the performance of several MLP classifiers in distinguishing sentences relevant to the diagnosis of AD. This corresponds to the “Train separate MLP network (sentence classifier) for each of 8 AD indicators” box in Figure 2.

As part of our AD phenotyping pipeline, we trained various MLP networks to classify when a given sentence embedding indicates the presence of an AD indicator, and we compared the performance of BioClinical BERT embeddings to BERT Base Uncased embeddings when training these MLP networks. In both cases, the classifier with the highest accuracy was the classifier for category 1 (sentences with direct mentions of AD). The classifiers with the 2 lowest accuracies were either the classifier for category 5 (sentences with mentions of dry or itchy skin) or the classifier for category 7 (sentences with mentions of asthma) for both the use of BioClinical BERT embeddings and the use of BERT Base Uncased embeddings. However, the accuracy in classifier 7 was lower when using BERT Base Uncased embeddings than when using BioClinical BERT embeddings.

In experiment 1, the accuracies across AD indicator classifiers ranged from 0.7373 (classifier 5) to 0.9002 (classifier 1), as shown in Table 5.

In experiment 2, the accuracies across AD indicator classifiers ranged from 0.7269 (classifier 7) to 0.9153 (classifier 1), as shown in Table 6.
AD Phenotyping With Patient Vector Representations

In this section, we compare performance in patient classification when using different methods for creating patient vector representations. This encompasses all 3 experiments and corresponds to the “Use vector patient representations to classify whether patient has AD” box in Figure 2.

In experiment 1, we leveraged BioClinical BERT sentence embeddings to train various MLP networks to discern sentence embeddings in different AD indicator categories. Then, we applied these trained MLP networks (sentence classifiers) along with an aggregation function (max operator) to assign values to each element of each patient’s vector representation. Lastly, we used each patient’s vector representation with their validated label to train various ML algorithms. We evaluated these on both a balanced and unbalanced testing set.

As shown in Table 7, the accuracy on the balanced testing set ranges from 0.5893 (decision tree) to 0.7321 (logistic regression and SVM).

As shown in Table 8, the range of accuracies on the unbalanced testing set is slightly lower, ranging from 0.5824 (decision tree) to 0.7253 (stacking classifier).

In experiment 2, we followed the same process as in experiment 1; however, we used BERT Base Uncased instead of BioClinical BERT. As shown in Table 9, the accuracy of our AD classifiers on the balanced testing set ranges from 0.5179 (AdaBoost) to 0.6250 (random forest).

As shown in Table 10, the range of accuracies of our AD classifiers on the unbalanced testing set is slightly higher, ranging from 0.5714 (logistic regression and SVM) to 0.6703 (random forest).

In experiment 3, we performed an ablation study and assigned binary labels to the elements of each patient’s vector based on whether medSpacy was able to identify at least 1 sentence in each of the AD indicator categories that each vector element corresponds to. As shown in Table 11, the accuracy across our AD classifiers on the balanced testing set ranges from 0.6964 (KNN) to 0.8036 (XGBoost).

As shown in Table 12, the lower bound of the range ofaccuracies across our AD classifiers on the unbalanced testing set is higher, and the upper bound of the accuracies is lower. The accuracies on the unbalanced testing set range from 0.7143 (Stacking Classifier) to 0.7582 (Random Forest and Stacking Classifier).

Discussion

Sentence Classification Results

We hypothesized that using BioClinical BERT sentence embeddings to train sentence classifiers would provide better performance than using BERT Base Uncased sentence embeddings due to the clinical setting of our data. Given the results in Tables 5 and 6, we observed that this was most often true in the context of sentence classification because we were able to achieve better performance in the majority (5 out of 8) of the sentence classification tasks when using BioClinical BERT embeddings as opposed to BERT Base Uncased embeddings.

Using BioClinical BERT sentence embeddings yielded stronger performance when distinguishing sentences in 5 of the 8 sentence categories: category 2 (mentions of hay fever allergies), category 3 (mentions of atopic allergies), category 5 (mentions of dry or itchy skin), category 6 (mentions of nonasthma medications), and category 7 (mentions of asthma). More specifically, we observed higher accuracies when using BioClinical BERT sentence embeddings for classifiers 2 (0.8954), 3 (0.8214), 5 (0.7373), 6 (0.8204), and 7 (0.7712) than their corresponding counterparts when using BERT Base Uncased embeddings for classifiers 2 (0.7730), 3 (0.7976), 5 (0.7288), 6 (0.8096), and 7 (0.7269). We observed that the differences in performance between using BioClinical BERT embeddings and BERT Base Uncased embeddings are most pronounced for classifiers 2 and 7, which correspond to mentions of hay fever allergies and asthma mentions, respectively. We hypothesize this is because hay fever allergies and asthma (and their synonyms) may be very common terms in clinical notes; therefore, models trained on clinical data (BioClinical BERT) may be able to provide stronger
performance than models trained on nonclinical text (BERT Base Uncased), which may not have as many mentions of hay fever allergies or asthma.

Conversely, using BERT Base Uncased embeddings yielded stronger performance when distinguishing sentences in the other 3 of 8 sentence categories: category 1 (direct mentions of AD), category 4 (mentions of eczema or rashes), and category 8 (mentions of asthma medications). More specifically, we observed higher accuracies when using BERT Base Uncased sentence embeddings for classifiers 1 (0.9153), 4 (0.8439), and 8 (0.8738) than their corresponding counterparts when using BioClinical BERT embeddings for classifiers 1 (0.9002), 4 (0.8284), and 8 (0.8299). We observed differences in performance between using BERT Base Uncased embeddings and BioClinical BERT embeddings, which are most evident for classifier 8, which corresponds to mentions of asthma medications. Although this is counterintuitive at first (we would expect a classifier using embeddings generated from BioClinical BERT to be able to better recognize allergy medicines), we believe that the performance benefit from using BERT Base Uncased can be attributed to the list of terms we gave to medSpacy when asking it to identify sentences in category 8. Many of the asthma medications in category 8 sentences are either monoclonal antibody medications ending in -mab (benralizumab, mepolizumab, omalizumab, etc) or hydrofluoroalkanes (hfa; atrovent hfa, flovent hfa, xopenex hfa, etc). Because monoclonal antibodies are very specialized types of medication, they may not occur as frequently as other terms in the corpus used to train BioClinical BERT, so a more general model such as BERT Base Uncased may provide more robust performance. Additionally, because the hydrofluoroalkane allergy medications in category 8 sentences are often abbreviated with “hfa,” which can have alternate medical meanings such as high-functioning autism or health facility administrator, the BioClinical BERT embeddings might not be representative of the presence of allergy medications in the sentence, so a more general model such as BERT Base Uncased may be able to provide better performance.

More broadly, looking at the results in Tables 5 and 6, we can see that the least accurate classifier has an accuracy of 0.7288, while the most accurate classifier is able to achieve an accuracy of 0.9153. Furthermore, when aggregating the most accurate classifiers from both tables we can see that we are able to achieve accuracies of 0.9153 (classifier 1) for identifying sentences that directly suggest the patient has AD, 0.8954 (classifier 2) for identifying sentences that mention hay fever allergies, 0.8214 (classifier 3) for identifying sentences that mention atopic allergies, 0.8439 (classifier 4) for identifying sentences that mention eczema or skin rashes, 0.7373 (classifier 5) for identifying sentences that mention dry or itchy skin, 0.8204 (classifier 6) for identifying sentences that mention nonasthma medications related to diagnosis of AD, 0.7712 (classifier 7) for identifying sentences that mention asthma, and 0.8738 (classifier 8) for identifying sentences that mention asthma medications. Because our training and testing sets were both class-balanced and the majority (6 of the 8) of the most accurate classifiers previously mentioned achieved accuracies between 0.8204 and 0.9153, we believe these results are promising and indicate that our sentence classifiers could potentially be used to save time in a clinical setting during chart review by identifying (and highlighting for review) sentences relevant to the diagnosis of AD when recruiting for clinical trials.

### AD Phenotyping Results

As per Tables 7-10, our earlier hypothesis holds: using clinical embeddings (BioClinical BERT) to generate the patient vector representation does provide better performance in patient phenotyping than using nonclinical embeddings (BERT Base Uncased). Comparing evaluations on the balanced testing set in Tables 7 and 9, we observe that using BioClinical BERT embeddings provides higher accuracy in almost all models, with the exception of Decision Trees where BERT Base Uncased provides better performance (accuracy of 0.6071) as compared with BioClinical BERT (accuracy of 0.5893). Comparing evaluations on the unbalanced testing set in Tables 8 and 10, we observed that the same trend follows: using BioClinical BERT embeddings provides higher accuracy in almost all models, with the exception of Decision Trees and XGBoost, where using BERT Base Uncased embeddings provides better performance (accuracy of 0.6484 for Decision Trees and 0.6374 for XGBoost) as compared with their counterparts with BioClinical BERT embeddings (accuracy of 0.5824 for Decision Trees and 0.6264 for XGBoost).

As part of our experimental design, we included an ablation study in experiment 3 so we could compare the difference in performance during patient phenotyping when removing the use of BERT models to create each patient’s vector representations. On the class-balanced testing set, we observed that accuracies range from 0.6071 to 0.7321 when using BioClinical BERT embeddings in Table 7, accuracies range from 0.5179 to 0.6250 when using BERT Base Uncased embeddings in Table 9, and accuracies range from 0.6964 to 0.8036 when removing the use of BERT models in Table 11 (experiment 3). On the unbalanced testing set, we observed that accuracies range from 0.5824 to 0.7253 when using BioClinical BERT embeddings in Table 8, accuracies range from 0.5714 to 0.6703 when using BERT Base Uncased embeddings in Table 7, and accuracies range from 0.7143 to 0.7582 when removing the use of BERT models in Table 12 (experiment 3).

In both cases (evaluation on the balanced testing set and evaluation on the unbalanced testing set), we found that models in experiment 3 (ablation study) generally outperform (or are as good as) their corresponding counterparts in experiments 1 and 2 (BERT experiments) across all metrics (accuracy, precision, recall, $F_1$-score, NPV, and specificity), with the exception that the stacking classifier in experiment 1 (BioClinical BERT) has marginally stronger accuracy and precision than the stacking classifier in experiment 3. This shows that traditional rules-based approaches (experiment 3) can outperform BERT-based approaches for generating a patient vector representation for downstream patient phenotyping.

We hypothesize that models in experiments 1 and 2 showed lower performance because errors from our sentence classifiers in earlier stages of the pipeline could have propagated to later stages of the pipeline during patient phenotyping. Because we
leveraged the max operator to aggregate probabilities that any given sentence in the patient record applies to each category, more sentences in each patient record would lead to a greater chance that an erroneous prediction with a high probability would lead to a false positive error in the creation of each patient’s vector representation in experiments 1 and 2.

Although there is a wide range in performance for our patients with AD phenotyping algorithms, we believe that we have reached our goal of developing a system capable of patient with AD phenotyping for clinical trial recruitment because Tables 11 and 12 show promising results. Furthermore, our system can be used as a first step during AD clinical trial recruitment to filter out most patients who may not qualify for AD trials and therefore save valuable clinician time. We believe our pipeline is important and valuable because, unlike other diseases, such as influenza, COVID-19, and cancer, there is no gold-standard test result that can be used to determine when a patient has AD. Instead, clinicians must spend large amounts of time undergoing chart reviews to individually determine whether each patient has AD.

**Limitations**

One limitation of this study was the small size of our data set. Although we had a total of 1926 patients in our data set, only 137 of them were validated as having AD. During training, we leveraged 109 of the 137 patients with AD and sampled another 109 patients without AD to create a class-balanced training set. The small size of the training set could lead to overfitting and therefore result in reduced performance on the testing set. Future work could involve obtaining more data from patients with AD as well as exploring the use of an imbalanced data set but using a class-weighted loss function to counteract the class imbalance.

A second limitation of this study was the input-limit size of the large language models that were used. Both BERT Base Uncased and BioClinical BERT had an input limit of 512 tokens. This meant that any input text that was longer than 512 tokens would be ignored when training BERT. Consequently, we could not simply directly concatenate all documents from each patient’s EHR and feed the tokenized documents of each patient into BERT with an added classification head for training as well as direct prediction of whether the patient has AD. Instead, we designed a pipeline around distilling information from all documents in each patient’s EHR into a patient vector representation and then using this patient vector representation to train various classical ML algorithms for phenotyping the patient. Future work could involve exploring the use of other large language models that are suited for long inputs, such as Longformer or Doc2Vec, for predicting when a patient should be labeled as having AD.

A third limitation of this study was the list of AD indicators we selected. We did not consider additional AD indicators, and we also did not consider the use of different combinations (or subsets) of the AD indicators selected. This is particularly relevant in considering that (1) our pipeline is intended to be used for identifying patients with AD, and (2) one of our AD indicators (category 1) directly targets whether there is any given sentence in the patient’s record that mentions AD, which could be in the context of a family history of AD, a potential (but not confirmed) diagnosis of AD, as well as a confirmed diagnosis of AD, among other possibilities. If this AD indicator is removed, then 1 interesting research question could be whether our pipeline is still able to maintain performance similarly to what it is currently able to achieve. Future work could involve assessing the performance impact of removing or adding the use of various AD indicators. We could then determine if our pipeline is relying too much on or overfitting 1 or more indicators. Furthermore, we could also redesign our patient vector and separate the feature for category 1 (any sentence that mentions AD) into 3 separate indicators: whether there is (1) a family history of AD, (2) an affirmed diagnosis that the patient has AD, and (3) uncertainty of whether the patient has AD. Doing so could potentially improve precision.

**Potential Applications**

Given the aforementioned results, we believe our AD classifier could be operationalized to facilitate reliable and efficient EHR chart review. For example, sentence classifiers could visually indicate AD indicators inline text, therefore reducing information foraging efforts by clinicians. Additionally, AD phenotyping classifiers could indicate the strength of a patient match to UKWP criteria, exact or partial, based on AD indicator sentence classifications. Furthermore, ranking patient cases by match strength could reduce the number of cases reviewed to generate both case and matched controls.

**Conclusions**

In conclusion, we present and validate a promising pipeline for phenotyping patients with AD during clinical trial recruitment. To do so, we compare a rules-based and transformer-based approach for creating a vector representation of each patient and compare downstream performance in patient phenotyping with various standard ML algorithms. We find that a traditional rules-based approach outperforms using a transformer-based approach (experiment 3). We hope that our pipeline can be deployed in hospital settings during clinical trial recruitment as an initial step to automatically filter candidates before manual review. Additionally, we show that MLP networks can identify whether sentences are relevant to AD diagnosis. These MLP networks can later be deployed in clinical settings to highlight which sentences are relevant for physicians during manual chart review, therefore reducing physician burden. Future work can involve extending our patient phenotyping pipeline to other data sets and other diseases.

**Acknowledgments**

This study was partially funded by the National Institutes of Health (NIH) and the National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS) P30-AR069589 as part of the Penn Skin Biology and Diseases Resource-Based Center (core: DJM and DM).
Authors’ Contributions
AW designed the experiments, performed the experiments, wrote the first draft of the manuscript, and revised the manuscript. DJM conceptualized and implemented the chart abstraction study, annotated the data set, interpreted the results, and revised the manuscript. RF annotated the data set and revised the manuscript. SH queried and deidentified the data set as well as revised the manuscript. DM conceptualized the study and experiment design, interpreted results, wrote and revised the manuscript, and provided secure storage and computer resources.

Conflicts of Interest
DJM is or recently has been a consultant for Pfizer, Leo, and Sanofi with respect to studies of atopic dermatitis and served on an advisory board for the National Eczema Association.

Abstract

Background: To date, most group-based diabetes self-management education (DSME) programs for type 2 diabetes (T2D) have been delivered in person. The rapid transition to remote care at the outset of the COVID-19 pandemic presented opportunities to test, evaluate, and iterate a new remote DSME program.

Objective: We aim to refine the delivery and evaluation of a multicomponent remote DSME program for adults living with T2D by examining several feasibility outcomes.

Methods: We recruited a convenience sample of patients from a London, Canada, outpatient diabetes clinic (serving high-risk, low-income adults) to participate in a 6-week, single cohort feasibility study from November 2020 to March 2021. This small ORBIT phase 1b feasibility study represents the first in a planned series guided by the ORBIT model for developing behavioral interventions for chronic diseases (phase 1: design; phase 2: preliminary testing; phase 3: efficacy; and phase 4: effectiveness). The feasibility of delivering and evaluating a remote DSME program, including (1) live video education classes, (2) individualized physical activity (PA) prescription and counseling, and (3) intermittently scanned continuous glucose and wearable PA monitoring, was assessed. Feasibility outcomes included recruitment and retention rates, program adherence, and acceptability (ie, technology issues and exit survey feedback). PA was assessed with Fitbit Inspire 2 (Fitbit Inc) and estimated glycated hemoglobin (HbA₁c) using the FreeStyle Libre (Abbot). Given the small study sample, group- and individual-level data are reported descriptively.

Results: A total of 10 adults living with T2D were recruited (female 60%; age 49.9, SD 14.3 years; estimated HbA₁c 6.2%, SD 0.5%). Recruitment and retention rates were 29% and 80%, respectively. Participants attended 83% (25/30) and 93% (37/40) of education classes and PA counseling phone calls, respectively. There were 3.2 (SD 2.6) technology issues reported per person, most of which were related to study data transfer. Exit survey responses suggest most participants (8/9, 89%) were “satisfied” with the program. Recognizing the small sample size and the fact that no inferential statistics were conducted, the mean (SD) for the weekly daily step count and estimated HbA₁c are provided for illustrative purposes. Participants accumulated 7103 (SD 2900) and 7515 (SD 3169) steps per day at baseline and week 6, respectively. The estimated HbA₁c was 6.2% (SD 0.5%) and 6.2% (SD 0.6%) at baseline and week 6, respectively.

Conclusions: This ORBIT phase 1b study served to refine the delivery (eg, automatic study data upload process recommended to reduce participant burden) and evaluation (eg, purposeful sampling of participants with baseline HbA₁c >8% recommended to address selection bias) of a remote DSME program. Preliminary proof-of-concept testing (ORBIT phase 2) incorporating some of these learnings is now warranted.

### Introduction

Chronic conditions such as type 2 diabetes (T2D) are best treated when the individual living with diabetes is engaged and supported in effective self-management [1,2]. Programs, such as diabetes self-management education (DSME), that promote successful T2D self-management behaviors can dramatically lower the risk of serious complications [2]. Group DSME programs promote sustained self-care [2]; however, in response to the COVID-19 pandemic, most group DSME programs were quickly transitioned to remote, one-on-one delivery [3]. To support this rapid transition, contemporary technologies were thrust into the forefront, including videoconferencing services (eg, WebEx and Cisco), intermittently scanned continuous glucose monitors (eg, FreeStyle Libre and Abbott’s Diabetes Care Division), and wearable activity trackers (eg, Fitbit) [3]. This preparatory study examined the feasibility of delivering and evaluating remote group DSME programming for adults with T2D in the COVID-19 era. This small cohort study, aligning with phase 1b of the ORBIT model for developing behavioral treatments for chronic diseases [4], is the first in a planned series aiming to systematically develop an efficacious remote group DSME program for broad rollout in Canada (the “LIBERATE” program [5]). The central goal of this work is to refine the delivery and evaluation of a remote group DSME program (the “treatment”) to promote efficiency while producing potentially relevant changes in behavioral (eg, physical activity [PA]) and clinical risk factors (eg, glycemic control) [4].

### Methods

#### Overview

A single-arm feasibility study (ORBIT phase 1b) was conducted between November 2020 and March 2021 in London, Ontario. Ontario COVID-19-related physical distancing policies were in place throughout the study period, with strict stay-at-home orders for 9 out of 16 weeks [6]. Despite well-documented pandemic-related recruitment challenges [7], we sought to recruit a convenience sample of 10 to 20 new patient intakes [8-12] from St Joseph’s Primary Care Diabetes Support Program, a London, Ontario outpatient clinic serving higher-risk, lower-income adults [13]. Prospective participants, physician-cleared to exercise and with access to a smartphone (ie, iPhone 7 iOS or higher or Android [operating system 5 or higher]), were invited to a study recruitment session by their physician during usual care.

#### Intervention

A 6-week remote group DSME program was delivered to participants between November 2020 and March 2021. A rolling intake was used, with participants completing the program over 6 consecutive weeks. The program included (1) live-video delivery (ie, WebEx) of biweekly group education classes by a multidisciplinary team (ie, physician, diabetes nurse educator, and exercise specialist) and grounded in Diabetes Canada’s Self-Management Education Guidelines [2]; (2) biweekly one-on-one PA counseling phone calls; and (3) enhanced self-monitoring using intermittently scanned continuous glucose (FreeStyle Libre; Abbot) and wrist-worn PA (Fitbit Inspire 2; Fitbit Inc) monitors. The Inspire 2 was selected as it was the most affordable Fitbit model, offering features required for the study (eg, daily step tracking and data exporting). Group education classes and PA counseling calls were designed to help participants learn from the biofeedback they were receiving (eg, draw important linkages between FreeStyle Libre-assessed glucose trends, diet, and PA behaviors) [14]. Fitbit data were used to generate individualized and adaptive daily step count goals [15] (ie, daily step count median from the past 14 days + 500 steps, equivalent to 5 more minutes of brisk walking [16]). The exercise specialist reviewed step goals with participants during biweekly PA counseling calls. Participants were instructed to submit Fitbit data (by downloading a Fitbit Excel file and uploading it to a secure file sharing website) and scan their FreeStyle Libre frequently.

#### Outcomes

The primary study objective was to refine the delivery and evaluation of the remote group DSME program in preparation for an ORBIT phase 2a study (preliminary testing: proof-of-concept). To do this, (1) recruitment and retention, (2) program adherence (ie, attendance, Fitbit data submission rates, and FreeStyle Libre data capture rates [active time]), and (3) acceptability (ie, number of technology issues reported and exit survey responses) data were collected. “Active time” is the mean biweekly percent of total glucose data captured by the FreeStyle Libre every 24 hours. To examine the potential impact of the program on behavioral and clinical risk factors, device-assessed (4) weekly mean daily step count and (5) estimated glycated hemoglobin (HbA1c; the average glucose level from the FreeStyle Libre readings for 14 or more days [17]) were collected.

#### Analysis

Given the small, single cohort and preparatory nature of this ORBIT phase 1b feasibility study, individual and group-level data are presented descriptively rather than with inferential statistics.

#### Ethical Considerations

This study was registered at ClinicalTrials.gov (NCT04498819) and approved by Western University’s Health Science Research Ethics Board (116071). Patients provided informed consent before participating. Deidentified study data were stored on Western University’s password-protected and encrypted OneDrive (Microsoft Corporation).
Results

Among 35 eligible new patient intakes, 10 were enrolled, meeting our a priori recruitment target (Table 1; 29% recruitment rate). Reasons for nonparticipation (n=5) included work-time conflict, a sick partner, being too busy, not wanting to wear the FreeStyle Libre, and feeling exercise and nutrition were well-managed. A total of 2 participants dropped out of the study (ie, participant 1 missed 2 consecutive biweekly group education classes, and participant 8 withdrew during week 5 citing lack of time). A total of 8 participants completed follow-up assessments (80% retention). Regarding program adherence, 83% (25/30) and 93% (37/40) of participants attended group education classes and one-on-one PA counseling phone calls, respectively. Additionally, 53% (16/30) of participants submitted Fitbit data, and the FreeStyle Libre captured 81% of blood glucose data during the intervention period (“Active time”). FreeStyle Libre use may have waned after week 4, as 4 out of 8 (50%) participants had their lowest data capture rates in weeks 5 and 6 (Table 2).

aIncluding coronary artery disease, heart failure, or arrhythmia.
Participants reported at least 1 technology issue, with 3.2 (SD 2.6) issues reported per person, including difficulties submitting Fitbit data (n=14), lost WebEx remote group education class link (n=6), FreeStyle Libre monitor falling off prematurely (n=7 of 32 sensors distributed in total), difficulty synchronizing Fitbit with participant smartphone (n=3), and losing a Fitbit altogether (n=2). Exit survey responses (Table S1 in Multimedia Appendix 1) suggested participants were satisfied with the program, with most (8/9, 89%) agreeing with the statement, “Overall, I was satisfied with the program.” Exit survey responses also indicated that combined biofeedback from FreeStyle Libre and Fitbit (4/9, 44%) was most helpful in optimizing self-management. Daily step counts for the total sample were 7103 (SD 2900) steps and 7515 (SD 3169) steps at baseline and week 6, respectively (Table 3). Lastly, estimated HbA1c was 6.2% (SD 0.5%) and 6.2% (SD 0.6%) at baseline and week 6, respectively (Table 2).

Discussion

Overview

The aim of this study was to refine the delivery and evaluation of a remote group DSME program in preparation for an ORBIT phase 2a study (preliminary testing: proof-of-concept). This DSME program showed promise, albeit with a small convenience sample, with most participants being satisfied with the program. Fitbit and FreeStyle Libre data capture was also high (>80% in both cases). Moreover, preliminary data suggest potential for behavioral risk factor (ie, PA) improvement over a short 6-week period. However, several opportunities to improve the protocol were identified (Table 4). These should be addressed before moving onto the ORBIT phase 2a study. For instance, reducing participant burden by offering automatic study data upload may increase evaluation and program efficiency. Additionally, purposefully sampling participants with higher baseline HbA\(_{1c}\) (ie, HbA\(_{1c}\) >8%) [18] may help address selection bias and the “floor effect” [19] in the future (eg, T2D was generally well-controlled among participants at baseline).

The findings should be considered in light of similar research. Our 29% recruitment rate, for example, was comparable to recruitment rates of 21% to 78% in similar studies [10,11,20-22]. Suboptimal recruitment rates could be attributed to (1) limited physician referrals to the study recruitment session, (2) additional participant stressors amid the COVID-19 pandemic (ie, employment insecurity), (3) seasonal effects (ie, colder winter months) [23], or (4) perceived study burden. Technology access and cost-related barriers did not appear to limit participation in this lower-income population [21]. High program adherence and study retention (>80%) suggest remote delivery of the DSME program was generally well-received in this small convenience sample, aligning with a modest but growing number of studies in this field (eg, remote group education class attendance in similar studies has ranged from 52% to 95%) [10,20].

This study is not without limitations. First, our sample was small, consisting of participants with well-controlled T2D (perhaps not representative of those who may benefit most from DSME). However, given the sample sizes of comparable studies [10,11,24] and the objectives of this preparatory work, we contend it is appropriate given the conclusions being drawn. Future recruitment rates may improve with the easing of COVID-19-related restrictions [25] and as we embark on year-round recruitment in the next study in this planned series. Second, this program was only 6 weeks long, providing little insight into sustained program adherence in a field where attrition is the norm [26]. Third, this program was resource-intensive (eg, required significant staff time). Scaling the program (ie, having monthly classes after the first 6 weeks) to reduce resource requirements for a longer program may be necessary. Lastly, discrete exit survey responses only provided so much insight (eg, compared to conducting focus groups [4,9]). Moving ahead to ORBIT phase 2a, focus groups will be conducted to gather deeper insights.
<table>
<thead>
<tr>
<th>Protocol</th>
<th>Areas for Improvement</th>
<th>Recommendations</th>
</tr>
</thead>
</table>
| Recruitment | • Low recruitment rate (29%), likely due to a low referral rate to study recruitment sessions by clinicians or the colder winter season  
• Potentially high participant burden | • Clearer recruitment instructions for clinicians  
• Recruit year-round for the ORBIT phase 2a trial  
• Streamline recruitment procedures (eg, in-person sign-up for study recruitment sessions, etc) |
| Sample | • Possible selection bias with generally well-controlled diabetes (baseline estimated $HbA_1c=6.2\%$) and technology as participation barriers  
• Both insulin and noninsulin users are included | • Purposeful sampling to include baseline estimated $HbA_1c>8\%$ and individuals who do not have ready smartphone access  
• Conduct subanalyses of insulin versus noninsulin users |
| Technology | • Issues (14 total) with study data submissions  
• Remote classes sound-related “feedback” issue  
• Early evidence of FreeStyle Libre attrition, with lower “active time” observed for some participants in Weeks 5 and 6 | • Provide the option to email or text a screenshot of the 2-week Fitbit step count summary or implement automatic data upload  
• Ensure class facilitators have “mute” capabilities  
• Create short booster sessions to encourage exploration of personal FreeStyle Libre data and shared experiences |
| Group class | • Limited group discussions leading to more didactic education  
• Difficulty “reading the room” when telephoning into remote classes  
• Rolling intake format | • Emphasize the importance of sharing and peer learning; provide 1-page content summaries to review before class; and provide assignments to reinforce learning  
• Encourage participation through a video platform with the camera on or off  
• Remove the rolling intake. Instead, have set start and end dates |
| Physical activity | • Daily step count prescriptions only. Participants had a choice on “how” to accumulate the steps  
• Cardiovascular fitness outcomes were not assessed  
• A daily step count of 500 steps or more was considered a full day worth of data (valid day) | • Offer a choice of time, type, and frequency of a preferred exercise (to compliment the daily step count goal); increase the frequency and automation of feedback  
• Use validated field test measures to assess cardiovascular fitness level changes (eg, a 6-minute walk test)  
• A “valid day” may include the time between the first and last daily step recorded |

$HbA_1c$: glycated hemoglobin; an estimation provided from 2 weeks or more of glucose data collected by the FreeStyle Libre.

*Active time is the mean percentage (%) of total glucose data captured in a 24-hour period every two weeks (the FreeStyle Libre requires at least 1 scan every 8 hours to collect the past 8 hours of data).*

**Conclusions**

This ORBIT phase 1b study has served to refine the delivery and evaluation of this remote DSME program. Proof-of-concept testing is warranted, with plans to progress to ORBIT model phases 3 (efficacy) and 4 (effectiveness). This may ultimately increase access to strong remote-group DSME programming in Canada.

**Acknowledgments**

The FreeStyle Libre devices were donated in-kind by Abbott’s Diabetes Care Division. The Fitbit Inspire 2 activity monitors were purchased through funding from the St Joseph’s Health Care Foundation Innovation Grants. The authors would like to thank Betty Harvey for her contribution to the conceptualization of this program and for providing invaluable feedback throughout the intervention’s development. We would also like to thank Amanda Mikalachki for her dedication to the ongoing development and her involvement in running the intervention. Finally, we would like to thank the study participants.

**Data Availability**

The data sets generated or analyzed during this study are available from the corresponding author upon reasonable request.

**Authors’ Contributions**

MSH, SMR, and MSM were involved in conceptualizing and designing the study. MSH led the intervention delivery, data collection, and data analysis. MSH and MSM were involved in data presentation and visualization. MSH wrote the manuscript with revisions and consultations from MSM and feedback from SMR. SMR led and supervised the intervention delivery on-site and provided guidance and direction on intervention rollout and adjustments to MSH. MSM supervised the project. All authors
provided critical feedback and helped shape the research, analysis, and manuscript. All authors approved the final version of the manuscript.

Conflicts of Interest

SMR has received an honorarium for attending advisory boards for Abbott’s Diabetes Care Division and has received an investigator-initiated grant from Abbott’s Diabetes Care Division to begin a clinical trial in 2022. She also holds the Dr Brian W Gilbert Chair in Primary Health Care Research at Western University. MSH and MSM have no competing interests.

Abstract

Background: Hypertension affects 1 in 5 Canadians and is the leading cause of morbidity and mortality globally. Hypertension control is declining due to multiple factors including lack of access to primary care. Consequently, patients with hypertension frequently visit the emergency department (ED) due to high blood pressure (BP). Telehealth for Emergency-Community Continuity of Care Connectivity via Home-Telemonitoring Blood Pressure is a pilot project that implements and evaluates a comprehensive home blood pressure telemonitoring (HBPT) and physician case management protocol designed as a postdischarge management strategy to support patients with asymptomatic elevated BP as they transition from the ED to home.

Objective: Our objective was to conduct a feasibility study of an HBPT program for patients with asymptomatic elevated BP discharged from the ED.

Methods: Patients discharged from an urban, tertiary care hospital ED with asymptomatic elevated BP were recruited in Vancouver, British Columbia, Canada, and provided with HBPT technology for 3 months of monitoring post discharge and referred to specialist hypertension clinics. Participants monitored their BP twice in the morning and evenings and tele-transmitted readings via Bluetooth Sensor each day using an app. A monitoring clinician received these data and monitored the patient’s condition daily and adjusted antihypertensive medications. Feasibility outcomes included eligibility, recruitment, adherence to monitoring, and retention rates. Secondary outcomes included proportion of those who were defined as having hypertension post-ED visits, changes in mean BP, overall BP control, medication adherence, changes to antihypertensive medications, quality of life, and end user experience at 3 months.

Results: A total of 46 multiethnic patients (mean age 63, SD 17 years, 69%, n=32 women) found to have severe hypertension (mean 191, SD 23/mean 100, SD 14 mm Hg) in the ED were recruited, initiated on HBPT with hypertension specialist physician referral and followed up for 3 months. Eligibility and recruitment rates were 40% (56/139) and 88% (49/56), respectively. The proportion of participants that completed ≥80% of home BP measurements at 1 and 3 months were 67% (31/46) and 41% (19/46), respectively. The proportion of individuals who achieved home systolic BP and diastolic BP control at 3 months was 71.4% (30/42) and 85.7% (36/42) respectively. Mean home systolic and diastolic BP improved by −13/−5 mm Hg after initiation of HBPT to the end of the study. Patients were prescribed 1 additional antihypertensive medication. No differences in medication adherence from enrollment to 3 months were noted. Most patients (76%, 25/33) were highly satisfied with the HBPT program and 76% (25/33) found digital health tools easy to use.
Conclusions: HBPT intervention is a feasible postdischarge management strategy and can be beneficial in supporting patients with asymptomatic elevated BP from the ED. A randomized trial is underway to evaluate the efficacy of this intervention on BP control.

Introduction

Hypertension is the leading cause of death and disability worldwide [1,2]. Long-term poor control of blood pressure (BP) can result in significant cardiovascular (CV) morbidity and mortality [3]. Severely asymptomatic elevated BP in the emergency department (ED) has recently been associated with undiagnosed hypertension and adverse CV outcomes [4,5], regardless of the initial reason (eg, pain or anxiety) for the ED visit [6]. In a meta-analysis of 12 studies (n=1240) of individuals with elevated BP in ED, 43.4% were diagnosed with hypertension at follow-up [7]. Among individuals discharged from ED with elevated BP, two-thirds still had uncontrolled BP at 6 months [8].

Hypertension is one of the few chronic conditions that can be monitored online, with home blood pressure telemonitoring (HBPT), which allows tele-transmission of BP in real time to central health portal, eliminating the need for in-person BP visits between patients and health care providers. Importantly, close monitoring of BP and data can be summarized by patients and providers, including calculating of BP averages, graphing temporal BP, and flagging high or low values [9,10]. This is particularly important for patients with asymptomatic elevated BP presenting to and discharged from the ED. Current ED guidelines recommends no routine ED management and outpatient follow-up without suggesting any additional monitoring or intervention with a few exceptions [11,12]. As these patients transition from acute to community settings, their BP can remain dangerously elevated or lowered with initiation of antihypertensive medications. Hypertension telemedicine studies have been shown to be highly feasible, effective, and acceptable to patients [13-17]. Although a promising intervention, to date, no studies have leveraged HBPT as a postdischarge management strategy for patients discharged from the ED with asymptomatic elevated BP.

Telehealth for Emergency-Community Continuity of Care Connectivity via Home-Telemonitoring Blood Pressure (TEC4Home-BP) is a pilot study to evaluate the feasibility of HBPT and physician case management as an integrated component of health delivery to support patients with asymptomatic elevated BP discharged from the ED to home. The primary objective of this pilot study is to report the feasibility of HBPT as a postdischarge management strategy and the secondary objective is to determine acceptability of this initiative. We hypothesize that the study procedures would be feasible and acceptable to patients.

Methods

Recruitment Procedures

The feasibility pilot study was an unblinded trial. Participants were prospectively recruited from 1 large academic urban ED in Vancouver, British Columbia, Canada, from May to December 2021. We included adults (older than 19 years of age) who presented to the ED with asymptomatic elevated BP confirmed at ED triage and average of 3 subsequent measurements performed in the ED (systolic blood pressure [SBP] ≥ 160 mm Hg or diastolic blood pressure [DBP] ≥ 100 mm Hg), who owned or had daily access to a smartphone, and agreeable to follow-up at the Vancouver General Hospital (VGH) Hypertension Clinic and tele-transmit home BP readings via the Sphygmo app. Individuals with 1 of the following conditions were excluded, patients with hypertensive emergencies with evidence of end organ involvement, stroke or acute coronary syndrome, people who are pregnant, acute intoxication, acute surgical or trauma, patients who are psychiatrically unstable, advanced cognitive impairment, patients requiring admission to hospital, inability to use or care for home BP monitor correctly, from long-term care facility, unstable housing, and are non–English-speaking with no family members who can help translate. Participants were recruited through 2 recruitment pathways. Potential participants were first identified via referrals from hospital ED staff and were screened by a research assistant in hospital ED (recruitment pathway 1). ED staffs were asked to refer the study team any patients presenting to the ED with suspected hypertension, patients whose BP was above SBP ≥ 160 mm Hg or DBP ≥ 100 mm Hg and in stable condition. Once the research assistant was notified of the patient referrals, the research assistant reviewed their medical records and excluded any patients who met exclusion criteria from screening. Only patients who appear to meet all inclusion criteria and remain potentially eligible were approached for further screening and have subsequent BP readings measured to confirm their eligibility. During the recruitment, the study team expanded referral streams to include patients with asymptomatic elevated BP who were referred to the VGH Hypertension Clinic following discharge from the ED to increase recruitment numbers due to limits on research activities in the ED during the COVID-19 pandemic (recruitment pathway 2). Physicians at the Hypertension Clinic screened all incoming referrals based on inclusion and exclusion criteria, and selected eligible patients for further contact. Eligible patients were contacted either in ED, immediately after discharge, or once the referral to...
Hypertension Clinic was received. Participants completed the consent process and were enrolled within 7 days from ED discharge.

**Ethical Considerations**

Ethics approval was obtained from the University of British Columbia Research Ethics Board (#H20-03207). The written informed consent was obtained from all participants. All data collected from the participants are de-identified and remain anonymous. A privacy impact assessment was completed to ensure the telemonitoring application is compliant with all University of British Columbia and Vancouver Coastal Health privacy policies. Participants were allowed to keep the BP telemonitor device at the end of the monitoring period as a gift for participating in the study.

**HBPT and Hypertension Clinic Intervention**

All patients were provided with a validated electronic upper arm oscillometric BP telemonitor device (A&D Ltd UA-641BLE) with wireless data transfer (Bluetooth) capabilities using a smartphone [18,19]. The research assistant assisted the patients to set up the Sphygmo app on their smartphones, and connected the BP telemonitor device to their smartphones via Bluetooth. Patients were then taught to follow the on-screen instructions in the app to complete and submit their BP readings, properly measure their BP, and view their current and previous BP readings. They were instructed to perform home BP monitoring schedules recommended by Hypertension Canada and International Society of Hypertension Virtual Management of hypertension guidelines, consisting of duplicate measurements in the morning and evening for 7 consecutive days [20,21]. For each 7-day HBPT series, the first day’s measurements were discarded and the mean of subsequent measurements calculated and used to guide medication titration. Home BP readings were transmitted and telemonitored via Sphygmo app on a smartphone, which is PIPEDA (Personal Information Protection and Electronic Documents Act)-, PIPA (Personal Information Protection Act)-, and HIPAA (Health Insurance Portability and Accountability Act)-compliant, with encryption on both ends and a medical server based in Ontario, Canada. Tele-transmitted home BP readings were monitored daily by a monitoring clinician, who would contact participants by telephone if BP was uncontrolled (SBP ≥ 180, DBP ≥ 100 mm Hg or SBP ≤ 100 mm Hg) according to BP management algorithm (Multimedia Appendix 1). Urgency of hypertension clinic follow-up was dependent on severity of telemonitored home BP readings post-ED discharge (Multimedia Appendix 1).

Patients were seen at the VGH Hypertension Clinic either in person or phone assessment. Physicians assessed patients using standardized hypertension intake forms, administered behavioral counseling, encouraged medication adherence, reviewed telemonitored BP summaries, adjusted BP medications accordingly, and arranged clinical follow-up as needed based on Hypertension Canada guidelines [20]. At minimum, patients were seen at the time of enrollment for initial consultation, and at 1 and 3 months for follow-up. Target home BP values were defined by Hypertension Canada of <135/85 mm Hg or <130/80 mm Hg for those with diabetes [20]. At the end of the study, a summary of participant’s home BP readings were sent to their primary care provider.

**Data Collection and Outcomes**

**Overview**

Baseline data including sociodemographic, ethnicity, education level, health behaviors, and relevant medical history were collected. Antihypertensive medication history was reconciled and number of antihypertensive medications, class of antihypertensive medications, and hypertensive defined daily dose (HDDD) were recorded according to patient self-report at enrollment and at 3 months (Multimedia Appendix 2). HDDD quantitatively describes the intensity of a patient’s overall antihypertensive medication regimen [22]. Medication adherences were assessed using the validated Hill Bone Medication Adherence Scale (HB-MAS) at the time of enrollment and at 3 months [23]. Health-related quality of life (QoL) was assessed using EQ-5D-5L at the end of the study [24]. Satisfaction surveys were sent to participants for completion at the end of 3 months via REDCap (Research Electronic Data Capture; Vanderbilt University; Multimedia Appendix 3). A total of 3 reminder emails were sent to participants to complete the surveys.

Feasibility outcomes were eligibility, recruitment, retention rate, and adherence rate. Eligibility rate was defined as proportion of participants who were deemed eligible to participate among all the patients that were screened. Recruitment rate was defined as the proportion of participants who are deemed eligible and who consented to participate in the study. Retention rate was defined as the proportion of the participants that completed 1 week of HBPT and attended first Hypertension Clinic visit. Home monitoring adherence was defined as the percentage of participants that completed 80% of HBPT at 1- and 3-month follow-up visits.

Secondary outcomes included the proportion of the participants meeting the definition of hypertension at 3 months (defined as mean home SBP ≥ 135 mm Hg or DBP ≥ 85 mm Hg or antihypertensive prescription), mean change in HBPM from enrollment to 1- and 3-month follow-ups, and proportion of participations meeting home BP targets (defined as mean home BP readings of <135/85 mm Hg or <130/80 mm Hg if having diabetes) at 3 months. Additional outcomes of interest were number of antihypertensive medications, HDDD, medication adherence (HB-MAS), health-related QoL (EQ-5D), and patient satisfaction questionnaires.

**Statistical Analysis**

Characteristics of included participants were described as mean, SD, median, IQR, and proportions. BP changes and changes in other study outcomes (baseline to 3 months) were summarized using means and SDs or median and IQR. For participants who had BP recordings within a window from 14 days before to 14 days after the target 90-day follow-up date, the 3-month BP was taken to be the average the BP recordings of up to 3 days closest to the target date. For participants who did not have BP recordings within this window, but who had data over at least 60 days, multiple imputation was used to assign the 3-month BP (see Multimedia Appendix 4 for details). The remaining
participants were excluded from the analysis of BP change as it was deemed not possible to assign them reliable 3-month BP values. Patients who completed either 3-month questionnaire were included in the analysis and descriptive statistics were used. Data were analyzed using Stata (StataCorp) and R (version 4.1.2; R Core Team).

Results

Recruitment

From May to December 2021, a total of 139 patients presenting to the ED with asymptomatic elevated BP were screened, including 99 identified in ED (recruitment pathway 1) and 40 identified from ED referrals to Hypertension Clinic (recruitment pathway 2). Potentially eligible patients that were referred to the research team by ED staff had an average triage BP of 192/94 and were contacted by the research assistant for additional BP measurements. Among the patients who had additional BP measured by the research assistant, those who were ineligible had an average BP of 147/81 (n=26), whereas eligible patients had an average BP of 194/99 (n=32). Including patients identified and screened through ED referrals to the Hypertension Clinic (recruitment pathway 2), 56 patients were eligible to be consented to the study (Figure 1), and 49 were enrolled. Eligibility and recruitment rates were 40% (56/139) and 88% (49/56), respectively. After enrollment, 3 participants were deemed ineligible and were excluded from the study due to requiring hospitalization (n=3). The final analyzed cohort consisted of 46 participants. Of which, 44/46 patients completed at least 1 week of HBPT and 1 clinic visit at the Hypertension Clinic, resulting in a retention rate of 98% (44/46). Home monitoring adherence was defined as the percentage of participants that completed ≥80% of the prespecified home blood pressure monitoring schedule at 1 and 3 months from enrollment. The proportion of participants that completed ≥80% of home BP measurements at 1 and 3 months were 67% (31/46) and 41% (19/46), respectively (Figure 2). A total of 4 patients did not have sufficient home BP readings at the end of 3 months to determine mean home BP and were lost to follow-up.

Figure 1. Flow diagram of patient participant screening and recruitment. BP: blood pressure; ED: emergency department.
Characteristics of Participants

Participants were mostly women (69%, n=32) with an average age of 63 (SD 17) years (Table 1). The ethnic diversity of participants was White (30%, n=14), Filipino (22%, n=10), and Chinese (15%, n=7). At baseline, the mean (SD) SBP and DBP in the ED were 193 (SD 23) mm Hg and 100 (SD 13) mm Hg, respectively. Of all the participants, 44 (96%) had been previously diagnosed with hypertension. Of all participants, 17 (37%) had an antihypertensive medication initiated or increased in the ED. Those who had an intensification of medications had higher mean BP in ED of 205/104 mm Hg compared to those who did not of 186/98 mm Hg.

Patient Outcomes and Experience

There were sufficient HBPT data to determine the 3-month BP end point for 42 (91%) participants, with imputation used for 1 participant. Mean home SBP and DBP decreased by 67.0 (SD 24.4) and 24.9 (SD 10.3), respectively, from ED triage or screening to study completion. Similarly, mean home SBP and DBP decreased by 13.2 (SD 17.8) mm Hg and 5.1 (SD 9.0) mm Hg, respectively, from the first 7 days to study completion. The proportion of individuals who achieved home SBP and DBP control at 3 months was 71% (30/42) and 86% (36/42), respectively (n=42). The number of adjustments in participant medications was 87 for the entire study, with most commonly having initiation of new antihypertensive medication (36/87), increase in dosage of current antihypertensive medication (23/87), and change in class of antihypertensive medication (14/87). Decreasing antihypertensive medications (9/87) and stopping antihypertensive medications (5/87) were uncommon.

At the end of the study, patients were prescribed 1 additional antihypertensive medication (2 vs 1 antihypertensive medication), but no difference in HDDD was noted from enrollment to end of the study (mean 1.58, SD 1.32 vs mean 1.77, SD 1.47; P=.39; Table 2). Most commonly patients at the beginning of the study were taking angiotensin-converting enzyme inhibitors or angiotensin receptor blockers (40%, 18/45), calcium channel blockers (40%, 18/45), and beta-blockers (24%, 11/45). At the end of the intervention, more patients were prescribed single pill combination antihypertensive medications (9%, 4/45 vs 29%, 13/45; Figure 3).

The response rate for completion of both the HB-MAS at enrollment and the end of the study was 72% (33/46). Among those who completed both questionnaires, no difference in medication adherence was noted (36 [IQR 36-33] vs 36 [IQR 36-35]) from enrollment to 3 months (Table 2). The response rate for completion of the EQ-5D validated questionnaire was 97% (44/46; Table 1). EQ-5D-5L and EQ-5D Visual Analogue Scale (EQ-5D VAS) scores were 0.77 (SD 0.23) and 69 (SD 20), respectively. Due to the pilot nature of the study, adverse events were not captured.

The response rate for the patient satisfaction surveys was 72% (33/46). Overall, patients were highly satisfied with the HBPT program (75%, 24/33) and would recommend it to others (79%, 26/33; Table 3). The majority of the participants found digital health tools easy to use (76%, 25/33) and felt that the intervention prevented the need to return to the ED with elevated BP readings (64%, 21/33). In total, 14% (7/46) of participants required family assistance to participate in the study. The most common reasons for assistance were language barrier (71%, 5/7), inability to apply the home BP monitor on their arm independently (14%, 1/7), and lack of their own smartphone (14%, 1/7). Patients who did not have their own smartphones navigated this barrier by using their family members’ phones.

Discussion

Overview

TEC4Home-BP is a pilot study to evaluate the feasibility of HBPT and physician case management as an integrated component of health delivery to support patients with asymptomatic elevated BP discharged from the ED to home. We found that HBPT was feasible as a postdischarge management strategy, given our recruitment and retention rate was 88% (56/139) and 98% (44/46), respectively. Patients reported high acceptability and satisfaction with the HBPT program.

Principal Results

HBPT combined with timely physician follow-up and management is a novel and promising postdischarge management strategy to help bridge the transition from ED to home and can play a proactive role in treating asymptomatic elevated BP in the ED. Our results show that the proportion achieving home SBP and DBP control at 3 months was 71% (30/42) and 86% (36/42), respectively, which is higher than the current Canadian hypertension control rates of 65% [25]. Furthermore, home BP decreased from the first week of completing HBPT to 3 months (final BP assessment) by −13/−5 mm Hg. This may correspond to an estimated 30% and 26% risk reduction in CV disease and stroke, respectively, but likely overestimated due to the limitations of our study design with regression of the mean and lack of a comparator group [26]. Overall, patients only required 1 additional antihypertensive medication to be prescribed. Improvement in BP may be due to increased use of evidence-based medications, including single pill combination therapies or the act of self-monitoring. Patients were highly satisfied with the program and found the technology to be user-friendly.

Comparison With Prior Work

Previous studies have shown that text-messaging services to encourage measuring home BP using a wrist cuff was a feasible intervention in patients who were discharged from the ED with high BP and reduced SBP by 9.1 (95% CI 1.1-17.6) mm Hg, but patients did not use remote HBPT program where home BP readings were transmitted to physicians to review and provide management strategies directly to patients [27]. Our results showed that the adherence to home BP monitoring was 67% (31/46) and 41% (19/46) at 1 and 3 months, respectively. This is similar to meta-analysis showing that among 13 studies (n=1662 patients), the average adherence to telemedicine-based hypertension management was high (76.8%; range 48%-90%) [28]. This is not surprising that as time persists from their initial ED event, patients may not be as adherent to strict BP monitoring. It will be important for our future randomized controlled trial (RCT) to develop a more pragmatic home BP monitoring schedule that is acceptable to patients and provide accurate information to health care professionals to monitor and manage their hypertension.

Previous studies from ED and inpatient hospital settings have shown that in patients discharged with asymptomatic elevated BP, 43.4% were diagnosed with hypertension at follow-up [7]. Our study showed that among individuals presenting the ED with an average SBP ≥ 160 mm Hg and DBP ≥ 100 mm Hg in ED, most had established hypertension that was uncontrolled and required additional treatment. This reaffirms that elevated BP in the ED is not benign and a significant proportion of these individuals have undiagnosed or undertreated hypertension. Of similar importance, is the portion of patients that do not go on to have a diagnosis of hypertension and are at risk of misdiagnosis and unnecessary treatment without close follow-up. Furthermore, with worsening hypertension awareness and control rates in Canada, the ED may be a useful location to screen individuals for hypertension, as BP is measured in all individuals regardless of the presenting complaint. Despite the
guideline recommendations that close follow-up is needed for individuals with asymptomatic elevated BP discharged from ED [12], only 7%–29% of patients with elevated BP receive any hypertension assessment, treatment, or referral in the ED [29-32]. Therefore, the development of novel postdischarge management pathways to ensure that these individuals have a close follow-up for their hypertension is greatly needed. At a minimum, ED practice guidelines should consider changing to at least recommend home BP monitoring for these patients immediately postdischarge and timely follow-up with physicians should BP remain elevated.

Our intervention improved BP after 1 week of HBPT to 3 months (final BP assessment) by −13/−5 mm Hg. Meta-analyses have shown that home BP monitoring supported by co-interventions (including medication adjustments by physicians or pharmacists, education, and lifestyle counseling) results in significant BP reduction (−6.1, 95% CI −9.0 to −3.2 mm Hg) that persists for 12 months [16]. Another meta-analysis of 23 RCTs (n=7037 patients) reported that HBPT significantly reduced BP by 5/3 mm Hg compared to the usual care (P<.001) [17]. Our results need to be verified by conducting a powered RCT to address issues with regression to the mean and lack of a comparator group.

Studies have shown that HBPT alone improved antihypertensive medication prescription and QoL [17,33], but we were not able to show this in our pilot study as it was not powered to detect these differences. Although there were no differences in HDDD prescribed, there was an increase in the number of single pill combination antihypertensive medications prescribed. We hypothesize that HDDD did not change because single pill combinations were more frequently prescribed which confers better BP lowering with combination therapy than full doses of antihypertensive medication [34]. Hypertension follow-up after an ED visit for asymptomatic elevated BP has been shown to improve evidence-based hypertension management [35]. Single pill combinations are endorsed by hypertension guidelines [20] as they have been shown to improve medication adherence and BP control while reducing medication side effects and CV events [36-39].

Our intervention was noted to be highly acceptable and usable by patients and their families, which is similar to other HBPT studies where patients reported higher satisfaction and greater convenience compared with usual hypertension care [40]. Almost 15% (7/46) of participants required assistance with our intervention, specifically due to language barriers. Given our multiethnic population, future RCT design should incorporate different languages in the technology to improve usability for everyone.

Limitations
There are a number of limitations in this study. The sample size for the TEC4Home-BP pilot study was relatively small and there may be systematic differences between those who enrolled for the study and adhered to the monitoring protocol and those who did not. Although the retention rate for participants attending the first visit was high, adherence to the monitoring schedule declined throughout the study and 4 patients were lost to follow-up. This insight on monitoring frequency has provided us with information on how to redesign on monitoring protocol to improve patient adherence. There is increasing evidence that a minimum of 12 BP readings is needed for home BP measurements to be valid [41], and more recently 3 days of BP readings appeared sufficient to prognostic home BP readings [42]. Furthermore, the exclusion criteria excluded many patients who presented to the ED with elevated BP and only stable patients who would be a good candidate for HBPT were recruited for the study. This limitation prevents our feasibility study from assessing the feasibility of HBPT in the full group of patients who present to the ED with elevated BP, and who may still benefit from and accept HBPT. The eligibility criteria may be underestimated, as we did not document all the reasons why patients were not eligible to be in the study due to resource issues. A majority of patients who had elevated triage BPs were not eligible to participate because their BP was below the inclusion criteria after the research assistant measured their BP 3 times consecutively. In addition, those who did not meet the incomplete survey questionnaires may limit the true acceptability and usability of this intervention, as participants who responded and did not respond may be very different. Finally, the lack of data from a control comparison is a true limitation of our feasibility study design and needs to be addressed. Although, these findings are promising and informative of the next steps, a more rigorous RCT design with a comparator group is required to test the true efficacy of this intervention.

Conclusions
HBPT with physician management is a feasible and acceptable postdischarge management strategy to monitor patients with asymptomatic elevated BP when they are discharged from the ED. Future multicenter RCTs are needed to evaluate the efficacy of this intervention in a large population.

Acknowledgments
We thank the TEC4Home team for answering our many questions. We also thank Vancouver Coastal Health Research Institute, University of British Columbia and Vancouver General Hospital Foundation, Vancouver General Hospital, University of British Columbia, and Sphygmo app for their support for this project.

Abstract

Background: Diabetes distress among adolescents with type 1 diabetes has been associated with suboptimal diabetes outcomes, including lower quality of life, increased diabetes self-management challenges, and suboptimal glycemic outcomes.

Objective: This study examined the feasibility and acceptability of a scalable self-led mindfulness-based intervention to reduce diabetes distress in adolescents with type 1 diabetes.

Methods: Adolescents (N=25) aged between 14 and 18 years diagnosed with type 1 diabetes completed a baseline assessment. Participants were randomized to receive a 10-week self-guided mindfulness-based stress reduction workbook program (e-book or paper option) immediately (n=15) or after a 10-week wait (n=10). During the intervention period, participants completed weekly assignments and feedback surveys. At 10 weeks and 20 weeks, follow-up assessments were completed.

Results: Findings indicated that participants did not find the original intervention feasible or acceptable. Adolescents reported barriers to completing the weekly material, such as that they forgot or that the material was not sufficiently related to their diabetes management. Adolescents also reported that a digital format rather than a workbook or e-book may be more acceptable. Results from weekly surveys provided the foundation for recommendations for future iterations of the mindfulness-based intervention for adolescents with type 1 diabetes.

Conclusions: Participant feedback informed recommendations for self-led mindfulness programs for youth with type 1 diabetes. Adolescents indicated that a shorter, digital mindfulness-based intervention focused on diabetes-specific behaviors may be more helpful.

KEYWORDS
adolescents; diabetes distress; diabetes; health group intervention; intervention; mindfulness; psychosocial intervention; self-led mindfulness; type 1 diabetes

Introduction

Adolescents with type 1 diabetes, an autoimmune disease that destroys insulin-producing cells in the pancreas, must engage in numerous daily health behaviors to manage their symptoms and prevent short- and long-term health complications [1]. The persistent challenges of disease management often result in diabetes distress, characterized as the burden, worries, and frustrations associated with diabetes [2]. Adolescents with greater diabetes distress experience lower quality of life, increased diabetes self-management challenges, and suboptimal
glycemic outcomes (glycosylated hemoglobin; HbA\textsubscript{1c}) [3,4]. Heightened diabetes distress may affect type 1 diabetes outcomes both indirectly, through decreased engagement in disease self-management behaviors, and directly, through the effects of physiological arousal, hormone secretion, and insulin resistance on blood glucose levels and the microvascular system [5,6]. Current interventions aimed at fostering diabetes self-management in adolescence have targeted distress management [7] and quality of life [8], yet less research has examined mindfulness-based stress reduction (MBSR) interventions in the context of adolescents’ type 1 diabetes distress and self-management. This is despite cross-sectional data supporting the link between greater mindfulness, greater diabetes self-management, lower diabetes stress, and lower HbA\textsubscript{1c} levels in adolescents with type 1 diabetes [9].

Increased mindfulness, enhanced through mindfulness-based interventions, is linked to numerous health benefits. One example is the MBSR intervention, a mind-body public health group intervention developed for medical patients to manage the stress of chronic medical conditions. MBSR consists of eight 2.5-hour-long, weekly sessions and 1 all-day practice session [10]. In adults with type 1 or type 2 diabetes, the benefits of mindfulness-based interventions include reduced distress and cardiovascular risk [11,12], and similar outcomes emerged for adolescents with chronic diseases generally [13]. More recently, mindfulness-based interventions have been considered in the context of improving type 1 diabetes management in emerging adults [14]. For example, among emerging adults with type 1 diabetes and suboptimal glycemic levels, an MBSR intervention was found to improve psychosocial outcomes but not glycemic outcomes and was highly acceptable [15,16]. Further, an additional study within the type 1 diabetes context found that a brief self-compression intervention, which is a core component of MBSR, was acceptable and feasible among adolescents with disordered eating and improved mindfulness and coping [17]. These findings support the possible benefits of improved mindfulness in reducing diabetes distress and improving diabetes self-management in adolescents with type 1 diabetes.

The goal of this study was to begin an iterative approach to developing a self-led, scalable MBSR intervention for adolescents with type 1 diabetes. The intervention was modeled on a 10-week bibliotherapy MBSR program implemented by Hazlett-Stevens and Oren [18] that was found to be feasible and acceptable for college students and to reduce distress and anxiety for those who completed the program. A self-led MBSR program approach may be particularly helpful for disseminating MBSR to adolescents with type 1 diabetes, a population that already experiences the intensive time burden of diabetes management [19]. This study examined the acceptability, feasibility, and potential utility of a 10-week self-led workbook (e-book or paper option) MBSR intervention for adolescents with type 1 diabetes through a randomized waitlist control design. It was hypothesized that participation in a self-led MBSR intervention would be feasible and acceptable, as evidenced by low treatment attrition and positive participant feedback. Finally, we provide recommendations for future iterations of self-led, digital MBSR interventions for adolescents with type 1 diabetes based on recommendations by participants.

### Methods

#### Ethical Considerations

All procedures and documents were approved by the institutional review board at the University of Nevada, Reno (1221205). Web-based parental consent was obtained for children aged 18 years or younger, in which case child assent was also obtained. Participants 18 years of age or older provided web-based consent. Participants earned US $10 for each assessment (up to US $30), US $10 for completing at least 6 of the 10 weekly surveys over the 10-week intervention period, and an additional US $10 for completing all 10 weekly surveys. The maximum earnings for each participant were US $50, in the form of an Amazon gift card. All measures were completed electronically through Research Electronic Data Capture (REDCap; Vanderbilt University). Participants were informed during the informed consent process that their answers and data would not be shared with individuals outside of the research team unless the research team was concerned about the participant’s safety.

#### Participants

Participants for this study included a sample of 25 adolescents (n=14, 56% female) aged between 14 and 18 years (mean age 16.25, SD 1.6 years) from urban and rural areas of Nevada. Most participants identified as White (n=22, 88%), 1 participant as Asian, 1 participant as Native Hawaiian or Pacific Islander, and 1 participant as biracial. Participants reported a wide range of diagnosis lengths, from less than a year to 16.15 years (mean diagnosis length 5.3, SD 4.1 years). A total of 19 (76%) participants reported using a continuous blood glucose monitor, and 17 (68%) endorsed using an insulin pump. Additionally, through self-report, 10 (40%) participants reported that they qualify for free lunch at school. Inclusion criteria included being an adolescent (aged between 13 and 19 years) with a type 1 diabetes diagnosis currently attending school or being a recent high school graduate. Participants were excluded if they were wards of the state, had severe psychiatric disturbances (eg, active psychosis), or had severe developmental delays that hindered their ability to self-report. Participants were not excluded based on the length of their type 1 diabetes diagnosis.

#### Procedures

Participants were recruited with flyers at a regional diabetes camp, flyers sent to community diabetes support groups, and direct recruitment by research staff in a local pediatric endocrinology clinic. All enrolled participants completed a baseline survey, including a self-report of their most recent HbA\textsubscript{1c} percentage value, and were randomized to either begin the 10-week intervention period immediately or after 10 weeks, with participants randomized to start the intervention after the 10-week waiting period acting as a control group. Randomization was computerized and stratified based on sex, duration of type 1 diabetes diagnosis (2 years or less vs more than 2 years), and most recent HbA\textsubscript{1c} (8.5% or below vs 8.6% or above). Participants also completed assessment questionnaires 10 weeks and 20 weeks after the study start date and a weekly survey for the 10 weeks of intervention participation.
Recruitment for this project began in the fall of 2018 and was completed in early spring 2020. Research staff were trained by 2 graduate students on recruitment procedures and eligibility criteria. A total of 64 participants contacted our research staff, indicating interest in participating in the study and providing permission to contact them either on the internet or in-person (Figure 1). Of the 64 participants who indicated interest in the study, 5 declined further screening, and 2 were not eligible after screening. During the study period, after 29 participants had consented and enrolled, it was determined, due to feedback from those enrolled participants as well as attrition and loss of follow-up, that the intervention required revision to increase acceptability; accordingly, recruitment was stopped at that time. An additional 28 participants expressed interest in enrolling but did not complete the consent process before the interim study end point was reached; this was also before the original goal of 60 participants was reached. Participant recruitment and enrollment are further discussed below as part of the analysis of feasibility and acceptability.
Intervention Program

The mindfulness-based intervention in this study was delivered through a teen MBSR workbook, either an e-book or paper workbook, and web-based communication across a 10-week period. If selected, the paperback workbook was mailed to participants’ home address; otherwise, access to the e-workbook was provided through email. Participants were assigned weekly readings and activities from an MBSR workbook [19]. Topics included understanding stress, an introduction to mindfulness, and mindfulness-based exercises recommended to be completed daily (eg, mindful eating). Mindfulness-based exercises were either self-led per instructions provided in the workbook or completed using audio-recorded instructions. Participants received emails twice per week with reminders about the current week’s assignments and to practice mindfulness each day. At the end of the week, participants received a reminder to complete a brief survey on the acceptability of that week’s content. This
survey included both multiple-choice questions and open-ended questions regarding how helpful participants found each exercise and what hindered them from completing the exercises that week. Participants completed the following measures at baseline and immediately following intervention completion.

**Measures**

Multiple measures were administered in the study. Only those relevant to this study are described below.

**HbA1c Percentage**

At intake, participants self-reported their most recent HbA1c level. Higher HbA1c percentages are associated with less optimal glycemic control in the past 2-3 months.

**Intervention Acceptability and Feedback for Recommendations**

Acceptability was measured both objectively based on participant engagement as well as per participant report. First, attrition was used as a proxy variable for acceptability. Second, at the end of each week of the intervention, participants completed both multiple-choice and open-ended questions pertaining to the intervention content that week. Information from weekly surveys was used to create recommendations for future intervention development. Specifically, the following questions were asked: “How much of the suggested readings from the book did you read over the past week?” (0=“not at all” to 5=“I read all of the suggested readings”); “What percentage of exercises from the suggested readings for the previous week did you complete while reading the chapter?” (0=“not at all” to 5=“I read all of the suggested exercises”); “How often did you engage in the exercises suggested in the chapter during the previous week?” (0=“none” to 3=“almost daily”); “What got in the way of you following the workbook?” (0=“I forgot”; 1=“I didn’t have time”; 2=“I didn’t understand the material,” “the material was too difficult to follow,” or “the instructions were unclear”; or 3=“other: explain”); and “Please tell us any other thoughts you had on the workbook readings, weekly exercises, or audio tracks this week.” (open-ended).

**Analyses**

To assess the feasibility and acceptability of the self-led MBSR intervention for adolescents with type 1 diabetes, we conducted descriptive statistics of level of attrition and quantitative questions from participants’ weekly feedback surveys. Qualitative feedback from the weekly feedback surveys was brief and informally and visually analyzed and summarized. We created recommendations for a more acceptable mindfulness-based intervention based on the feedback from the weekly surveys.

**Results**

All feasibility and acceptability analyses pointed to issues with the acceptability and feasibility of the initial intervention model. First, consistent with problems with study feasibility, many participants did not complete the full study period and were lost to follow up. Among the 29 enrolled participants, 25 completed their baseline survey and were randomized to intervention now (n=15) or waitlist (n=10); groups were not balanced as enrollment was stopped early. A total of 4 of the 29 participants passively declined to complete the baseline survey and were not randomized. Overall, 2 participants withdrew from the study after intake (reasons: busy with school and study participation was stressful). Additionally, 2 participants were lost to follow-up during the program, and 7 participants were lost to follow-up at 10 weeks (3 from intervention-first and 4 from the waitlist group). Another 6 were lost to follow-up at 20 weeks, 3 of those from the intervention first group that was now completing extended follow-up. This suggested challenges with the waitlist design at a minimum, as well as with maintaining participant engagement in the study process.

Second, we examined participant feedback on both reasons for attrition and low engagement. The indicated reasons for attrition included the conflict of busy schedules and the weekly time commitment for the intervention. In the weekly surveys, participants reported, through a Likert scale, barriers to engaging in the weekly material. Options for barriers were “I forgot,” “I didn’t have time,” “I didn’t understand the material or instructions,” and “other.” Average frequencies of selected barriers indicated that the most common barrier to engaging in the material was lack of time (50/120, 41.7%). Average frequencies for the 3 other barriers included 21.7% (26/120; “I forgot”), 23.3% (28/120; “other”), and 13.3% (16/120; “I didn’t understand the material”). When participants selected “other,” they were prompted to fill in a textbox describing the barrier. For the participants who did enter a reason in the textbox, responses included that they felt they did not need a mindfulness practice and noted that diabetes-specific activities would be more helpful than general activities. Additional responses included that the workbook intervention format reflected school tasks and that some of the reading and activities felt geared toward a younger audience. Textbox responses were brief, categorized by 2 graduate students, and reviewed by the principal investigator. However, due to the brevity of responses, no formal codebook was used to code responses. Feedback on acceptability and feasibility was integrated, and recommendations for a digitally tailored MBSR intervention for teens with type 1 diabetes were generated by the study team, including experts in adolescent diabetes management and mindfulness-based interventions.

**Discussion**

**Overview**

This study evaluated the feasibility and acceptability of a self-led MBSR intervention. Although there was no support for the feasibility and acceptability of the intervention model, participants provided feedback on multiple improvements that would enhance the feasibility and acceptability of the intervention program. Participants’ weekly feedback pointed to multiple domains where an MBSR intervention might be tailored to the type 1 diabetes context. Hurdles remain in understanding the feasibility and acceptability of these programs, especially in more scalable, self-led forms. For example, in the type 1 diabetes context, there are limited studies examining the feasibility of mindfulness-based interventions for young persons.
of color with type 1 diabetes populations [15]. Additional research on mindfulness-based interventions for adolescents with type 1 diabetes indicates that brief, digital sessions may be more acceptable and feasible for this population [17]. Further research is needed to clarify the long-term benefits and acceptability of mindfulness-based interventions on diabetes distress and glycemic outcomes for adolescents with type 1 diabetes.

Our research has identified multiple potential areas for increasing the acceptability of a self-led mindfulness program for adolescents with type 1 diabetes. In this intervention, feasibility and acceptability assessments indicated that adolescents prefer a shorter, web-based intervention focused on mindfulness regarding diabetes-specific behaviors. We have since identified 5 potential avenues for future mindfulness intervention development in the adolescent type 1 diabetes context that would address the concerns raised by the adolescents in our sample while maintaining a connection to mindfulness-based therapy approaches. First, decrease the amount of content in the self-led form to emphasize the connections between everyday mindfulness, acceptance skills, and diabetes management. Some participants indicated that the original modules and instructions were difficult to understand. Therefore, it may be beneficial to focus the program on a few basic mindfulness skills that are connected to diabetes management to help build an insightful mindfulness repertoire that is meaningful to daily diabetes management. For example, the early sessions of a self-led mindfulness-based intervention might teach an introduction to mindfulness with a guided body scan aimed at increasing self-compassion around diabetes symptoms and tasks. Body scans are a foundational mindfulness practice in MBSR and can be modified to emphasize self-compassion for physiological sensations and experiences that occur during diabetes management (wearing diabetes technology or experiencing hyper- or hypoglycemia). Following this early session, adolescents might be guided to engage in a formal practice audio recording of a diabetes-oriented body scan. Follow-on sessions might continue this same training and expand the experience with a diabetes-oriented body scan with new attention toward self-monitoring and glycemic awareness (symptoms of hypo- or hyperglycemia). Increasing interoceptive awareness through guided meditation may foster adolescent awareness of hyper- and hypoglycemia. Further, acceptability and feasibility may increase if the intervention were delivered through a website or mobile app. Second, the acceptability of a self-led mindfulness-based intervention for adolescents with type 1 diabetes might be increased by contextualizing the emotionally evocative nature of diabetes-management behaviors (changes in eating patterns and emotions in social environments) as life events where mindfulness may be a useful practice. For example, additional sessions might teach mindful eating practices to increase nonjudgmental awareness of food cravings or other hunger- or thirst-related diabetes experiences. Building mindful eating practices may also increase self-compassion about the changes in eating habits necessary to maintain on-target glycemic levels. In addition, mindful eating practice may also help build a repertoire of acceptance and nonjudgmental awareness to decrease diabetes distress when eating habits and glycemic levels are not aligned with medical professionals’ guidelines for type 1 diabetes management. Third, it may also be beneficial for acceptability to incorporate dialectical behavior skills into the mindfulness practice to balance the notion that diabetes-management behaviors are not naturally reinforcing (eg, finger sticks and pump site or sensor placements), yet they are still necessary to maintain health. Later sessions might introduce and teach mindful stopping for stress management to teach adolescents how to pause and engage in mindful savoring of positive life events when diabetes is challenging. Incorporating mindful stopping skills for diabetes-related stressors and activities in everyday life, as well as rumination about past and future diabetes challenges, might particularly benefit reductions in diabetes distress. Fourth, the acceptability of self-led mindfulness programs might be increased by adding a peer support component or a parent component. Although Ellis and colleagues [16] did not find links between a mindfulness-based intervention and improved glycemic outcomes, they did find that a control group peer support program did effectively improve glycemic outcomes, despite the peer support aspect of the program not focusing on diabetes management. The group learning environment is a key feature of live MBSR training that is not available in a self-led format. Periodic (eg, quarterly or monthly) web-based chat rooms or discussion boards moderated by a support staff member might allow a space to encourage peer support around learning self-led mindfulness skills without requiring the greater costs and time invested in live group-based MBSR programs. Further, adding a parent component may help reinforce skills that are learned and support a positive parent-adolescent relationship, the latter of which has downstream effects on glycemic control in this pediatric population [20,21]. Finally, future studies may benefit from the following methodological changes. First, researchers may consider incorporating the use of focus groups and semistructured interviews, as well as other approaches toward conducting community-based participatory research, to obtain information on intervention content and acceptability before recruitment. Second, researchers may consider monitoring recruitment for a representative sample and incorporate recommendations for race-conscious research [22,23] when examining if mindfulness is appropriate in light of historical antecedents.

These recommendations would benefit from testing and exploration in future research studying self-led mindfulness-based interventions in adolescents with type 1 diabetes.

Limitations

This study is limited by multiple factors. The sample that consented to the study was predominantly White and therefore is not generalizable to other races and ethnicities. The study was also limited in the scope of the time period in which participants were recruited and completed the study. Some participants had already completed the study before the COVID-19 pandemic, while others completed the study during the pandemic, which may have confounded the stress and mindfulness levels of the participants. Due to the sample size, we were not able to analyze the data for potential differences across participants who were enrolled before and during the COVID-19 pandemic. Most of the participants reported an...
HbA$_1c$ that was 8.5% or lower, which may limit the generalizability of the recommendations to adolescents with a higher HbA$_1c$. Although not asked in this study, it may be helpful for future studies to ask participants about their previous history with mindfulness and meditation.

**Conclusions and Future Directions**

While keeping the limitations in mind, the findings of this study provide important data to contextualize the content and delivery of mindfulness-based interventions for adolescents with type 1 diabetes and provide guidance for developing an acceptable and scalable self-led mindfulness-based intervention. First, mindfulness and stress-related processes may be particularly important to understand in the context of type 1 diabetes management, given the long-term health complications that involve the vascular system. For example, the primary cause of death in middle-aged and older adults with type 1 diabetes is cardiovascular disease [24], and cardiovascular disease as well as other macro- and microvascular complications [25] contribute to an almost 17-year decrease in life span for those with an early age of type 1 diabetes onset [1]. Mindfulness-based interventions have been shown to also diminish chronic biological stress regulatory system activation that directly contributes to cardiovascular disease [26], highlighting the importance of developing mindfulness-based interventions that are acceptable and feasible for adolescents and emerging adults with type 1 diabetes. Further research is needed to examine the long-term physiological effects associated with mindfulness-based interventions for individuals with type 1 diabetes and the potential cardio-protective benefits.

Second, the data from study participants provided critical information for guiding the development of scalable self-led mindfulness-based intervention models, including emphasizing content that directly links mindfulness practice to diabetes management with the inclusion of diabetes-specific mindfulness activities. Further research examining the acceptability and effects of self-led mindfulness-based interventions that meet the recommendations provided herein and within a sample of youths that includes persons of color and with socioeconomic disadvantages is needed to better understand and support research on mindfulness interventions and type 1 diabetes management in adolescents.

Finally, mindfulness-based interventions might have a role in addressing internalizing psychopathology that is known to impact glycemic outcomes and quality of life for adolescents with type 1 diabetes. Depressive symptoms may contribute to an environment where adolescents experience decreased energy, leading to decreased engagement in diabetes-management behaviors. Decreased energy then contributes to a coercive cycle where decreased glycemic control contributes to greater depressive symptoms [27]. Adolescents may also experience anxiety symptoms, such as worry. Rechenberg and colleagues [28] found that adolescents with type 1 diabetes reported increased worry about managing their health, particularly regarding hypoglycemia and correct insulin dosing. Mindfulness-based interventions may be useful in disrupting this cycle by reducing the underlying stress associated with many psychological concerns. Further research is needed to identify if subpopulations of adolescents with type 1 diabetes, such as those with internalizing symptoms, might particularly benefit from self-led mindfulness-based interventions.

Abstract

Background: Dental caries in preschool children is a global health concern. With increased access to technology and the disruption of health care during the pandemic, mobile health apps have been of interest as potential vehicles for individuals’ health maintenance. However, little is known about caring for their child’s teeth and what their preferences would be regarding the content or design of an oral health app.

Objective: This study aims to co-design the prototype of an app named App for Children’s Teeth with parents, providing a source of information for them about caring for their children’s teeth and promoting positive dental habits.

Methods: This multimethod study conducted user involvement research with a purposive sample of parents or carers of children aged ≤6 years to (1) understand their use of the internet through the eHealth Literacy Scale and interviews, (2) determine their opinions about content related to children’s oral health, and (3) collect feedback about the app’s acceptability using the Theoretical Framework of Acceptability. There were three stages: (1) interviews with parents to understand their needs, preferences, and abilities; (2) prototype design with app developers; and (3) parent feedback interviews using the think aloud method for data collection. Data were deductively analyzed using a codebook strategy, whereas data from the think aloud sessions were analyzed inductively using reflexive thematic analysis.

Results: The prototype design stage involved 10 parents who reported using the internet for health information but found it to be scattered and contradictory. Parents generally welcomed the App for Children’s Teeth but expressed concerns about screen time and practicality. They suggested guidance regarding oral hygiene practices, teething symptoms, and pain relief. Parents appreciated features such as clear fonts, categorization according to their child’s age, and “In a Nutshell” bullet points. Topics that resonated with parents included information about teething, finding a dentist, and breastfeeding. They believed that the app aligned with their goals and offered suggestions for future developments, such as outlining the process of finding a dentist and incorporating a forum for parents to communicate and exchange ideas.

Conclusions: The coproduction design approach highlighted parents’ need for solutions such as mobile health apps to access reliable information about oral health. Parents identified key design concepts for the app, including a simple and uncluttered interface, content categorization according to their child’s age, and practical guidance supported by visual aids. Despite potential challenges related to screen time restrictions, parents provided insights into how such an app could fit seamlessly into their lives.

Introduction

Background
Dental caries is the most common chronic disease of childhood, affecting >621 million children worldwide [1]. It negatively affects the quality of life of children and their parents [2]. The condition, dental caries, is biofilm mediated, diet modulated, multifactorial, and noncommunicable. It is dynamic in nature; it can start and stop depending on external factors (such as biofilm removal), and it can progress and regress (demineralization and remineralization), again depending on external factors such as the amount and frequency of sugar in the diet [3], removal of the biofilm, and fluoride application to the teeth during toothbrushing [4]. Evidence-based guidelines recommend that parents take responsibility for their children’s daily activities, care, and food choices to prevent dental caries [5]. These guidelines emphasize managing the external factors through personal care, including toothbrushing with fluoridated toothpaste (>1000 parts per million) and sugar reduction in food choices [5,6].

In recent years, the development and growth of mobile health (mHealth) apps have provided an opportunity to improve access to health information and promote health and well-being using mobile technologies [7]. mHealth has been defined by the World Health Organization as the “use of mobile and wireless technologies to support the achievement of health objectives” [8]. Smartphones are ubiquitous, with an estimated 88% of adults owning one in the United Kingdom in 2021 [7]. Internet use exclusively through smartphones is increasing, and in 2022, overall, 21% of users accessed the internet exclusively through their phones. As such, there is potential for high-quality and engaging health information to be easily accessible and affordable through mHealth. Although there is evidence that mHealth apps can play a role in improving health outcomes, including for oral health and dental plaque control [9], the quality and accuracy of internet-based health information is variable, with potential for harm from misinformation.

To maximize the potential of mHealth apps, it is crucial to prioritize user engagement by involving target stakeholders such as patients, caregivers, and health care providers in the co-design process. Co-design fosters collaboration and leverages the valuable insights of users and designers in the development of products or services. By incorporating user feedback and preferences into the design process, mHealth apps can better meet the needs of their target audience. Theoretical Framework of Acceptability (TFA) is a valuable tool to guide the co-design process. TFA proposes that the acceptability of any intervention, such as an mHealth app, is determined by its perceived appropriateness, effectiveness, and feasibility [10]. TFA provides an evidence-based checklist to assess these individual components in an mHealth app prototype, allowing deficiencies to be addressed and ensuring that it meets the needs and preferences of the target stakeholders, and guides the next steps in the development process.

As co-design is a user-centered process, it considers the target audience’s specific characteristics. Context, education, age, and eHealth competence of the end users, among other factors, can significantly influence the design and structure of mHealth apps. The eHealth Literacy Scale (eHLS) is a tool that measures individuals’ ability to access, comprehend, and use health information to make health care judgments. By considering the eHealth literacy of the target stakeholders, an app can be designed to be more appropriate, accessible, and user-friendly, thus improving the likelihood of it being used and, ultimately, its effectiveness [11].

The development of an mHealth app for parents and caregivers of young children that addresses gaps in knowledge and presents evidence-based information in a usable format might promote healthy oral hygiene practices and prevent dental caries in children.

Aims and Objectives
This study aimed to provide proof of concept for designing eHealth technologies in collaboration with the parents of young children, as end users, by designing a prototype of a medical health app to identify gaps in information, develop content, and collect feedback about acceptability.

The objectives were to conduct user involvement studies with parents or carers of children aged ≤6 years at the initial stage to do the following:

- Understand their use of the internet through eHLS and interview
- Determine their opinions about mHealth app content related to children’s oral health

Then, at a later stage of development of the medical health application, we aimed to do the following:

- Collect feedback about the acceptability of the medical health application according to the domains of TFA

Methods

Design
This was a single-site, multimethod, qualitative research study that evaluated parents or carers’ acceptability of a smartphone app prototype.

Ethical Considerations and Data Management
A favorable ethical opinion from Cardiff School of Dentistry Research Ethical Committee (reference number 2210a) was provided by the Dental School Research Ethics Committee on September 13, 2022. The study was conducted from October 2022 to May 2023. The project ensured participant safety and privacy by conducting interviews in safe and private locations,
implementing measures to keep both participants and researchers safe, and maintaining confidentiality of personal information. If sensitive information or harm was disclosed, the research team collectively decided about the further steps and documented the process. Participants seeking dental advice were directed to National Health Service (NHS) Wales. No identifiable information was used in reports or research papers. Study protocol was registered on the Open Science Framework.

All information collected from participants during the study was maintained strictly confidential, and any personal information they provided was managed according to Cardiff University requirements and following General Data Protection Regulation recommendations for data protection (2018) [12]. Records and study documents were stored in a password-protected folder within the university’s OneDrive (Microsoft Corp) cloud space and were accessible only to the research team. Paper-based consent forms were stored in a secure, locked drawer within a locked room on the university premises. Anonymized information and consent forms will be retained for 5 years before being destroyed. However, it could be retained indefinitely when it is likely to have continuing value for research purposes. None of the individuals were identifiable from the data in the reports provided to the funders and partners or in the published research papers.

Participants

Sample Size

A sample size was not set a priori with recruitment continuing until the research team agreed that the data set was sufficiently comprehensive and rich to address the research objectives. On the basis of similar research projects, the sample size was expected to be approximately ≤10 parents or carers [13].

Inclusion Criteria

Adults (aged ≥18 y) who (1) were parents or carers of children aged ≤6 years; (2) were willing to attend 2 in-person interviews; and (3) considered themselves to be fluent in English, Arabic, or Portuguese were eligible to participate.

Exclusion Criteria

Anyone who was working or had worked in the dental profession in any capacity was not eligible to participate.

Procedure

Overview

An overview of the project design is shown in Figure 1. In this study, a multimethod approach was used to comprehensively investigate the research question. Multiple qualitative methods were used, consisting of structured interviews conducted during the 2 stages of data collection, complemented by think aloud methods during feedback interviews. The structured interviews were designed in accordance with TFA, enabling a systematic exploration of various acceptability dimensions. Concurrently, think aloud methods provided real-time insights into participants’ interactions with the app. This integrated approach aimed to thoroughly assess parental perceptions about app acceptability and elucidate the underlying factors. The structured interviews offered a systematic framework, whereas think aloud methods provided spontaneous insights, augmenting the depth and validity of the analysis.

The study used structured interviews as the primary data collection method. These interviews followed a standardized format, with predetermined questions aligned with the research objectives and the TFA. The structured interview approach ensured consistency across all interviews and facilitated a comprehensive exploration of acceptability dimensions. The interviews were conducted in 2 stages to capture the initial impressions and feedback after app use and were set up in one-to-one format between the participant and one of the research team members (DPR or WA). They were conducted at a mutually agreed time and in either a quiet room in the university or at a community center, depending on participants’ preferences. Both were appropriate for conducting interviews—safe, accessible, and private.
Phase 1: Recruitment

Overview

A purposive recruitment strategy was adopted, in which 2 different routes were targeted (Cardiff University employees and attendees of a community center). A web-based invitation was posted on the “Taking Part in the Research” Cardiff University Yammer and on Cardiff University’s social media pages and shared within the researchers’ local community networks (Multimedia Appendix 1). Recruitment from Grangetown Community Centre was conducted by attending public engagement events, such as community fairs and local meetings, and by directly approaching the attendees. The researchers worked with the staff at the community center to help coordinate the recruitment and data collection efforts.

Participant Screening, Information Sharing, and Consent Process

Figure 1 describes the process further. The web-based invitation for both groups referred interested individuals to a web-based questionnaire for further information (Multimedia Appendix 2). This also acted as a first-line screen to guide potential participants regarding whether they met the inclusion criteria and asked them to give their contact details. A member of the research team contacted each person via phone or email within 2 weeks to perform further screening to identify those meeting the inclusion criteria and to explain the study, its aim, that it involved one-to-one interviews with the researchers, and any risks and benefits anticipated by participating in the study.

If they were eligible and still interested in participating, the participant information sheet (Multimedia Appendix 3) and a
consent form (Multimedia Appendix 4) were sent to the potential participants via email for them to review before meeting with the researchers during the face-to-face interview.

During the interview meetings, the interviewers discussed the study and checked the participants’ understanding, and a paper-based consent was signed if they were still agreeable to participate, before conducting the interview.

**Phase 2: Requirement Definition and Design Interview**

For the first data collection session (design interviews), participants were invited to complete a demographic questionnaire and the eHLS questionnaire. The interviewer explored with the participants the way they currently found and accessed information related to oral health, experience with using technology for health purposes, and potential ideas for the technical development of the app (Multimedia Appendix 5).

**Phase 3: Develop a Prototype With an App Development Team**

Participants’ inputs were analyzed and shared with the International Dental Federation (Fédération Dentaire Internationale) research team and the Swiss Tomato app development team to conduct brainstorming discussion meetings. The multidisciplinary team examined the results, proposed content and features for the app, and developed the blueprint for the app. The development team used the blueprint to further develop the prototype.

**Phase 4: Feedback Interview (Assess the App’s Acceptability)**

For the second data collection session (feedback interviews), the researchers maintained the same arrangements as in the first session and conducted the interview in person at a suitable and quiet location. Before the interview, a member of the research team contacted the participants to confirm the location, time, and date of the interview. During the interview, the interviewer presented the prototype to the participant as a web page and explained how to use it (Multimedia Appendix 6). The data were collected using 2 strategies. First, “Think Aloud,” where the participants were asked to navigate the prototype while expressing their thoughts and perceptions out loud. In addition, the interviewer asked questions based on the TFA theory at this stage. These questions may have focused on the user’s attitudes and perceptions toward the prototype, such as its perceived usefulness, ease of use, and intention to use the system.

**Data Handling and Analysis**

Recordings were transcribed verbatim using a Cardiff University–approved service. The research team anonymized all personal data collected from or about the participants, except for signed consent forms. Personal information in transcripts that could identify the participants was masked with pseudonyms or omitted if it did not affect the transcript’s context.

Descriptive analysis was used for the participant demographic questionnaire and eHLS data. Qualitative data were analyzed separately for each data collection session using NVivo software (Lumivero) under the Cardiff University license and then interpreted together using a complementary approach. Codebook thematic analysis was used for the design interviews and TFA data [10]. Data from think aloud transcripts were analyzed inductively using reflective analysis.

Participants’ demographic and eHLS details were presented in frequencies. Qualitative data were presented according to the topic summary, with direct quotations from participants’ accounts.

**Results**

**Participants and Interviews**

**Demographics**

The study included 10 parents, with 8 (80%) from Cardiff University and 2 (20%) from Grangetown Community Centre. Table 1 presents their respective demographic characteristics.

**Interview Characteristics**

All participants (10/10, 100%) participated in interview 1. The interviews ranged from 17 to 58 (mean 29.2, SD 11.4) minutes and lasted for a total duration of 292 minutes. However, for interview 2, a participant was unable to attend any of the proposed dates or times owing to a family illness. Therefore, 90% (9/10) of the participants was interviewed during this phase. The duration of the interviews varied, ranging from 23 to 52 (mean 31.1, SD 11.4) minutes and lasting for a total of 280 minutes.

**Phase 2: Understand Parents’ Needs and Their Thoughts About and Experience With mHealth Apps**

Parents were asked to fill an eHLS survey before the first interview. The survey was completed by 90% (9/10) of the participants. Most of them (7/9, 78%) thought that the internet was useful or very useful in helping them to make health decisions, and 89% (8/9) of the parents felt that it was important or very important for them to be able to access health resources on the internet (Multimedia Appendix 7).

The remaining 7 questions (Figure 2) showed that most parents (7/10, 70%) agreed or strongly agreed with the positive statements about their abilities related to using the internet for health purposes.

**Figure 2.** Participants’ responses to the eHealth Literary Scale questions (Qs) 3 to 10 (n=9).
Thematic Analysis of Interviews

Overview

The topic guide prompted the parents to discuss several key areas. First, they shared insights about their current sources of information, highlighting both the positive and negative aspects of the different sources they used. Second, they reflected upon their previous experiences with mHealth apps. Finally, they expressed their opinions about the development of an app to assist them in caring for their children’s teeth. During the discussions, the parents freely discussed a range of topics, which could be categorized into three main groups: (1) general comments, encompassing the perceived need for such an app and its compatibility with their lifestyles; (2) desired content and features they would like to see in the app; and (3) preferences regarding the app’s design and visual elements.

Current Sources of Information

Parents stated that they consulted many sources for a broad range of oral health information, with a focus on teething, oral hygiene practices, and identifying oral conditions. These searches were mainly through the internet, especially Google and government websites such as the NHS website. Although they perceived this as an easy-to-access and readily available tool to find information and give peace of mind regarding a topic, they highlighted several issues, including the often scattered and sometimes contradictory nature of the information on the internet:

...It’s so segregated, so almost every question you have is a separate search. [Parent 8]

Another issue they felt was that the information they found was very general in terms of the management without appreciating the variety of normal presentations:

...The problem with looking on the Internet for a picture of a condition is you’re often shown the worst example and also, you’re not showing the full spectrum of possible images...various health conditions can present in various different ways. [Parent 4]

They also felt that technical details about oral hygiene advice were often lacking:

The main things around the technicalities of it [Brushing]...Everything from selection of toothbrush, the firmness of bristles, the length of brushing and whether the age range that it’s safe for a child to brush themselves. [Parent 6]

There was a perceived lack of information on what parents thought were reliable sources of information, such as NHS website, especially about common oral issues that affected them, such as teething. Web-based forums such as Mumsnet and Facebook groups such as Gentle Parents were also commonly used, providing interactive, specific tips from other parents. A participant found Facebook groups to be particularly helpful for finding green alternatives to oral products:

They are [Gentle Parents Facebook group], generally very ethical and environmentally aware and quite

into natural products rather than more standardised. [Parent 9]

When it comes to credibility of other parents’ advice, parents used their experience to judge:

...If it resonates with my experience, then I would probably go ahead with that. [Parent 9]

Parent’s Previous Experience With mHealth Apps

The parents who were interviewed shared a diverse range of experiences with mHealth apps. Mental health apps, particularly the Headspace app, were the most common types of apps that parents had used. Some parents stated that they downloaded the app because their university provided free access to the “Paid” service, which they considered to be a good deal. Some parents mentioned that they still occasionally used the app as it provided easy-to-follow relaxing exercises, and they appreciated receiving regular updates and notifications. Other popular apps among the parents were the NHS COVID-19 app, which provided instant help about laboratory tests and nearest testing centers during the pandemic, and apps that focus on weight loss and tracking physical activity. None of the interviewed parents (0/10, 0%) reported using or looking for an app to help them find health information.

Parents’ Thoughts About the Development of an mHealth App for Oral Health

General Comments

Participants were positive about having access to an app to assist with children’s dental care, citing the need for a reliable and convenient source of information. They talked about potential challenges to using it. Several parents (2/10, 20%) questioned the app’s effectiveness, as people can easily search for answers to their questions on Google. They also worried about whether users would remember to use the app regularly. A possible solution was suggested by a parent: incentivizing app use by giving users “gold stars” for using it every day to encourage regular use. Another issue discussed was the challenge of integrating the app into busy morning routines. Finally, a parent noted the potential difficulty of using the app alongside other devices or apps and fitting it into their lifestyle but also tried to address these challenges with suggestions:

I still haven’t quite worked out how we could fit it in, in the morning because it’s so staggered...So, the whole idea of teeth time is this time in the morning is much more difficult to kind of work out rather than we’re all heading towards bed and therefore we’re all doing our teeth. [Parent 8]

Screen time concerns were highlighted by some parents as the app is intended to be used by both parents and their child:

I think a lot of parents in this day and age struggle already with the amount of screen time. So that would be a bit of a two-edged sword for me. [Parent 5]

Content Suggestions

Suggestions for the content of the app include accessible guidance to help identify potential oral health problems and about how to manage them. They particularly mentioned
teething, including timings, managing symptoms, providing relief, and understanding when things were normal or not in development:

I just wanted a dentist in my phone...I can check whether I need to go and see the doctor, or this is something I shouldn’t be worried about. [Parent 3]

They also wanted guidance and more precise details about how to perform oral hygiene practices, such as when to start brushing their child’s teeth, introducing flossing, how to handle brushing when the child is using inhalers, and importance of supervised brushing for proper cleaning:

Stuff about how you do it [brushing]? at what age do you let them have more control over it? Till when am I still doing it? Is the whole 2 minutes is still a thing if they don’t have all their teeth? [Parent 7]

Design Suggestions

Parents suggested incorporating notifications, videos, engaging games, stories, and brushing timers into the app. They emphasized the need for brushing timers to be in the form of a song as children may not have a proper perception of time:

Kids don’t actually have the ability to understand time...I would say five more minutes till we got to leave the park. That doesn’t actually necessarily mean anything to a child, but following a song they would be able to know that they’re in the middle of the song. [Parent 6]

Parents stressed the importance of using concise and straightforward language in the app and requested a simple design with the ability to return to the main screen at any time. They also suggested categorizing the app according to age for more targeted guidance. Incentives to download the app were discussed, with recommendations from health care professionals and trusted individuals being the most popular suggestions:

The midwives, they give you like a list of some good apps on new-born babies or these are good apps for tracking how often they’re feeding. [Parent 2]

I go to mother and baby groups, and they always have like posters or information. I guess if I saw something in that environment, I’d kind of be like, Oh, okay, maybe this is something that I should look at. [Parent 3]

Phase 3: Design and Develop a Prototype

The design stage of the study resulted in a prototype of an app named App for Children’s Teeth (ACT) based on parents’ views and their suggestions for content and design (Figure 3). The app was aligned with the Health Belief Model [14], including features to increase parents’ knowledge and self-efficacy regarding their children’s oral health practices as follows:

1. Perceived susceptibility—informs parents about the risks associated with poor oral health practices for their child’s overall health
2. Perceived severity—highlights the consequences of dental diseases if left untreated
3. Perceived benefits—educates parents about the benefits of proper oral health practices and incentivizes children with the stamps feature to brush their teeth regularly for better oral health outcomes
4. Perceived barriers—addresses common barriers to proper oral health practices, such as lack of knowledge, time, and resources, and provides strategies to overcome them, such as finding a local dentist
5. Cues to action—includes reminders and notifications to help parents establish good oral hygiene habits for their child
6. Self-efficacy—provides guidance and resources to help parents feel confident in their ability to perform proper oral health practices and prevent dental diseases from developing...
Phase 4: Assess the App’s Acceptability

Demographics
All participants, except for a woman parent (9/10, 90%), were interviewed for feedback about the app. Demographic information was similar to that in stage 1.

Main Findings
These data were gathered using the think aloud methodology by asking parents to share their thoughts about the design app prototype as they used it.

Content
The subjects that parents particularly wanted to see incorporated into the app included information about teething, how to brush children’s teeth, how much toothpaste to use, and what kind of toothpaste and toothbrush should be used. They also wanted a feature included to help them find a dentist. Although it was not possible to include everything in the prototype, they recognized when something they had asked about appeared in the app:

When I had my daughter, one of the things that I have researched the most was teething symptoms, signs, everything like that. The fact that it’s there and signs of it, how to alleviate. Amazing, love that. [Parent 3]

Design
Parents felt that the structure fitted with their suggestions and it was simple, easy to navigate, and user-friendly. Having a unique character (the beaver) was perceived as a good way to engage the children with the app activities. A parent suggested allowing the child to name their beavers to enhance familiarity and, hence, engagement. Stamps provided upon completing brushing was also another feature that they felt would improve children’s engagement.

Other positive feedback about the design was having a “home button” on the screen all the time, which allows the users to go back to the main screen regardless of wherever they are. The font used (Sans Serif font) was found to be clear; however, a parent suggested checking the accessibility of the text and whether it is sufficiently clear for people with neurodiverse needs.

During the feedback interview, parents found several aspects of the app design to be useful, including the “In a Nutshell” bulletin points at the beginning of each subject, topics being categorized according to child’s age, and the ability to set reminders. In addition, some parents suggested sending notifications about new updates to keep parents engaged with the app for long term but with the ability for parents to control the frequency of these notifications:
You have reminders for toothbrushing. That’s really good for an older child you can get them to put their reminders on. I think they’ll like that. You could also have some notification, if new research comes out, for example, on a topic that you have in...not daily because people are likely to turn them off. [Parent 9]

**TFA Questionnaire Analysis**

As part of assessing the acceptability of the app, the TFA constructs were analyzed using the parent responses (Table 2).
<table>

  system”                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                        |                                                                          | • “I would say so, especially this day and age, everything is so busy. I rely on my phone for many things. It’s helpful to have an app that offers options for setting reminders and schedules.” [Parent 6]                                                                                                                                                                                                                                                                                                                                                      |
|                        |                                                                          | • “The app is prioritising children, I think that’s brilliant.” [Parent 7]                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Burden                 | “Experienced burden: the amount of effort that was required to participate | • Thoughts about using an app such as ACT on a routine basis are variable; some parents thought that they can use such as app, but it will not be realistic to use it on a routine basis:  
  in the intervention”                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                        |                                                                          | • “I don’t think a parent is likely to read about oral hygiene every day or every other day. You’ll read it if there’s an issue.” [Parent 5]                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                        |                                                                          | • Others felt that it provides convenience owing to its structure and being an app:  
  • “No not at all, I think something that you can download on your phone, you can choose a convenient time when you want to look at it and you can just access it any time and just look at the tabs that you want to, I think it’s really useful you’ve got all of the mini tabs, just to quickly click into, right at the front page, so you don’t even have to go digging for information because you can just choose what information you want to access straight away really, so yes I think it would be really useful.” [Parent 5] |
| Opportunity costs      | “Experienced opportunity cost: the benefits, profits or values that were    | • Participants feel that using such a tool will be beneficial to learn about oral health:  
  given up engaging in the intervention”                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                        |                                                                          | • “I think it will be easier because usually, whenever it’s a health-related issue about my children, I just Google things, but now I know there is one place for all information.” [Parent 1]                                                                                                                                                                                                                                                                                                                                                                                                 |
|                        |                                                                          | • It can also be a useful option if the dentist is not accessible:  
  • “If I couldn’t get on a list to go to a dentist which is a big problem for lots of people, it would maybe feel like, well, I can’t do that but at least- Here’s an app that’s giving me information that doesn’t feel like a stretch, I’ve downloaded this app so I’m doing something,” [Parent 9] |
| Perceived effectiveness | “Experienced effectiveness: the extent to which the intervention is perceived | • ACT prototype was found to achieve its goals albeit having different priorities, but most parents emphasized the need to keep the app updated to continue achieving its objectives:  
  to have achieved its intended purpose”                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                        |                                                                          | • “I’ve learned two things just by looking at it, but the information should be regularly updated, I suppose.” [Parent 7]                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Self-efficacy          | “The participant’s confidence that they can perform the behaviour(s) required | • Parents have different views about whether they feel confident that using the ACT app will keep them informed. Most cautious opinions where around whether the app follows the child’s growth:  
  to participate in the intervention”                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                        |                                                                          | • “You’d have to see more, it certainly will keep me informed because I have a resource to go to, but it would depend on the full functionality. As the child ages up, does the information change to stay current? Does it prompt you that maybe you should be buying a different type of toothbrush at this age?” [Parent 3] |
Health Literacy and Participants’ Demographics

Suggestions for Further Development

Other suggestions were to enhance the app by addressing teeth shedding time, creating forum spaces for parent communication, and integrating augmented reality for guided brushing.

Discussion

Principal Findings

This study found that the interviewed parents felt there was a need for a reliable tool that they had confidence in, to assist them in managing their children’s oral health. This resonates with the worldwide trend of people using health apps to improve public health. With >55,000 health apps available globally on Google Store [15], these tools have, in some cases, been carefully evaluated to see how well they help with things such as diet [16,17], physical activity [18], or managing blood sugar [19]. mHealth apps are the most popular downloads from app stores.

They felt this would be particularly useful for young children who experience multiple landmarks during dental development such as teething, breastfeeding, and starting to brush their teeth.

An mHealth app for oral health was considered by them to be a viable possibility in filling this gap and would be easily accessible and useful for parents. Although a loose topic guide was used for the interviews, the parents were given the opportunity to talk broadly about oral health information, its sources, and the potential use of apps. Unsurprisingly, engaging the target population helped us understand their needs and preferences, and the iterative nature of the design process emphasized the need to continuously refine the prototype based on feedback. This is important in the development of digital health interventions such as mobile apps, which require a user-friendly interface and a seamless user experience to be effective.

Health Literacy and Participants’ Demographics

Health literacy is a relatively new concept. It is “linked to literacy and entails people’s knowledge, motivation and competencies to access, understand, appraise and apply health information in order to make judgments and take decisions in everyday life concerning health care, disease prevention and health promotion to maintain or improve quality of life during the life course” [20]. It is known to be linked to better health outcomes, as individuals with high levels of health literacy are more able to navigate health care systems, advocate for themselves, and make good health and prevention-based choices [20]. Approximately half of the adults in the United States have been found to have a low or marginal level of health literacy [21], with similar findings in Europe [22]. With both the risk of dental caries and low health literacy being linked to socioeconomically disadvantaged groups, there is a risk that those who are most in need of easily available evidence-based preventive advice and oral health information are the least likely to be able to find, access, and use it. Using eHLS, the population that volunteered for this study showed an overall high level of health literacy and was likely not representative of the overall Welsh and UK populations. Nevertheless, they were in a good position to help inform the development of the prototype and comment about it. We tried to recruit different populations by accessing a group through university employees and a separate population in an area of Cardiff with low socioeconomic status. We used a community hub to invite participants and it may be that those who attend the hub are more likely to have reached a higher level of education and therefore health literacy than those who do not access the hub. For the further development stages of the app, we would actively seek a more representative group, possibly by accessing patient groups.

It was interesting that some of the parents mentioned screen time for their children as perhaps being a barrier to having the child engage with the app. The 2022 Ofcom Report about media use for parents and children found that in the UK nations, parents in Wales were more likely to be very concerned about their child’s media use [7,23].

Design Process

Parents’ Current Source of Information

During the design interviews, parents reported that they primarily relied on search engines and government websites, such as the NHS website, for information about children’s oral health. However, they did not mention any specific resources dedicated to children’s oral health, indicating a need for better education and awareness about reliable sources of information. This may suggest that existing reliable resources have limited impact and reach, despite the funding and man power that are
Development With an App Development Team
During the development of the dental app, collaboration with the app development team brought both excitement and the natural occurrence of differing priorities. Cross-disciplinary synergy was a highlight, with the app developers effectively responding to parent feedback by creating a user-friendly interface with quick 1-click buttons and a home button for easy navigation. However, differing priorities emerged with the app developers aiming for minimization of the number of screens for cost control, whereas the dental team prioritized clinical relevance and usability. These variations in focus were resolved through dialogue and compromise, leading to a better product.

Feedback About the Prototype
The ACT app design and its content, created based on parents’ feedback and underpinned by the Health Belief Model, were felt by parents to have the potential to promote good oral health practices among children and parents. The positive findings of our project are consistent with the available evidence regarding the end user’s accessibility of using such technologies for oral health promotion [25-27]. Parents emphasized the importance of simplicity and user-friendliness of the app. These features were considered just as important as the quality of information provided in the app, highlighting the need to consider user experience in the design process and the importance of involving users in the development of health interventions. These findings are consistent with those of previous studies.

Key features of the app that were positively received included the incorporation of unique features such as a relatable character (the beaver). The character may have provided a sense of personalization and connection to the app. The “stamps” feature was designed based on gamification principles, providing a tangible and visible reward for completing oral-related tasks [9]. This type of engagement strategy has been shown in a meta-analysis to be effective in promoting positive oral health behavior change, such as regular toothbrushing and flossing, among children and parents [28]. The reminder and notification feature of the ACT app was positively received by parents, indicating its potential value in promoting long-term engagement with the app. Reminders and notifications can increase engagement and retention in digital health interventions and can lead to improved health outcomes.

Although the app has several positive features, some feedback highlighted the aspects to be considered for future development. Many parents (6/10, 60%) expressed the need for NHS endorsement as a crucial factor in engaging with the app. Securing NHS endorsement poses significant challenges owing to the stringent standards and guidelines established by NHS [29]. These complexities span clinical validation, regulatory adherence, incorporation of user feedback, engagement with stakeholders, conducting health economic assessments, and intricate management of legal and ethical considerations. Each of these facets demand meticulous attention and allocation of resources to align with NHS’s rigorou criteria and secure their indispensable support. Therefore, careful planning and consideration of these factors are necessary in further development stages.
Limitations
The study’s results may have been limited by several factors. First, most of the participants (8/10, 80%) were highly educated women, most (participants had university education; 9/10, 90%), and the age range was relatively narrow, with all participants (10/10, 100%) aged between 25 and 44 years. This was probably related to the recruitment strategy despite efforts to recruit diverse groups by targeting both a university employee cohort and local community center members.

Furthermore, the recruitment process relied on convenience sampling, which may have resulted in a sample that is not representative of the broad population. Although the researchers made efforts to recruit participants through multiple channels, all participants (10/10, 100%) were from 1 city, which may limit the applicability of the findings. This is particularly relevant because the app was developed in collaboration with the International Dental Federation (Fédération Dentaire Internationale), which aims to further refine the app with global perspective.

It is crucial to highlight that the exclusion of children as participants in our study significantly hampers our comprehension of their perspectives regarding the app. This is particularly important considering that parents expressed the belief that the app should be used collaboratively by both the parent and the child. By omitting children from the study, we miss valuable insights that could contribute to a more comprehensive understanding of the app’s use dynamics.

In addition, the development process may have been constrained by limited funding and man power, which may have influenced the extent of user testing and refinement of the app. However, despite these limitations, the study provides valuable insights into the importance of user-centered design and testing in the development of mHealth apps. Future studies can use these insights to further refine and evaluate the effectiveness of the app in improving oral health outcomes in diverse populations.

Conclusions
Digital health interventions, such as the ACT app, have the potential to promote healthy behaviors among children and have important implications for public health. The incorporation of theoretical framework, user cocreation in the design process, and emphasis on simplicity and user-friendliness have been identified as key factors contributing to the success of the intervention. These strategies have also been shown to be effective in promoting engagement and adoption of the intervention. Further studies are needed to build the app based on parents’ views and pilot test to evaluate its impact on promoting healthy behaviors among children.

The study highlights the importance of user-centered design when developing health-related tools and the value of conducting user research and iterative testing to ensure that the tool meets the needs of the target audience. The findings of this study can inform the development of similar tools in the future and ultimately help to improve oral health outcomes for young children.

Acknowledgments
This study was supported by the Higher Education Funding Council Wales Research Wales Innovation Fund through Cardiff University (Innovation for All). The sponsor had no role in data collection or publication. The authors would like to express their gratitude to Ms Annalisa Willmott for her valuable contributions and insightful discussions.

Data Availability
Preliminary data are available upon reasonable requests.

Authors’ Contributions
DPR, WA, NI, and MA conceived the study. WA and DPR conducted the participant interviews and collected the data. WA analyzed the data. WA, DPR, and NI drafted the manuscript. All authors read and approved the final manuscript before submission.

Abstract

Background: Web-based parent training (PT) programs can strengthen parent-child relationships by equipping caregivers with knowledge and evidence-based strategies to manage behavior. Hybrid facilitation of PT includes facilitator interaction paired with self-administered and web-based PT. Web-based administrative dashboards provide users (eg, administrators, facilitators, and researchers) with an integrated platform to monitor parent progress and activities within a PT program or website. Despite the utility and prevalence of administrative dashboards for web-based behavioral interventions, to our knowledge, no research studies have explored the perspectives and insights of dashboard users to enhance user experience and program delivery.

Objective: The purpose of this study is to evaluate the usability of the administrative dashboard (ezDashboard) for the ezParent program, a 6-module web-based PT program for parents of children aged 2-5 years.

Methods: This study used a descriptive, single-group design with administrators who were overseeing the implementation of the ezParent program and trained facilitators for hybrid ezParent delivery. Participants spent at least 30 minutes reviewing and evaluating the ezDashboard and then completed a survey of their experience with the dashboard. The survey included the validated 10-item System Usability Scale and open-ended questions focusing on user performance, navigation ease, and overall usefulness of the ezDashboard.

Results: Participants (N=15) indicated high usability of the ezDashboard with System Usability Scale scoring a total mean score of 83.5 (SD 16.3). Most participants (n=13, 87%) rated the overall user-friendliness of the ezDashboard as good (n=3, 20%), excellent (n=9, 60%), or best imaginable (n=1, 7%). Open-ended questions revealed the ezDashboard is or would be useful to monitor parent progress and trends in engagement (n=8, 53%) and for reviewing topics for discussion and communicating with parents (n=5, 33%). ezParent administrators (n=4) identified that real-time data for ezParent use helps overall management of program uptake. Suggestions for features to add to the ezDashboard included the ability to track partial progress of program modules (4/14, 29%), total time spent per module (2/14, 14%), and exportable reports (4/14, 29%). Other ideas for improvement included direct messaging capabilities, videoconferencing platform integration, and being able to modify participant account and contact information.

Conclusions: Results indicate that the ezDashboard is easy to use and provides functional information to facilitators and administrators in delivering ezParent. Qualitative results indicate that integrating suggested features into the ezDashboard may help provide a smoother experience for facilitators, administrators, and ultimately the parents using the program. Providing resources for facilitators and administrators in real time to monitor intervention participants’ progress in a program can be helpful in tracking progress and providing facilitated support in tailoring program content and program completion.

Introduction
Parent training (PT) programs—the gold standard for prevention and treatment of child behavior problems [1-3]—aim to strengthen parent-child relationships by providing caregivers with knowledge and evidence-based strategies to effectively strengthen their parenting skills and support their child’s positive behavior. Parents who have participated in PT programs have demonstrated improvements in multiple areas, including improvements in positive parenting skills, self-efficacy, and parent-child interactions; and reductions in negative or harsh parenting and parenting stress [2,4,5]. PT participants’ children exhibit improvements in child behavior, display decreased conduct problems and aggression, improvements in academic performance, enhanced coping skills, and strengthened relationships with both caregivers and peers [2,4]. Traditionally, PT programs have been offered in-person in group or individual settings; however, web-based adaptations have emerged to mitigate the geographic, logistical, and personal barriers of face-to-face delivery [6-8].

In addition to web-based programs, web-based administrative dashboards have emerged as a promising method to improve delivery and management of web-based interventions [9-11]. These dashboards provide an integrated platform to monitor user progress and activities within a program or website. Administrative dashboards are particularly useful tools for administrators, implementers, researchers, and others who require access to detailed information regarding user usage patterns, performance and achievements, and program progress and completion [10,12,13]. For example, in a research and practice context, dashboards can be used to monitor program fidelity and provide clear metrics to understand how the program is being used in real time.

In the context of web-based programs delivering behavioral interventions, administrative dashboards prove particularly valuable. For example, administrative dashboards can include timestamps for login and logout; activity completion; and fill-in responses to in-program prompts, quiz results, page clicks, and diary entries [9,11,14,15]. These program usage metrics enable administrators to make data-driven decisions, identify areas for improvement, and provide critical support to program and research staff when offering personalized guidance to users [10]. Researchers and program facilitators working directly with participants can leverage the dashboard to prepare for discussions by reviewing the participant’s last logins and progress, using fill-in prompt responses to ask tailored questions, and providing troubleshooting recommendations to encourage program engagement [9,11]. Armed with these data points, facilitators can improve their support of participant use of a program, tailor program materials, and ultimately support improvement for child and parent social-behavioral outcomes.

Despite the utility and use of administrative dashboards, to our knowledge, there are no research studies exploring the user experience of an administrative dashboard related to web-based behavioral interventions. Thus, there is an opportunity for further research to optimize existing functionalities and address limitations to better support administrative dashboard users. Usability, which plays a crucial role in the adoption, engagement, and overall effectiveness of web-based administrative dashboards supporting behavioral health interventions, becomes paramount. The usability of a web-based innovation is commonly assessed on several domains including the efficiency, intuitiveness, ease of use, and satisfaction experienced by the user [16]. The purpose of this study was to investigate the usability of the administrative dashboard for the ezParent program, a web-based PT program. Specifically, our goal was to establish a baseline for user performance, ease of navigation, and usefulness.

Methods

Study Design
This study was a descriptive, single group survey design with participants who were overseeing the implementation of the ezParent program (administrators) or trained facilitators for hybrid ezParent delivery (facilitators).

ezParent Program
The ezParent Program is the web-based delivery of the Chicago Parent Program (CPP). The CPP has been shown to be effective in improving positive parenting skills, parenting self-efficacy, and child behavior problems in a population of low-income, urban parents of children aged 2-5 years old [17,18]. The ezParent Program teaches parents and caregivers the evidence-based strategies of CPP using 6 modules that include a video narrator and vignettes of families using the skills, reflection questions, program activities, and in-home practice assignments [19]. In a pilot randomized controlled trial (RCT) of ezParent (n=83), parents completed 82% of the 6 modules, reported high satisfaction with the program, and we found comparable effect sizes in improvements in parenting practices and reductions in parenting stress and child behavior problems to the group-based CPP [20,21]. In an RCT of self-administered ezParent in primary care (n=287), we failed to find significant main effects for parent and child behaviors [22]. Based on our findings and the extant literature suggesting web-based programs are more effective when provided along with human support [22,23] we are currently testing 2 models of hybrid delivery. The first includes 1:1 brief coaching as part of an RCT funded study (see Greene et al [24]) and community-based delivery of ezParent paired with web-based group sessions [25].

ezParent Dashboard Design and Development
The ezParent program tracks user progress as parents use the program. Custom data tables collect and store user data with...
timestamps for logins, completed modules, end-of-module surveys, badges, practice assignments, and practice reviews. The administrative dashboard (ezDashboard) was developed to include these data points for hybrid delivery facilitators to monitor parent progress in the program and to inform hybrid sessions to encourage and support parent program uptake.

ezDashboard logins are created internally by programming staff and are provided to administrators and facilitators. Users access a “Parent Lookup” form by entering the unique ID given to parents during ezParent enrollment and the parent’s last name. These form fields are used together to ensure participant data security. The parent is added to the home page or “Parent List” if the user ID and last name match an individual user in the database. The parent list displays the user ID, last name, last login date, and the last viewed module. When a parent has completed their time in the ezParent program, users can easily remove that parent from their home page.

From the parent list, ezDashboard users can access more details for an individual parent user by clicking on a “Details” button. The top of the “Details” page displays the user ID, name, phone number, and participant email for easy contact. Contact information is followed by detailed use metrics, including a scrollable list of all login dates, completed modules with a green check mark to indicate completion and the date they were completed, module survey responses, completed badges and dates earned, and responses for practice assignments and practice reviews. Finally, a downloadable, individualized completion certificate is accessible once the last (sixth) module is completed. See Figures 1 and 2 for ezDashboard screenshots.

The ezDashboard’s user interface was made in React (version 17.0.2; MetaOpenSource), using responsive web design principles to allow access across different device sizes. Microsoft SQL Server stores real time user data, which the user interface fetches and displays.

Ethical Considerations
The research protocol for this study was determined exempt by the institutional review board at The Ohio State University (study number 2023E0289). Participants completed a web-based consent form. All survey data were deidentified and participants were informed that deidentified data may be used or shared without additional informed consent. Participants who consented and completed the survey received a US $25 gift card for participation in this study.

Participants
We invited ezParent administrators (n=4; individuals overseeing implementation of ezParent) and facilitators (n=19; trained facilitators for hybrid ezParent delivery) to participate in the usability study with a goal for a sample size between 10 and 15. Administrators and facilitators were invited as they may have unique perspectives related to usability depending on their ezParent role. Macefield [26] suggests that a sample size of 3-20 is valid in a usability study to discover usability and potential problems and a sample of 10 will probably reveal a minimum of 82% of the problems and be useful in future design changes. Of the 23 invited to participate in the usability study, 16 consented to participate, and 15 completed the review of the ezDashboard and usability survey.

Procedures
Potential participants received an email inviting them to participate in the usability study. The email invitation included a description of the project and a link to the consent form in REDCap (Research Electronic Data Capture; Vanderbilt University) [27]. Once consent was obtained, participants were instructed to spend at least 30 minutes reviewing the ezDashboard and evaluating the features. Participants who were not current users of the ezDashboard were provided with login access and instructed to add 2 sample users to their Parent List. Current users of the ezDashboard were instructed to sign into their accounts and review user accounts on their existing Parent List. Both groups were instructed to evaluate their users’ activity on the main page and on the detailed page of all modules in order to evaluate the usefulness of the ezDashboard. These procedures include typical tasks that a facilitator would take in evaluating and monitoring parent use of ezParent. Then, participants were prompted to complete the survey and asked to identify their current role using the ezParent program (eg, facilitator or administrator). At the completion of the survey, participants received a US $25 gift card for their participation.

Measures
The 10-item System Usability Scale (SUS) is a tool for assessing the usability of a product (eg, websites, cell phones, and apps). The 10 items are scored on a 5-point Likert scale (range 0 strongly disagree to 4 strongly agree). A total usability score,
representing a composite measure of usability is created by reversing the score of even-numbered items, summing the items, and multiplying by 2.5 to convert the original total scores of 0-40 to a 0-100 scale [28]. A score of 70 is considered average, 80 good, and 90 or above excellent usability [29,30]. The SUS is a simple and efficient tool for assessing the usability and user-friendliness of a technological platform with demonstrated reliability across multiple studies (α=.91) and strong evidence of a single factor structure [29]. Our administration of SUS reflected the revised language and overall rating of the user-friendliness introduced in Bangor and colleagues [30]. Survey responses were collected in REDCap [31,32].

Following completion of the SUS, participants were prompted to respond to open-ended questions to elicit further information on their opinions of the ezDashboard. Questions included the frequency of use and the helpfulness of the ezDashboard and items that may be missing or could be changed in future iterations. Facilitators were asked specifically how access to this real time information helps them work with parents using the ezParent program and administrators were asked how the information helps them with overall management of the program. Finally, participants were asked to self-report their race or ethnicity, age, and gender.

Analysis Plan

The composite SUS score was calculated by reverse scoring even-numbered items so that all items were scored in the same direction. Composite scores were then calculated by summing the item responses and multiplying them by 2.5 so that they fell on a scale of 0-100. Summary statistics were calculated for the composite scores and frequencies are reported for the overall rating of user-friendliness.

For analysis of the open-ended questions, 2 authors organized the responses by group (eg, administrators and facilitators) and conducted a thematic analysis of all responses based on the steps outlined by Braun and Clarke [33]. First, we reviewed all the responses and generated initial themes and categories. These categories were reviewed by the 2 authors and confirmed by a third author. Finally, we categorized the themes in order to provide a description and examples in this report. We quantified the comments in each category in order to provide a frequency related to participants’ ideas, suggestions, and ideas provided related to the usability of the ezDashboard.

Results

Participants

A majority of participants (N=15) were women (n=12, 80%), White (n=11, 73%), with a mean age of 40.9 years (SD 13.9; range 20-68; Table 1). Participants were ezParent facilitators (n=10) and administrators (n=4); 1 participant did not report their role with ezParent. Participants (n=9) who were actively using the ezDashboard at the time of the survey reported weekly use (n=3, 33%), once every few weeks (n=1, 11%), monthly (n=1, 11%), and less than monthly (n=4, 44%).

About SUS

Scoring of the SUS indicated high usability of the ezDashboard with a total mean score of 83.5 (range 47.5-100; SD 16.3; median 90, IQR 72.5-97.5). Overall, most participants (n=10, 67%) rated the overall user-friendliness of the ezDashboard as excellent (n=9, 60%), or best imaginable (n=1, 7%; Table 2). On average new users (n=6) ranked the ezDashboard higher (mean 90.8, SD 8.01) than existing users (n=9; mean 78.6, SD 18.84); however, this difference was not statistically significant (P=.16) and may be the result of high variability associated with small samples.

Open-Ended Survey Responses

Usefulness of the ezDashboard

Participants (N=15) reported that the dashboard allowed them to keep track of parent progress and identify potential problems that may arise with parent completion of ezParent modules and serves as a helpful cue for discussion with parents. Specifically, 53% (8/15) of participants, both current users and participants who had not yet interacted with the ezDashboard, identified that the ezDashboard is or would be useful for monitoring parent progress and identifying trends in parent participation. As 1 facilitator reported, “I typically check it right before the calls to see the participant's last login and how much of the program they have completed.” Another reported, “This makes it much easier to track program adherence and help support parents who need a little extra help in completing the program.” Finally, a participant wrote, “Overall trends of participation are helpful to learn if any systemic barriers to participation need to be addressed.” In addition to monitoring progress, participants (n=5, 33%) identified the ezDashboard as useful in reviewing topics for discussion and communicating with parents during the hybrid session. For example, 1 participant wrote “I would use the dashboard to...Refer back to specific content from modules,” and another “use it to inform the next group meeting, for example, if I noticed that everyone thought a previous module was difficult, I would give more time to that discussion.”

ezParent administrators (n=4) identified that real-time data for ezParent use helps overall management of program uptake and promotes parent motivation and accountability for module completion. For example, 1 program provides incentives for module completion and uses the ezDashboard for tracking program use for the provision of these parent incentives. Administrators also provided that this information “would also be helpful for facilitators in learning when/how/if they need to modify their approach” when facilitating hybrid ezParent and allows them to respond to questions from parents more promptly.

Suggested ezDashboard Changes

Participants (N=15) were asked if there was any information missing from the ezDashboard (14 responded). Overall, participants suggested potential data points in the ezDashboard to allow a more in-depth assessment of parent program use. Participants (n=4, 29%) identified that the ability to track partial progress through the modules would be useful, with suggestions of “it would be nice to see the # of logins for a week” and “it would be nice to differentiate if modules were completed or started, such as a sliding scale of how far through the module the parent has gotten so far.” In total, 2 (14%) participants suggested tracking the total time spent in each module as a method to understand meaningful engagement with the program and whether “a parent may be working a little too quickly through the program.” The administrative participants (n=4) believed “exportable, customizable reporting” would be useful for overall program management. In addition, more control in terms of modifying ezDashboard information was identified, including amending parent information (eg, name and phone number) and the ability to group parents by cohort for tracking. In total, 38% (6/16) of the participants indicated that they would change nothing to make the ezDashboard easier to use.

Beyond program metrics, participants identified changes that would integrate the hybrid delivery methods into the ezDashboard. For example, including attendance records for hybrid meetings and integrating a method to directly communicate and contact parents (eg, texting) with parents in the dashboard so they could “nudge parent to modules.” Another suggestion included integrating the videoconference system into the dashboard so all program activities could occur in 1 place.

Discussion

Principal Findings: ezDashboard Usability

The purpose of this usability study was to identify the overall performance of the ezParent administrative dashboard and understand users’ perceptions of the ease of navigation and usefulness of the ezDashboard in implementing hybrid delivery of the ezParent program. Further, we were interested in collecting users’ suggestions for changes or additions to the ezDashboard to improve the overall user experience for real-world use.

Overall, ratings on the SUS indicate good usability (mean 83.5, SD 16.3; median 90, IQR 72.5-97.5). According to Bangor and colleagues [29], a mean score of 83.5 is in the fourth quartile of scores, rated as acceptable, and falls between the good to excellent range using an adjective rating scale. In addition, overall ratings of the user-friendliness of the ezDashboard among all participants were positive (ok, good, excellent, and best imaginable). These initial ratings are promising, show an
acceptable level of usability, and the written feedback provides us with concrete methods for improving the ezDashboard.

This study’s participants reported variable use of the ezDashboard (eg, ranging from weekly to less than monthly). The differences in use may be a function of the individual’s role using ezParent (eg, administrators may only need to use the dashboard monthly for overall program management while a coach conducting weekly calls would use it weekly). We do, however, need to consider the variability of use as a potential function of the overall usefulness of the information provided in the ezDashboard. Therefore, our next steps will be to provide clear instructions and descriptions of ezDashboard use as well as integrate suggested changes. Changes to the ezDashboard to provide desired information of parent use may increase regular use and uptake.

Harrington and colleagues [10] highlight the importance of including program usage metrics in dashboards to allow interventionists to make data-driven decisions, identify areas for program improvement, and support the ability to provide personalized support to program users. Further, real-time data can support tailored approaches to increase program uptake. Overall, our participants reported that they were able to use the ezDashboard information to take an individualized approach to the hybrid delivery of the ezParent program, and administrators used the ezDashboard data to provide oversight and incentives to parent participants. In addition, there were several excellent suggestions for ezDashboard improvements. The suggested changes varied by participant role with ezParent.

Facilitator suggestions were primarily fine-tuning the data presented in the ezDashboard to provide more nuanced use metrics beyond module completion. Since most digital analytics provide summary statistics, the ability to gather use metrics at the individual level provides important information for the facilitation of program engagement [14]. The data points suggested were partial module completion, identifying the actual location within the module of last use, and average time spent on the page. While the ezDashboard currently provides time stamps for date and time, the modules were completed and allows for a rough estimate of the speed at which a parent is moving through the program; more specific analytics for time in the program could provide more meaningful estimates for engagement. In our previous work, we found that on average parents spent 37.2 (SD 22.2) minutes per module with a range from 26.4 (module 5) to 47.9 (module 2) minutes [21]. Variations across modules occurred because of variations in pages per module; however, there was a significant decrease in minutes/module over time (eg, participants spent less time on later modules) [21]. This information is important for facilitators to monitor parent engagement and to encourage active involvement in the modules, particularly in later modules when data support a decrease in overall time of engagement.

The administrative participants identified other types of metrics and functions that would be helpful for program management (eg, the ability to download individual and cohort reports of usage metrics to allow for more streamlined monitoring and administrative access to modify participant demographics). The goal of the ezDashboard is to present individual use data and adaptations to include monitoring cohorts, which could increase administrative efficiencies. A benefit of web-based interventions is the reach and accessibility of programs and the integration of administrator dashboards for monitoring and management and has the potential to increase program uptake and overall efficiencies in program delivery. Future evaluation of the ezDashboard will focus on the effects of ezDashboard use on implementation factors related to organizational and individual program uptake and delivery.

**Limitations**

Although deemed sufficient for usability testing to acquire feedback on user experience, our sample size was small. This study was an initial evaluation of the ezDashboard and provides valuable information for modifications. Our next steps are to integrate these findings into the ezDashboard to evaluate overall use of ezParent and dashboard use in a pragmatic ongoing trial with a larger sample of facilitators and administrators.

Additional limitations of this study include the usability testing being done virtually and at only 1 timepoint, which precluded our ability to examine participants’ actions in real time while using the ezDashboard in a pragmatic ongoing setting. Users’ feedback may change after continued use of the ezDashboard. The administrative dashboard was only tested for 1 specific intervention, ezParent; however, we believe these results could be applicable and inform the development of dashboards for different types of web-based programs.

**Conclusions**

The ezDashboard was initially developed to provide individual parent usage data to facilitators in real time to monitor parent progress in the program and support parent program uptake. The results of usability testing indicate that the ezDashboard is easy to use and provides functional information to facilitators in delivering the ezParent intervention. Providing resources for facilitators and administrators to aid in facilitation of the hybrid intervention may lead to improved parent uptake and outcomes [34]. Qualitative results indicate that integrating suggested features into the ezDashboard may help provide a smoother experience for facilitators, administrators, and ultimately the parents using the program. Administrative dashboards that provide real-time program usage data require an investment in the upfront cost of program development. The user facing program, in this case the ezParent, must be built to collect the user data that are to be displayed in the dashboard. For those considering integrating a dashboard for a web-based intervention, we suggest early planning during the initial development.
Acknowledgments
The authors gratefully acknowledge the coaches, facilitators, and administrators who participated in the evaluation of the eDashboard. This study is supported in part by a grant from the National Institute of Child Health and Human Development (NICHD; R01HD104072).

Abstract

Background: Public safety personnel (PSP) are individuals who work to ensure the safety and security of communities (eg, correctional workers, firefighters, paramedics, and police officers). PSP have a high risk of developing mental disorders and face unique barriers to traditional mental health treatments. The PSP Wellbeing Course is a transdiagnostic, internet-delivered cognitive behavioral therapy (iCBT) course tailored to assist PSP with symptoms of depression, anxiety, and posttraumatic stress disorder (PTSD). The initial course outcomes are promising, but some clients report some challenges with learning skills and recommend adding additional resources. Mindfulness meditations, which help people to experience the world and their reactions to the world in open and nonjudgmental ways, may complement the existing PSP Wellbeing Course.

Objective: This study aims to examine the feasibility of mindfulness meditations in iCBT tailored for PSP. Information was gathered to evaluate engagement and client experiences with mindfulness meditations, symptom change, and the relationship between mindfulness meditation use and symptom change.

Methods: A mixed methods study was conducted on PSP enrolled in the PSP Wellbeing Course who were offered 5 mindfulness meditations during the program (ie, 1/lesson). Clients completed questionnaires on depression, anxiety, PTSD, anger, insomnia, resilience, and mindfulness at pretreatment and at 8 weeks; an 8-week treatment satisfaction questionnaire; and brief weekly measures of mindfulness meditation engagement. We used paired sample $t$ tests (2-tailed) to assess changes in outcomes over time and partial correlations to assess whether mindfulness meditation use predicted outcomes at posttreatment. A total of 12 clients were interviewed about their perceptions of the mindfulness meditations, and interviews were analyzed using directed content analysis.

Results: Among the 40 clients enrolled, 27 (68\%) reported using the mindfulness meditations, practicing for an average of 4.8 (SD 8.1) minutes each week. Most interviewees described the mindfulness meditations as beneficial but also reported challenges, such as discomfort while sitting with their feelings. Clients provided suggestions for better integration of mindfulness into iCBT. Overall, clients who completed the PSP Wellbeing Course with mindfulness meditations experienced statistically significant improvements in symptoms of anxiety ($P=.001$), depression ($P=.001$), PTSD ($P=.001$), and anger ($P=.001$) but not insomnia ($P=.02$). Clients also experienced improvements in resilience ($P=.01$) and mindfulness ($P=.001$). Self-reported time spent meditating was not associated with changes in symptoms over time.

Conclusions: This study provides new insight into the integration of mindfulness meditations with iCBT for PSP. It demonstrates the partial feasibility of adding mindfulness meditations to iCBT, revealing that some, but not all, PSP engaged with the meditations.
and reported benefits. PSP reported using the mindfulness meditations inconsistently and described challenges with the meditations. Improvements can be made to better integrate mindfulness meditation into iCBT, including offering mindfulness meditation as an optional resource, providing more psychoeducation on managing challenges, and offering shorter meditations.

Introduction

Background

Public safety personnel (PSP: eg, border services officers, correctional workers, firefighters, Indigenous emergency managers, operational intelligence personnel, paramedics, police officers, public safety communicators, and search and rescue personnel) have greater exposure to potentially psychologically traumatic events than the general population and a greater risk for several psychological disorders. This heightened risk is, in part, attributable to the nature of their vocations [1-3]. In a recent pan-Canadian study, 44.5% of PSP screened positive for at least 1 mental disorder on a set of questionnaire measures [1], which is far higher than the rate of mental disorder diagnoses in the general population (ie, 10% [4]). Other studies show PSP also report high levels of anger [5] and sleep difficulties [6]. Despite the significant need for mental health treatment, PSP face several unique barriers to treatment as a function of their vocational cultures and requirements [7]. PSP report concerns about engaging in face-to-face mental health treatment options, including geographical barriers; the cost of treatment; difficulty navigating services; long wait times; and, in particular, concerns about privacy, confidentiality, and stigma [6,8-10].

Internet-delivered cognitive behavioral therapy (iCBT) appears to be well positioned to address barriers to treatment experienced by PSP, as it delivers treatment materials in a private and accessible web-based format. There is strong evidence that iCBT has comparable effectiveness with face-to-face cognitive behavioral therapy (CBT) among the general population [11]. A recent observational trial found that iCBT tailored specifically for PSP was associated with large pre-post reductions in symptoms of generalized anxiety disorder, major depressive disorder, and posttraumatic stress disorder (PTSD), although it was not compared with a control condition [9]. In written feedback, PSP who participated in iCBT reported appreciating several aspects of iCBT, including the format and content, the accessibility of the course, the additional resources and examples, and the therapist guidance [12]. Nevertheless, some PSP also reported challenges with learning skills [13] and provided suggestions for improving iCBT, including adding more resources [12].

The addition of mindfulness resources represents a promising addition to iCBT with PSP, given the growing research attention on the benefits of mindfulness [14-16] and its use in CBT [17]. Kabat-Zinn [18] provided the most commonly used definition of mindfulness: a three-component definition that calls for paying attention (1) on purpose, (2) in the present, and (3) nonjudgmentally. Mindfulness shifts awareness to focus on present-moment activities, thoughts, and sensations, which over time improves emotion regulation and, in turn, reduces symptoms [19]. Mindfulness may be cultivated through numerous activities that bring individuals into the present moment and into their experience without judgment. Mindfulness meditation, in particular, is a practice to cultivate mindfulness and refers to the practice of silently observing one’s own internal and external environment without attempting to change anything [19]. In the general population, several studies have shown that web-based mindfulness programs result in small but significant improvements in symptoms such as depression and anxiety [14-16]. In terms of PSP, mindfulness-based interventions have been associated with reductions in stress, insomnia, burnout, anger, anxiety, and depression [20,21]; however, research has been limited to pilot or feasibility studies, police populations, and in-person class delivery style [3,22].

Recent literature suggested that incorporating mindfulness may enhance the benefits derived from traditional therapies [17]. Mindfulness practice has been successfully integrated within face-to-face interventions, such as mindfulness-based stress reduction, mindfulness-based cognitive therapy, and acceptance and commitment therapy [17]. Moreover, a recent systematic review and meta-analysis reported that mindfulness-enhanced iCBT has demonstrated significant reductions in anxiety and depression in clinical populations, above and beyond comparison conditions [17], but to date, no research has focused on offering web-based mindfulness-enhanced iCBT for PSP. Although it is possible that the results of mindfulness-enhanced iCBT will generalize to the use of iCBT for PSP, this remains an empirical question. Some past research among PSP suggests that they may be more skeptical of mental health support [7]. Some studies on mindfulness among PSP have yielded mixed results, with only some participants reporting improvements [21]. Therefore, it is important to explore whether mindfulness meditations will be used and positively evaluated by PSP within the context of iCBT and whether adding mindfulness to iCBT will positively or negatively impact engagement, satisfaction, and outcomes. Adding mindfulness meditation to iCBT has the potential to increase the engagement, satisfaction, and effectiveness of iCBT. However, adding additional components could also reduce effectiveness through additional burden placed on users or if users have negative views of mindfulness meditations.

Objectives

As a first step in understanding the use of mindfulness meditation as part of iCBT for PSP, this study was designed to examine the feasibility of adding mindfulness meditations to an existing iCBT program for PSP, called the PSP Wellbeing Course, by (1) evaluating the level of engagement with the
mindfulness meditations (eg, practice length and frequency) as well as with the intervention; (2) assessing client experiences with mindfulness meditations during and after treatment; (3) measuring changes in measures of anxiety, depression, and PTSD to compare outcomes with previously published outcomes of the PSP Wellbeing Course [9]; and (4) assessing the relationship between mindfulness meditation use and outcome measures. We hypothesized that clients would actively participate in the mindfulness meditations, report positive experiences, and also identify areas for improvement in the mindfulness meditations. We also hypothesized that clients would report statistically significant improvements in symptoms of anxiety, depression, and PTSD and that greater mindfulness mediation use (ie, length and frequency) would predict less severe self-reported symptoms at posttreatment [23]. This feasibility study is the first step in assessing whether mindfulness meditations will be deemed usable and acceptable in iCBT for PSP.

Methods

Ethical Considerations

This study was approved by the Research Ethics Board of the University of Regina (2019-157). Clients were made aware of the details of the study and the potential risks and benefits of participating, and they provided informed consent before participation. Clients were given access to the PSP Wellbeing Course but were not otherwise offered incentives to encourage participation. Client data were stored on a secure server and deidentified before analyses.
