We obtained people-to-people connections up to the third level by counting 54 participants based on the team member list of projects throughout their careers. The researchers extracted in the second tier of connections, that is, those who had primary relationships with the 54 participants, totaled 982 and conducted 11,437 projects, of which 4381 (38.31%) were implemented by the 982 participants as principal investigators (Table 1). The types of colleagues were analyzed using the data of the research members for each project. We categorized the researchers who designated the participants as their project members based on whether they were upper-level or peer researchers of the participants. If they were peer researchers, we further categorized the person according to position rank. Connections with the participant were then classified according to their relationship. Analysis 2 focused not only on the totaled highest amount allocated for each project of the 52 selected researchers on their h-index, which represents the overall competitiveness of a given researcher with respect to publications, we found a positive correlation (Figure 1A). This result suggests that the variable defined previously is consistent with a researcher’s perceived competitiveness. The relationship between the dependent variable and the number of projects in which each researcher participated as a project member is shown in Figure 1B. We analyzed the determinants that contributed to success in obtaining GIA awards as principal investigators and focused on interpersonal relationships in the projects in which they participated as project members (models 1-4 in Table 2).

Results

Analysis 1

Multimedia Appendix 1 presents the descriptive statistics of the variables used in the analysis. When we regressed the totaled highest amount allocated for each project of the 52 selected researchers on their h-index, which represents the overall competitiveness of a given researcher with respect to publications, we found a positive correlation (Figure 1A). This result suggests that the variable defined previously is consistent with a researcher’s perceived competitiveness. The relationship between the dependent variable and the number of projects in which each researcher participated as a project member is shown in Figure 1B. We analyzed the determinants that contributed to success in obtaining GIA awards as principal investigators and focused on interpersonal relationships in the projects in which they participated as project members (models 1-4 in Table 2).
Figure 1. (A) Regression of the $h$-index value against the amount allocated to each participant as principal investigator (PI; includes Grants-in-Aid for Scientific Research, Grants-in-Aid for Specially Promoted Research, and Grants-in-Aid for Young Scientists). (B) Regression of the amount allocated to each participant as PI against the number of projects in which they participated as project members (N=52).
control variables, the coefficients of not having experience at to be highly influential throughout the analysis. Regarding the university rank at various stages in the researchers' career. to mitigate endogeneity, and model 3 includes variables for the number of papers and last-authored papers published. Model To examine the effects of publication performance, we included connections expressed through the using the value of betweenness centrality and quality of connections was examined using networking level as measured success, and research performance. The effect of human attributes, human connections in the history of GIA grant acquisition (models 1-4). The h-index value of the researcher who first invited the participant to become a project member, unstandardized coefficient (SE) had a significant positive impact on the participant's grant acquisition (models 1-4). The h-index of the researcher with whom the participant first became a project member, unstandardized coefficient (SE) was inconsistent with the correlation coefficients shown collaborative partners tended to win more grants; however, this result is not definitive. Considering research performance, the impact of last authorship was large (models 1-4).

Model 1 is the base model that includes the researchers’ attributes, human connections in the history of GIA grant success, and research performance. The effect of human connections was examined using networking level as measured using the value of betweenness centrality and quality of connections expressed through the h-index of the coresearcher. To examine the effects of publication performance, we included the number of papers and last-authored papers published. Model 2 controls for early career success in obtaining GIA awards to university rank at various stages in the researchers’ career. Model 4 is a simplified model with variables that were found to be highly influential throughout the analysis. Regarding the control variables, the coefficients of not having experience at nonuniversity institutions were significantly negative ($P<.001$). Difference based on sex exhibited no significant effect, but the number of female researchers in the analysis was small; thus, this result is not definitive. Considering research performance, the impact of last authorship was large (models 1-4).

Regarding human connections, researchers with fewer collaborative partners tended to win more grants; however, this trend was inconsistent with the correlation coefficients shown in Multimedia Appendix 1. Betweenness centrality, which indicates the visibility of each researcher within the collaborative network, did not exert a significant effect on lifetime grant acquisition (models 1-4). The h-index value of the researcher who first invited the participant to become a project member had a significant positive impact on the participant’s grant acquisition (models 1-4). The h-index of the researcher with whom the participant first became a project member was examined using networking level as measured using the value of betweenness centrality and quality of connections expressed through the using the value of betweenness centrality and quality of connections expressed through the

$^a$The dependent variable was the sum of the highest amount allocated for each project number of projects obtained as principal investigator. This included Grant-in-Aid for Scientific Research (S), (A), (B), or (C); Grant-in-Aid for Specially Promoted Research; and Grant-in-Aid for Young Scientists (S) or (A).

$^b$Variables were not included in the model.

$^c$These variables were quantified based on The Times Higher Education World University Rankings 2023 and have 7 levels of classification, with a higher ranking having a smaller numerical value, that is, 1 for the top 100 ranking, 2 for 201 to 600, a value of 3 for 601 to 1000, a value of 4 for 1001 to 1200, a value of 5 for 1201 to 1500, a value of 6 for 1501 to 2000, and 7 for out of ranking.

$^d$Variables were not included in the model.

$^e$The total allocation earned as principal investigator during the first 10 years after obtaining a PhD.

$^f$The Cytoscape software (version 3.4.0; Cytoscape Team) was used to calculate the value using people-to-people connections up to the third level starting from the participant based on the team member lists of all GIA projects throughout their career.

$^g$Variables were not included in the model.

$^h$Nonuniversity institutions were significantly negative ($P<.001$).
success (model 1). The effect of these 3 variables remained significant even after incorporating variables related to grant success in the early stages of the researchers’ career (model 2). The correlation between university rank and grant success shows that researchers affiliated with higher-ranked universities tend to be more successful (Multimedia Appendix 1); however, when considering the regression models, the rankings of the universities where a researcher obtained their PhD degree and where they were currently working did not, by themselves, affect grant success. When university ranks were incorporated into the regression model, the effect of the $h$-index value of the researcher who first invited the participant to become a project member was not significant (model 3). Overall, the result of the $h$-index value indicates the importance of having a good research guide as the first step but also suggests that a researcher’s grant success can be affected by the new connections established during career development. Finally, model 4, which retains this variable together with last authorship and number of collaborative partners, has the smallest Akaike information criterion value and was considered the best-fit model.

Initially, we assumed that the researchers who first invited the participants to become a project member were laboratory heads and direct superiors, but this was not always the case (Table 3). Only 29.6% (32/108) of the researchers were direct superiors, 5.5% (6/108) were subgroup heads other than professors, and 7.4% (8/108) were peers or subordinates in their own institution. Notably, 8.3% (9/108) were external upper-level professionals (ie, from other institutions; Table 3). The correlation matrix in Multimedia Appendix 1 shows that being a project member of a government-funded program leads to a significant positive correlation with grant success. Therefore, as an in-depth examination of the effect of human resources, we tested whether project experience in a prestigious government-funded program, often led by top researchers, would increase the likelihood of GIA success for the participants using the Japan Science and Technology Agency Strategic Basic Research Program (SBRP) as a case study [17].

$^a$All the projects won in the year in which each participant obtained projects for the first time were counted.

Figure 2 plots the cumulative average GIA award values obtained as principal investigators over time; the 2 groups are established based on the presence or absence of SBRP experience among the 52 participants. Researchers who had been project members of the Core Research for Evolutional Science and Technology subprogram were selected as the treatment group from a total sample of 52, whereas those who had been PIs of this program were excluded. Researchers with similar $h$-index values and career lengths as those in the treatment group were then selected as the comparison group. The mean $h$-index value was 63.7 (SD 40.4) for the treatment group and 61.3 (SD 20.9) for the control group, and the mean career length was 33.4 (SD 5.2) and 25.1 (SD 5.4), respectively. The timeline was anchored on 0 for the start year of the projects in which the treatment researchers participated. For the control group, we fixed the 13th year since obtaining a doctoral degree to 0, which is the average career length at the time participants in the treatment group joined the SBRP projects (n=7 for each group).

The 2 groups begin at the leftmost point with low cumulative grant amounts. In the period leading up to the zero point, we observe no evident difference between the 2 groups, with similar funding gains. However, after participating in the SBRP, the gains of the treatment groups increased dramatically (Figure 2). By the end of the observation period, the treatment group received a higher award amount than the control group.
Figure 2. Cumulative average Grants-in-Aid award values obtained as principal investigators (PIs) before and after participating in projects in the Strategic Basic Research Program (SBRP) as project members.

Analysis 2
To conduct a broader analysis of interpersonal relationships, we included 982 researchers, including 55 (5.6%) female researchers, identified as having collaborated with the researchers in the previous section (Table 1). The relationship between the number of years since obtaining a PhD and the amount earned as a principal investigator peaked at approximately 40 years after receiving the degree (Figure 3A). Using principal component analysis to evaluate each researcher’s grant success in terms of research impact, namely, the number of projects obtained, project acquisition rate for large programs, and project acquisition rate for small programs, we divided the researchers into 3 groups (Figure 3B). The term “%Small” indicates the percentage of projects from the Grant-in-Aid for Scientific Research (C) (either number of projects or amount awarded), which represents the smallest category, in the total number of projects obtained as PI. Similarly, the term “%large” indicates the Grant-in-Aid for Scientific Research (S) and Grant-in-Aid for Specially Promoted Research, which are considered large categories.

We conducted univariate logistic regression analyses to identify the factors that produced researchers with high grant success records in both large- and small-program categories (Table 4). Career length had a positive effect for large programs (odds ratio [OR] 1.07, 95% CI 1.04-1.10 for stratum 1) and a negative effect for small programs (OR 0.95, 95% CI 0.94-0.97 for stratum 1). Conversely, the variable “doctorate obtained by thesis,” which was introduced to observe the effect of age, had no significant effect. However, among the 30.8% (184/597) of researchers who received their PhD later in life, there were prominent researchers who had served as university presidents or on government committees. Earning a degree earlier or later in life did not uniformly affect a researcher’s competitiveness, and individual differences are likely to have a greater impact. Regarding differences based on sex, male researchers exhibited a negative effect on project acquisition of small programs (OR 0.29, 95% CI 0.12-0.70 for stratum 4). This indicates that male researchers are likely to move from small to larger programs.
Figure 3. (A) Regression of the amount allocated to each participant as principal investigator (PI) against years after doctorate; includes Grants-in-Aid for Scientific Research, Grants-in-Aid for Specially Promoted Research, and Grants-in-Aid for Young Scientists. (B) Principal component analysis for the researchers' grant success performance. Researchers were divided into 3 groups according to their performance (N=982). The term %Large indicates % large grants and the term %Small indicates % small grants.

Upon examining the impact of interaction with upper-level and peer researchers on grant success as principal investigators, we observed the following results (Table 4). More interactions with upper-level researchers resulted in fewer acquisitions of large programs (OR 0.67, 95% CI 0.50-0.89 for stratum 1) and more acquisitions of small programs (OR 1.21, 95% CI 1.07-1.36 for stratum 1) compared with the reference stratum. The differences in the ORs among the strata with different numbers of projects awarded indicated that the stronger the relationship with upper-level researchers, the higher the success rate in the smaller programs (OR 1.43, 95% CI 1.27-1.60 for stratum 4; Table 4).

After examining the impact of interaction with peer researchers separately at each stage of their careers, such as professor, associate professor, and assistant professor, we found that, in large programs, professor-professor interaction had a significant impact on the success rate of ≥2 research grants (OR 1.16, 95% CI 1.06-1.26 for stratum 2), which is not the case for the success of only 1 project (Table 4). More professor-professor interactions led to fewer acquisitions of ≥2 projects in the small category (OR 0.85, 95% CI 0.77-0.93 for stratum 2; Table 4). Interaction with peer researchers at the associate professor level and below had no significant effect on either large or small programs.
Table 4. Factors that affect grant success in terms of the relationship with the coresearchers (2-tailed χ² test)a.

\(^a\)The number of projects obtained by the participants as principal investigators was used as the dependent variable. The term large indicates projects from the Grant-in-Aid for Scientific Research (S) and Grant-in-Aid for Specially Promoted Research, which are considered large categories. Similarly, the term small indicates the Grant-in-Aid for Scientific Research category (C), which is considered the smallest category.

\(^b\)Number of projects obtained. Cases with no corresponding acquisitions were designated as stratum 0 and used as a reference. Cases with \(\geq 2\) corresponding acquisitions were defined as stratum 2 for large categories, and cases with \(\geq 4\) acquisitions were defined as stratum 4 for the small category.

\(^c\)Wald test (\(P\)<.05).

\(^d\)\(P\)<.001.

\(^e\)Doctoral degree conferred by submitting a doctoral thesis and passing its examination. We used this as a control variable and conducted an analysis by assigning a value of 0 for a regular degree and 1 for a doctorate obtained by thesis.

\(^f\)Interaction among researchers in the same position was expressed as the number of researchers who made the participant a project member.

\(^g\)\(P\)<.01.

\(^h\)\(P\)<.05.

\(^i\)No results were output by XLSTAT software for this stratum.

**Figure 4** shows the number of projects in which the researcher participated as a coinvestigator based on the years after obtaining a PhD. The researchers were divided into 3 groups based on their performance level, as shown in Figure 3B. The groups with higher research achievements had a greater number of projects during the 10- to 14-year postdegree period. Group 3, the group with the highest research achievements, had the largest number of projects during the 15- to 19-year postdegree period (Figure 4). Table 5 focuses on these years as key periods and presents the average scores of several indicators of grant success and interpersonal relationships. Although the most active researchers (group 3) obtained large-program grants and interacted with more researchers during the indicated periods, the less active researchers (group 1), who primarily won small-program grants, interacted with fewer researchers during this period, many of whom were upper-level researchers (Table 5).
Figure 4. The average number of projects in which the researcher participated as a coinvestigator by number of years after obtaining a PhD and by research performance.

Table 6 presents the results of the univariate logistic regression analyses on the impact of the frequency and quality of connections using the number of project acquisitions in large and small programs as dependent variables. When the frequency of interactions during the periods was categorized by the job relationships between the partner and the participant, the results showed that interactions with peer researchers and subordinates during the 10- to 14-year postdegree period had positive effects on ≥2 large-program acquisitions (OR 1.51, 95% CI 1.09-2.09 and OR 1.31, 95% CI 1.10-1.57, respectively; Table 6). Interactions with subordinates during the 15- to 19-year postdegree period also had positive effects (OR 1.25, 95% CI 1.25-1.07). In contrast, for the small programs, interaction with upper-level researchers was important both in the 10- to 14-year and the 15 to 19-year postdegree periods, with significant positive effects (Table 6). Notably, these results show that the frequency and quality of human interaction had opposite effects on acquisitions of large and small programs.

Discussion

Principal Findings

This study aimed to identify factors that influence researchers’ potential to obtain external research funding by surveying their stage of career development and the types of people they interacted with using the GIA project implementation structure. Early-career interpersonal relationships, as measured using the h-index value of the researcher who provided the participants with their initial experience as project members, had a positive effect on grant success (Table 2). The results revealed the importance of having a good guide. We propose that a good guide can broaden project members’ perspectives by demonstrating the “behind-the-scenes” elements of effective project implementation. A good guide, not necessarily an immediate supervisor, also serves as a channel for informing fellow researchers of the perspectives required to obtain larger funds.

The results based on nonuniversity experiences (Table 2) suggest that creating an attractive proposal based solely on individual research curiosity may be difficult. The breadth of scientific expertise expressed within a research group rarely matches that expressed by an academic committee [24]. Enhancing one’s perspective by participating in large, purpose-driven projects such as those conducted by companies is important. The fact that experiencing the SBRP (a prestigious government program) as a project member facilitated subsequent grant success also confirms this hypothesis (Figure 2). A unique feature of the SBRP is that a star researcher, as the research director, conducts various interventions to modify the proposed research plan [17]. This provides the project members with opportunities to learn not only about the research conception of the principal investigator but also about the overall view of the research field held by the star researcher above the principal investigators and the strategic goals determined by policy objectives.

The effect of human connections varies depending on the career stage at which the research collaboration occurs. We found that the signs of the coefficients for the number of coresearchers were inconsistent between Multimedia Appendix 1 and Table 2. This may be due to the fact that Table 2 shows the actual relevance of the indicator to researchers’ competitiveness at the individual level, whereas Table 2 shows the macro trends. Although a larger number of collaborators indicates a larger number of projects and more grant amounts obtained in general (positive coefficient in Multimedia Appendix 1), it also suggests the importance of implementing a small number of elite projects.
with selected collaborators to obtain large, trend-setting projects (negative coefficient in Table 2).

Our results suggest that greater collaboration among professors increases the number of large projects obtained (Table 4). After establishing one’s specialty and becoming a professor, collaborating with researchers in different fields and leveraging synergies to obtain greater funding is easier than when one is young [25]. It is assumed that highly competitive researchers who become professors early in their careers have more opportunities to conduct collaborative research among professors, and this collaboration and friendly competition with peers may stimulate their motivation to generate new ideas worthy of being supported by large programs. Meanwhile, factors that influence midcareer grant success remain largely unexplored despite challenging expectations regarding human resource development at universities and research institutions. This study did not present significant results regarding the midcareer level (Table 4); this is because collaboration during the earlier period may include protected time until each researcher refines their research and reconciles it with that of other researchers, after which truly meaningful collaboration occurs [26,27]. Tracking the process of research development, we found that interaction with others during the periods of 10 to 14 years and 15 to 19 years after obtaining a PhD determines the size of the project that the participant will obtain (Tables 5 and 6).

This study initially attempted to identify the factors that produce researchers with high grant success records, but as grant success depends on various factors, including the assignment of reviewers and other random factors, and given cases in which initial success may have been leveraged in subsequent years [28], it was difficult to obtain clear results when focusing on large programs alone (Tables 5 and 6). Interpreted in conjunction with the results from the project acquisition rate of small programs (Tables 5 and 6), midcareer relationships that remain narrowly focused, such as immediate supervisors, keep participants’ grant success limited to small programs throughout their careers and do not lead to the acquisition of large programs (Table 6). Liu [29] pointed out that the relationship between scholar productivity and tie strength exhibits an inverted U shape using data from tourism scholars. Researchers who devote their efforts to others’ research cannot concentrate on deepening their own studies. Considering the trade-off in collaboration between acquiring ideas and paying for effort instead of undertaking part of the supervisors’ initiatives, getting involved in diverse projects by peers and subordinates is important. In particular, participating in projects by subordinates is an effective way to be exposed to the fresh ideas of a younger person and look over their projects critically as an experienced person. This will ultimately help researchers become established figures who can conduct large-scale research projects as principal investigators.

Limitations

A limitation of this study is that we experienced some difficulties in obtaining clear data and subsequent results on the factors that influence the most prominent figures, such as those who had ≥3 projects in large programs (8/982, 0.8% in analysis 2), because of their rarity and the particular nature of their careers and research histories. These researchers tended to obtain large projects early in their careers instead of obtaining projects gradually increasing in size, which is related to the fact that they returned after international education pursuits or worked at nonuniversity institutions. Although initial success is likely to be influenced by almost uniform factors that apply to all researchers, such as publication performance relative to age, continued success is likely to be heavily influenced by individual enthusiasm and willingness to acquire large projects. Therefore, contextual analysis, such as interview surveys, will be necessary to identify the factors that produce prominent figures with outstanding achievements.

Another constraint is that the results of this analysis are limited to positive grant awards as, unlike positive awards, information on rejected projects is not publicly available. Under the Japanese grant system, the range of acceptance rates among researchers is not considered to be very large as proposals are submitted only once a year and the number of projects that can be applied for in a given year is limited by the grant system’s restrictions on duplicate applications. However, the differences among researchers with different application rates should be explored in a future study to better clarify the factors affecting researchers’ competitiveness.

Conclusions

This study explored objective measures of success in obtaining GIA with a focus on interpersonal relationships. Our results have several implications for future research. To improve one’s ability to obtain external funding, the following are necessary aspects: developing links with channels enabling access to quality information, gaining experience in collaborative research at the midcareer stage, and developing a research area in which one can take more initiatives in the future. The function of systematically training researchers has not been sufficiently developed in the Japanese medical community, and whether one can grow as a researcher is left entirely up to the individual. Researchers must broaden the scope of their research and increase their visibility in the academic field to actualize innovative ideas. In summary, individuals should understand the power of a collaborative network and strategically choose cooperative partners.

Abstract

Background: The development of digital health tools that are clinically relevant requires a deep understanding of the unmet needs of stakeholders, such as clinicians and patients. One way to reveal unforeseen stakeholder needs is through qualitative research, including stakeholder interviews. However, conventional qualitative data analytical approaches are time-consuming and resource-intensive, rendering them untenable in many industry settings where digital tools are conceived of and developed. Thus, a more time-efficient process for identifying clinically relevant target needs for digital tool development is needed.

Objective: The objective of this study was to address the need for an accessible, simple, and time-efficient alternative to conventional thematic analysis of qualitative research data through text analysis of semistructured interview transcripts. In addition, we sought to identify important themes across expert psychiatrist advisor interview transcripts to efficiently reveal areas for the development of digital tools that target unmet clinical needs.

Methods: We conducted 10 (1-hour-long) semistructured interviews with US-based psychiatrists treating major depressive disorder. The interviews were conducted using an interview guide that comprised open-ended questions predesigned to (1) understand the clinicians’ experience of the care management process and (2) understand the clinicians’ perceptions of the patients’ experience of the care management process. We then implemented a hybrid analytical approach that combines computer-assisted text analyses with deductive analyses as an alternative to conventional qualitative thematic analysis to identify word combination frequencies, content categories, and broad themes characterizing unmet needs in the care management process.

Results: Using this hybrid computer-assisted analytical approach, we were able to identify several key areas that are of interest to clinicians in the context of major depressive disorder and would be appropriate targets for digital tool development.

Conclusions: A hybrid approach to qualitative research combining computer-assisted techniques with deductive techniques provides a time-efficient approach to identifying unmet needs, targets, and relevant themes to inform digital tool development. This can increase the likelihood that useful and practical tools are built and implemented to ultimately improve health outcomes for patients.

Introduction

Digital health tools have the potential to advance health care efficiency, precision medicine, and patient health outcomes. Yet even the most high-performing digital tools using cutting-edge artificial intelligence and machine learning techniques are likely to be shelved if they do not address shared priorities among stakeholders [1] and their associated real-world unmet needs, leaving the promise of artificial intelligence and machine learning in health care unrealized [2]. There are currently 350,000 digital health apps worldwide that aim to address a range of functions (eg, condition management, wellness and prevention, and patient experience) and health conditions (eg, diabetes [3], neurological conditions [4], and psychiatric illnesses [5,6]). However, most of these apps are not regulated or clinically validated, and most are not widely used or integrated into clinical practice [7,8]. Although evidence suggests digital health tools are acceptable to both patients and clinicians, there are diverging needs, priorities, and attitudes among stakeholder groups within the digital tool ecosystem [1].

Gathering insights from key stakeholders is an essential step to ensure the development of digital tools that meet the needs of both patients and clinicians toward the goal of providing high-quality patient-centered care [9,10]. Using upstream stakeholder engagement methods can reveal actionable—but otherwise unforeseen—needs for targeted design and development of clinically impactful patient-facing digital tools with increased potential for widespread adoption [11,12]. Previous work has shown the benefits of qualitative research to assess hypothetical smartphone apps with content and function designs [13,14]. However, that work does not consider the motivation, or genuine need, for the app. Here we focus on the use of upstream qualitative research to first identify areas of real-world unmet need to serve as the foundation for hypothetical smartphone app ideation, design, and prototyping.

Qualitative research often involves designing and conducting a group of individual interviews and applying thematic analysis to transcripts of the resulting data. Conventional thematic analysis typically involves multiple researchers reviewing a subset of interview transcripts to identify themes [15] and developing a hierarchical system (codebook) of themes and subthemes (codes) to apply to sections of text (segments). The results of a conventional thematic analysis are typically presented in a table with broad summary themes, nested subthemes, and illustrative quotes from interview transcripts. The process of constructing the codebook can be time-consuming (eg, 3–5 times the amount of time taken to collect the data needed to review each interview [16]), subjective, and not always replicable [17,18].

While conventional thematical approaches are powerful for extensive investigations into a particular research area, a more time-efficient, scalable, and reproducible method is needed for digital health tool developers working in industry to swiftly identify key areas for the development of clinically meaningful tools. Indeed, in many settings of the digital health ecosystem, it is not feasible for researchers to dedicate substantial time to complete conventional thematic analysis. In some cases, it might be more appropriate to apply an automated text analysis that can be easily implemented by researchers, developers, and clinician scientists [19] to guide the identification of unmet needs and potential solutions. For example, recent work has applied text analysis to large qualitative research data sets to quickly identify common themes based on word frequency analysis [20-22]. Word combination frequency analysis provides a data-driven and repeatable approach to quickly identify frequently mentioned topics across a set of qualitative interview transcripts and potentially reduce the introduction of personal bias. Such approaches enable a faster and more convenient method to analyze a large amount of qualitative text data obtained from interviews with stakeholders [23]. Further, hybrid approaches that combine conventional thematic analysis with a data-driven inductive approach have the potential to leverage the strengths of both methods [24]. Importantly, such computer-assisted approaches to upstream qualitative research can be applied to engage and research any stakeholder group, including patients, to inform the development of clinically meaningful digital tools.

Given the limitations of conventional qualitative analysis—including the substantial time required for theme development—we demonstrate the utility of a hybrid approach leveraging the simplicity and accessibility of text analysis to identify stakeholder themes to support the initial stage of concept development for digital health tools. Specifically, we applied word combination analysis to a set of semistructured interviews with US-based psychiatrists specializing in treating outpatients with major depressive disorder (MDD) to reduce the amount of text for thematic analysis fivefold to facilitate uncovering common themes and unmet needs of clinicians and patients across advisors. We opted to demonstrate the use of simple text analysis over some of the more advanced natural language processing techniques to increase accessibility to those without advanced backgrounds in coding or computational techniques. We propose that this approach could serve as a straightforward and repeatable framework to identify unmet needs before concept development and implementation. We will discuss our findings around unmet needs in treating MDD and how this might affect digital tool development in psychiatry as an end-to-end demonstration of this method.

Methods

Ethical Considerations

The interviewed psychiatrists were originally recruited for market research purposes using the Guidepoint Expert Network (Guidepoint Global). The BRANY Institutional Review Board determined this study was exempt from review under category 4ii in 45 CFR 46.104(d). Participants were compensated for their time and participation. All reported data were stored in password-protected databases accessible only to approved study personnel.

Recruitment and Data Collection

We used purposive criterion sampling to recruit 10 US-based psychiatrists specializing in treating MDD outpatients in a variety of practice settings, including academic medical centers and teaching hospitals, community-based mental health clinics, health care systems, and independent private practices.
and private practices spanning urban and rural settings in the United States (Table 1). With only 2 exceptions, we recruited and interviewed psychiatrists who spent most of their time (≥50%) on direct MDD outpatient patient care and who had 10 or more years of experience postresidency. The interviewed psychiatrists were originally recruited for market research purposes using the Guidepoint Expert Network (Guidepoint Global).

\(a\)MDD: major depressive disorder.

Regarding sample size, previous work suggests most qualitative research data sets reach saturation—the point during data collection in which themes begin to repeat, new insights begin to wane, and future data collection becomes redundant—between 9 and 17 interviews [25]. Moreover, our inclusion criteria were designed to recruit a relatively homogenous sample of experienced clinicians specializing in outpatient MDD care, as we did not require any between-subject comparisons.

One researcher conducted individual, 1-hour, single-blinded, semistructured, recorded audio interviews following a predesigned interview guide (Multimedia Appendix 1). The interview guide was designed to include open-ended questions primarily targeted at understanding the clinicians’ experience in care management for MDD as well as the clinicians’ perceptions of patient experience in care management for MDD. We used MAXQDA Analytics Pro 2022 (version 22.1.1; VERBI GmbH) [26] to process and analyze the quality-checked interview transcripts (their official website provides help with using specific features). However, one can use other available software or open-source approaches to execute the simple word combination text analysis steps below.

Data Preparation and Overview

All transcription text segments were auto-coded as either “interviewer” or “advisor,” depending on the speaker. Only “advisor” text was used during the text analysis stage. The data-driven hybrid approach to identifying relevant themes involved a 4-step process (Figure 1): (1) During the computer-assisted stage, use MAXQDA (or other) software to identify the most frequent n-grams (n-word word combinations, n=2+ words) across the interview data set. (2) Extract the sentences containing each of those n-grams, along with the preceding and succeeding sentences relative to the sentence containing each n-gram. (3) During the “hybrid stage,” work iteratively with at least 1 other researcher to read and reread each computer-extracted text segment in order to inductively identify key content categories and assign a content category label to each text segment until 100% agreement is reached among researchers. Discordant content category assignments among researchers can be resolved during discussion. (4) Finally, in the “deductive stage,” manually examine the full list of key content categories to develop overarching themes and nest the key content categories under the broader themes characterizing priorities in the process of care management in treating MDD.
Figure 1. Visual depiction of the hybrid data-driven method to identify key themes and content categories. The dashed lines denote the 2 key differences between conventional thematic analysis and the present approach: a computerized text reduction step and a set of n-grams and their corresponding quotes that provide an organizing layer to assist with manual identification and the development of content categories.

Data Analysis

Identifying Word Combinations

First, we used the “word combination” feature in MAXQDA to identify the most frequently used phrases in the advisor’s responses. We used MAXQDA, but any software capable of word combination analysis can be used. We used n-word combinations instead of single-word frequencies to increase the specificity of theme identification. Within the search parameters, we required the resulting words to be at least 4 characters long. All words were lemmatized in English, and we applied the MAXQDA English language stop list [27] to remove articles, conjunctions, and other words likely to be redundant in the analysis. We additionally added word combinations that co-occurred with our disease state of interest to the stop list (eg, “major depression” and “mental health”), as these were unlikely to yield meaningful insights. Next, we filtered the resulting word combination frequencies to word combinations that also appeared in a majority (at least 60%) of the interviews. We opted for a majority threshold cut-off based on our sample (word combinations that appeared in at least 60% of interviews) to limit the subsequent research steps to a more focused set of word combinations that were not likely spoken just by random chance (ie, ≤50%). Our goal was to maximize the chance of developing a solution that would be impactful for the majority (>50%) of clinicians. However, depending on the goals, users may elect to use different thresholds. For completion, word combinations that appeared in 50% or more of the interviews are shown in the “Identifying Word Combinations” section, but only those that appeared in 60% or more of the interviews were included in the subsequent analysis.

Broadly, this first step served as a data-driven text analysis to identify commonly discussed themes or frequent expressions when discussing the care management process of the disease state of interest. Identifying key phrases used across stakeholders in a sample can give a sense of widely applicable needs and daily experiences. Identifying n-grams or word combinations is the crucial time-saving inductive step; however, to build meaning around the phrases, we recommend identifying key content areas by conducting follow-up deductive analyses of the context surrounding the word combinations.

Identifying Key Content Categories

Next, we extracted the resulting n-grams and their surrounding context for further analysis of the context in which these word combinations were uttered. Specifically, for each n-gram, we extracted the sentence containing the n-gram along with the 2 sentences before and after the appearance of each n-gram to provide context.

Next, 2 researchers systematically read the sentences surrounding each extracted word combination to understand the context in which the word combination was uttered. The researchers then worked iteratively through discussion and multiple independent readings to generate and assign relevant content categories for each n-gram. For expediency, the 2 researchers reconciled discordant labels through discussion until they reached 100% agreement. The researchers aimed to create content category labels for each word combination with definitions that were broad enough to accommodate multiple text segments but specific enough to distinguish among text segments from a given word combination. These researcher-generated content categories ultimately reflected the context surrounding the n-grams and provided a more in-depth understanding beyond the n-grams alone. Extracting and reviewing text around frequent and common n-grams helped to both focus the reading and deductive analysis of the text and substantially reduce the amount of text needed for review.

Next, we selected representative quotations for each content category to provide canonical examples of each of the chosen themes (Table S1 in Multimedia Appendix 2). This step represents a bridge between the text-analytic approach and the conventional deductive approach, in which researchers manually evaluate all the text to determine the appropriate content category represented in the segment. During this state, researchers review the text segments and apply their subject-matter expertise to sort the resulting text into subthemes.
However, the text analytic step saves time and increases process transparency by examining only the segments in each interview where the n-gram appears. This should ultimately limit the scope of the analysis to pertinent segments constrained by the list of word combinations established in the first step.

Researchers may choose to stop at this level of analysis and proceed with the development of digital tool concepts if unmet needs and potential challenges are adequately identified. The word combinations and content categories may be substantial enough to provide sufficient context to understand how to proceed with digital tool development. Here, we further analyzed the word combinations and content categories in order to identify overarching themes, bringing the results of the hybrid method even closer to those yielded from conventional analysis.

Developing Overarching Themes

Once the content categories were identified as described in the previous step, key overarching themes emerged across the content categories and word combinations. At this stage, we also included word combinations that appeared in 50% of interviews to help guide the identification of more robust overarching themes that accommodated more word combinations. During reading and analysis of the resulting n-grams and their corresponding text segments, themes should start to emerge that may have been deduced using the more conventional analysis approach. In essence, the word combinations and key content categories established in the first and second steps are essentially transposed to develop these overarching summary themes, highlighting areas of need. In this approach, the word combinations are reorganized and presented with word combinations nested within broad summary themes. The goal of this final step is to summarize the findings from the first 2 steps into an alternative table structure that may assist in conceptualizing unmet needs for patient-facing digital tool development. By following the first 2 steps, theme identification in this final step becomes a much more efficient and transparent process as compared to a more conventional approach.

Results

Identifying Word Combinations

All word combinations appearing in 50% or more of the interviews are shown in Table 2. Only bigrams resulted from the analyses. There were no word combinations of ≥3 words.

For a full summary of word combinations, content categories, detailed descriptions, and representative quotations, please refer to Table S1 in Multimedia Appendix 2.

Table 2. Frequently used word combinations listed by the percentage of interviews in which they were uttered and the total number of utterances across all interviews. The table elements are listed in descending order by the percentage of interviews in which they were uttered.

Critically, after extracting the sentences containing the set of word combinations and their preceding and succeeding sentences, we observed that the total advisor text word count to manually review reduced to 21% of the original stakeholder text word count, demonstrating the use of the approach to assist with focusing theme extraction on key areas of text containing n-grams (ie, the highly repeatable text reduction step).

Identifying Key Content Categories

After each researcher completed multiple readings of all word combinations and their surrounding contextual sentences, up to...
5 content categories for each word combination were identified, resulting in a total of 14 unique content categories across phrases (Table S1 in Multimedia Appendix 2): administration, care management, common side effects, conceptualization, desired clinical information, differential diagnosis, medical comorbidities, medical history, medication monitoring and management, patient experience, risk assessment, risk for substance use, side effect monitoring, and treatment planning. The researchers aimed for ≤ 5 content categories for each word combination to balance specificity with generality. However, this target can be changed to accommodate larger or smaller studies that might require a higher or lower threshold to balance these goals. In total, there were 14 unique content categories, as some content category labels emerged under multiple word combinations (e.g., care management emerged as a content category relevant to 2-word combinations, “side effects” and “primary care”).

### Developing Overarching Themes

In the final step, we identified overarching summary themes by transposing the word combinations and content categories identified in steps 1 and 2. In this analysis, we included word combinations uttered by 50% of advisors, which returned 11 additional word combinations (e.g., “bipolar depression” and “facial expression”). The full results expanding on these overarching themes can be found in Table 3, with the word combinations listed as relevant word combinations that support content categories and overarching themes. Through this process, we identified four overarching summary themes: (1) evaluation, (2) medication decisions, (3) tracking symptom progression, and (4) factors contributing to treatment adherence.

| **Medication decisions:** Providers revealed their treatment planning choices are driven by leveraging known medication side effects to counteract patient symptom profiles (typically based on baseline energy levels). | |
| Medical history | “patient come”, “primary care” |
| Medication management and monitoring | “make sure”, “primary care”, “treatment resistant” |
| Treatment planning | “treatment plan”, “energy level” |
| Patient experience | “side effect”, “feel comfortable” |
| Common side effects | “side effect” |

| **Tracking symptom progression:** Providers were concerned about their lack of ability to track patient safety, triaging to a higher level of care, and co-occurring substance use outside of the clinic. | |
| Risk assessment | “suicidal thought” |
| Risk for substance [ab]use | “substance use/abuse” |
| Side effect monitoring | “side effect”, “energy level” |

| **Factors contributing to treatment adherence:** Providers highlighted the impact of adverse side effects on adherence and the critical role family members play in both patient adherence and providing them with symptom insights. | |
| Side effects | “side effect” |
| Patient experience | “feel comfortable”, “side effect”, “come back” |
| Care management | “family member”, “primary care” |
| Administrative | “come back”, “make sure” |

To create overarching themes, the researchers applied a similar process to the content category labels as they did to the word combinations—identifying a label and definition that would provide an appropriate umbrella term under which to nest multiple of the key content categories. To illustrate how we arrived at these broader themes, we will walk through the development of the “evaluation” theme. Analysis of the retrieved segments in the sentences surrounding the word combinations “bipolar depression,” “make sure,” and “substance [ab]use” converged on a content category best summarized as “differential diagnosis.” Through a similar process, segments surrounding the word combinations “suicidal thought,”
“treatment resistant,” “facial expression,” “family history,” and “family member” converged on a content category best summarized as “conceptualization.” Ultimately, “differential diagnosis” and “conceptualization” fit together with “medical comorbidities,” “risk assessment,” and “desired clinical information” under the broad and overarching theme of “evaluation.”

Discussion

Overview

To ensure the development of clinically meaningful digital tools, developers must address real-world, unmet stakeholder needs. Understanding these needs at the outset of concept ideation and tool development ensures that developers are solving the most urgent challenges. Qualitative research is a powerful tool to understand the daily experiences of patients and clinicians and to better understand how potential digital tools will provide value and integrate seamlessly into a given environment. Here, we presented a hybrid data-driven approach to facilitate time-efficient discovery of unmet clinician needs to inform the direction of digital tool development in health care settings. With this approach, in the context of care management in MDD, we identified several key areas that are of interest to clinicians and would be appropriate targets for digital tool development.

Using Key Content Categories to Inform Digital Tool Development

The key content categories are consistent with challenges identified in the literature, suggesting this approach can highlight real-world problems and point developers to further information in previously unknown areas of research literature. For example, the phrase “side effect” consisted of the following content categories: treatment planning, side effect monitoring, care management, patient experience, and common side effects. Further investigation into the literature encompassing this topic provides additional support for the selection of this area as a target of digital tool development. Burdensome treatment-related side effects are a leading cause of nonadherence and discontinuation of antidepressant medications [28] and have a negative impact on treatment outcomes [29]. Patients frequently experience side effects early in antidepressant treatment [30], but a lack of understanding of side effects [31] and barriers to communicating these side effects to clinicians, especially primary care providers [32], lead to early discontinuation and poor outcomes [29]. Some evidence exists that interventions addressing these early barriers to adherence, which include side effects, could improve adherence, communication between patient and provider, and, ultimately, treatment outcomes [33,34].

In the context of MDD care management, building digital tools that address patient and clinician concerns related to side effects, medication adherence due to side effects, and medication decisions based on side effects might best address one aspect of the current needs of clinicians as expressed through the interviews. The strengths of digital tools that could be leveraged in this context include facilitating side effect monitoring and reporting in between visits using smartphone capabilities, increasing patients’ understanding and expectations around side effects with on-demand psychoeducation through a mobile app or customized website, increasing clinicians’ awareness of the emergence of side effects through smartphone-based remote monitoring, or increasing and enhancing patient-provider communication through digital platforms.

Using a single topic as a guide for concept development may be a reasonable starting point for digital tool development; however, it is important to consider other related content categories that arise from this procedure. Incorporating other themes or content categories may bolster the initial concept and increase the likelihood that patients or clinicians will adopt a tool in clinical practice. In the context of MDD care management, the content category “administration” emerged as an important consideration for clinicians, signaling that workflow and administrative components of care management are also important to keep in mind while developing digital tools to ensure consideration of practical integration into workflows.

Incorporating New Ideas With Existing Best Practices

Overall, the topics identified through the approach outlined in this study should line up with current thinking and best practices around digital tool development in health care. This includes, but is not limited to, prioritizing ethical considerations around data sharing and privacy [35,36], considering the legal implications of digital tool implementation [37], and considering the balance between addressing unmet needs and integrating tools into the current care management workflow [38]. While identifying specific themes and content categories for a given disease state will elucidate current unmet needs for clinicians, established guidelines around digital tool development should be included as well.

Limitations

The approach outlined in this study has the potential to facilitate digital tool development across numerous clinical environments due to its ease of use and relative efficiency. Nevertheless, the comprehensive nature of conventional qualitative analysis may yield more nuanced findings from stakeholder interviews using a more deductive coding process. Moreover, limiting the amount of text for analytical review to those sentences surrounding frequent key word combinations across advisors is both a strength and a limitation of this method. While this approach increases efficiency, there could be a loss of sensitivity to important learnings outside of the extracted text segments, as well as some important one-off learnings uttered by only 1 advisor that could potentially be excluded from the text extracted for deductive analysis. Although the current sample size falls within a reasonable range to reach theme saturation across interviews [25], a more expanded sample size has the potential to reveal even more insights and accommodate analysis by psychiatry subspecialties (eg, addiction, child, adolescent, and geriatric psychiatrists). Furthermore, given that this method seeks to find consensus among spoken terms describing themes and unmet needs among clinicians and patients, it is possible that diverging opinions among stakeholders might be obscured. Finally, although the word combination analysis is 100% repeatable, further work would be needed to determine
confirmability (ie, results confirmed by an independent set of researchers) [39].

Future Directions
Here, we first interviewed clinicians because they are uniquely positioned within the digital health ecosystem to simultaneously identify and communicate patient needs, unmet clinician needs, potential for real-world clinical impact, and influence patient engagement with appropriate apps due to the trust patients place in their clinicians [1,7]. One challenge that blocks patient engagement with relevant digital tools is integration into clinician workflow [1], because clinicians have limited bandwidth to integrate patient-facing digital tools into their workflow. However, to ensure the most clinically relevant tools are created for and with patients, future work is needed to identify overlapping priorities between patients and clinicians. The method outlined here could be applied to patient interviews to reveal common and frequent unmet needs among patients.

The current framework provides a foundation for developers in the technology space to identify concepts that are worthy of further investigation and validation. Researchers following this framework may consider validating findings from this approach through follow-up methods such as: (1) triangulation studies (eg, test for convergence of results from this framework with focus group results or text from other sources, such as peer-reviewed articles about MDD), (2) quantitative survey methods, and (3) member-checking by presenting responses with the results to confirm the interpreted data and identified concept results resonate with their experience (respondent validation) [40] before moving further into conceptualization and prototyping.

Conclusions
We presented a hybrid computer-assisted method for identifying unmet needs expressed in semistructured interviews, which provides an efficient and user-friendly approach to this problem. The presented method offers some of the efficiencies of a purely analytic approach (eg, topic modeling), while the incorporation of manual analysis of the surrounding context sentences offers some of the benefits of finding more interpretable and relevant concerns, as in a traditional qualitative analysis. By contrast, in topic modeling alone, researchers often consider the topics (lists of words) outside of their surrounding context when trying to interpret their meaning. Thus, this hybrid approach falls between these 2 approaches and gives digital health researchers a feasible approach for conducting upstream research to inform ideation and the development of high-impact patient-facing digital tools.

Acknowledgments
The authors would like to thank the participating psychiatrists for their time and insights.

Conflicts of Interest

Abstract

Background: Digital screening and intervention tools have shown promise in the identification and reduction of substance use in health care settings. However, research in this area is impeded by challenges in integrating recruitment efforts into ongoing clinical workflows or staffing multiple study clinics with full-time research assistants, as well as by the underreporting of substance use.

Objective: The aim of the study is to evaluate pragmatic methods for facilitating study recruitment in health care settings by examining recruitment rates and participant characteristics using in-person–based versus flyer approaches.

Methods: This study compared recruitment rates at a Women’s Health clinic in the Midwest under 2 different recruitment strategies: in person versus via a flyer with a QR code. We also examined the disclosure of substance use and risk screener positivity for the 2 strategies. We also obtained information about the current use of technology and willingness to use it for study participation.

Results: A greater percentage of patients recruited in person participated than those recruited via flyers (57/63, 91% vs 64/377, 17%). However, the final number recruited in each group was roughly equal (n=57 vs n=64). Additionally, participants recruited via flyers were more likely to screen positive for alcohol use risk on the Tolerance, Annoyed, Cut Down, Eye-Opener alcohol screen than those recruited at the clinic (24/64, 38% vs 11/57, 19%; χ²₁=4.9; P=.03). Participants recruited via flyers were also more likely to screen positive for drug use risk on the Wayne Indirect Drug Use Screener than those recruited at the clinic (20/64, 31% vs 9/57, 16%; χ²₁=4.0; P=.05). Furthermore, of the 121 pregnant women, 117 (96.7%) reported owning a smartphone, 111 (91.7%) had an SMS text message plan on their phone, and 94 (77.7%) reported being willing to receive SMS text messages or participate in a study if sent a link to their phone.

Conclusions: The distribution of flyers with a QR code by medical staff appears to be an efficient and cost-effective method of recruitment that also facilitates disclosure while reducing the impact on clinic workflows. This method of recruitment can be useful for data collection at multiple locations and lead to larger samples across and between health systems. Participant recruitment via technology in perinatal health care appears to facilitate disclosure, particularly when participants can learn about the research and complete screening using their own device at a place and time convenient for them. Pregnant women in an urban Midwestern hospital had access to and were comfortable using technology.
Introduction

Screening, brief intervention, and referral for treatment (SBIRT) approaches proactively address substance use in primary care settings and potentially reach those at risk, regardless of willingness to seek treatment. Large proportions of at-risk groups can be reached with SBIRT, particularly in the perinatal period where most pregnant women seek prenatal care. The consequent need for proactive screening, together with the promising efficacy of brief interventions for alcohol use [1], has led to recommendations that SBIRT be a standard element of prenatal care [2]. However, studies comparing self-report of drug use to objective indicators show that underreporting is common [3-5], especially in settings where disclosure can have heightened negative consequences such as during pregnancy [4,6,7]. The disclosure of substance use during pregnancy can be both socially stigmatizing and increase the woman’s risk for potential legal consequences. Currently, 18 states view substance use during pregnancy as child abuse, and 15 states have laws stating that health care workers are mandated reporters for drug abuse during pregnancy. Laws such as these increase the social stigma and the internal shame and guilt women may feel. This in turn limits the proportion of women who are willing to disclose substance use to their providers, suppressing disclosure and impacting the health of them and their unborn child [8-10]. This underreporting is a substantial obstacle to proactive screening efforts that seek to identify at-risk pregnant and postpartum women, the majority of whom do not seek treatment for substance use [11]. Additionally, the implementation of SBIRT approaches has been challenging. First, there are considerable time, financial, and logistic obstacles to integrating screening and brief intervention programs into ongoing medical practice [12,13]. For example, one estimate suggests that conducting all recommended prevention-related activities would take a primary care physician 4.4 hours per working day [14]. This issue is exacerbated by the fact that such services are only recently and not consistently being reimbursed by third-party payers. Second, many medical professionals express discomfort with the screening and intervention process and report doubts about its effectiveness—even when voluntarily participating in a formal demonstration program [13]. This discomfort and skepticism may in part explain findings of very low levels of physician adherence to recommended brief intervention guidelines, even after training [12,14,15]. Training in brief approaches such as motivational interviewing is expensive, time-consuming, and may have modest or transient effects [16]. Technology provides an exciting option. It can be implemented consistently across patients, with minimal staff involvement, and conducted during natural waiting periods, integrating easily within the workflow of the clinic [17-19]. It has also been shown to improve disclosure of substance use in anonymous studies [20]. However, studies involving technology in health care settings often struggle with recruitment, particularly given time constraints on the part of clinic staff who must provide an initial introduction to the study. Typically, clinical trials are addressed via multisite trials using face-to-face recruitment. Despite being a time-tested gold standard, several limitations to this approach exist. First, the combination of a low base rate of substance use during pregnancy with high levels of underreporting makes recruitment lengthy and challenging even across multiple sites. Second, even multisite trials are only able to measure a limited range of participant characteristics specific to only a few geographic locations. Third, well-funded and tightly controlled trials often use methods (eg, a research assistant [RA] or study nurse) that do not readily translate to how the program could be implemented without research funding. Fourth, multisite research can also quickly become impractical if staffing each clinic with a full-time RA is required. There is increasing recognition of the need for highly pragmatic trials that take translational and implementation issues into account [21]. Research is therefore also needed on pragmatic methods for facilitating recruitment in these settings. The provision of flyers describing the study and allowing enrollment on the web is a possible solution, but relative recruitment rate for this approach, as compared to traditional approaches, is not known and is partly dependent on rates of technology ownership.

This study analyzes data exploring how to best leverage technology to identify risk during pregnancy, particularly whether different approaches in recruitment can increase disclosure. The study had 3 goals. The first goal was to obtain current substance use risk levels of women attending their prenatal care intake at a large Midwestern hospital’s outpatient clinic. The second goal was to compare the disclosure of substance use risk under 2 different recruitment strategies, in person versus via flyers, and determine recruitment rates for the 2 approaches. The last goal was to better understand the access and comfort of using smartphones and SMS text messaging for study participation. It was hypothesized that in-person recruitment would have a higher acceptance rate for study enrollment, but that participating in the study on their own device in the privacy of their home would increase disclosure.

Methods

Participants

Participants were 121 pregnant women attending a new pregnancy intake at an outpatient clinic that is part of a large health system in the Midwest. Eligibility criteria included being 18 years or older of age, understanding spoken English, and being pregnant with the intention to carry the pregnancy to term.

Recruitment

Data collection began in September 2018 and concluded in May 2019. An RA was present at the clinic on 2 half days per week;
during this time, willing participants were introduced to the RA by the nurse who was completing the intake with the patient. At all other times, clinic staff gave patients a flyer describing the study and provided a website (via QR code, along with a unique login ID) through which patients could enroll in and complete the study. The flyer was provided by intake nurses at the end of the appointment, and participants used their own device to complete the study.

Procedures
Participants who enrolled in the study completed a series of screening questions regarding substance use before and during pregnancy, as well as questions related to demographics, general health, and technology access. Those recruited by the RA were given a tablet to complete the study at the clinic following their intake appointment. Those enrolling in the study via the flyer used their own device and completed screening at a time and place convenient for them. In addition, those who screened positive for any substance were offered within the app to participate in a subsequent extended assessment (duration of 10 to 20 minutes) with separate consent. The app would link participants to the next screening if they agreed to participate.

Ethical Considerations
All procedures for the study were approved by both the university (#085518B3A) and health system (#12267) institutional review boards. The app used for data collection read aloud the consent form that explained to participants that the study has 2 parts. Electronic information sheets were used for the study. Participants agreed to participate in the study in the computerized questionnaire by clicking a box and then answering the questions. There were no physical copies of the consent form. Part I included content regarding broad health behaviors such as nutrition and sleep, as well as brief questions on smoking, alcohol, and marijuana use during the month before they became pregnant. For part II, patients who screened positive for smoking, alcohol, or marijuana use in the month before becoming pregnant were invited to complete a 15- to 20-minute survey asking additional questions about risk factors. This assessment included more sensitive information regarding substance use, traumatic experiences, partner violence, depression, and anxiety. Participants who completed part I received a US $10 Target gift card, and those who were eligible and completed part II received an additional US $20 Target gift card. No identifying information was collected until after participants completed the assessment items. Once participants completed the portions of the study they were eligible for, they were linked (within the survey) to a separate survey, where they entered their email or phone number to receive their gift cards and a copy of the consent form. The data participants gave in order to send the gift cards were kept in a separate password-protected spreadsheet from the rest of the data and were destroyed once the study was complete. Participants who completed the survey in the clinic received the consent form and gift card directly from the RA.

Measures
All participants were asked to complete 47 items regarding alcohol, marijuana, and tobacco use before pregnancy and during the past month, as well as questions about pregnancy and general health. These items included, but are not limited to, the following:

1. The Tolerance, Annoyed, Cut Down, Eye-Opener (T-ACE) alcohol screen [22] is a 4-item alcohol risk screening questionnaire that asks about the amount of drinks to feel high, if people have annoyed you by criticizing your drinking, if you have ever thought you should cut down, or if you need to have a drink first thing in the morning. Scores of 2 or higher result in a positive screen.
2. The Wayne Indirect Drug Use Screener (WIDUS) [23] is a 6-item screening instrument that identifies risk for drug use in the perinatal period by asking about correlates of drug use without directly asking about use. Scores above 3 are considered positive. Examples of true or false questions include “most of my friends smoke cigarettes” and “I get mad easily and feel the need to blow off steam.”
3. The National Institute on Drug Abuse (NIDA) Quick Screen [24] consists of 4 questions asking respondents to indicate the frequency with which they had 4 or more drinks in a day, use of illegal drugs, use of prescription drugs for nonmedical reasons, or use of tobacco products in the past year. The alcohol and drug use items have been validated as single-item questionnaires [25,26]. These items were adapted to evaluate use in the past month rather than the past year and to include a separate item for cannabis use.
4. Participants were also given 4 technology questions regarding technology access and use (smartphone ownership, having an SMS text messaging plan, willingness to receive SMS text messages, and willingness to participate in research via a link sent to their phone).

Statistical Analysis
Chi-square analyses compared differences between in-person– and flyer-based recruitment as well as differences in disclosure on the T-ACE, WIDUS, and each item of NIDA Quick Screen. Chi-square analyses used all available screening information from each participant. However, participants with missing items were dropped from that specific analysis. Two individuals had missing data for the NIDA Quick Screen binge drinking and tobacco questions. One person had missing data for the NIDA Quick Screen prescription drug and illegal drug use questions. There were no missing data for the T-ACE or WIDUS.

Results
Participant Characteristics
Study participants were primarily Black and African American (92/121, 76%) and had a mean age of 27.7 (SD 4.9) years (Table 1). Approximately half (66/121, 54.5%) of the participants had completed some education beyond high school.

**Risk Screen Positivity**

Between-group differences in positivity rates were examined for 2 validated screening tools, the WIDUS and the T-ACE. A total of 20 (31%) out of 64 participants recruited through flyers screened positive for drug use risk on the WIDUS versus 9 (16%) out of 57 participants recruited at the clinic ($\chi^2=4.0; P=.05$). Additionally, a total of 24 (38%) out of 64 women recruited through flyers screened positive for alcohol risk on the T-ACE versus 11 (19%) out of 57 participants recruited at the clinic ($\chi^2=4.9; P=.03$; Table 2).

**Disclosure of Past Month Substance Use**

Chi-square analyses compared the disclosure of substance use (on the NIDA Quick Screen) for participants recruited in person versus via the flyer. Questions included the frequency of binge drinking (4 or more drinks per day), tobacco use, prescription drugs for nonmedical purposes, and illegal drugs in the past month. Each NIDA Quick Screen item was treated as dichotomous reflecting either any or no reported use (Figure 1). There were no significant differences across groups in binge drinking ($\chi^2=0.1; P=.72$), tobacco use ($\chi^2=0.3; P=.58$), prescription drug use for nonmedical reasons ($\chi^2=2.0; P=.26$), or illegal drugs ($\chi^2=2.0; P=.15$).
Figure 1. Recruitment rate comparison for the in-person and flyer clinic recruitment methods for patients attending prenatal care between September 2018 and May 2019.

Recruitment Rates for Each Method of Recruitment
Of the 121 participants recruited overall, 57 were recruited directly by the RA, and 64 responded to the flyer. Nurses handed out 377 flyers resulting in 64 participants, representing 17% of those given the flyer. In contrast, of 109 patients completing a new pregnancy intake when the RA was in the clinic, 63 (57.8%) were introduced to the RA by the intake nurse, and 57 (91%) of the 63 agreed to participate and completed the screener (57/109, 52.3% of all available patients). Notably, flyer recruitment showed a stable increase over the course of the study (Table 2). This increase occurred following the introduction of a new approach, in which the RA and project coordinator began attending monthly staff meetings and updating nurses on the study progress, bringing in snacks, and building upon the relationships with the intake nurses in the clinic. This change in approach started in January, with an increase in nurse engagement and enthusiasm for the study happening in the next few months, resulting in an increase in flyer recruitment because many more were handed out. During the winter months of February and March, there were fewer intakes overall because of the weather. This decrease corresponds with an expected decrease in in-person recruitment during those months.

Technology Accessibility and Willingness to Use for Participation
Of the 57 participants who were recruited in the clinic and used the tablet provided by the RA, 56 (98%) reported owning a smartphone, and 55 (96%) reported having an SMS text message plan on their phone. In total, 44 (77%) of these participants said that they would be willing to receive SMS text messages as part of a research study, and these participants also said that they would be willing to participate in additional surveys or programs if sent a link on their phone.

Discussion
Principal Findings
This study was set up to obtain substance use risk levels for women attending prenatal care at a large Midwestern hospital’s outpatient clinic, compare 2 different recruitment methods to examine which had higher recruitment rates and disclosure rates, and document participants’ access and comfort using smartphones and SMS text messaging for study participation. Recruitment via flyers distributed by health care staff was less efficient than when those same staff introduced patients to an on-site RA (57/109, 52.3% vs 64/377, 17% enrollment). However, participants in the flyer group were more likely to report substance use risk than those in the on-site RA group (20/64, 31% vs 9/57, 16% for the WIDUS and 24/64, 38% vs 11/57, 19% for the T-ACE). Most study participants owned a smartphone (56/57, 98%) and had an SMS text message package on their phone (55/57, 96%). Additionally, of the 121 participants, 94 (77.7%) were willing to receive SMS text messages or a link to further study participation on their devices. Despite the lower overall enrollment compared to the on-site RA, the flyer approach requires less effort for medical staff and removes the need for a full-time RA at each study clinic. The flyer approach was also associated with greater disclosure on some measures of substance use. As is often the case, maintaining regular communication with clinic staff was particularly important in the flyer-based recruitment approach. These findings suggest that eligibility determination for substance use studies may be more successful and more representative (because of the wider possible reach with the same level of staffing) when using electronic screening with flyers rather than relying on full-time staff in the clinic. Flyer-driven recruitment appears to be a practical approach, given the high levels of access to technology among the pregnant urban participants and their willingness to use their personal
devices for research. These latter findings are consistent with national survey data suggesting that smartphone ownership rates are high [27], and research suggesting that low-income patients are willing to use their own smartphone to participate in research [28].

**Limitations**

The sample size, homogeneity of the sample, and preliminary nature of this research all contribute to clear limits in the generalizability of these findings. In addition, our sample size limited the ability to understand what variables may contribute to higher disclosure within the flyer recruitment group (ie, maternal age, parity, past substance use, or socioeconomic status).

**Conclusions**

Using electronic methods for eligibility determination appears to facilitate disclosure and, thus, recruitment efficiency. Although flyer-based approaches are less efficient than in-person recruitment with an on-site RA, they may also facilitate disclosure and can allow cost-effective recruitment at multiple sites. Even low-income patients in perinatal settings are very likely to own a smartphone and be willing to use their own device to participate in research. This method can allow for larger study samples by decreasing the amount of money needed to support full-time RAs in each recruitment site. Instead, 1 RA could be used across multiple sites, which can free up funds for a larger number of site locations. This can allow for a wider variety of participants across the country and could be more translatable and easier to replicate or continue once funding ends.

**Acknowledgments**

This research was supported by internal funds from the Office of Vice President of Research at Wayne State University, who were not involved in the review and approval of the paper for publication. The authors wish to gratefully acknowledge the invaluable assistance of the women who participated in this study, Ms Edith Combs, and the medical staff from the Henry Ford Health New Center One Women’s Health clinic.

Abstract

Background: Research gaps refer to unanswered questions in the existing body of knowledge, either due to a lack of studies or inconclusive results. Research gaps are essential starting points and motivation in scientific research. Traditional methods for identifying research gaps, such as literature reviews and expert opinions, can be time consuming, labor intensive, and prone to bias. They may also fall short when dealing with rapidly evolving or time-sensitive subjects. Thus, innovative scalable approaches are needed to identify research gaps, systematically assess the literature, and prioritize areas for further study in the topic of interest.

Objective: In this paper, we propose a machine learning–based approach for identifying research gaps through the analysis of scientific literature. We used the COVID-19 pandemic as a case study.

Methods: We conducted an analysis to identify research gaps in COVID-19 literature using the COVID-19 Open Research (CORD-19) data set, which comprises 1,121,433 papers related to the COVID-19 pandemic. Our approach is based on the BERTopic topic modeling technique, which leverages transformers and class-based term frequency-inverse document frequency to create dense clusters allowing for easily interpretable topics. Our BERTopic-based approach involves 3 stages: embedding documents, clustering documents (dimension reduction and clustering), and representing topics (generating candidates and maximizing candidate relevance).

Results: After applying the study selection criteria, we included 33,206 abstracts in the analysis of this study. The final list of research gaps identified 21 different areas, which were grouped into 6 principal topics. These topics were: “virus of COVID-19,” “risk factors of COVID-19,” “prevention of COVID-19,” “treatment of COVID-19,” “health care delivery during COVID-19,” and “impact of COVID-19.” The most prominent topic, observed in over half of the analyzed studies, was “the impact of COVID-19.”

Conclusions: The proposed machine learning–based approach has the potential to identify research gaps in scientific literature. This study is not intended to replace individual literature research within a selected topic. Instead, it can serve as a guide to...
formulate precise literature search queries in specific areas associated with research questions that previous publications have earmarked for future exploration. Future research should leverage an up-to-date list of studies that are retrieved from the most common databases in the target area. When feasible, full texts or, at minimum, discussion sections should be analyzed rather than limiting their analysis to abstracts. Furthermore, future studies could evaluate more efficient modeling algorithms, especially those combining topic modeling with statistical uncertainty quantification, such as conformal prediction.

Introduction

Background
Scientific research relies on applying systematic scientific methods and actions to increase knowledge in fields or specific topics [1]. One essential first step in engaging in scientific research is identifying research gaps [2], where insufficient data, knowledge, or understanding limit our ability to draw conclusions in a given field or topic [3]. Research gaps can also be referred to as unanswered questions that have not yet been addressed or are undere xplored in the existing body of knowledge, either due to a lack of studies or inconclusive results [4,5]. Research gaps can also serve as a starting point for research as well as motivate further research [6]. Researchers have classified research gaps into seven categories [3,6,7]: (1) evidence gaps—where contradictions in the findings of the previous research exist; (2) knowledge gaps—where knowledge may either not exist in the literature or the results deviated from what was expected; (3) practical-knowledge conflict gaps—where the goal is to discover the reasons and scope of differences between professionals’ behaviors versus their advocated behavior; (4) empirical gaps—where there is a need to empirically evaluate and verify research findings or propositions; (5) methodological gaps—where shortcomings may arise due to having a single methodology influencing the research results; (6) theoretical gaps—related to examining gaps that exist in theories and their models and compare them with prior research; and (7) population gaps—where a population is not adequately represented or underresearched in prior studies.

The sheer volume and accelerated pace of scientific research output present both opportunities and challenges. Identifying potential interventions, best practices, and policy recommendations, all backed up by evidence is made easier by the wealth of information available. However, researchers face challenges with staying up-to-date with the latest findings, identifying redundancies in research, and objectively identifying research gaps that need to be addressed. Therefore, it becomes paramount to accurately identify the research gaps to advance our understanding of the issue or topic, better use the allocation of resources, and better inform evidence-based policy making.

Traditionally, several methods are used to identify research gaps, including literature reviews, systematic reviews, expert opinions, and consensus-building activities (eg, developing guidelines). Yet, such methods require an intensive time commitment, are prone to bias, and can be labor intensive. Additionally, such methods may not be suitable to address issues, where the evidence or research subject is rapidly increasing in volume and pace or is time sensitive (eg, COVID-19). Consequently, there is a need for innovative and scalable approaches to systematically assess existing literature, identify research gaps, and prioritize areas for further study in the topic or field of interest.

Machine learning (ML) techniques have demonstrated great potential applications of scientific insights and discoveries by addressing challenges related to information retrieval, knowledge discovery, and natural language processing [8]. ML is a branch of computational science and a subset of artificial intelligence (AI); it focuses on the development of algorithms that enable machines to learn from [9-12] and make predictions or decisions based on data, without being directly programmed [13]. Broadly, ML algorithms can “learn” through supervised learning, unsupervised learning (eg, reinforcement learning), or a mixture thereof, referred to as semisupervised learning [14,15].

Research Problem and Aim
In the context of identifying research gaps, ML techniques may facilitate the discovery of research gaps by analyzing large volumes of scientific evidence in a systematic, scalable, and efficient manner. To understand the current status quo of scientific evidence available, several studies leveraged ML to perform natural language processing, bibliometric analysis, and text mining, which have yielded promising results in several domains, including health care [9-12], social sciences [16-19], and environmental sciences [20]. However, the application of ML and its potential for identifying research gaps in rapidly evolving fields remains underexplored. To the best of our knowledge, there are no previous studies that leveraged ML-based techniques for identifying research gaps.

This paper aims to propose an ML-based approach to detect research gaps in the literature. In this work, we use the novel COVID-19 pandemic, caused by the SARS-CoV-2 virus, as a case study due to the fast and time-critical pace it evolved, along with the urgent need to comprehend this global pandemic. Since its emergence in late 2019, COVID-19 has had a profound global impact which not only halted many activities, triggered economic fallouts, and caused significant hardships, but it also claimed more than 6.8 million lives. In turn, the scientific community united to address the various challenges presented by the global spread of the virus.

https://formative.jmir.org/2024/1/e49411 JMIR Form Res 2024 | vol. 8 | e49411 | p.1810
(page number not for citation purposes)
Through unprecedented levels of scientific activities, researchers generated a vast amount of research output, with thousands of research papers being published each month, which discuss various aspects of the virus, its transmission, diagnosis, treatment, and prevention strategies [9,21,22]. However, with the rapid pace of information generation and dissemination, there is an increased risk of overlooking research gaps or underexplored areas that may be critical to understanding and mitigating the virus’s impact. Thus, this aims to propose an ML-based approach to detect research gaps in the literature using COVID-19 as a case study.

Methods

Study Data Selection
We used the COVID-19 Open Research (CORD-19) data set, produced by the Allen Institute for AI and made available on the Kaggle platform [23]. It was updated every week until June 2, 2022, to include the most recently published COVID-19 papers. We used the final version, which contains 1,121,433 entries. The search terms used by Allen Institute for AI to retrieve these studies were “Coronavirus” OR “Corona virus” OR “COVID-19” OR “2019-nCoV” OR “SARS-CoV” OR “Severe Acute Respiratory Syndrome” OR “MERS-CoV” OR “Middle East Respiratory Syndrome” [24]. The sources of studies in the CORD-19 data set were PubMed Central, PubMed, the World Health Organization’s (WHO) COVID-19 Database, arXiv, bioRxiv, and medRxiv [24]. The data set includes a CSV file containing meta-information about all the papers, such as article DOI, CORD UID, PMCID, PUBMED ID, title, abstract, journal, authors, and publication date. We removed duplicate papers, entries with empty and non-English abstracts, and papers published before January 1, 2020. We selected abstracts containing the keywords “novel coronavirus,” “coronavirus 2019,” “2019-nCov,” “COVID-19,” “COVID 2019,” “severe acute respiratory syndrome coronavirus 2,” and “SARS-COV-2” to include only COVID-19–related papers.

Data Preprocessing
We cleaned the abstracts and removed nonalphanumeric characters, punctuations, and sectioning keywords “BACKGROUND,” “OBJECTIVE,” “METHOD,” “RESULT,” “CONCLUSION.” We used the Python programming language in a Jupyter Notebook environment and Python libraries such as pandas, NumPy, langdetect, re, string, and TextBlob. We then searched abstracts that mentioned any term related to research gap: “unknown,” “not known,” “little is known,” “unrevealed,” “uncertain,” “undetermined,” “understudied,” “unexplored,” “not fully understood,” “literature gap,” “research gap,” “knowledge gap,” “future studies,” “future research,” “research problem,” “more studies,” “more research,” “further studies,” and “further research.” We decided to use these terms in an abstract search rather than a full-text search for 2 reasons. First, using these terms in a full-text search may lead to the inclusion of a significant number of unrelated studies, increasing the likelihood of inaccurately identifying research gaps that are not pertinent to the subject of interest. Second, the CORD-19 data set that we used in this study does not contain the full text of the studies. With this process, we identified 33,206 abstracts of scholarly papers published after January 1, 2020, related to COVID-19 and containing the gap words. We analyzed these abstracts, and from each abstract, we extracted 3 sentences: 1 sentence that includes the gap word, 1 sentence before, and 1 sentence after the sentence containing the gap word. We used a full stop (“.”) as a sentence marker. We converted the selected sentences to lowercase text. Next, we used the Python NLTK library to remove the stop words and tokenize the sentences. Finally, we used the clean sentences after the preprocessing steps for clustering.

Analysis

Overview
For clustering the sentences into semantically similar topics, we used the BERTopic algorithm [25]. The BERTopic algorithm is an unsupervised learning algorithm for topic modeling. It uses the Bidirectional Encoder Representations from Transformers (BERT). BERTopic does not require labeled data as it extracts topics from an input text in a supervised way [26]. BERTopic gained popularity due to its potential to capture context-aware information in a given input text and does not rely on a predefined number of topics [26]. Besides topic modeling, BERTopic is also useful in the clustering of documents and text summarization [26]. The BERTopic topic modeling method produces dense clusters by combining class-based term frequency-inverse document frequency (TF-IDF) and transformers (BERT embeddings). In addition, it makes it simple to comprehend and visualize the generated topics. The 3 stages in the BERTopic algorithm are presented in Figure 1 and discussed in the next subsections.
Figure 1. Stages of the BerTopic modeling algorithm. c-TF-IDF: class-based term frequency-inverse document frequency; MMR: maximum marginal relevance; HDBSCAN: hierarchical density-based spatial clustering of applications with noise; UMAP: uniform manifold approximation and projection.

**Embedding Documents**

In this stage, the BERTopic algorithm extracts document embeddings using BERT sentence transformers. Each document embedding is generated using word embeddings, which represent each word in the document in multidimensional space. It ensures that words with related meanings have comparable representations. This way, words are represented by numbers in a vector space, where vectors are defined by TF-IDF weights. TF-IDF describes the importance of a term relative to a document in a corpus. Neural networks are the primary foundation of embedding models. Typically, word embeddings are used to compute document embedding into 2 phases. The word embedding is first applied to every word in the text and then the word embeddings are aggregated by averaging over each dimension to produce document embeddings.

**Clustering Documents**

Documents embeddings produced in the previous step are usually very sparse. Therefore, our first stage of the analysis uses uniform manifold approximation and projection to decrease the dimensionality of the embeddings [27]. Then, we use the hierarchical density-based spatial clustering of applications with a noise approach to cluster reduced embeddings and produce clusters of texts with comparable semantic properties.

**Representing Topics**

In this stage, class-based TF-IDF weights are used to extract topics. These topics are reduced and further improved by finding the coherence of words using maximum marginal relevance. We used BERTopic to cluster the extracted sentences and found 191 clusters. Then, we applied the topics reduction technique of BERTopic and found a total of 50 clusters. We assigned labels to each cluster by checking their representative words. When it was challenging to assign labels to a cluster based on its representative words, we reviewed sentences containing the specified research gap terms, along with the sentence before and after in most studies within that cluster. After that, we merged clusters that had similar labels to identify 21 unique labels (research gaps). Finally, we grouped these clusters into 6 broader categories. Multimedia Appendix 1 shows the code used for the analysis of bibliographic data to identify research gaps.

**Results**

**Search Results**

By June 2, 2022, the CORD-19 data set contained 1,121,433 papers (Figure 2). Of those, we excluded 1,088,227 papers for the following reasons: (1) abstracts were unavailable (n=300,540); (2) the papers were published before January 1, 2020 (n=225,964); (3) the papers were written in a language other than English (n=6499); (4) papers did not contain search terms related to COVID-19 (n=195,498); and (5) papers did not contain search terms related to research gap (n=359,726). Consequently, we included 33,206 papers in the analysis of this study.
Results of Gap Identification

Overview

As mentioned earlier, 191 clusters of the 33,206 papers were generated by our analysis. Then, the number of clusters was reduced to 50 when we applied a topics reduction technique. We deleted 6 clusters as we could not identify the research gap from them. Further, 23 clusters were merged with other clusters as the same research gaps were identified in these clusters. Overall, we identified 21 different research gaps from 4646 papers. As shown in Table 1, these research gaps were grouped into 6 topics, which are discussed in the next subsections.
Table 1. Topics and the corresponding subtopics identified in this study (N=4646).

**Topic 1: Virus of COVID-19 (n=647, 13.9%)**

**Origin of COVID-19**
There are 318 studies related to the origin of COVID-19. Despite various theories and pieces of evidence, the exact source of SARS-CoV-2 remains unknown according to the majority of studies on this topic.

**Emerging Variants**
According to the 202 studies on this topic, the full extent of the impact of new variants on the course of the pandemic and the effectiveness of current prevention and treatment strategies on the new variants are still not known. Furthermore, it is uncertain how the emergence of new variants may affect the duration of immunity after recovery. In addition, it is not clear how accurate the prediction models are in predicting the emergence of new variants and their impact.

**Transmission of COVID-19**
A total of 75 studies have revealed several unknown aspects of the virus such as the role of asymptomatic carriers in the spread of the virus, the true level of global spread, and the extent to which COVID-19 may be circulating undetected in some areas, and the influence of environmental factors (e.g., temperature and humidity) on the transmission of COVID-19.

**Role of the Immune System**
In 52 studies related to this topic, several research gaps were identified. Specifically, while it is known that the virus elicits an immune response, it is still unclear the specifics of how the immune system responds, the duration of immunity after recovery, the relationship between the severity of illness and the strength of the immune response, and how the immune response may differ between individuals.
Topic 2: Risk Factors of COVID-19 (n=142, 3.1%)

Obesity
From 77 studies related to this topic, we found that the relationship between obesity and COVID-19 is still largely a mystery. While some studies have suggested that obesity may increase the risk of severe COVID-19 outcomes, the exact mechanisms behind this are still unknown. Additionally, it is unclear whether weight loss can reduce the risk of severe illness and death from COVID-19 in individuals with obesity. Furthermore, there is no consensus on the optimal BMI cut-off for identifying individuals with obesity who are at increased risk of severe illness and death from COVID-19.

Ethnicity
A total of 65 studies identified a significant research gap in understanding the relationship between ethnicity and COVID-19. Despite the numerous studies conducted, the reasons for these disparities remain largely unknown.

Topic 3: Prevention of COVID-19 (n=631, 13.6%)

Vaccination
A total of 447 studies have revealed that the long-term efficacy and safety of COVID-19 vaccines remain largely unknown. Although initial clinical trials have demonstrated promising results, it is uncertain how long the protection provided by the vaccines will last and what potential long-term side effects may be. Further, vaccine hesitancy and the factors that contribute to it are not fully understood. Moreover, the safety of COVID-19 vaccines in patients with chronic diseases (eg, chronic hepatitis, diabetes, heart failure, renal failure, and epilepsy) remains unknown.

Precautionary Measures
A total of 124 studies were related to precautionary measures implemented to prevent the spread of the virus. According to these studies, the effectiveness of many precautionary measures such as social distancing, wearing masks, hand hygiene, respiratory etiquette (eg, covering mouth and nose when coughing and sneezing), and ventilation systems is still unknown. Further, the duration of quarantine or isolation for individuals with COVID-19 remains uncertain.

Wastewater Surveillance
In total, 60 studies were related to using wastewater surveillance to detect the presence of the virus in communities. According to these studies, it is unclear how accurately wastewater surveillance can predict or track COVID-19 outbreaks and what the potential false-positive or false-negative rates may be.

Topic 4: Treatment of COVID-19 (n=291, 6.3%)

Medications of COVID-19
The role of medications (eg, remdesivir and corticosteroids) in managing severe cases of COVID-19 was discussed in 170 studies. According to these studies, there are still many unknowns about the medication for COVID-19, including the potential for long-term effects on the heart, lungs, and other organs; the optimal treatment protocol (eg, timing, dose, and duration) for different stages of the disease and age groups; the effectiveness of existing medications against new variants and new medications against multiple variants; the safety and efficacy of a combination of medications; the best combinations and dosages; the safety and efficacy of medication in children; and the effect of the combination of medication and dietary supplements.

Herbal Medicine
Herbal medicine was the main topic in 66 studies. According to these studies, much remains unknown about the effectiveness, safety, standardization, dosage, and potential interactions with other treatment regimens.

Support System
A total of 55 studies were related to support systems that provide several services (eg, social support, mental health, and financial assistance) to individuals affected by COVID-19. According to these studies, the effectiveness and long-term impacts of support systems on patients with COVID-19 remain largely unknown.

Topic 5: Health Care Delivery During COVID-19 (n=555, 11.9%)

Telehealth
The COVID-19 pandemic has seen a dramatic surge in the use of telehealth; yet, a total of 305 studies have revealed that there are still many unknowns about its effectiveness and accessibility. These unknowns have the potential to create new privacy and security risks, as well as to impact health care disparities.

Surgeries
According to the 158 studies discussing this topic, there is still no consensus on planning to maintain surgical care preparedness in ongoing and future pandemics. This includes understanding the risk of transmission, perioperative testing criteria, postoperative outcomes in specific populations, and effective strategies for resource allocation.

Organ Transplantation
A total of 92 studies have revealed that there is still much to be discovered about the best way to manage organ transplantation during the COVID-19 pandemic. Specifically, there is still much to be uncovered about COVID-19 in relation to organ transplant recipients, including identifying risk factors, developing strategies to minimize transmission, understanding outcomes for transplant recipients who contract COVID-19, and determining the best treatment for COVID-19 in organ transplant recipients considering their immunocompromised status.

Topic 6: Impact of COVID-19 (n=2380, 51.2%)

Health Complications
From 1552 studies, we found that the long-term health complications of COVID-19 remain largely a mystery. To be more precise, there is a lack of evidence on the long-term impact of COVID-19 on the respiratory system (eg, asthma and chronic obstructive pulmonary disease), cardiovascular system (eg, hypertension, deep vein thrombosis, and pulmonary embolism), neurological system (eg, confusion, dizziness, and headache), endocrine system (eg, diabetes, hepatic system (eg, liver injury),
olfactory system (loss of smell and taste), and mental health (eg, anxiety, depression, and posttraumatic stress disorder).

**Special Groups**

According to 434 studies, the impact of COVID-19 on special groups is still largely unknown. Specifically, there are still many unanswered questions related to the impact of COVID-19 on pregnancy. For example, what is its impact on the risk of preterm birth and respiratory distress? What is the long-term effect on fetuses and babies? And how is the virus transmitted from mother to baby during pregnancy, labor, or delivery? Further, there is still much to learn about the impacts of the virus on pediatric populations and patients with cancer in terms of diagnosis, treatment, and complications. The long-term effects of COVID-19 on health care workers remain uncovered.

**Education**

The COVID-19 pandemic has profoundly impacted education, with schools and universities shutting down or moving to web-based learning to slow the spread of the virus. A total of 136 studies on this subtopic revealed that there is still much unknown about the impact of COVID-19 on education.

**Media and Communication**

The COVID-19 pandemic has had a profound impact on media and communication, and while much research and analysis have been conducted, there are still many unknowns. A total of 109 studies explored this topic. From these studies, we found that there are still many unanswered questions related to media and communication. For example, Will the increased media consumption habits that have emerged during the pandemic persist in the long term, or will people revert to their prepandemic habits? How will media organizations adapt to the financial challenges posed by the pandemic, and will it lead to long-term changes in the media landscape? What will be the long-term effects of social media on the spread of misinformation and society as a whole? How will the increased reliance on digital communication tools, such as video conferencing and messaging apps, impact our relationships and social dynamics in the long term?

**Mortality**

A total of 87 studies were related to the mortality of COVID-19. According to these studies, there is a lack of evidence on factors affecting mortality rates over time and on whether new strains of the virus are more deadly or have different mortality rates than the original strain.

**Food Security**

In total, 62 studies have revealed that the impacts of COVID-19 on food security remain largely unknown. While some studies have suggested that the pandemic may worsen food insecurity in certain populations, the true extent of the problem is still unclear. In addition, the long-term effects of food insecurity during the pandemic on health and well-being are yet to be determined.

---

**Discussion**

**Principal Findings**

This study proposed an ML-based method to identify research gaps in the literature. We used COVID-19 literature as a case study. Our proposed method enabled us to identify research gaps in 21 subtopics that were grouped into 6 topics. The largest topic that was identified in more than half of the analyzed studies is the “impact of COVID-19” (topic 6). This is hardly surprising, since we, as a society, are still struggling to come to terms with the long-lasting impact of the pandemic, which continues to affect many aspects of our lives. Long-term health complications are still poorly understood, given the relatively short time since the initial outbreak, which is less than 4 years. In addition, understanding the precise impact of the disease on body systems and organs proves challenging given that it is a complex disease that affects multiple organs, there is a lack of data about the virus, and its impact may vary among different populations.

The second largest topic identified in this study is the “virus of COVID-19” (topic 1). The lack of knowledge about the COVID-19 virus is attributed to its novelty as a new strain of coronavirus not previously identified in humans. Further, tracing the origins of zoonotic diseases can be difficult as they may pass through multiple animal hosts before reaching humans. Moreover, due to its rapid evolution into new variants, studying each variation of the COVID-19 virus within a short timeframe poses a significant challenge.

Topic 3 (ie, prevention of COVID-19) was the third largest topic in this paper. The lack of knowledge in this area may be attributed to the limited long-term data on vaccine safety and efficacy. Additionally, the emergence of new variants may impact vaccine efficacy, raising concerns about the effectiveness of the current vaccines against these new variants. Further, a significant challenge in assessing the long-term effects of the COVID-19 vaccine is vaccine hesitancy, which is not fully understood and can hinder data gathering on long-term effects.

The COVID-19 pandemic has impacted health care delivery, and this was topic 5 in this study. One of the subtopics in this topic is telehealth, which has seen a significant surge. Telehealth is a relatively new technology that has only recently become widely available. As a result, there may not yet be enough data available to fully evaluate its effectiveness. Telehealth is often used in conjunction with other health care interventions, such as in-person visits or medications, which can make it difficult to separate the impact of telehealth from other factors. Importantly, there may be biases in the types of patients who are most likely to use telehealth. Thus, it is difficult to generalize findings to the broader population. Another subtopic in this topic is organ transplantation. Research gaps related to this subtopic may be attributed to the following reasons: (1) while there have been some studies on the impact of COVID-19 on organ transplant patients, the number of patients in these studies is often relatively small. These limited data can make it difficult to draw definitive conclusions about the impact of COVID-19 on this population; (2) organ transplant patients are a heterogeneous population, and the impact of COVID-19 may vary depending on factors such as age, comorbidities, and the
type of organ transplant; (3) organ transplant patients may be at increased risk of complications from COVID-19 due to their underlying health conditions and the immunosuppressant drugs they take to prevent organ rejection. Therefore, it can be difficult to isolate the impact of COVID-19 from these other factors.

We found that there are research gaps related to the treatment of COVID-19 (topic 4). This may be due to several factors. First, addressing research gaps related to this topic needs many rigorous clinical trials, which usually take several years to complete all 3 phases before the licensing stage. Second, such clinical trials are very expensive, and therefore only researchers with large funds can carry out these trials.

Critical gaps in our understanding of the relationship among obesity, ethnicity, and severe COVID-19 outcomes exist (topic 2). The relationship among obesity, ethnicity, and COVID-19 outcomes is likely influenced by a complex interplay of biological, behavioral, and environmental factors, making it difficult to determine the precise nature and extent of these relationships. Disentangling the effects of these different factors on health outcomes can be challenging, and limitations in the quality and availability of data on obesity and ethnicity in certain populations can make it difficult to accurately measure the relationship between these factors. Moreover, known statistical challenges are related to controlling confounding factors such as age, sex, and comorbidities that affect the nature, behavior, and interpretation of the relationship among these factors.

In February 2020, a 2-day meeting organized by the WHO brought together more than 400 participants worldwide [28]. The objective was to develop a research road map that would facilitate and expedite global research efforts aimed at controlling the transmission of COVID-19 [28]. The research road map identified many knowledge gaps and grouped them into 8 areas. All research gaps identified in this review were mentioned in the road map except for topic 6 (impact of COVID-19). This may be attributed to the fact that this topic was less important at that stage of the pandemic (2 months after the onset of COVID-19).

After 3 months of the WHO research road map, a mixed methods study was conducted on 4087 participants (researchers, policy makers, health care workers, etc) to check which of the early WHO road map priorities are still most pressing and identify any newly emerging priorities that warrant attention [29]. The study revealed that the WHO research road map is still globally applicable. However, it identified a number of new research priorities that align with the evolving nature of the pandemic and provide insights into areas where knowledge gaps exist. One of these new research priorities is the impact of COVID-19, which aligns with topic 6 in our study.

About 10 months after the onset of COVID-19, a team from the WHO Southeast Asia Region conducted a web-based survey of 48 experts to identify COVID-19 research priorities in the Southeast Asia Region [30]. The study identified 27 research priorities, which include all 6 research topics identified in this study.

Our findings are also in agreement with previous work [31] that similarly used the CORD-19 data set to determine research priorities during the COVID-19 pandemic. The earlier study identified 10 hotspots, 4 of which overlap with our identified research gaps: virus of COVID-19, risk factors of COVID-19, prevention of COVID-19, and treatment of COVID-19. Notably, our analysis further includes 2 additional topics, which are health care delivery during COVID-19 and the impact of COVID-19. The earlier study also identified additional areas: nursing and health care, diagnosis and testing, drugs and vaccines, social psychology, infection process, and clinical characteristics. The discrepancy between the 2 sets of findings may be attributed to the period when the studies were conducted. The prior study was conducted during the initial phase of COVID-19–related research (January to September 2020), during which the emphasis was predominantly on diagnosis, testing, infection processes, and clinical characteristics. At that early stage, the short- and long-term impacts of COVID-19 were less clear, as was its effect on health care delivery.

Limitations
This study has several limitations that need to be considered when interpreting the results. First, clusters generated by the BERTopic modeling algorithm were subject to noise. In other words, we noticed that several studies in a cluster are not relevant to that cluster. Therefore, not all studies on a topic reported a research gap related to that topic.

Second, the studies included in our analysis were limited to those published up to June 2022, given the Allen Institute for AI stopped updating the data set, and new research has been published since then. Therefore, it is likely that several research gaps identified in this review have been addressed and new research gaps have emerged.

Third, it is likely that this study missed other important research gaps for several reasons: (1) studies in the CORD-19 data set were retrieved from only 5 databases; therefore, the CORD-19 data set did not include studies from other common databases such as Scopus, Web of Science, Embase, and PsycoloQ; (2) our analysis relied on abstracts rather than full texts, in which especially introduction and discussion sections commonly identify research gaps; (3) this study only considers papers in English. Consequently, potential insights from studies published in other languages may have been overlooked; and (4) we cannot rule out that we missed some terms relevant to research gaps; therefore, it is likely that many studies relevant to this work were not included in the analysis.

Fourth, we do not attempt a trend analysis in favor of a compact and concise overview, and we do not yet provide automated means to analyze original research gaps that have been addressed since the publication of a given paper. However, we believe that the presented analysis is still useful as we observe clear “hot topics” that resonate with earlier thematic research areas defined by the WHO which are extremely unlikely to have been researched fully since formulating the gap.

Practical and Research Implications
This study’s aim is not to generate research topics automatically that, when worked on, guarantee impact or publication. Instead, we scope the landscape of research gaps outlined in the literature. This study should therefore be taken as a help to
identify and prioritize “hot” topics that need addressing. This study also does not seek to replace individual literature research in a chosen topic, but it can serve as a guide to formulate specific literature search queries in specific areas related to research questions left as future work by prior publications. Therefore, literature reviews or scoping reviews are still required. Nevertheless, we anticipate that with the advent of more advanced techniques like Large Language Models, the performance of such approaches will enhance in the foreseeable future, subsequently reducing the necessity for literature reviews or scoping reviews to identify research gaps.

To overcome the above-mentioned limitations of our approach, thereby improving the identification of gaps, future research should use an up-to-date list of studies that are retrieved from the most common databases in the target area (eg, MEDLINE, Scopus, Web of Science, Embase, PsycINFO, IEEE Xplore, and ACM Digital Library). If practical, researchers should also analyze full texts, or at least discussion sections, rather than only abstracts. Moreover, additional terms related to research gaps (eg, limited evidence, inconclusive findings, and insufficient evidence) should be used to identify the relevant studies and sentences appropriate for analysis. Further, there is a need to improve the performance of the BERTopic modeling algorithm in clustering studies, specifically with respect to removing outliers from the clustering. From a technical perspective, this may require further research to combine topic modeling with statistical uncertainty quantification, such as conformal prediction [32,33].

The process of clustering text documents is an essential technique used in the text mining area, as well as in a variety of applications including ML and pattern recognition. Since clustering text documents is an optimization problem, several meta-heuristics (MH) optimization algorithms have been presented as possible solutions to this nondeterministic polynomial-time hard problem. However, while obtaining the best solution, individual optimization MH algorithms may run into serious problems including poor convergence and being stuck in local optima. To address these issues, the hybridization concept was applied to combine the strengths of 2 hybrid search methods (ie, MH algorithms) and so avoid their weaknesses.

From the dominance of topic 6, we see that most research is needed to understand the long-term effects of the pandemic. Especially where COVID-19 “temporary” solutions have become established practice (telehealth, hybrid education, the logistics of resilient food supply, etc), more research is needed to answer questions regarding the efficacy and sustainability of such solutions. Long-term health complications will continue to be a topic for quite some time in the future, given that COVID-19 has only been studied for less than 4 years. As new complications and variants emerge, this subtopic arguably has the highest potential to serve humanity and create a real impact.

Conclusions

This paper showed that ML has the potential to identify research gaps in scientific literature. Our proposed method identified research gaps in 21 subtopics that were grouped into 6 topics: virus of COVID-19, risk factors of COVID-19, prevention of COVID-19, treatment of COVID-19, health care delivery during COVID-19, and impact of COVID-19. This study is not intended to replace individual literature research within a selected topic. Instead, it can serve as a guide to formulate precise literature search queries in specific areas associated with research questions that previous publications have earmarked for future exploration. Future research should leverage an up-to-date list of studies that are retrieved from the most common databases in the target area. When feasible, full texts or, at minimum, discussion sections should be analyzed, rather than limiting their analysis to abstracts. Moreover, additional terms related to research gaps should be used to identify the relevant studies and sentences appropriate for analysis. Furthermore, future studies could evaluate more efficient modeling algorithms, especially those combining topic modeling with statistical uncertainty quantification such as conformal prediction.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Authors’ Contributions

AA-A, AJN, and ZS developed the protocol for this paper. Data collection and preprocessing were carried out by ZS. Data analysis was performed by AA-A, AJN, and ZN. DA and WA wrote the introduction. The Methods section was written by ZS and HA. The Results section was written by AA-A and AJN. The Discussion and Conclusion sections were written by all authors. The paper was revised critically for important intellectual content by all authors. All authors approved the manuscript for publication and agree to be accountable for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic disrupted postgraduate certification examinations globally. The Colleges of Medicine of South Africa continued hosting certification examinations through the pandemic. This was achieved by effecting a rapid transition from in-person to web-based certification examinations.

Objective: This formative evaluation explored candidates’ acceptability of web-based structured oral examinations (SOEs) hosted via Zoom (Zoom Communications Inc). We also reported the audiovisual quality and technical challenges encountered while using Zoom and candidates’ overall experience with these examinations conducted during the early part of the COVID-19 pandemic. Additionally, performance in web-based certification examinations was compared with previous in-person certification examinations.

Methods: This mixed methods, single-arm evaluation anonymously gathered candidates’ perceptions of web-based SOE acceptability, audiovisual quality, and overall experience with Zoom using a web-based survey. Pass rates of web-based and previous in-person certification examinations were compared using chi-square tests, with a Yates correction. A thematic analysis approach was adopted for qualitative data.

Results: Between June 2020 and June 2021, 3105 candidates registered for certification examinations, 293 (9.4%) withdrew, 2812 (90.6%) wrote, and 2799 (99.9%) passed, and 1525 (54.2%) were invited to a further web-based SOE. Examination participation was 96.2% (n=1467). During the first web-based examination cycle (2020), 542 (87.1%) of 622 web-based SOE candidates completed the web-based survey. They reported web-based SOEs as fair (374/542, 69%) and adequately testing their clinical reasoning and insight (396/542, 73.1%). Few would have preferred real patient encounters (173/542, 31.9%) or in-person oral examinations (152/542, 28%). Most found Zoom acceptable (434/542, 80%) and fair (396/542, 73.1%) for hosting web-based SOEs. SOEs resulted in financial (434/542, 80%) and time (428/542, 79%) savings for candidates. Many (336/542, 62%) supported the ongoing use of web-based certification examinations. Only 169 technical challenges in using Zoom were reported, which included connectivity-related issues, poor audio quality, and poor image quality. The thematic analysis identified 4 themes of positive and negative experiences related to web-based SOE station design and content, examination station environment, examiner-candidate interactions, and personal benefits for candidates. Our qualitative analysis identified 10 improvements for future web-based SOEs. Candidates achieved high pass rates in web-based certification examinations in 2020 (1583/1732, 91.39%) and 2021 (850/1067, 79.66%). These were significantly higher (2020: N=8635; χ²₁=667; P<.001; 2021: N=7988; χ²₁=178; P<.001) than the previous in-person certification examination pass rate of 58.23% (4030/6921; 2017-2019).

Conclusions: Web-based SOEs conducted by the Colleges of Medicine of South Africa during the COVID-19 pandemic were well received by candidates, and few technical difficulties were encountered while using Zoom. Better performance was observed.
in web-based examinations than in previous in-person certification examinations. These early findings support the ongoing use of this assessment method.

Introduction

Background
The COVID-19 pandemic severely disrupted the postgraduate specialty and subspecialty certification examinations globally [1-5]. The Colleges of Medicine of South Africa (CMSA) continued hosting postgraduate certification examinations during the pandemic [6]. This decision ensured that the national pipeline of specialist workforce would not be disrupted and that the careers of international medical graduates completing postgraduate training in South Africa would not be unduly delayed. Hosting these examinations during the pandemic was achieved by effecting a transition from in-person to web-based written and oral examinations within a period of 8 weeks.

Prepandemic Certification Examinations
CMSA, a nonprofit organization founded in 1954, comprises 29 constituent member colleges, each representing a primary specialty practiced in South Africa, such as College of Pediatricians, College of Surgeons, College of Physicians, College of Family Physicians, College of Obstetricians and Gynecologists, College of Anesthesiologists, and so on [6]. CMSA conducts certification examinations at the beginning (entry level) and end of postgraduate training (exit level) for all specialties and subspecialties registered with the South African statutory medical licensing authority, the Health Professions Council of South Africa [7]. Currently, there are 65 specialties (pediatrics, internal medicine, general surgery, ophthalmology, otorhinolaryngology, anesthetics, etc) and 30 subspecialties (pediatric pulmonology in the specialty of pediatrics, trauma surgery in the specialty of general surgery, gynecological oncology in the specialty of obstetrics and gynecology, etc) practiced in South Africa. For the purposes of this paper, the term, postgraduate certification examinations, denotes all postgraduate certification examinations conducted by CMSA for all specialties and subspecialties practiced in South Africa. These examinations are similar to other international postgraduate certification examinations such as board certification examinations offered by the American Board of Medical Specialties [8] or membership examinations offered by Royal Colleges in the United Kingdom [9]. Before the COVID-19 pandemic, CMSA certification included handwritten examinations, and successful candidates were invited for in-person, patient-based, clinical examinations and in-person, unstructured oral examinations (viva voce).

Transition to Virtual Certification Examinations
The transition occurred during the first 8-week hard lockdown phase of the pandemic, which included closure of all public facilities except for emergency care, food, and health care; complete ban on in-person meetings and any form of intercity travel; and national curfew from 9 PM to 6 AM [10]. Weekly web-based meetings were used to provide staff with information updates and training, supplemented by digital information manuals and web-based training sessions for all examiners and candidates learning to use Zoom (Zoom Communications Inc), an interactive web-based software meeting platform.

Handwritten examinations were replaced by web-based written examinations (short-answer questions and single, best-answer questions) using commercially available software. In-person, patient-based examinations were largely discontinued, except where geographically decentralized in-person clinical examinations could be offered in COVID-19–compliant settings. For all member colleges, a new emphasis was placed on developing web-based structured oral examinations (SOEs) to assess diagnostic reasoning, clinical decision-making, and patient management, which were previously assessed during real patient encounters. It was acknowledged that web-based SOEs could not assess bedside clinical skills (history taking and physical examination), as was previously done. This compromise, accepted as an emergency measure during the pandemic, was predicated on an agreement that implementation of workplace-based assessment in South African postgraduate training would be prioritized after the pandemic [10-12].

Design of Web-Based SOE
Web-based SOEs were designed as case scenarios, each comprising a case description with supplementary information including laboratory test results, photographs, video clips, and radiographic and histopathological images, where appropriate. The case scenarios were prepared by national panels of examiners working remotely via Zoom. Each scenario was prepared as a Microsoft PowerPoint presentation, which was screen shared with candidates during the oral examination hosted via Zoom. Candidates answered the standardized questions posed by examiners working alone or in pairs. Zoom calls were also attended by moderators and trainee examiners (observers). Examiners scored the candidates’ responses independently during Zoom calls using downloaded and printed memoranda, and examiners’ handwritten notes were digitally transcribed and submitted with final examination scores to conveners at the conclusion of the examination proceedings. All Zoom calls were booked and collated on timetables with embedded hyperlinks for individual calls, which were shared with the examiner panels 1 week before the examination events. Individual Zoom calls varied in length from 15 to 60 minutes, depending on the number of case scenarios discussed per call. Candidates undertaking a web-based SOE were typically...
exami ned on 4 to 12 case scenarios, depending on the specialty or subspecialty.

Conducting Virtual Certification Examinations

CMSA set up 14 examination venues (8 in South Africa and 6 elsewhere in southern Africa) equipped with 12-inch laptop computers; 24-inch high-resolution monitors; and internet connectivity using wireless, microwave, and fiber technology. Owing to electrical power supply interruptions (load shedding) in South Africa, all examination venues were equipped with dual power supply arrangements. On-site IT support and on-site proctoring by trained staff were provided at all venues.

Candidates undertook all web-based examinations (written and oral) at an examination venue closest to their home (<3 h travel by road). Overnight accommodation was not permitted. National occupational health and safety COVID-19 protocols were observed at all examination venues [13]. Examiners joined the Zoom calls from their home or place of work, whichever was more convenient and had better bandwidth and a stable electricity supply.

Process of Evaluation

When CMSA implemented web-based SOEs for postgraduate certification examinations in early 2020, there were few reports in the literature. There was little reference to their use for high-stakes postgraduate specialist certification processes [14-17]. Most referred to in-person SOEs for undergraduate students [18-21]. Given the paucity of data, we set up a preliminary evaluation during the initial period of implementation to obtain early insights into candidates’ perceptions about the acceptability of this assessment method and their performance in web-based examinations as compared with in-person certification examinations. Despite its known limitations, we structured our evaluation process on the Kirkpatrick model of program evaluation (reaction, learning, behavior, and results) using four questions to address level 1 (reaction) and level 4 (results) of the model [22-25]:

1. Are web-based SOEs acceptable to examination candidates?
2. What technical challenges did examination candidates encounter while using Zoom?
3. On the basis of candidates’ experiences, how could we improve the web-based SOE experience?
4. Are pass rates for web-based and in-person certification examinations different?

Methods

Design

The evaluation was conducted as a cross-sectional observational study using a mixed methods design.

Participants

The study population included all postgraduate certification examination candidates who were invited to undertake web-based SOEs after successfully completing the written component of the national certification examinations in 2020 and 2021.

Procedure

The first cohort of examination candidates who undertook a web-based SOE between June 1, 2020, and November 15, 2020, was invited to complete the web-based survey immediately after completing their web-based SOE at one of the examination venues. A web-based study information leaflet was provided to potential participants before recruitment. The web-based questionnaire was administered on laptop computers at the examination venues. Participants were recruited to the study before releasing any examination results.

Survey Design

The survey, designed as a Google Form, consisted of 28 items (Multimedia Appendix 1). A total of 23 closed-ended questions focused on candidates’ perceptions of the adequacy, fairness, and quality of web-based SOEs and the technical adequacy and personal time and cost savings of using Zoom to host SOEs. Closed-ended questions required either a binary (yes or no) response or a 5-point Likert-scale response (completely disagree, disagree, neutral, agree, or completely agree). Candidates’ acceptability of web-based SOEs was defined as candidates’ perceptions of the adequacy of the web-based assessment process, overall fairness, and quality of examination material used. Parameters used to determine the adequacy of the assessment process included the following: adequate assessment of clinical reasoning, judgment, insight, and decision-making; appropriate complexity of case scenarios and questions; appropriate duration of examination; appropriate time allocation per case scenario; and preference for in-person patient encounter or in-person examiner. Fairness was explored in terms of perceived overall fairness and the use of more case scenarios than previously during in-person examinations.

Quality of examination material referred to clarity of material presented during the Zoom call. Candidates’ acceptability of Zoom as the hosting platform was defined in terms of perceptions of (1) overall acceptability and fairness of the web-based assessment process, (2) audiovisual quality of Zoom, and (3) personal benefits of web-based SOEs to examination candidates (time and financial savings). The survey also included 5 open-ended questions, which required a typed text response. These questions explored candidates’ overall positive and negative experiences regarding the web-based examination process. The survey was administered immediately after the examination proceedings, and we chose to anonymize all the information so as to allay candidate concerns about possible bias when deciding whether to participate in the survey. They only reported about the examination venue attended and certification examination undertaken.

Quantitative Data Analysis

Quantitative data from the web-based questionnaire were exported into a Microsoft Excel spreadsheet before analysis. For questions using a Likert-scale response, answers were reported in 3 categories: agree (strongly agree and agree responses), neutral (neutral responses), and disagree (strongly disagree and disagree responses). Percentages were calculated and rounded to 1 decimal point.
The respective pass rates for the first 2 cycles of web-based certification examinations, 2020 and 2021, were compared with the overall pass rate for the preceding 6 cycles of in-person certification examinations conducted between 2017 and 2019 using the chi-square test for independence with a Yates correction. *P*<.01 was taken as the level for significance.

**Qualitative Data Analysis**

Qualitative data from the open-ended questions were captured on the web using Google Forms, exported into an Excel spreadsheet, and subjected to thematic analysis using the 6-step approach to thematic analysis by Braun and Clarke [26]. The qualitative responses were read with the stated question in mind, after which a set of themes was developed by members of the research team (FM and JKM). The responses were reread and assigned to themes, which were further refined as more themes emerged. The responses were reread a third time (JKM), and the themes were reviewed. Discrepancies were presented to a third author (VB) and discussed until consensus was reached.

**Ethical Considerations**

The study was approved by the human research ethics committee of the University of Cape Town (HREC 280/2020), CMSA, South African Committee of Medical Deans, and Health Professions Council of South Africa. Participation was voluntary, and informed consent was obtained before inclusion in the study. This study, which involved human participants, was performed in accordance with the Declaration of Helsinki. All examination candidates gave signed informed consent before participation in the study. All methods were conducted in accordance with relevant guidelines and regulations. Declared consent for publication is not applicable as no identifying images or information was used in the paper.

**Results**

**Participants**

Table 1 shows that during the first 12 months of the COVID-19 pandemic, from June 2020 to June 2021, a total of 3105 candidates registered for postgraduate certification examinations conducted by CMSA. After announcing a transition to web-based examinations, of the 3105 candidates, 351 (11.3%) candidates withdrew (written: 293/351, 83.5%; oral: 58/351, 16.5%); overall participation was 88.7% (2754/3105) during the pandemic. Of the 2754 entrants, 1912 (69.43%) passed the written components of the certification examinations, and 1525 (55.37%) were invited to a web-based SOE, of which 1467 (53.27%) attended the SOE (1467/1525, 96.2% participation).

\(^b\)Overall pass rate: total=86.5% (2433/2812, year 2020=91% (1583/1739), year 2021=79.2% (850/1073).

\(^c\)SOE: structured oral examination.

\(^d\)Only exit-level certification examinations include virtual SOEs.

**Questionnaire Completion**

The web-based survey was administered to the first cohort of candidates who participated in web-based SOEs between June 1, 2020, and November 15, 2020. Of the 622 potential participants, 542 (87.1%) completed the web-based survey.

**Are Web-Based SOEs Acceptable to Candidates?**

**Candidates’ Perceptions of Web-Based SOEs**

Table 2 shows that, broadly speaking, candidates expressed a positive opinions about web-based SOEs. They considered web-based SOEs to be a fair method of examination (374/542, 69%), which tested their clinical reasoning and insight appropriately (364/542, 67.2%), more cases better displayed their knowledge (369/542, 68.1%). Less than one-third (173/542, 31.9%) felt that real patient encounters would have been preferred, and a small minority (152/542, 28%) would have preferred an in-person oral examination.

What Technical Challenges Did Candidates Encounter While Using Zoom?
The first 2 cycles of virtual SOEs required 6258 Zoom calls, all of which were successfully completed on the appointed examination day. All candidates were able to complete their web-based SOE using Zoom. Altogether, 173 technical challenges were reported during the first examination cycle (2020). All (173/173, 100%) were successfully resolved. Of the 173 challenges, a total of 164 (94.8%) were specifically described in the open-ended section of the survey. Overall, 3 major themes were identified: connectivity-related issues with poor-quality connection, disconnection, and laptop battery failure; poor audio quality of Zoom call with sound delay, poor quality or interruption, and low sound intensity from examiners sitting very far from the microphone; and poor image quality on Zoom call with video or photograph either very small or unclear:

Some issues with connectivity in one station. [It] was quickly resolved and another examiner took over [the] questions so I don’t feel disadvantaged due to it. [Candidate 383]

Electricity load-shedding occurred with the generator being switched on at the venue. The volume of the speaker was low and the invigilator increased the volume. [Candidate 263]

Sometimes it would appear as though an examiner had frozen on the screen where their broadband signal had become temporarily weak. This did not disturb the call entirely given that we had the buffer 5 minutes in case of technical glitches. [Candidate 128]

Some audio disturbance, and can hear the exam next door is a bit distraction. [Candidate 414]

On the Basis of Candidates’ Experiences, How Could We Enhance the SOE Experience?

Overview
Thematic analysis of the open-ended questions allowed us to better understand the positive and negative experiences of candidates undertaking web-based SOEs using Zoom. We identified 27 themes, which we categorized into 4 overarching themes, as shown in Table 4.

Table 4. Themes from qualitative analysis of candidates’ responses.

*No negative personal benefits reported.

Examination Design and Content
Candidates endorsed the lack of a home-ground advantage:

The fact that all candidates are on the same footing. The home candidates have a clear advantage when it comes to clinical OSCE with patients. Those travelling to other provinces do so at great cost and emotional stress. The examination as it was done now should be the way forward. [Candidate 257]

Candidates appreciated the standardization of case scenarios and examination questions:

Excellent standardisation. All candidates had the same examiners, same questions, same experience. Removed all bias from exam. [Candidate 22]

A great number of case scenarios also contributed to a fair examination in the virtual context than in previous in-person oral examinations:
I really enjoyed that the number of cases in the examination was increased as I think that one is able to get a good impression of a candidate if they are examined over broader spectrum rather than certain cases as depicted by the examiners, so that if a candidate does badly in one case they still have a shot at redemption. [Candidate 238]

It was good to have a wider range of cases including paediatric and emergency cases that we normally would not be examined on. I found the experience of virtual presence of the examiners less intimidating. [Candidate 33]

Candidates also felt that virtual oral examinations were fair and more transparent because there was limited examiner-to-examiner interaction:

I think it was also great that examiners where not in the same room and each examiner examined the candidate independently [examiner not aware what another examiner scored for a particular candidate] and that they did not discuss what mark should be given to a particular candidate. Think this brings fairness and transparency. [Candidate 238]

Mock examinations were also perceived favorably. However, the long waiting times before and after the examination were negatively received:

The Zoom Mock exam was reassuring, thank you for giving us clarity. Though it was unpleasant to wait for 2 hours before exams start, I did appreciate the session slots. It was very organized, I commend the team. [Candidate 487]

Unfortunately the duration of the examination process is tedious. If this platform goes ahead it would be preferable to have wrapped up the exams in a shortest time frame. [Candidate 485]

Negative experiences that candidates felt could be improved included an overview of the station before it begins:

Ask examiners to provide a brief overview of the length of the station/number of questions in order to plan answers/timing accordingly. [Candidate 167]

Participants also wanted to add preparation time to each station:

Inadequate time to review slides and prep, many stations required you time to grasp the concepts and integrate the information. It was difficult to do in the time frame provided. Difficult to read the slides and process information and feedback [to examiners]. [Candidate 63]

Candidates wanted better control of the media included in the case scenarios, for example, scrolling through computed tomography imaging studies:

Inability to interact with images and unavailability of dynamic acquisitions. [Candidate 222]

Unable to control imaging myself to make an assessment. [Candidate 386]

They also wanted the option of viewing video clips more than once:

For the video station, to have an option of watching the video twice if you would like to do so because in a real case scenario when examining a patient, you can repeatedly ask the person to do something. Some of the stations should be made realistic, like the emergency station, in a real-life situation, the patient comes in, you don’t get history first the ask to see the patient. [Candidate 481]

Although the candidates enjoyed the breadth of knowledge that was assessed, they wanted an additional way to portray their clinical maturity and insight:

Feeling unable to give a proper account of my knowledge. There is no room for clinical discussion or arguments when answering against a rubric all the time. Maybe one or two stations would be valuable where there’s no rubric and just a discussion around a topic or a case etc. [Candidate 90]

Other negative experiences included a reflection of case scenario design and highlighted the importance of designing appropriate questions for a virtual examination environment:

The examination should have either a model or a device with which the candidate could demonstrate their skills [if the candidate is being asked to demonstrate use of such device]. Adequate resolution of images is also a necessity. [Candidate 70]

Participants suggested administering the case scenarios in a more authentic way to better reflect a real patient encounter:

Because there are no real patients perhaps show pictures of not only the positive findings that the examiner needs to candidate to comment on, but also important negative clinical findings. For example, if the main pathology is in the external ear, it would be helpful to show a picture of a normal TM [tympanic membrane]. When the candidate now interprets the scan, it helps to know that the middle ear was normal. [Candidate 33]

**Examination Environment**

Candidates really appreciated the helpful, compassionate, on-site proctoring staff:

Invigilators were very supportive and accommodating, they gave us 5-star treatment, Thank you very much. Examiners were very empathetic. [Candidate 487]

Moreover, they specified that efficient troubleshooting and reliable technical support were important:

Well organized, flowed well with on-the-spot problem solving, excellently managed. [Candidate 421]

Having an efficient way to call for rapid technical assistance was identified as a possible improvement:

...Have a buzzer or bell in the exam room to enable you to ask for assistance if signal is lost. Or having
Inform the candidates how the examination will be conducted. [Candidate 443]

...Explain the role of the technician prior to examination... [Candidate 44]

Clear instruction about the conduct of the examination was also considered important:

*I felt that the examiners engaged with you more during the zoom meeting because there were no patients.* [Candidate 226]

However, the virtual environment required more examiner engagement with candidates to reassure them that they were being heard:

*Due to lack of in person examiners, examiners need to be engaging and acknowledge the participants response. Not guide or prompt, but make it clear to the participant that they could be heard.* [Candidate 123]

Furthermore, candidates did not approve of examiners being distracted during virtual examinations conducted in their homes:

*Examiners should have their phones off and not be distracted by other factors if examining from home.* [Candidate 130]

Examiners’ visibility on the screen was viewed both positively and negatively:

*I wasn’t actually told I had to have the examiners’ video visible, so I switched it off and found this a much more pleasant experience than what I had been expecting based on colleagues’ related experiences of previous examinations.* [Candidate 251]

Candidates noted that there was less “positive” examiner cueing because it was not possible to read the examiners’ body language:

*Lacking positive reassurance from visual cues given by examiner in a normal setting. Although it is not a given that you would receive that even in a face to face oral.* [Candidate 352]

*Lack of examiners’ eye contact with the camera was specifically mentioned:* [Candidate 125]

Candidates found the examination design to be overwhelmingly positive. It was associated with financial savings, reduced levels of anxiety, travel convenience, and availability of home comforts:

*No travel. No need to adjust to unknown environment and clinical setting. Costs saved.* [Candidate 349]

*To be based locally in a huge relief. It alleviates a lot of the stress during an already very stressful time.* [Candidate 365]
I liked that it started later, reduced anxiety of traffic and allowed me to sleep better. [Candidate 431]

Home, familiar surroundings, and staff very helpful. [Candidate 373]

Textbox 1. Suggestions from candidates for enhancing the web-based structured oral examination (SOE) experience.

Suggestions from candidates
- Provide candidates with an overview of time allocation per station or desk timer in station
- Allocate preparation time before station begins
- Design case scenarios such that strong candidates can demonstrate their clinical maturity
- Provide paper for candidates to make notes during virtual SOEs
- Allow candidates to control media content, including scrolling and screen share capability
- Allow candidates to use headphones or headsets to improve audio quality
- Provide dual screen capabilities when additional examination material needs to be viewed
- Allow candidates the option of not seeing their examiners (examiners have their video off)
- Train examiners the option of not seeing their examiners (examiners have their video off)
- Minimize the duration of digital isolation while maintaining examination integrity

Are Pass Rates of Web-Based and In-Person Certification Examinations Comparable?

Most candidates (1159/1467, 79%) who undertook web-based SOEs were ultimately successful in passing their certification examinations and gained admission to the respective member colleges of CMSA. The pass rates for 2020 and 2021 were 91.4% (1583/1732) and 79.7% (850/1067), respectively. The average pass rate for postgraduate in-person certification examinations conducted by CMSA 3 years before the pandemic (2017-2019) was 58.23% (4030/6921). This was significantly lower than the pass rate for the first 2 cycles that included web-based certification examinations (2020: N=8635; χ²=667; P<.001; 2021: N=7988; χ²=178; P<.001).

Discussion

Principal Findings

This paper reports about >1500 candidates’ experiences of web-based SOEs conducted via Zoom as part of postgraduate specialty and subspecialty certification examinations hosted by CMSA during the early part of the COVID-19 pandemic. Despite the short time frame in which this transition to web-based examinations was executed, the initiative was well received by candidates. Overall, they perceived web-based SOEs to be a fair and appropriate assessment method, were generally satisfied with the use of Zoom for hosting the examination proceedings, and reported surprisingly few technical challenges. The qualitative data provided a rich analysis of their positive and negative experiences and provided constructive suggestions that could further improve the web-based SOE experience.

An important finding of our study was the observation that candidates undertaking web-based certification examinations performed better than candidates previously undertaking in-person certification examinations. This study did not set out to explore the possible reasons for this observation, but some qualitative observations from candidates may be of interest in this regard. First, candidates reported feeling less intimated by examiners during web-based oral examinations. Second, improved standardization of the examination process using identical case scenarios and standardized questions with marking memoranda may have contributed to fair examination conditions supporting better overall candidate performance. Third, candidates found the overall web-based examination experience to be less stressful, and this may have positively influenced their performance. Fourth, examiners were required to score candidates’ performance independently without conferring before awarding a final score. This limited examiner-examiner interaction may have limited examiner coercion and had a positive impact on the final scores awarded.

Important Improvement Considerations

On the basis of the findings of the thematic analysis, we compiled 10 suggestions that could possibly further improve the web-based SOE experience for candidates. They are listed in Textbox 1.

On the basis of the findings of the thematic analysis, we compiled 10 suggestions that could possibly further improve the web-based SOE experience for candidates. They are listed in Textbox 1.
verbal engagement with candidates to ensure a more authentic experience for candidates.

Findings of Other Studies

There are several pre-pandemic papers reporting favorably about the use of in-person SOEs in medical education [14-21]. Although these reports were encouraging and supported the use of SOEs for assessment, they did not speak in the context of web-based oral examinations for high-stakes postgraduate certification purposes, which is the topic of this paper. When looking specifically at this context, it is apparent that this is an emerging field that has gained momentum during the pandemic. Currently, there are a few recent reports directly relevant to the key findings of this study. Before the pandemic, McGrath et al [27] reported a study comparing web-based oral examinations with in-person oral examinations for anesthesiology residents. The study randomized 35 residents to testing conditions using an immersive learning environment. Although an immersive learning environment is not the same as a web-based oral examination conducted via Zoom, the paper broadly contributes to the conversation about moving postgraduate oral examinations into a web-based setting. It is worth noting that the authors reported similar academic performance in both groups, which is consistent with our findings of the noninferior performance of candidates undertaking web-based oral examinations. In the study, as also seen in our study, most examination candidates preferred the web-based experience, found it to be less intimidating than in-person oral examinations, and commented about the cost saved by not traveling to testing sites.

Recently, Chaurasia et al [5] conducted a small pilot study of 8 radiation oncology postgraduate trainees and 8 examiners testing the use of web-based oral examinations conducted via Zoom. Candidates were engaged in 8 stations of 25 minutes each, using breakout rooms. Similar to us, they found Zoom to be easy to use, adequate for examination purposes, and free of serious technical difficulties and described it as a fairly seamless experience. They used screen share and annotate for anatomy review, contouring, and treatment plan evaluation for virtual radiation oncology cases. Users described the web-based experiences easier or the same for ease of understanding of the cases and reported preparation to be the same or less time consuming than for in-person oral exams. The authors concluded that a move to web-based oral examinations for postgraduate certification examinations in radiation oncology should be considered as a feasible alternative.

In 2021, a total of 44 senior vascular surgery postgraduate trainees from 17 US training institutions undertook web-based mock oral examinations with 2 remote examiners via Zoom [28]. For each candidate, examiners selected 4 cases from a book of 30 vascular scenarios, and candidate performance was assessed using a standardized scoring sheet. Consistent with our findings, the authors reported no difference in how well the knowledge base of candidates could be examined compared with in-person oral examinations. They also reported that candidates could adequately express their confidence in the web-based setting and concluded that web-based oral examinations are a viable option to consider for examination purposes. They also mentioned the cost saved by remote examinations. The most important considerations highlighted in that paper was the fairness of test grading achieved by using a standardized marking sheet and the equity of test questions achieved by using a standardized set of case scenarios. This speaks to factors that may contribute to favorable candidate performance as already mentioned by us.

In 2022, the Vascular Surgery Board reported about the successful implementation of web-based certification examinations [29]. They reported about the findings of 356 successful candidates who each undertook three 30-minute virtual oral examinations hosted via Zoom. Similar to the findings of our study, the examination process was well received by candidates and found to be technically adequate. Similar to our candidates, they raised concerns about image quality and time constraints to answer all questions but expressed appreciation for good planning and execution, convenience of local examination conditions, and avoidance of travel costs. Overall, candidates were significantly more in favor of continuing web-based examinations as compared with examiners (87% vs 32%; P < .001). The authors make a case for the feasibility and convenience of continuing web-based certification examinations beyond the COVID-19 pandemic. Questions about IT support costs and the cost of remote proctoring are also raised in the paper.

The American Board of Obstetrics and Gynecology also recently published the outcome of their web-based oral certification examinations that were also conducted via Zoom [30]. Between 2021 and 2022, a total of 1491 specialty and 830 subspecialty candidates undertook three 1-hour oral examinations using 3 pairs of examiners per candidate. They found that candidates performed similarly in the web-based certification examinations as compared with previous in-person oral certification examinations. Similar to our findings, they experienced few technical difficulties, and candidate satisfaction with the remote examination was high; however, they expressed anxiety about the use of technology (remotely at home or elsewhere). Despite the success of these remote oral examinations, the issues of remote proctoring and the technical burden placed on candidates being examined in their homes have resulted in a decision to return to testing center–based in-person examinations.

The American Board of Surgery also recently published the findings of their first web-based certification examination for general surgery candidates conducted in 2021 [31]. They report about 306 successful candidates who also completed a web-based satisfaction survey after the examination. They also found that the pass rates for web-based oral examinations were no different from those of in-person oral examinations and that the new examination format was well received by candidates. Audio and video quality were adequate, and 78% of the survey respondents indicated that web-based certification examinations were preferred. The authors argue that the findings support the expanded use of this method of assessment.

The American Board of Ophthalmology has also reported about their success in conducting web-based oral examinations via Zoom for >1000 candidates over the past 12 months. Similar to our study, they took the opportunity to improve the standardization of the examination process and used 2
independent examiners. They described the inordinate preparation and planning required to effect a rapid transition from in-person to web-based certification examinations. They also found that the examination was very well received by both candidates and examiners who felt that the ability to assess knowledge, insight, and judgment using web-based oral examinations was the same as in-person examinations. Positive opinions regarding the use of the assessment method after the pandemic were expressed by a range of stakeholders. However, they did express some ambivalence over the continued use of web-based oral examinations.

Strengths and Limitations
Most current reports in the literature focus on small numbers of candidates. At the time of writing, this was one of the largest published studies reporting about web-based SOEs for postgraduate certification purposes. There are, however, important limitations in this study. We only reported about the initial 12 months of implementation, and a follow-up report is needed. Candidates may have viewed web-based oral examinations more favorably during the pandemic, and this opinion needs to be reviewed. The most significant limitation of the study is that the opinion of examiners was not captured. This was not possible during the pandemic because examiners were overburdened with additional clinical responsibilities and were setting up a new examination method with very little preparation time before the web-based examinations process began. Clearly, their opinion is needed, and after 36 months of implementation, it will contain a wealth of important considerations. Finally, this is a single-country study, and reports from elsewhere are needed.

Future Directions
Internationally, the move from in-person to web-based oral examinations, as part of postgraduate specialty certification examination processes, has gathered momentum [2,3,29-32]. There are, however, lively debates about the ongoing use of web-based oral examinations in the postpandemic era, and it seems that opinions are currently divided on the matter [29-32]. Cost and time savings and convenience of arranging and attending are significant factors in favor of remote oral examinations. Major disadvantages of web-based oral examinations include the cost of IT support and remote proctoring [33] and the inability of examiners to assess bedside skills (history taking and physical examination). Increased uptake of workplace-based assessment in postgraduate training programs should effectively address the ongoing concerns about clinical competence. More cost-efficient delivery of IT support and the challenges of remote proctoring require further studies.

Conclusions
This study highlights the value of conducting formative research about the use of web-based SOEs as part of postgraduate certification processes. We found that this method of assessment was well received by examination candidates, could be conducted via Zoom with surprisingly few technical challenges, and did not have a negative impact on candidates’ academic performance. Our encouraging findings are consistent with early reports from elsewhere that provide positive preliminary evidence supporting the ongoing use of this novel web-based assessment method in postgraduate medical education.

Acknowledgments
The authors wish to thank the candidates for participating in the study, and they extend a special thank you to Bianca van der Westhuizen and Riefda Thomson for the time they spent in assisting the authors with data extraction. No funding was obtained for this study.

Authors’ Contributions
VB was involved in the conceptualization of the study, proposal design, study implementation, data analysis, and manuscript preparation and review. Abstract

Background: Patients with unmet social needs and social determinants of health (SDOH) challenges continue to face a disproportionate risk of increased prevalence of disease, health care use, higher health care costs, and worse outcomes. Some existing predictive models have used the available data on social needs and SDOH challenges to predict health-related social needs or the need for various social service referrals. Despite these one-off efforts, the work to date suggests that many technical and organizational challenges must be surmounted before SDOH-integrated solutions can be implemented on an ongoing, wide-scale basis within most US-based health care organizations.

Objective: We aimed to retrieve available information in the electronic health record (EHR) relevant to the identification of persons with social needs and to develop a social risk score for use within clinical practice to better identify patients at risk of having future social needs.

Methods: We conducted a retrospective study using EHR data (2016-2021) and data from the US Census American Community Survey. We developed a prospective model using current year-1 risk factors to predict future year-2 outcomes within four 2-year cohorts. Predictors of interest included demographics, previous health care use, comorbidity, previously identified social needs, and neighborhood characteristics as reflected by the area deprivation index. The outcome variable was a binary indicator reflecting the likelihood of the presence of a patient with social needs. We applied a generalized estimating equation approach, adjusting for patient-level risk factors, the possible effect of geographically clustered data, and the effect of multiple visits for each patient.

Results: The study population of 1,852,228 patients included middle-aged (mean age range 53.76-55.95 years), White (range 324,279/510,770, 63.49% to 290,688/488,666, 64.79%), and female (range 314,741/510,770, 61.62% to 278,488/448,666, 62.07%) patients from neighborhoods with high socioeconomic status (mean area deprivation index percentile range 28.76-30.31). Between 8.28% (37,137/448,666) and 11.55% (52,037/450,426) of patients across the study cohorts had at least 1 social need documented in their EHR, with safety issues and economic challenges (ie, financial resource strain, employment, and food insecurity) being the most common documented social needs (87,152/1,852,228, 4.71% and 58,242/1,852,228, 3.14% of overall patients, respectively). The model had an area under the curve of 0.702 (95% CI 0.699-0.705) in predicting prospective social needs in the overall study population. Previous social needs (odds ratio 3.285, 95% CI 3.237-3.335) and emergency department visits (odds ratio 1.659, 95% CI 1.634-1.684) were the strongest predictors of future social needs.

Conclusions: Our model provides an opportunity to make use of available EHR data to help identify patients with high social needs. Our proposed social risk score could help identify the subset of patients who would most benefit from further social needs
screening and data collection to avoid potentially more burdensome primary data collection on all patients in a target population of interest.

**Introduction**

Addressing social needs and social determinants of health (SDOH) challenges in the health care system has emerged as a key component of addressing health disparities [1]. Patients with unmet social needs continue to face a disproportionate risk of increased prevalence of disease, health care use, higher health care costs, and worse outcomes across a range of health-related domains [2-5]. Thus, health disparities cannot be resolved through traditional clinical interventions in the health care system. Targeted interventions to address social needs and SDOH challenges, especially among minority populations, are necessary to overcome widespread disparities [6].

The use of coding systems such as International Classification of Diseases, Tenth Revision (ICD-10) codes for social needs (ie, Z-codes) has increased in recent years, suggesting that clinicians and provider organizations are increasingly aware of social needs and SDOH challenges and the importance of screening for and documenting such needs [7]. Social needs are also extensively documented in unstructured electronic health records (EHRs), such as free-text provider notes [8-12]. Moreover, the rapid adoption of EHRs nationwide and the creation of associated health information technology tools have made it possible to use this growing body of data on social needs and SDOH challenges in risk prediction and adjustment models [13-21].

Some existing predictive models use EHR and administrative claims data on social needs to predict patterns of health care use, cost, and health outcomes [16,18-20,22]. Population-level data on community characteristics is a key component of understanding and addressing SDOH challenges and their impact on health care use, cost, and outcomes [23,24]. Therefore, some EHR-based models have developed linkages to these population-level data to better account for community-level information in their risk predictions [17,21,25-27]. Some existing models have also used the available data on social needs and SDOH challenges to predict health-related social needs [14,15] or the need for various social service referrals [13]. Despite these one-off research and pilot efforts, the work to date suggests that many technical and organizational challenges must be surmounted before SDOH-integrated health information technology solutions can be implemented on an ongoing, wide-scale basis within most US-based health care organizations.

Using both patient- and population-level data, we sought to develop a social predictive risk score based entirely on electronic information readily available within most health care delivery systems. Predictive models such as this could help providers to systematically identify patients at risk of having future social needs, who represent likely targets for further in-depth assessment of their social needs and ultimately potential referral to community-based organizations to address such needs. Using a systematic electronic case-finding screening approach such as this would help the health care system avoid burdensome and inefficient social needs assessment (eg, primary data collection from every patient at every visit).

**Methods**

**Data Sources**

This was a retrospective study using the Johns Hopkins Health System (JHHS) Corporation’s EPIC-based EHR structured data from July 2016 to June 2021. Based on the patient’s home address during the in-scope study periods, we linked community-level data (at the census block group level) from the US Census American Community Survey, 2018 five-year cohort [28]. We developed a prospective model (using current year-1 risk factors to predict future year-2 outcomes) within four such 2-year cohorts (ie, 2016-2017, 2017-2018, 2018-2019, and 2019-2020). Each cohort contained model predictors in the first year (2016 in the first, 2017 in the second, 2018 in the third, and 2019 in the fourth cohort) and model outcomes in the second year (2017 in the first, 2018 in the second, 2019 in the third, and 2020 in the fourth cohort). The overall data were randomly split into training and validation data sets (80% of the data were used for model development while the remaining 20% were used for validation). The final model was applied to the 2020-2021 cohort to evaluate its accuracy.

**Study Population**

Adult patients aged 18 years or older at the time of entering the observation period who were alive at the end of the observation, had at least 1 eligible encounter in the first and second years of each study cohort, and had a valid address for linkage to population-level data were included in this study.

**Variable Selection**

We identified variables with the highest potential impact on the health and social well-being of minority populations through a review of the literature and consultation with minority health, population health, and social needs and SDOH experts at JHHS. We also sought input from primary care providers and frontline workers, such as social workers and care managers,
representatives of community-based organizations, and patients and their caregivers.

We identified a comprehensive list of predictors of interest available within the EHR’s structured data, including various patient- and community-level characteristics as well as health care use measures (Table 1) [29,30].

To develop the variable on previous social needs, we obtained any ICD-10 codes presenting social needs using the “Compendium of Medical Terminology Codes for Social Risk Factors” developed by the Social Interventions Research and Evaluation Network [31] or any information on social needs available in the JHHS-EHR Wellness Registry, a data mart table in EPIC storing information related to general patient health, consolidated from many subject areas including social history and risk scores. After reviewing the classification of the ICD-10 codes by Social Interventions Research and Evaluation Network, we developed 13 subdomains and 5 domains of social needs (Figure 1).

aN/A: not applicable.
bICD-10: International Classification of Diseases, Tenth Revision.
cACG: Adjusted Clinical Group.
The Adjusted Clinical Group (ACG) System Resource Utilization Band represent a simplified population segmentation system based on the overall morbidity burden of each patient. Representing expected future use based on current morbidities, the measure is calculated using all available ICD-10 codes for a person in the EHR during year 1, ranked from low to high according to the expectations of resources used during year 2.

**Statistical Analysis**

We used a generalized estimating equation (GEE) model to predict prospective social needs, adjusting for the effect of the geographically clustered data as well as the effect of multiple visits for each patient (the records were clustered at the patient and 5-digit zip code level). The model selection was based on the goodness of fit test for GEE modeling, and the final risk score was composed using the variables identified as having the highest impact in the GEE model. We also validated the model using multiple denominators to ensure generalizability and retrained and tested the model for each subpopulation of interest (eg, individuals aged 65 years or older, racial and ethnic minority populations, and those living in the most and least disadvantaged neighborhoods).

**Ethical Considerations**

The institutional review board of the Johns Hopkins Bloomberg School of Public Health reviewed and approved this study as exempt. The board approved the EHR data extraction for the secondary analysis of deidentified data.

---

**Results**

**Demographics**

The final study population included 1,852,228 patients in total. To be included in the sample, the patients had to be in at least 1 of four 2-year study cohorts (Table 2). The characteristics of patients across the study cohorts were comparable. Study cohorts included mostly middle-aged (mean age range 53.76-55.95 years across study cohorts), White (range 324,279/510,770, 63.49% to 290,688/488,666, 64.79%), and female (range 314,741/510,770, 61.62% to 278,488/448,666, 62.07%) patients from neighborhoods with high socioeconomic status (mean area deprivation index [ADI] percentile range 28.76-30.31). Between 8.28% (37,137/448,666) and 11.55% (52,037/450,426) of patients across the study cohorts had at least 1 social need documented in the ICD-10 codes or EPIC Wellness Registry, with safety issues and economic challenges (ie, financial resource strain, employment, and food insecurity) being the most common documented social needs (87,152/1,852,228, 4.71% and 58,242/1,852,228, 3.14% of overall patients, respectively; Table S1 in Multimedia Appendix 1 provides details on the social needs domains across study cohorts). Between 18.67% (95,350/510,770) and 21.18% (95,393/450,426) of patients across the study cohorts had high or very high Resource Utilization Band, indicative of having a high disease burden, as reflected by many serious comorbidities.
Table 2. Characteristics of the study population for the development of the social risk score using electronic health record data at Johns Hopkins Health System between 2016 and 2021: overall and by 2-year enrollment cohorts (all characteristics are reported based on the first year of each cohort unless otherwise indicated).

\(^a\)Neighborhood characteristics for the person’s residence of the longest duration are reported as a percentile of national rank [30].

\(^b\)ICD-10: International Classification of Diseases, Tenth Revision.

\(^c\)These clinical measures are derived from the Johns Hopkins Adjusted Clinical Group (ACG) System version 12.0. The Resource Utilization Band represents expected future use based on current morbidities [29].

GEE Modeling

Details of the GEE models are presented in Table 3. The GEE model had an area under the curve (AUC) of 0.702 (95% CI 0.699-0.705) in predicting prospective social needs in the overall study population. The strongest predictors of future social needs in the whole population in descending order were social needs documented in the EHR during the previous year period (odds ratio [OR] 3.285, 95% CI 3.237-3.335), ≥1 emergency department visit in the previous periods (OR 1.659, 95% CI 1.634-1.684), and a very high Resource Utilization Band measure indicative of a significant morbidity burden (OR 1.371, 95% CI 1.317-1.427).

^aOR: odds ratio.

^bNot available.

^cNeighborhood characteristics for the person’s residence of longest duration are reported as a percentile of national rank [30].

^dThese clinical measures are derived from the Johns Hopkins Adjusted Clinical Group (ACG) System version 12.0. The Resource Utilization Band represents expected future use based on current morbidities [29].

To help assess bias and applicability to various subpopulations, we identified comparable performance for models of select subgroups, with AUCs of 0.701 (95% CI 0.696-0.706), 0.711 (95% CI 0.706-0.716), and 0.711 (95% CI 0.708-0.714), respectively, for individuals aged 65 years or older, Black patients, and those living in the most disadvantaged.
neighboring. The strongest predictor of future social needs in the study subpopulations remained the previous social needs, with ORs of 3.043 (95% CI 2.96-3.128), 2.9 (95% CI 2.82-2.977), and 3.390 (95% CI 3.334-3.447) among individuals aged 65 years or older, Black patients, and those living in the most disadvantaged neighborhoods, respectively.

To ensure that the most common social needs (ie, safety and economic challenges) were not the main drivers of the model's performance, we performed a sensitivity analysis and ran the model after excluding patients with any social needs in subdomains of safety and economic challenges. This resulted in a slightly better-performing model with an AUC of 0.768 (95% CI 0.763-0.773). In this instance, previous social needs were by far the most significant predictor (OR 11.857, 95% CI 11.521-12.202), followed by emergency department visits (OR 1.916, 95% CI 1.865-1.969), need for an interpreter (OR 1.528, 95% CI 1.397-1.672), and Black race (OR 1.307, 95% CI 1.273-1.342). Contrary to the analyses performed with all social needs included, patients with higher Resource Utilization Band had slightly less risk of increased social needs, and lower Resource Utilization Band had slightly greater protective value regarding social needs (Table S2 in Multimedia Appendix 1 provides details of the GEE model).

Discussion

Overview

Achieving a comprehensive assessment of a person’s health and addressing health disparities goes beyond just documenting clinical diseases and medical interventions. We must also capture, standardize, analyze, and report reliable information on social needs and SDOH challenges within operational clinical decision support systems that are built into EHRs. Moreover, the rapid change toward “value-based” health care models [32] in the United States has required the incorporation of social needs and SDOH contexts and frameworks to ensure that the health care systems and health plans equitably address the needs of minority and disadvantaged communities [33,34]. For these value-based models to perform well, it is critical that clinical and social interventions are aligned and that no financial disincentives are imposed on providers who disproportionately serve minority and disadvantaged patients [33,34].

To achieve these goals, applied research is needed to identify optimal solutions for the effective collection and application of social needs and SDOH information within EHRs, link provider-based data to community-level data describing the characteristics of patients’ neighborhoods, and anchor such information to the providers’ digital workflow. This approach will provide the vehicle for harnessing social needs and SDOH data to target interventions at the point of care (eg, referrals of an individual); the health delivery system level (eg, hiring a social worker in the clinic); or the community (eg, building or strengthening community-based initiatives) [35]. To avoid burdensome and inefficient social needs assessment and data collection, it is essential to develop automated screening tools using EHR or community-based data to help identify the subset of patients who would most benefit from social needs assessment and data collection.

Several EHR-based screening tools for social needs assessment have been piloted in recent years, and results have shown these tools to be effective in determining social needs and SDOH challenges [36,37]. However, the feasibility of such tools remains unclear, with health care systems needing to dedicate considerable time and budget to train and educate staff and manage workloads [21]. Our proposed social risk score aimed to reduce the burden of this process and increase its accuracy by identifying patients at high risk of having any social needs for more efficient screening.

Comparison With Previous Evidence

Our proposed model was based on a large and diverse data set of patients in the JHHS-EHR. The AUC of our model in predicting prospective social needs was 0.702 (95% CI 0.699-0.705) in the overall study population. This AUC may be the result of many instances of false negatives related to the documentation of social needs in structured EHR data. At the time of completing this study, social needs screening and referral were not common practices at our institutions. Thus, we expect many patients with social needs did not get a proper screening and documentation of such needs. The new mandate established by the Centers for Medicare and Medicaid Services requires hospitals to report to the Inpatient Quality Reporting Program 2 brand new measures of social needs (ie, the number of patients screened for social needs and the number of patients identified with selected social needs) [38]. We expect the health care system to establish more systematic and uniform processes for screening and documentation of social needs. This effort will increase the volume of data on social needs in the EHR, which will result in better performance of our models in the future.

Our findings were comparable with those in the study by Holcomb et al [14], where they predicted health-related social needs using EHR and community-level data and machine learning modeling for Medicare and Medicaid beneficiaries participating in the Accountable Health Communities project. Their models performed relatively well, with AUCs ranging from 0.59 to 0.68 for patients with different domains of social needs. Another notable mention was the study by Byrne et al [15], where they used EHR data, including responses to the Veterans Health Administration’s Homelessness Screening Clinical Reminder Survey, to develop and test predictive models of housing instability and homelessness. All their models performed well, with the random forest models performing better than the logistic regression models for both the housing instability (85.4 vs 78.3) and homeless (91.6 vs 87.1) outcomes. Lastly, Kasthuriratne et al [13] built random forest decision models to predict the need for social work referrals using clinical and population-level data on SDOH challenges. The performance of the model ranged from an AUC of 0.713 for the model using both clinical and SDOH data to 0.731 for the model using clinical data.

Moreover, our results demonstrated that the most significant predictive factor for having prospective social needs was the documentation of previous social needs. This study also found associations between prospective social needs with previous ED visits and morbidity-related high resource use presented in Resource Utilization Band. Lastly, our model showed a
minimally increased risk of social needs in association with characteristics of the neighborhood of residence, presented as the ADI measure. This finding was similar to the results of the study by Nguyen et al [39], where they identified a small statistically significant association between the ADI and total score on social needs from the Health Leads Social Needs Survey among pediatric patients’ families receiving primary care at a large academic institution. A review by Chen et al [21] also indicated the low success of the integration of population-level data for predictive modeling and risk stratification purposes, including the prediction of social-related service referrals [13], in contrast to the performance of models using individual-level data in referrals to a social worker [40]. Overall, these findings indicated that individual characteristics played a more crucial role in predicting future social needs than neighborhood characteristics.

Clinical Implications
The implementation of an EHR-based social risk score such as the one we developed would have many implications for clinicians and practice organizations. At the point of care, our social risk score could be integrated directly with EHR-derived data warehouses; thus, the proposed risk score could be leveraged to allow clinicians to tailor more personalized care and modulate care coordination efforts. This personalized social risk score could also help support tools tailored to the needs of patients, which would empower the navigation of available social services [35]. At the health delivery system level, the linkages of geo-derived databases could improve the assessment of social needs and SDOH challenges for health systems and provide opportunities for longer-term plans to address those factors in current and future care management programs. Additionally, the merged clinical and nonclinical databases could enable providers to follow patients with social needs and SDOH challenges over time through their interaction with the health system. At the community level, the social risk score and the social needs or SDOH data could enhance care coordination efforts by integrating community-level data into clinical decision support tools and coordinated interventions [41].

Limitations
Several limitations existed for this study. First, EPIC Wellness Registry data were essentially nonexistent between the years 2016 and 2018, which, in addition to the possibility of ICD-10 codes being underused by providers, might lead to an underrepresentation of social needs in this study’s population. Second, Latino and Hispanic patients were underrepresented in this study’s population, which may have impacted the generalizability of the proposed model. Furthermore, data on racial and ethnic minority groups such as American Indian and Alaskan Native, Native Hawaiian, Other Pacific Islander, and multiracial individuals were limited in our data set. Another important factor that might have affected our results was the potential for more frequent screening of social needs in female individuals, ethnic and racial minority populations, those with higher disease burdens, and superusers of health care services [42], leading to biased results for these individuals. Misclassification and inconsistency in documenting social needs in the EHRs could influence our results.

Moreover, the use of EHR data as the sole source of information limited our data to services provided to patients across the JHHS facilities and did not include other services outside JHHS. Also, we used the patient’s home address to link the EHR data to the American Community Survey community-level data. Thus, we did not include patients with a missed or invalid home address. This may have resulted in missing some patients with social needs, such as residential instability. Finally, our final model was applied to the 2020-2021 cohort to evaluate its accuracy, which included patient encounters during the first peak of the COVID-19 pandemic. While some subpopulations of patients experienced more social needs during the pandemic, the challenges that the health care systems faced during this period impacted the screening and documentation of social needs and may have resulted in missed data on social needs for this cohort.

Conclusion
Screening for social needs and SDOH challenges using available secondary EHR data represents an important step toward addressing health disparities more efficiently and improving patient care and population health. Our proposed model integrates community-level data with patient-level data to arrive at a social risk score that can be used to systematically identify patients at increased risk of having future social needs and is thus appropriate for in-depth assessment of their social needs and potential referral to community-based organizations to address these needs. Our model identified previous social needs and high morbidity levels as the strongest predictors of future social needs. Missing data in the EHR reflecting past clinician documentation of social needs may have impacted the performance of our proposed model, and the predictive accuracy of models like ours will likely increase as the capture of such information becomes more commonplace. Future studies should focus on developing EHR-integrated clinical decision support tools to make this information available in the providers’ digital workflow and at the point of care.

Abstract

Background: Sexual pain is a common but neglected disorder that affects approximately 3% to 18% of women and an unmeasured number of gender-diverse people worldwide. Despite its wide prevalence, many people feel reluctant to visit conventional health care services or disclose their symptoms due to the fear of stigmatization. To alleviate this stigma, various web-based interventions have been developed to complement and, in some cases, replace conventional sexual health interventions. However, the way these web-based interventions are developed could inadvertently reproduce, perpetuate, or exacerbate stigma among end user patients.

Objective: The purpose of this study was to understand patients’ perspectives on how sexual pain–related web platforms can be designed to alleviate stigma or prevent the unintended effects of stigma among patients who use web-based interventions.

Methods: Individual semistructured interviews were conducted among 16 participants with lived experiences of painful sex in a large urban city in Western Canada. Participants were recruited via social media platforms, newsletters, and a provincial health volunteer website. Using a sample sexual pain website to provide context, participants were interviewed about their experiences of stigma and how they think web platforms could be designed to address stigma. The interviews were conducted via Zoom (Zoom Technologies Inc) and analyzed using thematic analysis.

Results: The findings revealed 4 overarching themes that represented participants’ perspectives on designing web platforms that may alleviate or prevent the unintended effects of stigma. These findings suggested the design of inclusive web platforms, having a nonprovocative and calming user interface, having features that facilitate connections among users and between users and providers, and displaying personal testimonials and experiences of sexual pain.

Conclusions: This study highlighted patient-centered design approaches that could serve as a reference guide in developing web platforms that alleviate or prevent the unintended effects of stigma, particularly among nonheterosexual and gender-diverse people. While this study was conducted in the context of sexual pain, the results might also apply to web platforms on other potentially stigmatizing health-related disorders or conditions.

stigma; digital health; sexual pain; destigmatizing; end user patients

Introduction

Sexual pain is a common but neglected problem, predominantly experienced by females, that is estimated to affect approximately 3% to 18% of women globally [1]. The disorder affects multiple aspects of one’s life including absenteeism from work, poor interpersonal relationships, and impaired social functioning with a profound impact on the quality of life [1]. Despite the
negative effects of sexual pain, many women feel reluctant to visit service providers or disclose their symptoms to family and friends due to the fear of stigma [2]. Stigma is defined as an attribute and dynamic social process characterized by widespread social disapproval, blame, rejection, devaluation, and segregation [3]. The extent to which people with sexual pain are affected by stigma depends on the nature of the disorder and whether it is concealed or exposed. According to Tyler and Slater [4], people with invisible conditions or disorders are more likely to be affected by internalized stigma, while those with visible conditions or disorders may be predisposed to public stigma. Public stigma refers to the overt discriminatory practices that are directed at someone, while internalized stigma refers to the acceptance of negative attributes and a reduced sense of self-worth as a result of possessing a supposedly stigmatizing attribute [2]. While hidden disorders like sexual pain may not immediately provoke public stigma, people with such disorders may still be concerned about an impending negative reaction from the public or even stigma from present and future intimate partners if their pain status is eventually revealed [4]. The fear of disclosing a condition can be classified as anticipated stigma, and this is quite common among people with sexual health–related disorders [5]. Therefore, people with sexual pain may face both internalized and public stigma of various proportions at the personal, interpersonal, and societal levels. As stigma becomes more of a dynamic social process [3], the modalities of managing this issue are becoming increasingly complex and challenging, especially for people with hidden disorders like sexual pain.

In response to the negative impact of stigma on people with sexual pain, various web-based platforms have been developed to complement, and in some cases, replace conventional care services [2,6,7]. Web-based platforms on painful sex could range from educational resources, decision support systems, web-based social support platforms, and therapy-based platforms [8-12]. Even though web-based platforms are increasingly used as resources inquiring about and managing sexual pain [13,14], available evidence suggests that sexual health–related web-based platforms could inadvertently foment stigma among end users [15]. Other studies revealed that merely using a sexual health platform in public spaces could be interpreted as having a disorder and could lead to stigma in what is termed stigma by association [6]. Notably, people who use sexual health–related web platforms may likely link the appearance of certain images and content to an existing social stigma, thereby resulting in technology-mediated experiences of stigma [7]. Furthermore, the replacement of face-to-face conversations with web-based tools may further emphasize the feeling of discomfort or stigma associated with in-person interactions as it gives an indication that sexual pain is not something to be discussed but self-discovered using web-based tools.

The likelihood of web-based platforms resulting in technology-mediated experiences of stigma may be attributed to the general lack of attention to the issues of stigma when developing sexual health–related digital platforms [16]. Even though patients’ views and opinions are usually sought when developing sexual health–related digital technologies [17,18], their perspectives on how web-based platforms can be designed to alleviate stigma are usually not considered when developing such interventions. The apparent lack of attention to stigma may not only lead to a mismatch between people’s expectations and web-based platforms but could inadvertently reproduce and perpetuate stigma among patients who may find such platforms undesirable [7].

We attempted to address this gap in our prior studies by developing a set of destigmatizing design guidelines to provide a reference guide for developers of sexual health–related web-based platforms [16,19]. However, these guidelines were based on expert opinions and did not address the salient concerns of patients regarding stigma. With a disorder like sexual pain, patients often withhold sharing their diagnosis publicly, and we believe that many of the stigma-related considerations for designing web-based platforms could only be obtained from people with lived experiences of the disorder. The purpose of this research was thus to examine the perspectives of people with sexual pain on how web platforms could be designed to alleviate stigma or prevent digital platforms from inadvertently fomenting stigma among end user patients. The findings of this study are expected to produce user-interface design recommendations not just for sexual pain digital platforms but for web-based platforms on other stigmatized conditions or disorders in sexual health and mental health.

Methods

Study Design
A semistructured interview was conducted among 16 people with lived experiences of sexual pain in a large urban city in Western Canada. Participants were recruited via (1) social media platforms, (2) newsletters, and (3) a provincial health volunteer research website. To be eligible, potential participants must have been at least 18 years old, experienced or self-reported sexual pain (alone or partnered), and reported previous or current use of a health-related web-based platform. Due to the limited involvement of male partners in prior sexual health–related studies [8], we decided to recruit people who also identify as biological males and report experiences of painful sex.

Interview Guide
A semistructured interview guide (Multimedia Appendix 1) was developed based on the person-centered care model by focusing on the participants’ emotional needs and preferences about how digital health technologies can be developed to be less stigmatizing and emotionally safe. The interview guide was developed to address key areas including demographic information, participants’ experiences with stigma, and their perspectives on how web-based platforms can be designed to alleviate stigma or prevent the unintended effects of stigma. The interview guide was reviewed by our patient advisory team, pretested on 3 patients outside of this study sample, and was revised accordingly.

Data Collection
The interviews were conducted by the first author (AFA), with assistance from the second author (HN). Since different web-based platforms exist, we decided to contextualize our study by providing participants with a sample website that we developed in a previous study [10]. A link to this website was
sent to participants at least 3 days before the interviews. Participants, particularly those who have never used a sexual pain web platform, were asked to explore the sample website before the interviews. The interviews were conducted via Zoom with participants’ videos turned off to protect their confidentiality. Participants were asked questions related to the design of web-based content, interactive features, images, colors, sex, gender, and class representations on digital platforms that can help alleviate the stigma of painful sex. Depending on participants’ backgrounds and prior experiences of stigma, probing questions were asked regarding how web platforms can be designed to address the experiences of stigma related to their identity. Data collection occurred from April to July 2023, and each interview lasted approximately 1 hour. All interviews were recorded onto the University of British Columbia’s accredited Zoom Cloud and transcribed using TEMI web-based transcription services (Temi Inc).

**Data Analysis**

The transcribed data were imported into the NVivo software (version 11; QSR International). Data were analyzed using a thematic analysis approach [20]. The data analysis occurred alongside data collection. The first and second authors familiarized themselves by reading over the first 4 transcripts multiple times. The 2 authors independently developed a coding framework inductively from the first 4 transcripts. We compared the 2 coding frameworks and arrived at a common coding scheme at the end of the fourth interview. Any differences between the coders were resolved by discussing with other members of the research team. We then applied the unified coding scheme to the rest of the data as they emerged from subsequent interviews. As the data analysis proceeded, the coding scheme was revised as new data emerged. The coded data were sorted and organized into categories, and themes were then generated from the categories depending on their overall importance to the research questions. We compared data from people in different age groups, sex, and gender identities to understand if such identities reflected specific preferences on how web platforms can be designed to alleviate stigma.

**Ethical Considerations**

The study was approved by the University of British Columbia behavioral research ethics board (REB # H23-00273). All participants provided written informed consent before the data collection. All data were anonymous because participants were informed not to state or mention any identifying information during the interview. Each participant was provided with CAD $50, which was equivalent to US $35 honoraria in appreciation of the time spent on the study.

**Results**

**Demographic Characteristics**

A total of 16 participants were interviewed. Data saturation occurred after the 14th participant, and we decided to interview an additional 2 participants. Regarding gender identity, 12 participants identified as women, 2 identified as men, and 2 identified as two-spirit. Regarding racial identity, 8 participants identified as White, 3 identified as a person of color, and 2 identified as Indigenous. Participants’ ages ranged from 25 to 63 years, with the majority of them younger than 30 years old. Even though all participants had used health-related websites, 6 of them had additional experiences using sexual pain–related websites. While we did not specifically ask people about their sexual identity, 3 of them openly stated their sexual identity as nonheterosexual. Seven participants stated they are marginalized by being identified as a woman, nonheterosexual, and Indigenous. On one hand, participants who indicated a marginalized identity also reported feeling stigmatized at some point in their lives or a feeling of impending stigma from their experiences of sexual pain. On the other hand, participants who did not express any marginalized identities were not very concerned about stigma, with 1 participant indicating that they do not associate sexual pain with stigma.

**Participants’ Perspective on Design Approaches to Alleviate Stigma**

The analysis generated 4 main overarching themes that reflected participants’ perspectives on how sexual pain–related web platforms can be designed to alleviate stigma or prevent such platforms from inadvertently fomenting stigma. Some of the broader thematic areas contain subthemes that come together to define each overarching theme.

**Theme 1: Inclusive Design of User Interfaces**

**Overview**

Inclusive design emerged as a major theme that reflected participants’ perspectives on how digital platforms could be developed to prevent the unintended effects of stigma. Participants recognized the diversity of people who may have direct or indirect experiences of sexual pain and the need to design digital platforms that satisfy the experiences of people with different racial or cultural backgrounds and sexual and gender identities. Three subthemes emerged under the overarching theme of inclusive design.

**Subtheme 1: Design to Include Diverse Sexual Experiences**

The participants indicated that web platforms on sexual pain should not just be limited to information on penis-vagina sex but include other forms of sexual experiences. According to the participants, other forms of sexual experiences like anal sex and the use of sex toys could equally elicit pain and therefore must be captured on web platforms. Participant 3 stated saying:

> Sex is not just penis to vagina interaction. There’s also sex toys and different ways in which people partake in sex. And so being very inclusive of that sense so that everyone feels safe in that website environment. And touching on the fact that there are different toys and people who are trans, for example, use dilators which can also bring pain.

The participants stated that these other forms of sexual experiences are already stigmatized by society and excluding them from digital platforms could worsen the stigma associated with such sexual experiences. The desire for inclusion of information on diverse sexual experiences was common among younger people. In fact, 2 participants who were older than 60
years were not open to the idea of other sexual experiences beyond penis-vagina sex.

**Subtheme 2: Design to Include Diverse Sexual and Gender Identities**

The participants also recognized that people may have different gender identities apart from being a woman and still experience painful sex. They specifically stated that not all people who identify as a woman may have a vagina and not all people that identify as a man may have a penis. To accommodate gender-diverse people in web-based platforms, participants suggested having inclusive pronouns by having drop-down menus or subsections on websites that account for people with different gender identities. Other participants argued that including pronouns of all gender-diverse people on web platforms may be difficult or impossible to achieve. Thus, they suggested the use of gender-neutral terms as a way of reducing the stigma associated with other stigmatized sexual identities. Participant 8 stated the need for gender-neutral terms by stating:

> Oh my god, my ovaries are partially removed because I had a tumor. And I think that using less gendered language would be very, very, very, destigmatizing for people like me and for people who are trans. Because I love when people actually think of us and it shows that we are not as bad as some people think. I would probably stick with non-gendered wording, like people with uteruses or just like talking about the specific parts that may show pains.

While participants argued for designs to include diverse gender identities, they agreed that painful sex may be more common among cisgendered people. In addition to the gender-diverse pronouns, participants suggested that web platforms on painful sex should include male partners who may not directly experience pain but may be part of the activity that produces sexual pain. Participant 6 noted the need to include male partners by stating:

> But honing in on the partners aspect, I think is really to make sure that there are resources for partners as well who aren't actively dealing with the pain. Okay. It's something that I've noticed is missing a lot.

**Subtheme 3: Design to Reflect Cultural, Religious, and Ethnic Diversities**

The participants also indicated their preference for designs that include people with different cultural, religious, and ethnic identities. This theme occurred across participants who identified as Indigenous or other marginalized identities. Participants expressed the need to see their culture or ethnicity represented when visiting web-based platforms regarding painful sex. Participant 14 specifically stated:

> I was talking to one of my friends and she's a black woman and she said when she was looking up sexual pain, she only saw white women on the websites. And so, she didn't think the information applied to her. She didn't see anyone who looked like herself. So, I think if images are used, it has to be intersectional so people can see themselves on the website.

According to participants, these minority groups are already marginalized and stigmatized in society, and such stigma may only intensify if their cultural and racial identities are not represented on web platforms. Some participants with religious backgrounds also noted the importance of religious sensitivity and how that can alleviate stigma, particularly stigma relating to traumatic sexual experiences. Participant 7 stated:

> I think that having that cultural sensitivity aspect embodied in a digital platform is important. Whether that be having individuals who have religious trauma associated with sex and who have gone through this experience give a testimonial or talk about it on a video or having religious supports or access to resources on the website, whether it be clickable links, phone numbers, whatever it might be on there.

**Theme 2: Nonprovocative and Calming User Interfaces**

**Overview**

Participants also reiterated the use of nonprovocative and what they termed “calming user interfaces” as an approach to alleviating stigma via web interfaces. According to participants, people with experiences of painful sex may already be overwhelmed by some form of hidden trauma and stigmatized feelings associated with the disorder. Thus, they suggested that calming and uncluttered interfaces could be an appropriate design approach to alleviating such stigmatized feelings. They specifically argued for the content on the landing pages to provide comfort to website users before they dive into the actual content of the website. The use of (1) nonprovocative and nonexplicit images and (2) subtle and calming colors emerged as subthemes that together defined the overarching theme of uncluttered and calming user interfaces.

**Subtheme 1: Nonprovocative and Nonexplicit Images**

Many participants argued for the use of nonexplicit images. Participants with a health science background thought explicitly displaying anatomical images of sexual organs might help in educating patients on the specific location of pain. Participant 2 stated:

> For me personally, I feel like the more graphic and anatomical images, the better because when I was younger, I literally didn't know anything about sexual anatomy. it's probably not allowed on the internet, but I think having those images would be helpful.

However, the majority thought that such images could be uncomfortable and might inadvertently foment stigmatized feelings. Participant 1 stated her abhorrence for seeing explicit content on sexual health–related web platforms and indicated how that made her feel uncomfortable:

> I read on one medium where they have provocative pictures of people, you know, in the lovemaking act. It wasn't pornographic but certainly explicit and personally, I am uncomfortable with that.

**Subtheme 2: Subtle and Calming Colors**

Participants’ views on addressing stigma via web platforms extended beyond the use of nonexplicit images to include the...
color of the images and the general color scheme of websites. There was unanimity in participants’ preference for colors like blue, green, dark, purple, soft greens, turquoise, and so forth. These colors were perceived to be calming and comforting for an already distressed user population of people with painful sex experiences. On the contrary, participants were generally unfavorable to bright colors like red and pink as such colors were thought to symbolize pain. Participant 9 indicated his desire for calming colors by stating:

so probably not like bright pink and that kind of thing. You know painful sex comes with its own trauma and having all these bright colors may be a put-off. I liked the one I saw in this interview, it was like really calm colors, and they weren’t too noisy, so you really focused on the information on the site and it was like, I think calming colors are maybe a good idea too.

Apart from indicating how these calming colors may be comforting to the eyes, participants were not explicit on how these color schemes could help address stigma when probed further.

**Theme 3: Interpersonal Connection via Web Platforms**

**Overview**

As a way of addressing stigma, participants indicated a preference for integrating interactive features on web-based platforms that allow the creation of interpersonal connections among people with similar experiences or with health care professionals. According to participants, being connected to others will be crucial in addressing stigma for a hidden disorder like sexual pain. Two subthemes emerged under this overarching theme.

**Subtheme 1: Creating Forums to Connect People With Similar Pain Experiences**

There was a strong preference for forums, discussion boards, and messaging boards that would enable people with similar sexual disorders to connect, interact, and share experiences with each other while remaining anonymous. Participant 9 compared this to Reddit, and how a Reddit-like function on web platforms can offer a free, easy, and anonymous forum for people to discuss sensitive topics.

_I think in that sense; the forums open up the isolation. The experiences and stories of strangers who have the same condition and you know such varied experiences will tell me that I am not alone in this and should not harbor any negative feelings. You know the internet gives us this fantastic gift of connection without obligation._

While participants acknowledged the importance of forum posts in addressing stigma, they also recognized the security and privacy risks associated with forum posts and how they can inadvertently perpetuate stigma. One participant noted how such forums can be used as avenues for harassment, bullying, and other risky behaviors. To prevent digital health platforms from inadvertently fomenting stigma, the participants suggested developing rules and regulations that govern forum posts, the use of pseudonyms and having designated professionals who would moderate web-based platforms.

**Subtheme 2: Creating Avenues to Connect With Health Care Professionals**

In addition to creating avenues on web platforms for people to connect, participants also reiterated the importance of creating avenues to connect with health care professionals, especially if it is a local website. According to participants, connecting with health care professionals via web platforms can “serve as a shield” from being exposed to the public stigma—a situation that participants found helpful during the COVID-19 pandemic. Participant 13 noted the importance of connecting to professionals by stating:

_speaking to a medical professional is more easily accessible and then having kind of the barrier of the screen in between, like not having to talk to someone face to face about it, but be able to type, I think could be helpful and, and perhaps start as a way to reduce the stigma._

According to participants, these forms of web-based interactions via web platforms can facilitate web-based consultations, thereby reducing the stigma people encounter by visiting onsite services.

**Theme 4: Displaying Personal Accounts and Experiences of Painful Sex**

The data revealed that displaying personal experiences on web platforms could help alleviate the stigma of painful sex among web users. The participants stated that seeing or hearing what others have gone through can help them relate to other people’s personal accounts of sexual pain while validating their own experiences. Participant 2 stated:

_When you find websites like this sharing information, it makes you feel like, I’m really not that strange. I’m not weird. Like there are a lot of other people who experience this too and that’s why they’re putting forward this information on this platform. So, it kind of makes people realize that it’s more common than they think. And that also helps to alleviate fear surrounding it._

Some participants suggested the use of video testimonials to convey experiences, while others suggested a combination of text and video testimonials but from different sources. According to participants, reading about people’s stories; hearing their voices; and understanding what they went through, how they discovered their diagnosis, and how it was treated will help others learn and understand their situation and clarify myths and misconceptions that often fuel stigma. Some participants also suggested the use of comic images and videos to convey their experiences of painful sex as a way of addressing stigma. Participant 3 stated:

_I like the comic thing. Like having people talking about these sorts of things in a comical style and that can make it less terrifying. By making it comical, you make it more entertaining, and people are more likely to pay attention to these sorts of things._
Discussion

Principal Findings

This study examined the perspectives of people with lived experiences of sexual pain on how web-based platforms can be designed to alleviate the unintended effects of stigma. While we acknowledge current practices of involving end users in developing sexual health–related digital interventions [21,22], no study has specifically investigated how such technologies can be designed to address the unintended effects of stigma. To the best of our knowledge, this is the first study that examined patients’ perspectives on how to address stigma through the design of digital health web platforms. Our study identified 4 broad categories that represented patient-centered strategies on how sexual health–related web platforms can be designed to address stigma. These categories include the design of inclusive web technologies, having a nonprovocative and calming user interface, having features that facilitate connections between users, and displaying personal accounts and experiences of sexual pain on web interfaces. Our sample revealed varying demographic information that ranged from marginalized populations including Indigenous, nonbinary, and people of color to White or Western populations. Participants’ indication of a marginalized identity suggests that the stigma of sexual pain may not exist in isolation but may intersect with multiple stigmatized identities to produce what is known as intersectional stigma [23].

These findings may help provide a conceptual or practical user-interface design guide for service providers to design digital health intervention that lessens or avoids the potential of fomenting stigma among people using sexual pain–related web platforms. We believe that these findings are not just applicable to sexual pain web platforms but could be applied to web-based platforms on other stigmatized conditions or disorders. By including male participants, this study also adds another dimension to sexual pain research in what is generally considered to be a woman’s health problem. The inclusion of people who identify as men male partners might have addressed the general lack of men’s involvement in sexual health research [24]. Even though participants who identified as men were not necessarily partners of those who identified as women as suggested in our prior study [10], they nevertheless illuminated the aspects of sexual pain that are specific to men yet often overlooked (eg, pain resulting from men who have sex with men).

Strategies to Addressing Stigma in Web Design

The themes identified from this study reflect patients’ perspectives on how web-based platforms can be designed to alleviate the stigma of sexual pain. The findings highlight the importance of inclusive user interfaces for people with diverse sexual pain experiences; gender-diverse people; and people with different cultural, ethnic, and religious identities. The findings of this study thus extend the idea of inclusive design beyond addressing the usual age, physical, mental, language, and accessibility limitations [25-27] to include specific stigma-related concerns that are often associated with people of diverse sexual and gender identities (two-spirit, lesbian, gay, bisexual, transgender, queer, and questioning, intersex, asexual) as well as diverse sexual preferences (anal sex and sex toys).

It is worthwhile to note that sexual pain is often discussed in relation to heterosexual encounters, people who engage in anal sex or sex using vibrators or sex toys may experience worse pain that, unfortunately, often ends up ignored in sexual pain–related platforms [28]. Designing to include these sexual perspectives is critical to foster inclusivity and may eventually help address some of the myths and misconceptions that often fuel stigma related to nonheterosexual forms of sexual encounters. On the contrary, user-interface design practices that exclude such groups from web platforms could be considered a form of marginalization through design [29]—a practice that may not only places people with nonheterosexual experiences into isolation but also amplifies the stigma associated with such sexual encounters.

The use of nonprovocative images was seen as a good design strategy for addressing stigma. We understand that intervention developers may want to display anatomical images of sexual organs on web platforms for enhanced comprehension and clarity of the information presented [30]. While useful, such practices may need to be reconsidered in sexual health web platforms as they may inadvertently reproduce, perpetuate, or exacerbate stigmatized feelings among people who find such explicit content undesirable. Participants’ suggestion for the display of nonprovocative images supports our previous assertion that provocative and explicit sexual images on web platforms could inadvertently foment stigma among end users [7,15,22]. It further confirms the assertion that the stigma of sexual health issues may be amplified through digital content, particularly digital images [31]. Furthermore, even though there was a general desire for inclusive images of nonheterosexual encounters and gender-diverse people, care should be taken to ensure that such images are not provocatively displayed on digital platforms that may end up stigmatizing an already stigmatized group. A possible solution may involve user testing of such content among the different user populations before they are displayed on web platforms.

Participants did not only recommend the use of nonprovocative images but also expressed a desire for the colors of such images, and the general color schemes of web platforms, to be calming and nondistress ing to users. The differences in color preferences might be a reflection of the diverse cultural backgrounds of the participants. Participants’ position on the use of calming colors like green, yellow, and blue confirms Goethe’s theory of colors where he associated certain color categories (eg, yellow and green) with positive emotional responses of warmth and excitement, while other categories (eg, red) were associated with negative arousal [32,33]. Even though participants were not explicit on how the choice of colors can address stigma, the current theories on colors suggest that less distressful color schemes like green and yellow could have a healing effect on people who have experienced the trauma of painful sex [33]. While we identified what is considered as calming colors, the differences in these colors might also pose a new challenge in determining a unified color scheme that is considered calming to a significant majority of web users. Thus, further research is needed to examine how the visual effects and different
combinations of colors on user interfaces could alleviate the stigma of sexual pain.

Interpersonal communication features have been shown to provide informational support, instrumental support, belonging support, self-esteem, and emotional support to people with similar health conditions [34]. Participants’ recommendation for the integration of anonymous and interpersonal communication features (chat rooms, forum posts, and messaging boards) confirms the use of these interventions for people with other stigmatized conditions like HIV and AIDS [35]. The recommendations for networking functions in web platforms also support the use of social networking sites as an effective educational strategy for reaching out to people with diverse sexual experiences who often experience stigma [35]. With the increasing use of digital health technologies, such interpersonal connection features might move a significant part of sexual health services onto web-based platforms (eg, consultation, testing, and prescription). Beyond that, such interaction features could also foster new friendships for isolated individuals while providing opportunities for people to share and validate their personal experiences that are often internalized as negative feelings. These opportunities for interpersonal connection might not only make people feel less isolated but may also normalize their sexual pain experiences, thereby alleviating stigma [36].

Forums could have more effect on stigma reduction when people with internalized negative feelings can read personal accounts and testimonials from other people with the same disorder. Such testimonials may not just be limited to forums or messaging boards but could be displayed on landing pages, particularly if they are coming from popular personalities. Text or video testimonials from “famous” personalities have been shown to be very persuasive and might help elicit healthy emotions and memory [37]. Testimonials from famous personalities are especially important given the significant role of power and power dynamics in stigma formation [38]. Web-based video testimonials have shown effectiveness in alleviating explicit and implied stigma of mental illness among students [39], thus suggesting their usefulness for other stigmatized disorders in sexual health. Despite the importance of interpersonal connections on web platforms, it is important to be aware of the inherent security and privacy risks that could inadvertently expose people to further stigma or restigmatization [40]. The use of anonymous chat rooms and forum posts and moderation of web-based platforms by trained personnel is recommended to prevent the privacy risk associated with such platforms [41].

**Strengths and Limitations**

Our study relied on web-based data collection methods, which provided some degree of anonymity and might have boosted the confidence of participants to discuss a sensitive topic like painful sex. We believe that the diversity of our sample may have enriched our findings by bringing a nuanced perspective of gender-diverse and nonheterosexual experiences of painful sex and their associated stigmatized feelings. Males engaging in nonheterosexual sexual acts like anal sex or females using sex toys may experience worse forms of stigma and sexual pain, yet are often ignored on web platforms.

Despite these strengths, this study was not without limitations. Even though we included participants who identified as men, two-spirit, and nonheterosexual people, their involvement was limited to 2 and 3 participants, respectively. The relatively lower participation rate could not have allowed us to delve deeper into the unique perspective of two-spirit and people who identify as men on how to address stigma via web-based platforms. Thus, further studies are needed to examine sexual pain stigma specific to each minority group (men, two-spirit, and nonheterosexual people) and highlight ways to incorporate the findings into web-based platforms. By just showing participants only our sample website, we also believed their responses might have been limited to a single website. It is possible that participants’ responses might have differed if they had been shown other websites on sexual pain. Despite this limitation, using a single website helped participants, particularly those who might not have used sexual pain-related websites before to be more articulate on how to develop websites to alleviate stigma.

**Conclusions**

Web-based platforms on sexual pain have the potential to empower people, promote the development of new web-based friendships, and promote the sharing of personal experiences, thus reducing feelings of isolation. However, the manner in which these platforms are developed has implications by either alleviating or exacerbating the stigma of sexual pain. This study highlighted patient-centered design approaches that could serve as a reference guide in developing destigmatizing web platforms for people with sexual pain, particularly for those who feel stigmatized by their gender, racial, and sexual identity. While this study was conducted in the context of sexual pain, we believe that the results may also be applicable to web platforms on other stigmatized sexual health–related disorders or conditions and to stigmatized issues in mental health. As a next step, intervention studies may be needed to investigate how these guidelines might be applied in practice and whether web platforms resulting from these findings would indeed be less stigmatizing compared to websites that did not adopt such destigmatizing approaches.

Abstract

Background: New federal policies along with rapid growth in data generation, storage, and analysis tools are together driving scientific data sharing in the United States. At the same, triangulating human research data from diverse sources can also create situations where data are used for future research in ways that individuals and communities may consider objectionable. Institutional gatekeepers, namely, signing officials (SOs), are therefore at the helm of compliant management and sharing of human data for research. Of those with data governance responsibilities, SOs most often serve as signatories for investigators who deposit, access, and share research data between institutions. Although SOs play important leadership roles in compliant data sharing, we know surprisingly little about their scope of work, roles, and oversight responsibilities.

Objective: The purpose of this study was to describe existing institutional policies and practices of US SOs who manage human genomic data access, as well as how these may change in the wake of new Data Management and Sharing requirements for National Institutes of Health–funded research in the United States.

Methods: We administered an anonymous survey to institutional SOs recruited from biomedical research institutions across the United States. Survey items probed where data generated from extramurally funded research are deposited, how researchers outside the institution access these data, and what happens to these data after extramural funding ends.

Results: In total, 56 institutional SOs participated in the survey. We found that SOs frequently approve duplicate data deposits and impose stricter access controls when data use limitations are unclear or unspecified. In addition, 21% (n=12) of SOs knew where data from federally funded projects are deposited after project funding sunsets. As a consequence, most investigators deposit their scientific data into “a National Institutes of Health–funded repository” to meet the Data Management and Sharing requirements but also within the “institution’s own repository” or a third-party repository.

Conclusions: Our findings inform 5 policy recommendations and best practices for US SOs to improve coordination and develop comprehensive and consistent data governance policies that balance the need for scientific progress with effective human data protections.

Introduction

The rapid growth in human research data, storage, and analysis tools and skilled researchers combined with the declining costs and new federal policies are creating an immense drive for research data sharing [1]. At the same time, triangulating human research data of diverse types can accentuate the risks of reidentification when used for secondary research purposes. It also invites the potential for group and other individual dignitary harms that institutional ethics review committees may be underequipped to properly protect participants against [2] or prevented from considering outright based on statutory interpretation of the US Common Rule [3,4].

The lack of standardized methods for accurately tracking the provenance of data and their permitted uses further complicates the problem [5-7]. Most institutional oversight bodies (eg, institutional review boards [IRBs], privacy boards, and data access committees [DACs]) are also ill-equipped to audit whether and how well secondary data uses align with the terms outlined in participants’ initial consent. These inabilities hinder opportunities for transparency, recourse, or accountability if uses are maligned, and gaps in policy as well as tool development leave the research community vulnerable to unintentional data misuse.

The responsibility for overseeing the ethical conduct of research involving human subjects traditionally lies with IRBs. However, the sensitivity and complex nature of data governance in genomics research present a new challenge that can exceed the review capacities and expertise of traditional IRB oversight [2,8-10]. While DACs have emerged as potential solutions to this issue [11], they are not yet widely implemented in many research institutions and are still in the early stages of growth and practice [12].

Despite these challenges, the expectation to share data has broadened [13] under new federal policies (eg, National Institutes of Health [NIH] Data Management and Sharing [DMS] [14]) and is aided considerably by cloud storage and analysis platforms [15]. The new NIH DMS policy came into effect in January 2023. It requires, among other things, that scientific data stemming from NIH-supported projects must be made publicly accessible without delay and with few exceptions. The final DMS policy defines scientific data as “The recorded factual material commonly accepted in the scientific community as of sufficient quality to validate and replicate research findings, regardless of whether the data are used to support scholarly publications. Scientific data do not include laboratory notebooks, preliminary analyses, completed case report forms, drafts of scientific papers, plans for future research, peer reviews, communications with colleagues, or physical objects, such as laboratory specimens” [14]. Emerging cloud computing environments afford new opportunities for tracking, auditing, and enforcing granular permissions [15] for scientific data in ways that were largely impracticable just several years ago. Yet, the broad use of provenance tracking tools continues to lag, creating situations where data stewards impose stricter barriers for access to data once up front, only to loosely permit the secondary use of these same data later in the research data lifecycle [16]. This situation is analogous to a house with a vaulted front door but a wide-open back door.

A clear example is the rigorous process of both a researcher and signing official (SO) agreeing to terms and conditions for the initial secondary access request. Subsequent sharing and use of consented data that transgress the consent, however, would likely go unmonitored by both the DAC approving access and the data recipient’s institution. This reality perversely incentivizes researchers to engage in informal data sharing to sidestep institutional data access review, which risks participants’ rights to privacy and the reputation of the research community. It is our view that limiting informal sharing pathways is consequential for both participant data protection and for maintaining trustworthy data governance practices. Investing resources into optimizing compliant pathways that are easier and more expedient for data requestors without sacrificing participant terms of use should therefore be a high institutional priority.

Research institutions and repository managers could also confront increased liability burdens from inaccurate, inconsistent, or unspecified data use permissions and restrictions [17]. Misattributing use restrictions can result in regulatory noncompliance and instill a lack of confidence among prospective and current research participants that institutions will respect the terms of their data contributions. SOs, who often serve as signatories on data submission and access request agreements, bear significant responsibility for ensuring the appropriate transfer and use of research data within their institutions in this regard [17].

According to the NIH, SOs have the authority to “legally bind the institution in grant-administration matters by providing signature approval on grant application submissions” [18]. A graphical diagram of where SOs intervene on the data sharing and management processes is depicted in Figure 1. SOs further monitor “grant-related activities within the extramural organization” to ensure compliance with all grant requirements. Although SOs play a leadership role in research compliance, we know very little about the ways in which new data sharing requirements for researchers affect their scope of work and data governance responsibilities in the wake of new agency policies.
This descriptive survey addresses a significant knowledge gap about the roles of US SOs, their knowledge about where research data from extramurally funded projects are deposited, how these data are accessed, and where data can be found after grant funding sunsets. Better understanding the roles and capabilities of SOs is important for identifying where institutional gatekeepers can intervene along the research data lifecycle to improve data provenance tracking and ethical data reuse in light of new NIH data sharing requirements [14]. We explore issues surrounding data sensitivity, consent tracking, institutional responsibilities, and liability considerations of SOs. As such, we seek to underscore the urgency of improving the distribution and coordination of institutional oversight bodies responsible for research data governance involving humans.

**Methods**

**Study Design**

We designed an anonymous survey of institutional SOs (Multimedia Appendix 1). The purpose of this survey study was to establish a baseline of existing institutional policies and practices as well as how these may change in light of new data sharing and management requirements for federally funded research in the United States. Survey items probed where data generated from extramurally funded research are deposited, how researchers outside the institution access these data, and what happens to these data after extramural funding ends.

**Recruitment**

Survey respondents were recruited from the websites of numerous institutions in the United States that receive funding from the NIH. We identified active SOs and used publicly available email addresses to contact them. Links to participate in the web-based survey were sent via email to each identified contact, and we used the software platform Qualtrics to administer the survey.

**Ethical Considerations**

This study was exempted by the Broad Institute of MIT and Harvard Office of Research Subject Protection. All survey responses were anonymized. Before advancing to the survey itself, respondents were presented with a detailed description of the study, its purpose, realistic risks and benefits of completing the survey, as well as information regarding the investigators and the funders before advancing to the survey itself. Consent to participate was indicated if respondents proceeded to complete the survey after reviewing the above study information. Respondents were not compensated for their participation.
The survey took approximately 5 minutes to complete and probed SOs about the impacts of the new DMS policy on their institutional tasks and responsibilities. The survey response rate was 19%: a total of 56 participants (of 287 prospective participants who were contacted) completed the survey between February 6 and April 12, 2023.

The 56 respondents represented institutions including academic-affiliated research institutes (n=43, 77%), academic institutions (n=10, 18%), nonprofit research institutes (n=2, 4%), and a health care or hospital system (n=1, 2%; Table 1). Of the 56 respondents, 52% (n=29) indicated that they will submit more than 250 grants in the next calendar year (Table 2).

Two-thirds (37/56, 66%) of respondents reported that less than 50% of scientific data generated by NIH funding will be controlled access data. When asked about the percentage of controlled access data generated by NIH funding, 46% (n=26) answered “less than 25%,” 20% (n=11) answered “25% to 49%,” 11% (n=6) answered “50% to 74%,” and 5% (n=3) answered “75% to 100%.” However, there is the potential for additional data sets to be categorized as controlled access data. We found that respondents defaulted to controlled access for data sets when a research participant’s preferences for “open access” versus “controlled access” were unclear in the original consent forms. In total, 27% (13/48) responded that they “always” default to controlled access sharing when the terms of access were unknown, while 52% (25/48) responded they “sometimes” do (Table 3).

Table 3. Nearly 80% (48/56) of survey respondents reported they default to controlled access for data where participant terms of use are unknown or ambiguous.

The respondents reported that most investigators will not only deposit data into “an NIH-funded repository (eg, dbGaP, AnVIL, and BioDataCatalyst)” to meet the DMS requirements but also within the “institution’s own repository” as well as “a third-party repository (eg, Generalist Repository Ecosystem Initiative repositories, Terra, and Data Use Oversight System).” For respondents who reported depositing in an institutional repository, a combined 62% (22/35) reported there was no process for researchers external to the institution to view, request, or access data or that they did not know whether such a process existed (Table 4). Moreover, 77% (10/13) responded that they were unaware if data needed to be downloaded for

For respondents who reported data deposits into a third-party repository, nearly 69% (20/29) said that their institution will keep a copy of the data (Table 5). In total, 31% (9/29) of the respondents who selected “a third-party repository” as a chosen platform (Table 6) reported that they are unsure about what will happen to the data at the end of the funded storage period paid for by the DMS allocated costs in each grant. The results suggest that there is a lack of clarity on the management and sharing of the data after the funded period for storage ends. This lack of clarity could mean a significant divergence in the life span and accessibility of publicly funded research data beyond the limited funded periods of storage made possible by DMS funding.

Respondents felt that principal investigators (PIs) were best positioned to determine where data should be stored to comply with the DMS policy (Table 7). Nearly 58% (38/66) reported that “individual investigators” should decide on which repositories to submit data, while other parties included “chief compliance officer,” “SOs,” “chief information or technology officer,” and “librarians.” Few mentioned that the decision-making should be a shared responsibility among various stakeholders including PIs, IT officers, and SOs.

When asked about who will oversee DMS policy compliance, 33% (19/56) reported that “SOs” should primarily serve that role, while 17% (10/56) mentioned “chief information or technology officer.” 16% (9/56) said “chief compliance officer,” and 9% (5/56) said “PIs.” Approximately 10% (6/56) noted that DMS policy compliance is responsible for multiple institutional offices.

Only 23% (12/52) reported that their institutions track where data from federally funded projects would be deposited, and nearly 37% (19/52) reported they are unaware whether such a tracking system exists. For respondents who reported a lack of a tracking system, 29% (n=6) reported their institutions plan to set up such a system. These data suggest nearly 77% (n=15) of institutions do not have a searchable method for determining where scientific data have been stored to track compliance with the new DMS policies (Table 8).

Table 8. Results from 52 survey respondents indicating that more than 77% (n=15) do not track where research data are deposited or are unaware of such tracking at their institution.

Discussion

Principal Findings

Our survey data suggest that SOs approve data deposit into various repositories to comply with the DMS policy but may be unclear about how data stored within the institution are accessed or analyzed by researchers outside the institution. SOs report that many investigators will deposit data into both an NIH-funded repository to meet the DMS requirements and in their institution’s own repository, as well as sometimes in a third-party repository. Such duplicitious deposit has consequences for data storage, security, and costs, which are underacknowledged in the literature.

Investigators may store data in an institutionally controlled repository to comply with new DMS requirements and institutional data retention policies. However, these data may be more difficult for external investigators working in similar fields to find, access, and share in practice and thus could conflict with the FAIR (findability, accessibility, interoperability, and reusability) principles [19]. Storing the same data set in more than 1 repository or database effectively doubles the storage space and costs without the added benefit of improved ease or efficiency of access insofar as institutions rely on commercial companies to provide storage services.

While storage costs are typically reimbursed only once as a dedicated line item in grant budgets, commercial service providers profit twice: once for services rendered to store data in NIH-controlled repositories and also for storing these same data on institutional servers or in institutionally controlled databases.

This double storage problem also leads to inconsistent standards for data access management. Access requests for data hosted within NIH repositories and knowledge bases undergo more standardized processing by dedicated staff who review applications and verify authorized users. Data hosted on local institutional servers, in contrast, tend to be more liberally distributed to nonauthenticated users and governed post facto, if at all.

Few SOs know what happens to research data at the end of the contract or storage period for data stemming from federally funded research under the new DMS budget allocations. The most frequently cited reason was that legal or contractual obligations for different data types preclude any one uniform procedure for data handling. Sunsetting projects also threaten the availability of data in perpetuity when allowed costs for data management end. The lack of familiarity or knowledge of access processes outside the institution impedes SO’s abilities to promote sustained use of the data resource longer term.

https://formative.jmir.org/2024/1/e49822
Less than a quarter (12/25, 23%) of SOs work at institutions that track where data from federally funded projects have been deposited to meet DMS policy requirements. Tracking where data are deposited is critical to verifying compliance with the DMS policy as well as ensuring the repository meets participant-defined terms of use. Without knowing where data end up, SOs are unable to communicate to funders about the state of data availability or provide an accurate accounting of institutional resources needed to steward that data.

As a result, SOs defaulted to imposing greater access controls for data where consent was unclear or unspecified. In total, 27% (13/48) of SOs always defaulted to controlled access for data sets where participant consents were unclear or unspecified, which can translate to downstream issues for authorized data access. A precautionary default approach is advantageous for sensitive data sets where access controls are justified and should have been applied in the first place. Applying controlled access defaults for data that should otherwise be open, however, places undue access barriers that hinder compliant research.

SOs are prone to overcontrolling data when there is ambiguity in consent. Data from this survey suggest that more data will undergo controlled access even if permissioned broadly for general research use. Institutional data stewards, including SOs and DACs, will therefore need to manage increased demands for data. Our prior work with DACs showed they see value in testing automated decision support tools and software to improve the efficiency of access requests without sacrificing consistency or quality [16]. SOs participating in this survey were unaware of such tools, creating clear opportunities for targeted outreach and training.

**Textbox 1.** Recommendations for institutional signing officials to promote data provenance tracking, data stewardship, and improved observance of secondary data use permissions.

- Investigators should be encouraged to store data in a centralized location that can be accessible to authorized users at a distance.
- Recognize privileged access rights for original submitters of data for secondary use, provided they comply with data use terms and, where applicable, are approved by an institutional review board.
- Allow principal investigators to negotiate with National Institutes of Health program officers and committees about how research stemming from the use of private data sets should be publicly disseminated.
- Retain a master list of where all research data stemming from funded projects have been deposited.

To prevent paying double for data storage and management costs, investigators should be encouraged to store data in a centralized location that can be accessible to authorized users at a distance. Public-private partnerships with large commercial cloud service providers, including Amazon Web Services and Microsoft Azure, accentuate the immediacy of this problem, considering they are poised to host some of the nation’s largest research data sets in the coming years [23]. This practice would be highly beneficial for cloud-based repositories, for researchers whose preferred repository to deposit data is cloud-based, and for institutions that support researchers who rely on data sets managed in the cloud to secure future research grants. It is said that centralized storage could reduce the risk of data loss if the original files are corrupted. Data storage is also a growing environmental concern, favoring options that lessen the carbon footprint [24].

Facilitating data access in perpetuity is a reasonable benefit to offer researchers who contributed these data in the first place and could, in turn, incentivize more sharing. However, recognizing this privilege also assumes they will always use the data in ethical ways. While researchers could preserve a private copy of the data, a policy that recognizes special rights of access to original submitters of research data could still be considered insofar, as the proposed research uses accords with consent permissions and, where applicable, has been approved by an IRB.

There are many compelling reasons why researchers prefer to use private data sets [25]. Companies protect their proprietary
interests in the data sets they generate by not sharing them freely with the research community. NIH-funded researchers who nevertheless opt to use private data sets in their work do so with full knowledge of company policies against broad data sharing but should not be absolved of their responsibilities to comply with the DMS policy. The NIH could consider enforcement alternatives that help to close this loophole, possibly suspending funds for investigators who are noncompliant or negotiating the sharing of summary-level data to the extent feasible and possible. The government should be reimbursed for data management and storage costs in cases where the benefits of research knowledge using private data sets cannot be recovered. Research funding agencies, as well as individual institutions, should have a master list of where all data stemming from funded projects have been deposited. Researchers should easily be able to see where data generated from funded projects have been deposited, with accessible links to those repositories to directly request access. For example, a widget on the existing NIH Research Portfolio Online Reporting Tool could facilitate this.

Conclusions
The new NIH DMS policy is a significant step toward responsible data sharing, which will lead to accelerated scientific discoveries and innovation. However, it leaves the details of data sharing and management practices to be determined by individual investigators and their respective institutions. This could create inconsistencies and inefficiencies in data governance, as witnessed in the genomic data sharing ecosystem.

Our survey of institutional SOs in the United States demonstrates a lack of clarity in terms of the location and duration of data storage, costs, and data security. Respondents suggested that scientific data generated by NIH funding are stored at multiple locations, including their institutions’ own data repositories, and are often unsure how external researchers gain access. Additionally, our survey shows that there is a pressing need for the development of proper tracking mechanisms to maintain and ensure the integrity of data sets, as many institutions currently do not keep track of where scientific data are stored once funded projects sunset. While more than half of the respondents suggested that PIs would be the sole decision makers on where to deposit data, respondents also acknowledged that compliance with the DMS policy will require institutional support and facilitate coordination between multiple offices.

Acknowledgments
This work was funded by the National Human Genome Research Institute (U24HG011025). The authors wish to thank the respondents for their time and willingness to participate in the study as well as anonymous peer reviewers who significantly helped strengthen earlier versions of this paper. During the preparation of this work, the authors used ChatGPT-4 available through OpenAI [26] to refine the grammatical structure of the text in the abstract and introduction of the paper. The authors take full responsibility for the content and accuracy of the data reported in this publication.

Abstract

Background: In this paper, we present an automated method for article classification, leveraging the power of large language models (LLMs).

Objective: The aim of this study is to evaluate the applicability of various LLMs based on textual content of scientific ophthalmology papers.

Methods: We developed a model based on natural language processing techniques, including advanced LLMs, to process and analyze the textual content of scientific papers. Specifically, we used zero-shot learning LLMs and compared Bidirectional and Auto-Regressive Transformers (BART) and its variants with Bidirectional Encoder Representations from Transformers (BERT) and its variants, such as distilBERT, SciBERT, PubmedBERT, and BioBERT. To evaluate the LLMs, we compiled a data set (retinal diseases [RenD] ) of 1000 ocular disease–related articles, which were expertly annotated by a panel of 6 specialists into 19 distinct categories. In addition to the classification of articles, we also performed analysis on different classified groups to find the patterns and trends in the field.

Results: The classification results demonstrate the effectiveness of LLMs in categorizing a large number of ophthalmology papers without human intervention. The model achieved a mean accuracy of 0.86 and a mean F₁-score of 0.85 based on the RenD data set.

Conclusions: The proposed framework achieves notable improvements in both accuracy and efficiency. Its application in the domain of ophthalmology showcases its potential for knowledge organization and retrieval. We performed a trend analysis that enables researchers and clinicians to easily categorize and retrieve relevant papers, saving time and effort in literature review and...
information gathering as well as identification of emerging scientific trends within different disciplines. Moreover, the extendibility of the model to other scientific fields broadens its impact in facilitating research and trend analysis across diverse disciplines.

**Introduction**

**Background**

A literature review is an integral component of the research process that involves systematically reviewing, evaluating, and synthesizing existing scholarly publications from databases such as MEDLINE (PubMed), Embase, and Google Scholar. The standard approach for a literature review involves using a bibliographic search engine to conduct an initial comprehensive search. Researchers use relevant keywords and filters, including clinical query filters, to retrieve a wide range of articles. The next steps include manually screening the retrieved articles by reviewing titles; abstracts; and, in most cases, full texts to assess their relevance and inclusion criteria. This combination of automated search and manual screening ensures a thorough review while targeting specific research objectives.

However, a literature review can be a challenging and time-consuming task for researchers, requiring meticulous examination of numerous sources and a critical analysis of their findings. The process demands substantial time and effort to effectively navigate through the vast expanse of scholarly literature from different databases and extract meaningful insights. Artificial intelligence tools have been used to facilitate this search process [1].

**Classical Methods**

Machine learning models have been applied to perform the text classification task based on feature engineering [2-4]. A semi-automated model was proposed for article classification in systemic review articles based on mechanistic pathways [5]. A total of 24,737 abstracts from both the PubMed and Web of Science databases and 861 references were found to be relevant. They evaluated the Naive Bayes, support vector machines, regularized logistic regressions, neural networks, random forest, LogitBoost, and XGBoost models. The best-performing model achieved a sensitivity and specificity of approximately 70% and 60%, respectively. Kanegasaki et al [6] used long short-term memory networks for the classification of abstracts. They used 2 data sets with 1307 and 1023 articles and achieved 73% and 77% respectively. These machine learning approaches were primarily based on feature engineering, which requires domain expertise.

**Supervised Natural Language Processing Models**

Natural language processing (NLP) applications have significantly advanced in recent years and gained tremendous popularity due to their wide range of applications across various domains. With the increasing availability of large data sets and advancements in computational power, NLP has made remarkable progress, revolutionizing the way we interact with technology [7-10]. In particular, NLP has gained interest in the field of information retrieval. NLP techniques, such as keyword extraction, document clustering, and semantic search, have improved the accuracy and relevance of the search results.

Hasny et al [11] used the Bidirectional Encoder Representations from Transformers (BERT) model for classifying articles into human, animal, and in vivo groups. Ambalavanan and Devarakonda [12] used SciBERT to classify scientific articles into 4 major categories, including format, human health care, purpose, and rigor. The format category included original studies, reviews, case reports, and general articles. The human health care category encompassed all articles discussing human health. The purpose category included articles discussing etiology, diagnosis, prognosis, treatment, costs, economics, and disease-related prediction. Rigor class included the studies that presented design criteria specific to a class purpose. The model achieved an F1-score of 0.753 on the publicly available Clinical Hedges data set. Devlin et al [13] used the BERT model for the classification of scientific articles on randomized controlled trials. The BioBERT variant, trained on titles and abstracts, showed the highest performance of 0.90 in terms of the F1-score.

Another study [14] fine-tuned variants of the BERT model, including BERTBASE, BlueBERT, PubMedBERT, and BioBERT, for the classification of human health studies. They used the abstracts and titles of 160,000 articles from the PubMed database. BioBERT showed the best results and achieved a specificity of 60% to 70% and a recall of >90%. The study [15] proposed a weakly supervised classification of biomedical articles. The model was trained on a weakly labeled subset of the biomedical semantic indexing and question answering 2018 data set based on MeSH (Medical Subject Headings) descriptors. BioBERT was used to generate the embedding for words and sentences, and then the cosine similarity was used to assign labels. The proposed model achieved an F1-score of 0.564 for the BioASQ 2020 data set. BERT and its variant models have shown better performance for the text classification.

**Zero-Shot Learning Methods**

Conventional approaches to text classification have traditionally relied on the assumption that there is a fixed set of predefined labels to which a given article can be assigned. However, this assumption is violated when dealing with real-world applications, where the label space for describing a text is unlimited and the potential labels that can be associated with a text span an infinite spectrum, reflecting the diverse and nuanced nature of textual content. Such complexity challenges the conventional methods and calls for innovative strategies to navigate the expansive and unbounded label space.

The best-performing model achieved a sensitivity and specificity of approximately 70% and 60%, respectively. Kanegasaki et al [6] used long short-term memory networks for the classification of abstracts. They used 2 data sets with 1307 and 1023 articles and achieved 73% and 77% respectively. These machine learning approaches were primarily based on feature engineering, which requires domain expertise.

**Supervised Natural Language Processing Models**

Natural language processing (NLP) applications have significantly advanced in recent years and gained tremendous popularity due to their wide range of applications across various domains. With the increasing availability of large data sets and advancements in computational power, NLP has made remarkable progress, revolutionizing the way we interact with technology [7-10]. In particular, NLP has gained interest in the field of information retrieval. NLP techniques, such as keyword extraction, document clustering, and semantic search, have improved the accuracy and relevance of the search results.

Hasny et al [11] used the Bidirectional Encoder Representations from Transformers (BERT) model for classifying articles into human, animal, and in vivo groups. Ambalavanan and Devarakonda [12] used SciBERT to classify scientific articles into 4 major categories, including format, human health care, purpose, and rigor. The format category included original studies, reviews, case reports, and general articles. The human health care category encompassed all articles discussing human health. The purpose category included articles discussing etiology, diagnosis, prognosis, treatment, costs, economics, and disease-related prediction. Rigor class included the studies that presented design criteria specific to a class purpose. The model achieved an F1-score of 0.753 on the publicly available Clinical Hedges data set. Devlin et al [13] used the BERT model for the classification of scientific articles on randomized controlled trials. The BioBERT variant, trained on titles and abstracts, showed the highest performance of 0.90 in terms of the F1-score.

Another study [14] fine-tuned variants of the BERT model, including BERTBASE, BlueBERT, PubMedBERT, and BioBERT, for the classification of human health studies. They used the abstracts and titles of 160,000 articles from the PubMed database. BioBERT showed the best results and achieved a specificity of 60% to 70% and a recall of >90%. The study [15] proposed a weakly supervised classification of biomedical articles. The model was trained on a weakly labeled subset of the biomedical semantic indexing and question answering 2018 data set based on MeSH (Medical Subject Headings) descriptors. BioBERT was used to generate the embedding for words and sentences, and then the cosine similarity was used to assign labels. The proposed model achieved an F1-score of 0.564 for the BioASQ 2020 data set. BERT and its variant models have shown better performance for the text classification.

**Zero-Shot Learning Methods**

Conventional approaches to text classification have traditionally relied on the assumption that there is a fixed set of predefined labels to which a given article can be assigned. However, this assumption is violated when dealing with real-world applications, where the label space for describing a text is unlimited and the potential labels that can be associated with a text span an infinite spectrum, reflecting the diverse and nuanced nature of textual content. Such complexity challenges the conventional methods and calls for innovative strategies to navigate the expansive and unbounded label space.
these issues, zero-shot techniques [16-18] have been developed and are gaining popularity. Zero-shot learning (ZSL) involves classifying instances into categories without any labeled training data [19]. It leverages auxiliary information such as semantic embeddings or textual descriptions to bridge the gap between known and unknown categories. This enables the models to generalize to novel classes and make predictions for unseen categories. Mylonas et al [20] used zero-shot model for classifying PubMed articles into emerging MeSH descriptors. Instead of using the standard n-grams approach, the method exploited BioBERT embeddings at the sentence level to turn textual input into a new semantic space for the Clinical Hedges data set [21]. Unlike traditional models, the ZSL model does not explicitly require the labeled data; however, these models performed well on downstream tasks.

In this study, we have used large language models (LLMs) that include ZSL for categorizing the ophthalmology articles extracted from the PubMed database into different categories based on title and abstract. We fine-tuned the BERT model and its variants BERTBASE, SciBERT, PubmedBERT, and BioBERT for those categories that did not show good results from the ZSL model. Several powerful models, including Decoding-enhanced BERT with Disentangled Attention (mDeBERTa), Bidirectional and Auto-Regressive Transformers (BART), and the recently introduced Llama 2, present competitive alternatives to ChatGPT. However, Llama 2, despite its potential, imposes significant demands on graphics processing unit and memory resources. Even its smaller variant, with 7 billion parameters, requires substantial computational power, posing challenges for users with limited access to high-performance computing resources. To ensure broader accessibility, we prioritized a model with lower resource requirements. Accordingly, we selected the open-source BART model that is executable on central processing unit, thus providing both acceptable performance and enhanced accessibility to broader users. In addition, we performed a trend analysis based on the classified results, providing researchers with insights into emerging trends in the field to stay updated on the latest developments and identifying key areas of interest. Overall, we provide a method that enhances the efficiency, relevance, and interdisciplinary potential of the literature review process.

The rest of the study is organized as follows: the Methods section presents the materials and methods of the proposed framework for text classification and trend analysis. The Results section discusses the results of the different experiments performed for the evaluation of the proposed model. The Discussion section includes the principal findings and concludes the proposed work.

Contributions

Various classification models have been proposed in the literature for biomedical articles to retrieve relevant information [1-21]. Fine-tuned BERT and its variants have been used for text classification. Following are the main contributions of the studies:

- We have explored the ZSL models for the classification of biomedical articles.
- We have developed different use cases targeting the field of ophthalmology.
- To evaluate the model, we have generated a data set that includes 1000 articles related to ocular diseases. The articles were manually annotated by 6 experts into 15 categories.
- The ZSL model BART achieved a mean accuracy of 0.86 and an $F_1$-score of 0.85.
- In addition to the classification of articles, we also performed a trend analysis on different classified groups.
- The model is adaptable to other biomedical disciplines without explicit fine-tuning or training.

Methods

Data Set

There are several annotated data sets available for various NLP tasks in the biomedical domain. However, in the field of ophthalmology, there is a scarcity of publicly accessible data sets for performing NLP tasks. To address this gap, we have taken the initiative to curate a data set focused on ocular diseases. Our retinal diseases (RenD) data set comprises 1000 articles sourced from PubMed, covering various conditions such as diabetic retinopathy (DR), glaucoma, diabetic macular edema, age-related macular degeneration, cataract, dry eye, retinal detachment, and central serous retinopathy. To ensure accurate categorization, we enlisted the expertise of 6 domain specialists who meticulously annotated the articles based on abstracts. To ensure accuracy and reliability in the annotation process, each article in our data set is reviewed and annotated by at least 3 individual annotators (refer to Table S1 in Multimedia Appendix 1 for the guidelines for data annotation). This multiple-annotator approach helps mitigate potential biases and inconsistencies that could arise from a single annotator’s perspective. Once the annotation is completed, the final label for each article is determined based on majority voting. Each article was annotated against 28 labels (Table S1 in Multimedia Appendix 1), and due to not having enough samples in some categories, we dropped those in further classification tasks. Thus, we selected 19 categories and grouped them into 4 categories (Table 1).

We will make this data set publicly accessible to the community for advancing research, facilitating comprehensive analysis, enabling more targeted investigations into ocular diseases, and promoting open science.

**Study Design**

Our framework automates the entire literature review process in the ophthalmology domain (Figure 1). More specifically, by incorporating user-defined criteria, including keywords, the number of articles, inclusion criteria, and categories for classification. Our framework performs a systematic retrieval and analysis of relevant articles automatically. Initially, a keyword is fed into PubMed, and the related articles are fetched, including the abstract, title, publication year, and link. The preprocessing step in this context involves the selection of a specific subset of articles from a larger corpus of fetched articles. This selection process is contingent upon the application of predefined inclusion criteria, with a specific temporal constraint. In this study, articles falling within the temporal range spanning from 2015 to 2022 are considered for inclusion in the subsequent analyses. This temporal delimitation serves as a crucial preprocessing measure, narrowing down the data set to a more focused and relevant time frame for the research objectives. The selected articles are then fed into the LLM for classification based on user-defined categories. For LLM, first we targeted using the ZSL models that can classify the text without explicit training. If the ZSL model is unable to achieve better performance, then we fine-tune the BERT model. Finally, after the article classification by LLM, we have performed 2 types of trend analysis.
Figure 1. Flow diagram of the proposed framework. The model takes input (keyword, inclusion criteria, and categories for classification), and articles are fetched from PubMed based on keyword. The inclusion criteria are fed into the preprocessing module to select the desired articles from the fetched data. A large language model classifies the articles based on the predefined categories. Finally, trend analysis is performed on classified categories.

Zero-Shot Classification

Zero-shot classification is an approach to predict the class of instances for categories they have never seen during training, using auxiliary information or semantic embeddings. It enables generalization to unseen classes and expands the classification capabilities beyond the limitations of labeled training data. We have used BART [22], which is pretrained based on a sequence-to-sequence model that combines bidirectional and autoregressive techniques for improved text generation and comprehension. BART has 12 transformer layers with a hidden size of 1024 that was initially trained on Wikipedia and the BookCorpus data set and fine-tuned on Multi-Genre Natural Language Inference tasks. BART is an amalgamation of the bidirectional encoder found in BERT and the autoregressive decoder used in Generative Pretrained Transformer (GPT) (details of architecture can be found in Figure S1 in Multimedia Appendix 1). While BERT comprises approximately 110 million trainable parameters and GPT-3 consists of 117 million parameters, BART, being a combination of the 2, has approximately 140 to 400 million parameters. This larger parameter count in BART accommodates its sequenced structure, which incorporates both encoding and decoding capabilities for a wide range of NLP tasks. The model receives the title and abstract of an article as input and generates probabilities for each class, and if the probability for a specific category is higher than a threshold value, the article is assigned the label corresponding to that category.

Trend Analysis

In addition to the classification of articles, we performed 2 additional analyses as well. More specifically, we performed a technology trend analysis to obtain valuable insights into the distribution of research across different classes, highlighting classes with higher or lower publication frequencies. This information aids in understanding the emphasis and focus of research efforts, enabling resource allocation, and identifying areas that may require further attention or investigation. We also performed an interest trend analysis to provide a comprehensive view of publication trends over specific periods. By identifying the popularity of techniques or topics over time,
this analysis facilitates the detection of emerging trends and the evaluation of long-term patterns. These trend analyses, applicable to all levels of classification categories, contribute to an enhanced understanding of the dynamic nature and evolving landscape of research in the field.

Ethical Considerations
We have not included any human and animals in our study.

Results
This section presents the experiments we have performed to evaluate the LLMs for classification.

Experimental Details
We evaluated our models based on the RenD data set that we annotated. In addition, we evaluated the models to classify categories based on 2 review studies related to dry eye disease and glaucoma (Table 1). We present the results in terms of accuracy, area under the curve (AUC; $F_1$-score, precision, and recall for each data set. For multilabel classification, we evaluated the model in terms of $F_1$ micro, Pv micro, Re micro, and AUC.

Ablation Study
Overview
Our study encompasses both multiclass and multilabel classification tasks. To accomplish this, we used the ZSL model and fine-tuned the model for which the ZSL was not performing well. Through a series of ablation experiments, we systematically investigated the impact of different settings (refer to the subsequent sections) on the performance of the model. By modifying and assessing various settings, we gained insights into the individual contributions and effects of each setting, allowing us to refine and optimize our approach accordingly.

ZSL Model Selection
In our study, we conducted an evaluation of the ZSL state-of-the-art models and multiple variants of the BART model. On the basis of a comprehensive analysis, we identified the model variant that exhibited the most favorable performance in our specific context (Table 2).

We selected the BART model that showed the best performance. In addition, we performed experiments using different keywords for the different categories. It was observed that for the ZSL model, the prompts should be more descriptive and provide some information about related categories to improve the accuracy (Table 3).

For the category “Clinical, Experimental, and Automated Model,” we have tested various keywords and found that “Clinical finding based on humans,” “Experimental study based on animals,” and “Technical study based on automated model” keywords showed the best results with an accuracy of 0.91 and an $F_1$-score of 0.92. During our evaluation, we investigated the potential of using abstracts and titles for classification across various categories. We discovered that classification solely based on titles closely approximates the results obtained from using abstracts for most of the categories. However, the abstract and title together enhance the efficacy of the classification.

Hyperparameters for Fine-Tuning BERT

For the categories in which the ZSL model (BART) provided poor results, we fine-tuned the BERT model and its variants to perform categorization. We conducted hyperparameter tuning based on this to enhance the model’s reliability and significance. By carefully selecting and fine-tuning hyperparameters such as the learning rates, batch sizes, and regularization strengths, we aimed to achieve accurate and meaningful results (Table S2 in Multimedia Appendix 1). For the BioBERT model, we selected a learning rate of 1e-05, a batch size of 8, a maximum length of 400, and a number of epochs of 20.

Evaluation Results

Article Classification Evaluation

This section presents the results based on the metrics that were selected in the ablation experiments. On the basis of the evaluation, BART demonstrated the best performance among...
the tested models. Therefore, further classification tasks were conducted using the BART model to capitalize on its superior performance. Table 4 shows the classification results using BART for the RenD data set for the categories of article type, ocular diseases, clinical studies subclass, and automated studies subclass.

The article type group was classified into 3 subcategories: clinical, experimental, and automated studies. The BART model demonstrated promising performance for the article type group, with an accuracy of 0.91, an $F_1$-score of 0.92, an AUC of 0.91, a precision of 0.93, and a recall of 0.91. For the article group type, classification based on only abstract and only title and combination of both are performing consistent. The automated model group is further categorized into image processing techniques, machine learning models, and deep learning models. For the automated study subclass group, the ZSL model achieved the best performance for title-based classification, with accuracy, $F_1$-score, AUC, precision, and recall of 0.92, 0.95, 0.94, and 0.92, respectively. However, the second-best scores were achieved by classification based on abstract and title.

The clinical studies are further categorized into screening, diagnosis, prognosis, etiology, and management, constituting a multilabel classification scenario. However, ZSL achieved the best score of F1 micro of 0.52, AUC of 0.68, precision micro of 0.49, and recall micro of 0.61. The ocular group is classified into DR, diabetic macular edema, age-related macular degeneration, glaucoma, dry eye, cataract, central serous retinopathy, and retinal detachment. In terms of accuracy, $F_1$-score, AUC, precision, and recall, the classification based on titles yielded the most favorable outcomes. Specifically, the results for the title-based classification were 0.85 accuracy, 0.85 $F_1$-score, 0.92 AUC, 0.89 precision, and 0.86 recall. Following closely were the results for the abstract-based classification, with values of 0.85 accuracy, 0.83 $F_1$-score, 0.91 AUC, 0.87 precision, and 0.85 recall.

**Trend Analysis**

A category-wise analysis was performed for the article type and ocular disease groups based on the RenD data set (Figure 2). Some other results are also reported in Figure S2 in Multimedia Appendix 1.

Category-wise analysis showed more frequent papers on clinical studies compared to experimental- and automated-based studies. For ocular diseases, more studies have discussed DR and glaucoma compared to other ocular diseases. A timewise analysis was conducted for the subgroup of automated studies from 2015 to 2022. The trends indicated that, in the initial years, these studies primarily relied on image processing techniques. However, as time progressed, machine learning gained traction, and eventually, deep learning models became increasingly popular in this field, reflecting how technology is evolving in ophthalmology. For the time-wise analysis of diseases, refer to Multimedia Appendix 1.
Figure 2. Trend analysis of classified articles: (A) and (B) category-wise analysis for article type and ocular diseases group, respectively, and (C) timewise analysis for automated studies subclass group: image processing techniques, machine, and deep learning models. AMD: age-related macular degeneration; CSR: central serous retinopathy; DME: diabetic macular edema; DR: diabetic retinopathy.

Discussion

Principal Findings

We have proposed a framework aimed at streamlining the literature review process. This framework entails an automated system that operates by taking user-specified keywords as input. By leveraging these keywords, the system retrieves relevant articles from the PubMed database. In addition, the user specifies the desired categorization for these articles. This approach aims to simplify and expedite the traditionally time-consuming task of conducting literature reviews. We investigated the efficacy of using the LLM model to perform article classification.

LLMs, particularly ChatGPT, have gained huge popularity due to their versatility in performing various tasks, including
question answering and trend analysis within specific fields. Moreover, these models demonstrate the capability to generate research papers, letters, and other written content, showcasing their potential for creative text generation. However, the generated content is not always entirely authentic, as it can occasionally produce fake references and links, raising concerns about the reliability and accuracy of the information presented. Therefore, we proposed a framework for automating the literature review process and finding different trends in various disciplines. However, a limitation of ChatGPT-3.5 is the fact that it is not equipped with information beyond September 2021; therefore, it may not provide facts or knowledge beyond this date. We target using open-source LLMs for article classification and then performing category-wise and timewise analysis. Other open-source LLMs have become available recently. For instance, mDeBERTa, BART, and the recently released Llama 2 and its variants may outperform ChatGPT. However, using Llama 2 requires significant graphics processing unit and memory resources. Even the small variant of the model, with 7 billion parameters, demands substantial computational power to function effectively. These resource requirements can pose challenges for users with limited access to high-performance hardware.

Hence, our primary goal is to select a model that not only delivers robust performance but also requires fewer computational resources, thereby enhancing accessibility for a broader user base. The BART model aligns with these criteria as it is open source, allowing seamless execution on central processing unit. This choice ensures a balance between efficiency and performance, making advanced NLP capabilities accessible to a wider community. In a direct comparison with alternative models, BART stands out, showcasing superior overall performance across various evaluation metrics and in terms of computational resources.

Categorization, Classification, and Trend Analysis

We used BART as the ZSL classifier, and we used the abstract and title separately for article classification. After obtaining the probabilities from each model, we combined the probabilities and performed classification. In addition, we also appended the title to the abstract and added it to the models.

The BART model showed compromising results for the categories article type, ocular diseases, and automated studies subclass of the RenD data set. The classifications based on abstract and title are nearly similar in performance. For clinical studies subclass grouping, the BART achieved an F1 micro score of 0.52 and an AUC of 0.68. To improve the performance for this class, we fine-tuned BERT and its variant, BioBERT, which performed best with an F1 micro score of 0.67 and an AUC of 0.70. The lower performance in this class is likely due to the class imbalance, which typically affects the model’s ability to generalize and accurately predict instances of the minority class.

We also evaluated the performance of the BART model to classify the articles into different categories for 2 undergoing review studies including DEye and DemL. The articles in both the review studies were annotated by reviewing the entire article. However, we just used the abstract and title, and for DEye, our model achieved an AUC of 0.79 and an $F_1$-score of 0.63. To improve the performance of the BART model, we performed a hierarchical analysis in which the multilabel task is divided into a binary classification. Classification was performed across different thresholds for each class, and the optimal value was chosen based on the best results achieved (Table S3 in Multimedia Appendix 1). The results showed that converting the multilabel problem into binary classification improves the performance of the BART model. In addition to this, we also observed that abstract-based classification and whole article–based annotation provided comparable results for each class (Table 5).

On the basis of the DemL data set, the BART model’s classification is based on the abstract, and the title is as accurate as the whole article–based annotation for the DemL data set.
Table 5. Bidirectional and Auto-Regressive Transformers (BART) model evaluation for classification of the Dry eye and DemL data sets.

Comparative Analysis of Computational Time

We have performed a comparative analysis of the processing time between the LLM and human annotators, which has unveiled intriguing insights. This analysis delves into the time required for classification based on the abstract, the title, and both the title and abstract of scientific articles. Manually annotating articles is a time-consuming task, as human annotators require a significant amount of time to label each article. The overall process can span over several weeks, depending on the number of articles and the number of categories for annotations. For instance, annotating the abstract of 1 article with 2 categories may take, on average, 4 to 5 minutes. However, automated models take notably less time to complete similar tasks (Table 6).

Notably, using both title and abstract as input led to a slightly increased processing time for the BART model, although it remained significantly faster than human annotation. We conducted 2 types of trend analysis: category wise and timewise. These analyses can be applied to any classified category and can highlight different trends in a concise and quick manner. A report is generated at the end, encompassing user-specified inclusion criteria and other relevant aspects to aid researchers (Figure S3 in Multimedia Appendix 1).

**Limitations**

The limitation of this study is that we have included articles from the PubMed database, which may have resulted in the exclusion of relevant articles related to the chosen keyword. However, future plans involve the integration of additional databases such as Google Scholar, IEEE Xplore, and Springer to address this limitation and ensure a more comprehensive coverage of relevant literature. Articles from various databases can unveil trends and patterns that transcend specific domains, increasing the applicability of the findings.

We used the ZSL model for text classification. As the model is not specifically trained for downstream tasks, there are several potential biases and challenges to consider. The model may not fully comprehend the semantics or nuances of the new task, leading to biases in predictions or misinterpretations. Downstream tasks have different data distributions compared to the original ZSL task, causing the model to struggle with new patterns or biases.

We selected BART as the ZSL model, as it is the latest open-source model. BART pretraining results in the creation of semantic embeddings that capture various linguistic nuances. These embeddings enable the model to understand the semantics of different tasks, even for those tasks it has not been explicitly trained on. Its task-agnostic pretraining allows it to be adapted for various other fields by providing task-specific prompts during inference. Leveraging BART for zero-shot tasks often involves careful prompt engineering. By formulating prompts that guide the model to perform specific tasks or make predictions for unseen classes, users can harness the model’s prelearned linguistic capabilities. This can be addressed by carefully designing the prompt and adding a little description instead of using 1 word for each category, and then the model will perform better (Table 3). A limitation of the ZSL is its potential to exacerbate inequality. If the categories are not carefully designed, ZSL models may unintentionally reinforce inequalities by favoring certain classes or groups. This can also be addressed by prompt engineering. Another limitation we found is that the ZSL model will face difficulties in performing multilabel classification when categories are closely related. This issue can be resolved by dividing the multilabel classification into binary classification for each class.

The computational demands and knowledge cutoff limitations in LLM are also constraints that can be addressed by leveraging reinforcement learning techniques. The implementation of adaptive learning, active learning strategies, and exploration-exploitation balancing is being explored to address computational challenges while minimizing the impact of the knowledge cutoff. In addition, user-driven reinforcement and collaborative efforts within the research community are being incorporated to refine the models. These reinforcement learning strategies are expected to enhance the adaptability, efficiency, and overall performance of LLM, ensuring its continued relevance and effectiveness.
Conclusions

We developed a framework based on BART ZSL for the categorization and trend analysis of articles and demonstrated a proof-of-concept scenario in the field of ophthalmology. We used the ZSL model for the categorization of articles in the field of ophthalmology, but it is extendable to other categories and fields without requiring any additional training. The model can generalize to new classes it has not observed during training, making it adaptable to different domains and applications.

The results demonstrated that the model achieved promising outcomes across most categories. In addition to article classification, trend analysis highlighted the evolution of technology in ophthalmology. Accurate and quick classification of scientific papers enables efficient information retrieval, allowing researchers to access relevant studies more quickly and obtain insights into the trend of technology and future directions. Future research directions include exploring more specialized LLMs for further improvement. In addition to this, we also have plans to develop an automated literature review tool. This tool aims to streamline and enhance the literature review process by incorporating advanced algorithms to efficiently analyze and summarize relevant research findings.

Abstract

Background: There is great interest in using artificial intelligence (AI) to screen for skin cancer. This is fueled by a rising incidence of skin cancer and an increasing scarcity of trained dermatologists. AI systems capable of identifying melanoma could save lives, enable immediate access to screenings, and reduce unnecessary care and health care costs. While such AI-based systems are useful from a public health perspective, past research has shown that individual patients are very hesitant about being examined by an AI system.

Objective: The aim of this study was two-fold: (1) to determine the relative importance of the provider (in-person physician, physician via teledermatology, AI, personalized AI), costs of screening (free, 10€, 25€, 40€; 1€=US $1.09), and waiting time (immediate, 1 day, 1 week, 4 weeks) as attributes contributing to patients’ choices of a particular mode of skin cancer screening; and (2) to investigate whether sociodemographic characteristics, especially age, were systematically related to participants’ individual choices.

Methods: A choice-based conjoint analysis was used to examine the acceptance of medical AI for a skin cancer screening from the patient’s perspective. Participants responded to 12 choice sets, each containing three screening variants, where each variant was described through the attributes of provider, costs, and waiting time. Furthermore, the impacts of sociodemographic characteristics (age, gender, income, job status, and educational background) on the choices were assessed.

Results: Among the 383 clicks on the survey link, a total of 126 (32.9%) respondents completed the online survey. The conjoint analysis showed that the three attributes had more or less equal importance in contributing to the participants’ choices, with provider being the most important attribute. Inspecting the individual part-worths of conjoint attributes showed that treatment by a physician was the most preferred modality, followed by electronic consultation with a physician and personalized AI; the lowest scores were found for the three AI levels. Concerning the relationship between sociodemographic characteristics and relative importance, only age showed a significant positive association to the importance of the attribute provider ($r=0.21$, $P=.02$), in which younger participants put less importance on the provider than older participants. All other correlations were not significant.

Conclusions: This study adds to the growing body of research using choice-based experiments to investigate the acceptance of AI in health contexts. Future studies are needed to explore the reasons why AI is accepted or rejected and whether sociodemographic characteristics are associated with this decision.

KEYWORDS

artificial intelligence; skin cancer screening; choice experiment; melanoma; conjoint analysis, technology acceptance; adoption; technology use; dermatology; skin cancer; oncology; screening; choice based; trust
Skin cancers are the most common groups of cancers diagnosed worldwide, with more than 1.5 million new cases estimated in 2020 [1]. Melanoma is the deadliest form of skin cancer. Based on demographic changes, it is estimated that more than 500,000 new cases of melanoma and almost 100,000 deaths from melanoma should be expected worldwide by 2040 [1]. As melanoma case numbers are expected to increase in the future, high-cost treatments will continue to put a strain on the already overburdened health care budgets. To combat the rising mortality rate of melanoma, early detection is critical. Currently, the German national treatment guidelines [2] recommend skin cancer screening as a standardized full-body skin examination performed by dermatologists who have completed specialized training in the early detection of skin cancer. In addition, dermatologists should use dermoscopy to diagnose suspected skin cancer. Given the rising number of cases as well as increasing scarcity of trained dermatologists [3-5], there has been substantial research into the feasibility of artificial intelligence (AI) to augment or replace traditional skin cancer screening regimens [6].

AI describes machines (or computers) that mimic the cognitive functions associated with human thought, such as learning and problem-solving. These systems observe their surroundings and adopt action to reach their targets directly [7]. Further, AI has the ability to learn from images and subsequently provide an image-based diagnosis. Dermatology, as an image-based field of medicine, retains a dominant position in the AI evolution with the ability to classify skin lesions [8].

Research into the technical quality of AI-based skin cancer screening technologies has shown that these systems achieve detection rates that are on par or better than those of highly trained clinicians [9-13]. This highlights the great potential of AI for future skin cancer screening in the general population. As part of apps, AI systems offer immediate access to dermatological screening for all patients with mobile digital devices, enabling health care and treatment to be provided regardless of time and place and close to everyday life [6]. Thus, AI systems capable of detecting melanoma and nonmelanoma skin cancer could avoid unnecessary care, reduce health care costs, offer solutions to the increasing scarcity of clinicians, and reduce the waiting times for an appointment and for a diagnosis [3-5]. However, there is a risk that some melanomas will be missed and treatment delayed if the apps incorrectly reassure the user that their lesion is of low risk [14].

Although the technical quality has improved, there is also a growing awareness that patients do not generally accept the use of AI-based systems in health care settings. There is still no consistent definition of technology acceptance in the literature. Terms such as “acceptability,” “acceptance,” and “adoption” are often employed in this context, sometimes interchangeably. Dillon and Morris [15] defined user acceptance “as the demonstrable willingness within a user group to employ IT [information technology] for the tasks it is designed to support.”

Khullar et al [16] conducted an online survey to examine patients’ perspectives about applications of AI in health care, showing that 31% of respondents reported being very uncomfortable and 40.5% were somewhat uncomfortable with receiving a diagnosis from an AI algorithm that was accurate 90% of the time but incapable of explaining its rationale. Longoni et al [17] demonstrated that consumers are very hesitant about being examined by an AI system and consumers’ willingness to pay decreases when an equivalent service is performed by an AI system. Additionally, they concluded that patients’ perceived neglect of uniqueness leads to more resistance to medical AI [17].

Past research has also identified several factors that might impact patients’ preferences to use AI-based health care services. The European Commission [18] interviewed citizens of the 28 member states of the European Union (N=27,900) and concluded that younger participants with a high educational level are more likely to use online health care services. This finding was also replicated in oncology patients, where younger patients indicated higher acceptance of and a greater intention to use digital tools and apps to manage their cancer [19]. The European Commission [18] also found that the opinion on AI strongly depends on exposure to related information and knowledge. This relationship is also supported by a series of experiments showing that resistance to the utilization of medical AI is driven by the subjective difficulty of understanding algorithms [13].

Concerning skin cancer, previous research has shown that patients were generally reluctant to use AI-based systems in the field of dermatology. Snoswell et al [6] examined the consumer preference and willingness to pay for mobile teledermoscopy services in Australia using a discrete-choice experiment (N=199). They found that patients prefer a trained medical professional to be involved in their skin cancer screening and that patients are less willing to pay money for teledermatology [6]. However, Snoswell et al [6] did not take into account sociodemographic factors that may have had an impact on the patients’ decisions. In a multicenter clinical study assessing the performance of automated diagnosis of melanoma with a self-completion questionnaire (N=65), Fink et al [20] found that most patients agreed that computer-assisted diagnoses are trustworthy and may generally improve the diagnostic performance of physicians. However, participants rejected the idea of AI-based systems completely replacing physicians and instead strongly favored hybrid solutions in which diagnoses by a physician are supported by automated systems [20].

To date, only three studies have directly addressed the question of which factors are associated with patients’ preferences regarding AI-based skin cancer screening [21-23]. Ghanie et al [22] studied public interest in teledermatology, which was found to be positively associated with a younger age, higher educational attainment, and higher household income. Chang et al [21] examined sociodemographic differences in teledermatology acceptability with a cross-sectional survey (N=13,996), showing that respondents who were interested in teledermatology were more frequently 18–39 years of age, men, college graduates, and tablet or smartphone users. Similarly, young age, male gender, a previous history of melanoma, and higher educational level were significantly associated with a more positive attitude toward skin cancer–related apps [23]. However, it is unclear whether these results from questionnaires
can be replicated in choice-based experiments that rely to a lesser degree on introspection and are thus one step closer to actual behavior [24].

As described above, provider and costs for a skin cancer screening have high relevance for the user [6,16,17,20]. For this choice-based conjoint analysis, we further added the attribute waiting time for a diagnosis, because studies have shown a strong negative correlation between patient satisfaction and waiting time [25,26]. AI provides the opportunity to get a skin cancer screening immediately, without any waiting time [3]. Due to the shortage of medical professionals, waiting time for a skin cancer diagnosis is also an important attribute for the user [5,7].

The aim of this study was two-fold based on the following two research questions: (1) How important are the attributes provider, costs for screening, and waiting time for diagnosis for participants’ preference for skin cancer screening? (2) Are sociodemographic characteristics, especially age, systematically related to the relative importance scores of participants to the various attributes?

**Methods**

**Study Design**

This cross-sectional study used a choice-based conjoint analysis to examine the acceptance of medical AI for a skin cancer screening from the user perspective. Conjoint analysis is a quantitative marketing research method that quantifies the value consumers place on the attributes of a product [27]. Respondents are asked to make a choice between 2 or more different choice sets, where each set is described in terms of several predefined attributes, each with different levels. Given a sufficient number of choices per respondent, it is then possible to statistically estimate the importance of each attribute and level for the choice in terms of part-worth utilities. This method offers a behavioral approach and is less susceptible to social desirability and other biases [28].

This study systematically manipulated three attributes (provider, cost, and waiting time) for a hypothetical skin cancer screening. Participants were presented with 12 different choice sets one after another, each consisting of three different modes of skin cancer screenings that were generated by combining different levels of the three attributes (see Figure 1 for an example). The choice sets were generated by the conjointly algorithm using default settings [29].

**Figure 1.** Example choice set (1€ = US $1.09).

Which of the following health care services would you choose?

- **Physician treatment**
  - Immediate diagnosis
  - 40€ copayment

- **Personalized artificial intelligence**
  - 4 weeks waiting time
  - 10€ copayment

- **Artificial intelligence**
  - 1 week waiting time
  - 0€ covered by health insurance

**Survey**

Before the survey was conducted, it was tested with the “think-aloud” method by three volunteers to find out if there were any comprehensibility problems. For this purpose, the pretest participants had to speak their thoughts aloud while completing the survey [30].

The questionnaire started with informed consent, where participants were informed about the nature and scope of the survey and about the protection of their data. Before starting the questionnaire, participants completed the consent form and agreed to participate in the anonymous study. The participants then moved on to the choice-based conjoint task, which consisted of 12 different choice sets. The participant’s task for each choice set was to indicate the skin cancer screening that they most prefer (ie, they selected one of the three options as their preferred choice). After responding to the choice sets, participants were asked whether they had undergone a skin cancer screening in the last year and at which type of provider.

Finally, the sociodemographic characteristics (age, gender, education, status, income) were assessed. Finally, the survey asked again whether the data could be used for analysis in anonymized form in case respondents changed their minds during the course of the survey and to filter out people who just wanted to “click through” without seriously answering the questions.

**Participants**

Recruitment was based on a convenience sample through the social environment; individuals were asked to participate in the open voluntary survey shared with contacts via WhatsApp and Instagram. Standard procedures for conducting and reporting online surveys [31] were followed. Furthermore, conjointly’s default methods were used to identify and bar potential duplicate entries from the same user. Data were collected during the time period of September 29, 2022, through October 20, 2022.

The link to the survey was clicked 383 times by unique site visitors. Of these potential respondents, 126 (32.9%) people
filled out the conjoint survey completely and gave their agreement for processing their data. In total, 220 (57.4%) respondents opened the link but did not complete the survey and another 33 (8.6%) people were disqualified from the study because they answered the survey several times. Three people (0.8%) did not give their agreement to process their data and a single respondent (0.3%) was excluded because the survey was answered too quickly. Respondents took an average of 4.7 minutes to complete the survey. Table 1 provides an overview of the respondents’ sociodemographic characteristics. There was a relatively equal proportion of participants identifying as male and female. The average age of the participants was 37.6 years and the median age was 29 years.

Table 1. Sociodemographic characteristics of participants sampled from September 29, 2022, to October 20, 2022 in Germany (N=126).

Ethical Considerations

Our online study was conducted in accordance with the American Psychological Association’s Ethical Principles of Psychologists and Code of Conduct. In particular, data collection was anonymous; harmless to participants; and did not involve deception, injury, or place participants under high levels of physical or emotional stress. In line with 2023 guidelines of the German Research Foundation, formal ethical approval was not required because our study did not include aspects that would necessitate a statement, per subsection two of the “Information on proposals in the field of psychology” [32]. Informed consent was obtained from all participants after the purpose of the study and the data collection were outlined in the survey introduction. Participants indicated their consent by clicking a button. Study data and identifiers were anonymized during the data collection and data analysis to maintain confidentiality. No compensation was awarded to participants.

Results

Table 2 provides an overview of the relative importance values of the attributes and part-worth values of each level for each attribute as determined by conjointly to answer the first research question [29]. A treatment by a physician that is completely compensated by insurance and has no waiting time emerged as the most preferred mode of treatment. Overall, provider was the most important attribute, followed by costs and waiting time. For all attributes, we found two levels with part worths around zero and one positive and negative level. For provider, the physician had a positive part worth and the AI system had a negative part worth, while both the personalized AI and teledermatology had near-zero part worths. For waiting time, immediate results had a positive part worth and a 4-week wait had a negative part worth, while a 1-day and 1-week wait had similar near-zero part worths.

Figure 2 shows an overview of the relationships between sociodemographic characteristics and the relative importances to answer the second research question. We found a medium-sized positive relationship between age and provider. In addition, there were two nonsignificant trends. The first indicated an inverse relationship between age and the importance of costs and the second indicated an inverse relationship between income and the importance for costs. All other importances were not systematically related to sociodemographic variables (Table 3).

Discussion

The aim of this study was to determine how important the attributes provider, costs, and waiting time are for users’ preference for skin cancer screening and to investigate whether sociodemographic characteristics, especially age, are systematically related to participants’ individual importances. We found that provider was as equally important a factor for participants’ decisions as cost and waiting time. While a physician was the most preferred level of this attribute, AI-based treatment was disliked and a personalized AI had the same value for participants as teledermatology.

Concerning the relationship between sociodemographic characteristics and relative importances, we found that only age showed a reliable positive association to provider, in which younger participants place less importance on the provider than older participants. In the following, we discuss these findings in turn before discussing the limitations of the study and providing a general outlook.

Regarding the role of the provider in users’ decisions, other studies underline our results that patients exhibit hesitant behavior toward medical AI. Patients would rather not have a treatment than be examined by an AI system, even if the AI system shows the same or better accuracy as a physician [17]. However, the same study also found that patients prefer personalized AI over nonpersonalized AI. Similarly, earlier discrete-choice experiments [6] as well as surveys [33] found that patients prefer a trained medical professional to be involved in their skin cancer screening; 41% of respondents were open to using AI as a standalone system for skin cancer screening and 94% were open to using it as a support system for physicians [33]. Together, existing studies indicate that personalized AI and teledermatology are generally more accepted than nonpersonalized AI for skin cancer screening, while the physician remains the most preferred option.

Regarding income and educational factors, our findings do not align with those of previous studies. Ghani et al [22] concluded that higher education attainment and a higher household income increased the interest in using teledermatology. Chang et al [21] came to similar conclusions, indicating that college graduates showed the greatest interest in teledermatology. In addition, Steeb et al [23] showed that a high educational level was associated with a positive attitude toward skin cancer-related apps. While we were not able to show significant relationships to income and educational background, the smaller sample size in this study compared to those of earlier studies might explain this inconsistency.

Previous studies also identified gender differences in the acceptance of AI in skin cancer screening. Chang et al [21] came to the conclusion that men are more likely to use teledermatology than women. Steeb at al [23] found similar results in which male gender was significantly associated with a positive attitude toward skin cancer-related apps. However, the gender difference that was reported in earlier studies was not visible in our data. Again, this might be a factor of sample size.
size, but it also might also be that these gender differences reported in earlier questionnaire studies reflect differences in the technology self-concept [34] rather than actual preferences.

Several aspects must be considered in interpretation of our findings. First, the sample was not randomly selected but was based on a convenience sample. While a wide range of recruitment means were used, the results are likely not generalizable to the general public but rather more specific to highly educated young adults. Further research is needed with the target group. Although the sample size may not seem particularly large, sensitivity analysis showed that this sample size was in fact sufficient to detect a medium-sized correlation ($r=0.28$) with a power of 90% and error rate of 5%. Second, some participants contacted us about the meaning of the attribute waiting time because they were unsure whether this pertained to the waiting time for a diagnosis or the waiting time for an appointment. Future studies should make this distinction more explicit to study possible differential effects of these two types of waiting times.

Taken together, we believe that this study adds to the growing body of research using choice-based experiments to investigate the acceptance of AI in health contexts. This approach offers additional insights and is less susceptible to social desirability and other biases [35]. However, the choice-based conjoint analysis only allows studying a small number of potential attributes at a time [24]. Because we included personalized AI as a level for the attribute provider, our study adopted the findings of Longoni et al [17] that personalized AI increases patient acceptance. In addition, we examined factors that may have an impact on patients’ decision-making following the study of Snoswell et al [6].

For the future, it could be interesting to add “AI as a physician support system” to the choice set [33]. It might also be interesting to find out whether patients who perceived themselves as more individualized are less accepting of AI [17]. Additionally, it could be interesting to explore whether specialized knowledge about AI systems would increase patient acceptance [13] and which other factors might have an influence on patients’ acceptance. Ideally, this would not only rely on correlational evidence as used here but also on experimental evidence that shows how preferences and importances may be altered. The variables such as income and educational background cannot be manipulated easily. Nevertheless, we believe that the magnitude of these effects provides some benchmarks for future studies that aim to use experimental methods to alter preferences.

In summary, while there have been technological advances in the effectiveness of AI for supporting skin cancer screening and health care more generally, we believe that the true potential of AI systems can only be realized if patients’ needs and demands are taken into account.

Abstract

Background: Digital health is increasingly used to meet the needs of perinatal people, with estimates of pregnancy-related internet use ranging from 90% to 97% of pregnant people. As digital health takes on greater importance during the perinatal period, it is essential that providers and developers of digital health content understand why perinatal people use these resources and the features that enhance their experience. However, gaps remain in understanding the content that is most helpful and how the platforms are navigated. Learning directly from perinatal people about their needs will help ensure alignment between perinatal needs and available content.

Objective: This formative study aims to identify the reasons why perinatal people use digital health resources; the features of the digital health platforms that are of greatest importance to them; and how these differ by perinatal stage (pregnancy vs postpartum), mental health conditions, parity, and demographics (race and ethnicity).

Methods: This mixed methods study used interviews; surveys; and secondary data on demographic, health, and pregnancy characteristics to identify the digital health needs and preferences of pregnant and postpartum people who used the Maven digital health platform in the United States during their pregnancy or postpartum period. The interviews informed the content of the surveys and provided additional insights and examples for interpreting the survey results. The surveys were used to collect data from a sample of Maven users, and the results were linked to the secondary data set. The interviews were thematically analyzed, and survey data were analyzed using descriptive statistics and stratified by parity, race, and mental health status.

Results: Overall, 13 people were interviewed (including n=4, 31% pilot interviews), and 147 pregnancy and 110 postpartum survey respondents completed the surveys and had linkable secondary data. Top reasons for using digital health resources during pregnancy were to (1) know what is normal or typical during pregnancy, (2) have access to a health care provider when needed, and (3) know how the baby is developing. Top reasons for postpartum use were to (1) help with breastfeeding, (2) know what normal baby development is, and (3) help with the baby’s health issues. Top platform features during pregnancy and the postpartum period were (1) credible and trustworthy information and providers, (2) nonjudgmental information and support, and (3) no cost to the user. In general, more reasons for using digital resources were identified as extremely important during pregnancy compared with postpartum. The results showed minor variations across strata.

Conclusions: This formative research found minor differences in digital resource needs and preferences across user characteristics among perinatal people in the United States. Future work should examine whether there are variations in interests within topics by user characteristics, which may provide additional opportunities to better meet user needs.

Introduction

Background

Digital health, which refers to digital health applications, ecosystems, and platforms [1-4], is increasingly used to meet the needs of perinatal people [5-8], with estimates of pregnancy-related internet use ranging from 90% to 97% of pregnant people [9-13]. Digital health is expected to have growing importance because of its potential to provide health prevention, consultation, treatment, and management while simultaneously providing an opportunity to reduce costs and improve access to care and patient satisfaction, which together may lead to better informed and more engaged patients [1,4,14,15].

To date, research on perinatal digital health needs falls into 2 categories: self-report via surveys or qualitative data collection (interviews and focus groups) and content analysis of perinatal digital forums. Previous research has shown that access to perinatal digital health information provides reassurance and support [5,16,17]. Both types of studies have found that most people use digital resources during pregnancy to access information on maternal health (eg, pregnancy ailments, pain and complications, and health and nutrition during pregnancy) and during the postpartum period to access information on baby-related topics such as infant sleep and feeding (especially breastfeeding) [18,19]. Self-report studies have also indicated interest in childbirth, fetal and infant development, and infant illnesses, and studies of web-based forums have revealed interest in people and relationships [5,10,11,18-21]. The relative interest in these topics and the specific content within them vary throughout the perinatal period [17,19,20]. Research has also found that a positive experience using digital health resources is characterized by being easy to access and navigate, providing trustworthy and unbiased information, and being customized (eg, trackers and localized information) [4,22,23]. Perinatal digital health users specifically value an experience that provides information that is proactively delivered; offers immediate access; and provides information that is practical and concise, entertaining, and reassuring [5,24,25].

As digital health takes on greater importance during the perinatal period, it is essential that providers and developers of digital health content understand why perinatal people use these resources and what contributes to a positive user experience [26]. The information sought by perinatal people differs from the information that health care providers prioritize and offer. For example, postpartum people seek information on sleep, emotional changes, and breastfeeding, whereas providers focus on medical issues such as bleeding and infection [27,28]. Although there is a growing body of literature, there remain gaps in understanding of the content that is most helpful and how the resources are navigated [5]. There is a demand for more detailed analyses, including which digital resources are most helpful [16], with a particular need to understand what is valued during the postpartum period [18]. Research is needed on digital health needs and experience among perinatal people with mental health conditions, especially pre- and postpartum anxiety [20], and more insights are needed on barriers to and facilitators of using digital health, especially with newer technologies such as apps [4,20]. Learning directly from perinatal people about their needs will help ensure alignment between perinatal needs and available content [18,29]. The design of digital health content should be directly informed by individuals and their experiences. However, the research on patients’ user experience of digital health is limited, especially during the perinatal period [4].

Objectives

This mixed methods study, which used formative interviews and surveys, investigated the reasons why pregnant and postpartum people use digital health resources and what contributes to a positive user experience. Using a national sample of pregnant and postpartum users of Maven [30], a comprehensive reproductive and family digital health platform that includes patient education, care coordination, and provider services, this formative study identified how needs and preferences differ by perinatal stage (ie, pregnancy vs postpartum), mental health conditions, parity, and demographics (race and ethnicity). The results from this study can be used to inform a user-centered approach to developing the content and design of digital health resources and improve the alignment between resources and users. In recognition of the fact that patients have diverse gender identities, we have used gender-inclusive language throughout this paper. If a participant described themselves using gendered language (ie, “as a working mother...”), we used their terminology. When describing the results of previous research, we used the terminology used by the study investigators.

Methods

Study Design

In this mixed methods study, we identified the digital health needs and preferences of pregnant and postpartum people who used the Maven digital health platform during their pregnancy or postpartum period. The study used formative interviews to inform the content of surveys and provide additional insights and examples for interpreting the survey results. Surveys were used to collect data from a sample of Maven users that could be linked to a secondary data set of demographic, pregnancy, and health characteristics in the Maven platform (Figure 1).
Digital Platform Background

Maven was developed in 2014 as a digital platform to support perinatal people and their families. Users have a primary point of contact called a care advocate, an allied health professional (e.g., social worker or nurse) who works with the user to navigate the services and resources on the platform. Services and resources include web-based classes; educational materials; and internet-based appointments with a diverse team of health care providers, including obstetrician-gynecologists, mental health professionals, midwives, and doulas. Access to Maven is a sponsored benefit through an employer or the health plan of the user or their partner. The study investigators are Maven employees of the Maven clinical research team. When activating their Maven accounts, users consent to the use of their contact information by Maven for various reasons, including research. The investigators only have direct contact with Maven users or access to identifiable data within the scope of specific research projects, in accordance with institutional review board (IRB) approvals, and in concordance with Health Insurance Portability and Accountability Act regulations. Access to user data is minimized by requesting recruitment lists and platform-based data from the Maven product analytics team, which deidentifies the information before sharing it with the research team. To recruit Maven users for interviews and the survey, the recruitment parameters were sent to the product analytics team, which generated a list of deidentified IDs of users who met the parameters. This list of deidentified IDs was sent to the Maven team responsible for direct communication with users, which sent out recruitment emails (using email addresses linked to the deidentified IDs).

Formative Interviews

In September 2022 and October 2022, semistructured interviews with postpartum people were conducted virtually via Zoom (Zoom Video Communications) to identify the reasons why perinatal people use any digital health resources, not just Maven. To help encourage participants to think about digital use broadly, at the start of the interview, they were asked to list all the digital resources used during their pregnancy and the postpartum period, and throughout the interview, they were reminded to think about digital resources in general. The first part of the interview was open-ended, and participants were prompted not only to describe the reasons why they used digital resources but also to identify additional reasons for which they would like to use them. In the second part of the interview, participants were shown (via screen sharing on Zoom videoconferencing) a list of reasons why digital resources could be helpful during the perinatal period. Participants were asked whether they had used a digital resource for each individual reason or whether they would like to use a digital resource for each individual reason in the future. Finally, participants were asked about the importance of digital health resources being inclusive of their entire identity, which was explained as including anything that the participant considered part of their identity, such as race, gender, sexual identity, geography, social or economic status, and mental and physical health conditions, and to describe their experience with (lack of) inclusion.

Pilot interviews were conducted with 4 postpartum Maven staff members who had used Maven during pregnancy and the postpartum period and were post partum at the time of the interview. The interview guide was modified based on their feedback and the interviewer’s learnings from conducting the pilot interviews. Following piloting, interviews were conducted with 9 Maven users, all of whom were post partum so that they could speak to their digital needs and preferences throughout the perinatal period. Participants were recruited with an emphasis on including people from a range of ethnicities and races, health conditions, and parity. Participants were recruited via email. Interviews lasted approximately 1 hour, were conducted via Zoom, and were recorded. An interviewer and a notetaker were present, and transcripts were autogenerated on Zoom. Participants (Maven staff and nonstaff) consented to the interview, had the option of having the video on or off, and could decline to have the interview recorded (one participant...
declined, and we relied on detailed notes for that interview. The consent form was included in the recruitment email and reviewed at the start of the interview, and consent was provided verbally. Participants were given a US $50 Amazon gift card as a thank you for their participation.

The prevalence of each reason for using digital resources was calculated by counting the number of interviews (Maven staff and nonstaff) in which the reason was mentioned as important. The reasons that were mentioned as important in the most interviews were included in the survey.

Survey Development
In addition to the semistructured interviews, separate quantitative surveys were developed to inquire about digital resource use during pregnancy and the postpartum period. Through the qualitative analysis, it emerged that participants were describing 2 aspects of digital resource use: the information or support they were seeking and features of the digital health platforms. Consequently, the survey contained 2 sections, each addressing one of these aspects. To focus on common needs and remove outliers that were mentioned by only 1 or 2 participants, reasons for using digital resources and features affecting experience were excluded from the surveys if they were cited by less than one-third of the interview participants. In each section of the survey, participants indicated the importance of each item on a Likert scale that included a description of each option (a little important or doesn’t matter to me—I don’t care much about this, important—I would like to have this but I’m OK without it, very important—I care about this a lot but it’s not absolutely necessary, and extremely important—a “must have”) and subsequently picked the 5 most important items (not ranked). We opted to allow participants to select up to 5 items as a means to balance the tension between the high number of reasons why pregnant and postpartum people are turning to digital resources and the need to prioritize to inform actionable decisions about what content to provide in these resources. To reduce the potential bias of basing responses on their use of Maven, the instructions in the survey reminded respondents to think holistically about digital health resources. The following is an example of the instructions from a section of the pregnancy version of the survey: “Thinking about the reasons you might use any digital resource during pregnancy, rate how much each of these reasons matter to you. Digital resources include websites, apps, videos, blogs, search engines, etc.”

The surveys were piloted with 4 Maven staff members who had used Maven during pregnancy and the postpartum period and were post partum at the time of piloting. The wording and format were modified based on their feedback. The revised surveys were piloted with 4 Maven nonstaff users. During piloting, we identified that nearly all items were selected as very important. To minimize ceiling effects, the response options were revised to provide more response options that reflected higher levels of importance and add definitions (eg, extremely important: a must have). We also opted to reverse the order of the options (with a little important or not important to me as the first option rather than the last). In addition, we included a section for selecting the 5 most important reasons for use and platform features, which would provide information on the relative importance of the items if we continued to have a ceiling effect.

On the basis of feedback from the staff and nonstaff member pilots, we added 2 items that had not emerged in the interviews: using digital resources to help with formula feeding and feeding solid foods. These were added as participants felt that the survey was not inclusive or relevant to the entire postpartum period if it only asked about breastfeeding.

The survey was built in SurveyMonkey (SurveyMonkey Inc) using a Health Insurance Portability and Accountability Act–compliant account.

Survey Administration
Survey respondents were recruited from current Maven users. To be eligible for the pregnancy survey, users had to be between 0 and 6 months post partum and have had a Maven account during pregnancy. To be eligible for the postpartum survey, users had to be 3 to 12 months post partum and have a Maven account during the postpartum period. Recruitment was via email, which included a link to the survey. Each survey link was associated with the user’s unique Maven identifier to link the survey responses to user demographic characteristics previously recorded on the Maven platform (described in the Secondary Data section). A reminder email was sent 1 week after the initial email to anyone who had not clicked through to the survey. The survey remained open for 2 weeks from the time of the initial email. A consent form appeared before the start of the survey, and consent had to be provided digitally to access the survey. Participants were entered into a draw for a chance to win 1 of 5 US $100 Amazon gift cards per survey (5 for the pregnancy survey and 5 for the postpartum survey). Data were collected from January 18 to 29, 2023.

Secondary Data
Maven users are encouraged but not required to fill out a questionnaire when they activate their account. The Maven pregnancy questionnaire collects data on physical and mental health, pregnancy conditions, demographics, and parity. The Maven postpartum questionnaire collects information on demographics, mode of delivery, and previous pregnancy conditions. For survey participants who completed the Maven questionnaires, we linked their survey responses with their Maven questionnaire data using their unique Maven identifier. Maven users consent to the use of their Maven questionnaires for research when they activate their accounts, and the research team does not have access to any identifying information.

Analyses
Survey Analysis
Respondents who completed the survey and a Maven questionnaire were included in the survey analysis. Figure 2 shows the pathway for inclusion in the analysis, from eligibility to be recruited to starting and completing the survey and completing a Maven questionnaire. The quantitative data from both the pregnancy and postpartum surveys were assessed primarily through the evaluation of descriptive statistics. Chi-square and Fisher exact tests were used to assess differences among pregnancy items, postpartum items, and user experience...
features by parity, presence of any mental health conditions, and race and ethnicity. A user was considered to have a mental health condition if they reported any of the following: a history of anxiety, depression, perinatal mood disorder, or high pregnancy-related anxiety. A history of anxiety or depression was assessed in the Maven questionnaires using the following question—“Do any of these conditions apply to you or did they in the past?”—with the selection of Anxiety or depression from a list of conditions. Experience of perinatal mood disorder was assessed using the following question—“Have you experienced any of the following during this pregnancy?”—with a selection of Perinatal mood disorder. Pregnancy-related anxiety was assessed on a 5-item Likert scale in response to the following question—“On a scale of 1-5, how anxious are you feeling about your pregnancy?”—with responses of 4 (very) or 5 (extremely) indicating the presence of pregnancy-related anxiety. For analyses stratified by race and ethnicity, we recategorized individuals who identified as Hispanic, Black, Asian or Pacific Islander, or multiracial into 1 category labeled non-White because of our small sample of people of racial and ethnic minorities. Consistent with the study’s aim of identifying differences in needs and preferences between respondents with these characteristics, P values were calculated to determine whether the differences were statistically significant (with results considered to be statistically significant if the P value was <.05). Statistical analyses were conducted using RStudio (Posit Software, PBC).

Figure 2. Flowchart of the pregnancy survey respondents (A) and postpartum survey respondents (B) included in the survey analysis.

Interview Analysis

The interviews were analyzed thematically using a framework analysis [31-36]. Themes were identified deductively based on the interview guide and inductively based on the messages that emerged from the interviews. Themes and their definitions were reviewed by all team members who participated in the interviews (as interviewers or notetakers) and were modified based on group discussion and consensus. The analysis table was populated based on the notes taken during the interviews and subsequent analysis discussions. Audio recordings and transcripts were referenced if the notes were unclear or lacked sufficient details to populate the analysis table. All entries in the analysis table were reviewed by NH, who attended all but one of the interviews. Any information that was missing or potentially miscategorized in the table was flagged for review by the person who entered the information and, if necessary, discussed to reach a consensus. To better understand the experiences and perspectives associated with the topic of each of the items in the quantitative surveys, the corresponding interview themes were summarized, and representative anecdotes or quotes were selected. All quotes were verified using the audio recordings. Quotes and anecdotes are cited using the interview participant number (eg, P1 refers to participant 1), and it is specified whether the participant was from the pilot interviews (eg, Pilot P1 refers to the first interview among the pilot participants).

Ethics Approval

The study protocol was approved by the WCG IRB (study 1338443). The use of secondary data was deemed exempt by the WCG IRB under 45 Code of Federal Regulations § 46.104(d)(4).

Results

Survey Sample Characteristics

In total, we had 147 pregnancy survey respondents and 110 postpartum survey respondents with complete Maven questionnaires (Table 1 and Figure 2). All survey responses
were collected within 48 hours of sending the initial recruitment email. The average age of the respondents was 32.8 (SD 4.6) years and 32.7 (SD 3.5) years for pregnancy and postpartum survey respondents, respectively. On the basis of those who reported their race and ethnicity, our sample was comparable with the overall US population in terms of the percentage of people identifying as non-Hispanic White (134/257, 52.1%) and multiracial (5/257, 1.9%), with an overrepresentation of people identifying as Asian (31/257, 12.1%) and an underrepresentation of people identifying as Black (4/257, 1.6%) or Hispanic (16/257, 6.2%) [37]. A total of 44.9% (66/147; pregnancy survey) and 51.8% (57/110; postpartum survey) of the respondents had household incomes of $>100,000. Approximately 28% (72/257) of the sample reported a history of a mental health condition (Table 1).

\(a\)Variables with <15% of missing data: age, race, social vulnerability, BMI (pregnancy survey respondents), mental health history (pregnancy survey respondents), and parity (pregnancy survey respondents). Variables with 15% to 30% of missing data: household income and BMI (postpartum survey respondents). Variables with 30% to 40% of missing data: parity (postpartum survey respondents) and mental health history (postpartum survey respondents).

\(b\)Measured using the Centers for Disease Control and Prevention Social Vulnerability Index.

\(c\)A total of 65.5% (72/110) of postpartum survey respondents provided parity or mental health data. Therefore, the sample size for those variables is 72.

**Reasons for Use of Digital Resources During Pregnancy**

On the basis of the survey responses, the most important reasons for using digital resources during pregnancy were to know what is normal or typical during pregnancy, have access to a health care provider when needed, and know how the baby is changing and developing during pregnancy (Table 2).
Table 2. Reasons identified as extremely important when using digital health resources during pregnancy by parity, mental health status, and race and ethnicity (N=147).

<sup>a</sup>Respondents who selected I prefer not to say for race and ethnicity were not included in this comparison.

In interviews, participants described the role that digital resources play in meeting these needs (Table 3), and they emphasized the importance of these resources during their first pregnancy (Pilot P1 and P2). Among the information they sought about what is normal, participants wanted to know what they would encounter during each phase of labor and delivery and were looking for information such as how long to expect to push. A participant described learning about the phases during a digital birth-planning appointment:

[The digital appointment with the birth planning specialist] was very helpful to know what to expect at the hospital during birth, and actually I feel like they were more helpful than the in person doula that I hired...I remember them stepping through the birth process. You know, active labor and transition, the pushing and talking about the ring of fire. [P5]

<tbody>
<tr>
<td>During pregnancy</td>
<td></td>
</tr>
<tr>
<td>To know the size of my baby throughout pregnancy</td>
<td>“What is baby now today? Let’s see. I will also open the app up and see. So that was a good thing as well. So this is like ‘What vegetable is your baby right now?’” (P2)</td>
</tr>
<tr>
<td>To help me manage discomfort during pregnancy or postpartum</td>
<td>“[The digital resource helped with] cracked and bleeding nipples” (P9).</td>
</tr>
<tr>
<td>To become more empowered to speak up for myself during pregnancy and labor</td>
<td>“I read a ton of articles [online] because I felt like otherwise it was like the blind leading the blind. My husband had never done that before. I’m an only child like my mom was going to be there, but she hadn’t done it in thirty years. So it was kind of like, Okay, Who in this room knows what they’re doing? The answer was going to be nobody...So I read a lot just to know these are all the possible outcomes. This is how it might go. These are the things that I’m going to be asked, and I wanted to know, while I’m in a calm and sound state of mind, like is my answer Yes? Is my answer No? What are the implications if I say yes or no. And then [I can] communicate that to my partner and my mother. So if they needed to advocate for me [they could]” (P4).</td>
</tr>
<tr>
<td>To explore my options for labor and delivery</td>
<td>“[Exploring my labor and delivery options] I would say [getting support on Maven] helped a little but that was more so because of me, and I didn’t look into it as much as I should have...Because, I thought I would have a natural birth. But I ended up having a C section, but just not knowing what to expect, and more so it was on the process of like what an induction is, and like how your body would look like afterwards, because I didn’t get to in my entire pregnancy. But all the drugs they pumped into you to induce you caused me to blow up after, and I just didn't expect that, no one tells you, right? They just tell you to consent, and you say yes, so like all that, I wish I knew. But I don't think that I looked into it as much, because I just didn't know” (P8).</td>
</tr>
<tr>
<td>During the postpartum period</td>
<td></td>
</tr>
<tr>
<td>To help me with feeding my baby breast milk</td>
<td>“I didn’t see lactation consulting in person until after birth, which was at the pediatrics office. So it’s nice to have that, to be able to talk to one [online] beforehand, to know what to prepare for. And then also I talked to one after as well, after giving birth. That was super helpful” (P5).</td>
</tr>
<tr>
<td>To help me with my baby’s health issues</td>
<td>“[My baby] was very colicky, I took an [online] appointment and showed the doctor what was happening, so they also gave me a hint she might have a milk allergy, [and said to] check with your doctor and check the stools and all” (P2).</td>
</tr>
<tr>
<td>During pregnancy or the postpartum period</td>
<td></td>
</tr>
<tr>
<td>To know what is normal or typical during pregnancy or postpartum</td>
<td>“[Getting digital help on my baby’s sleep] helped a lot, because I had a lot of questions about what’s normal, what’s not normal and they answered everything. It made me feel like I wasn’t doing something bad” (P8).</td>
</tr>
<tr>
<td>To know how my baby is changing and developing during or after pregnancy</td>
<td>“I had like three apps on my phone to track [how my baby was changing] like every week” (P4).</td>
</tr>
<tr>
<td>To have access to a health care provider when I need them</td>
<td>“It wasn’t just 8 to 5 that I could access someone...The sleep consultant was like you can just message me any time, and I’ll respond and help you real time with what you need. That’s something that you can’t get with any in person care provider” (P3).</td>
</tr>
<tr>
<td>To help me with being physically active during pregnancy or the postpartum period</td>
<td>“I was trying to be physically active during pregnancy but then there were times where I stopped because of the spotting. They didn’t know what was going on. Then I found out it was okay. But then the last trimester it got tougher since I was tired a lot and having pain...It would have been nice to see what I could do, like modifications and exercises I could do around the pain I was having” (P5).</td>
</tr>
<tr>
<td>To help me with healthy eating during pregnancy or the postpartum period</td>
<td>“Just offering ideas of foods, more nutritious foods to eat, healthier options, because you can look around on the Internet but just talking to a person who is, you know, that’s their specialty, and you can give them personal information about yourself so they can help you” (P9).</td>
</tr>
<tr>
<td>To help me manage anxiety or depression</td>
<td>“I was in so much pain and I thought maybe [the baby will] be also in pain, or somehow it will affect the baby, because I’m not happy. So then I talked to [an online] doctor, and one of the doctors was very good and she talked to me more than the time of appointment, and she was very kind, and she said, I know how you are feeling, but she gave me so much support, emotional support, and she said, ‘You can come to talk to me anytime.’...So she then she assured me, ‘Everything is fine, and you don’t need to worry’” (P2).</td>
</tr>
<tr>
<td>To help me manage my health problems (chronic, ongoing, or related to pregnancy or postpartum)</td>
<td>“I have arthritis and Hashimoto. So two autoimmune diseases. So when I got pregnant, I had a lot of concerns about that, and how that would affect my pregnancy, or vice versa” (P8).</td>
</tr>
<tr>
<td>To get recommendations of things to buy to care for my baby or myself</td>
<td>“I’m a working mother. At the time, you know, working while pregnant, and so I didn’t have time to spend hours and hours going down the rabbit hole of like, this stroller versus that stroller. Like just like, tell me what you recommend, and we’re moving on. So it felt like the research had been done for you” (P4).</td>
</tr>
</tbody>
</table>
In interviews, participants talked about being able “to count on” accessing health care providers on the internet for urgent situations, such as a participant (P1) who used a digital health care provider when she did not feel her baby kick for a while and wanted to know whether she should go to the emergency room.

Almost all the participants talked about the importance of knowing how their baby was growing and developing during pregnancy. They described wanting to know about the development week by week and found that digital resources could easily provide this information.

In the survey, nulliparous respondents were more likely than parous respondents to find knowing what was normal (P=.004) and how their baby was developing (P=.06) to be extremely important (Table 2). Compared with non-Hispanic White respondents, respondents identifying as Hispanic or people of racial and ethnic minorities were more likely to report that digital health resources were extremely important for the management of anxiety or depression (P=.003) and chronic health problems (P=.002). Compared with respondents without a mental health history, respondents with a mental health history were more likely to find it important to receive web-based help with healthy eating during pregnancy (P=.04; Table 2).

Reasons for Use of Digital Resources During the Postpartum Period

On the basis of survey responses, during the postpartum period, the most important reasons for using digital resources were to help with feeding the baby breast milk, know what is normal baby development (eg, developmental milestones), help with the baby’s health issues, and help with feeding the baby solid foods (Table 4).

The reasons for using digital resources during the postpartum period were described in interviews (Table 3). When asked specifically about the use of digital health resources for help with feeding, interview participants primarily spoke about support for breastfeeding. In particular, participants found it valuable to connect with a lactation consultant during pregnancy to prepare for breastfeeding and during the postpartum period for tips that facilitated feeding:

I didn’t see lactation consulting in person until after birth, which was at the pediatrician’s office. So it’s nice to have that, to be able to talk to one [online] beforehand, to know what to prepare for. And then also I talked to one after as well, after giving birth. That was super helpful. Just things I could do for milk supply. And then the one major helpful thing that I learned is about the pump parts where I can just store them in the fridge, and I don’t have to wash it after every time, because it was a hassle, too. [P5]

In interviews, participants described using digital resources to know what to expect about life with a baby and to find out whether the things they encountered were normal, such as struggling with the baby’s sleep schedule, and what it is really like to breastfeed. Participants voiced frustration that this type of information was not provided by in-person providers, so they looked for answers on the internet:

They don’t tell you anything [at the hospital]. A big one for me was breastfeeding, like just how complex it is. There’s just so many things in the hospital they don’t tell you anything, either. They just ask you like, “Are you going to breastfeed, yes or no,” and you have to decide on the spot, and, like you don’t know anything about this. After that, coming home, I definitely did research on [a digital platform] and the resources that they had for help. [P8]

Participants also wanted digital resources to provide information on what is normal for babies as they grow, including what developmental milestones to expect at each age. A participant described using an app to know what to expect as her baby changed:

[There] is an app that when you put in the baby’s due date, this helps you to see your baby’s development, like milestone-wise. So week by week, you know some of the things to look for. And mainly I use it to see like, when are one of the cranky times coming up because they’re going through a milestone leap where they’re learning, you know lots of new things. [P9]

In interviews, participants provided anecdotes about the value of digital resources for helping with the baby’s health issues, especially the ability to access support when it is needed. A new parent described meeting with a digital sleep coach in the middle of the night when her baby would not sleep, a service she said she could not obtain from her in-person providers as they only handled emergencies after hours:

It wasn’t just 8 to 5 that I could access someone...The sleep consultant was like you can just message me any time, and I’ll respond and help you real time with
what you need. That’s something that you can’t get with any in-person care provider. If you call their after-hours number it’s because it’s an emergency right? Not because you are just, like, wondering why your baby is fussy, or awake window, or, you know whatever. [P3]

In the survey, nulliparous respondents were more likely than parous respondents to find it extremely important that digital resources help with feeding their baby solid food (P = .01) and with their own health problems (P = .06; Table 4). Respondents identifying as Hispanic or people of racial and ethnic minorities were more likely than non-Hispanic White respondents to report that it is extremely important that digital resources can be used to connect them with a community of people who have a baby of the same age (P = .02) and to obtain recommendations of things to buy to care for their baby or themselves (P = .08). Respondents with a mental health history were more likely than those without a mental health history to find it important to obtain web-based help with breastfeeding their baby (P = .01; Table 4).

</tbody>
</table>

a A total of 65.5% (72/110) of postpartum survey respondents provided parity or mental health data.

b Respondents who selected “I prefer not to say” for race and ethnicity were not included in this comparison.
The reasons for using digital resources that the fewest survey respondents selected as extremely important during the perinatal period were uses related to general wellness (ie, healthy eating, exercise, and losing weight), connecting with a community in the same perinatal stage, and obtaining recommendations of things to buy to care for their baby or themselves. Notably, these lowest-ranked reasons were still selected by 8.2% (9/110) to 22% (32/147) of the respondents (Tables 2 and 4).

In contrast to the surveys, help with healthy eating was one of the topics that the most interview participants identified as a reason for using digital resources, although it was usually in response to specifically being asked about it in the structured part of the interview. When discussing the use of digital resources for healthy eating, participants tended to refer to access to personalized information such as food recommendations that fit with their dietary restrictions. A participant described why tailored information would be helpful to her on a digital health platform:

> Because if I had dietary restrictions I’m going to have to go searching more for that information on my own. [P9]

### Importance of Digital Health Platform Features During Pregnancy and the Postpartum Period

The 3 most important features of digital health platforms identified through both the pregnancy and postpartum surveys were credible and trustworthy information and providers, digital resources that are free to the user, and nonjudgmental information and support. Although access to appointments (ie, fast access and access at convenient times) was not among the top 3 most important features, approximately half of the respondents felt that it was extremely important (Table 5). See Multimedia Appendices 1 and 2 for digital health platform features identified as extremely important by parity, mental health status, and race and ethnicity during pregnancy and the postpartum period, respectively.

Table 5. Digital health user experience features identified as extremely important during pregnancy and the postpartum period.

Interview participants described why the features of digital health resources were important (Textbox 1). When looking to interact with content that was trustworthy, participants mentioned a range of ways in which they determined whether digital content was credible. A couple of participants explained that they trusted the content if it was consistent with the information they received from their in-person providers. This was done by taking the information from the digital content to the in-person provider for verification or by seeing that the content was consistent with what they had already been told:

> Whatever I heard from the [web-based] doctor, it was matching with my experience and my other doctor as well...it builds trust since my doctor is saying the same thing. [P2]

> So it was like things that the [web-based] practitioner might have suggested or recommended that I would then mention at my doctor’s appointment...kind of to get a check box from my regular doctor, but it was always like, she agreed with what had been communicated. [P4]
## Textbox 1. Illustrative quotes regarding features of digital health resources (pregnancy and postpartum interviews).

### Credible and trustworthy information and providers
- “Sleep schedules, again, with so much information online, you get really caught up in, like, ‘Am I doing the right thing?’ especially in the beginning. I remember one thing, I was struggling with my baby’s sleep schedule. And so I went to this sleep expert from [my digital platform]. And they said that’s normal, like, a baby shouldn’t really have a sleep schedule until six months. They’ll never have one, and it’s like everything online, says the opposite! So just like having information that is accurate and like coming from experts [really helped]” (P8).

### Digital resources that are free to me
- “But because this service was free to me I felt like ‘well, it’s there, and I might as well use it,’ so I’ve taken advantage of it” (P3).

### Nonjudgmental information and support
- “And these platforms really help because, one, you’re able to speak to someone different that may not even have your medical history. They don’t have your medical history in front of you. So maybe it’s the medical system, health care system thinking or judging you based on your history, right, rather than just listening to this specific one time incident. So maybe they’re less biased ‘cause they just have the one thing they’re looking at” (P8).

### Fast access to appointments
- “If I’m struggling with a situation that I think is super important with the baby like the baby has a cold and has a runny nose, fever, I’m gonna want whoever is available next” (P9).

### Easy to find information; easy to navigate
- “[My app] did not help [for finding information on baby’s development] because the information, I guess I didn’t seek it out, but I also didn’t see it readily available” (P9).

### Access to appointments at convenient times
- “Especially for a new mom, if you’re trying to work around is my baby napping or not, and that’s not always predictable, just to be able to quickly touch base with someone. I used it during pregnancy as well, so I feel it kind of rounds out the care you are receiving from your in person doctor” (P4).

### Information that is actionable (specific recommendations for what to do)
- “In my state it is legal to end the pregnancy, right? So [the online provider] gave me the support that if you want to go for this, this will happen, or if you go, these are the steps you need to follow, and all...She was telling me all the steps, what I need to do, and what I not to do, and she gave me a support for keeping this pregnancy” (P2).

### Receive fast responses to my digital messages
- “When I messaged, it wasn’t always [the same person] that responded, it was someone else. But it’s nice to have that, too. Like, someone quickly getting back to me. So I didn’t mind that” (P5).

### Resources that are specific to my needs (personalized)
- “Because if I had dietary restrictions I’m going to have to go searching more for that information on my own. [And it would be helpful to] come up with a list of foods that would be specific to me, because we didn’t do that. I realized that may be asking a lot of someone. But that's just what I see would be super helpful” (P9).

### Access to a lot of information on each topic (depth of information)
- “I like the options when I went in, and I would read through an article. It’s like, Oh, here’s some other related stuff to this. If you’re still interested, I really like that because there was a couple of times with a few articles where, like I want to know more about this, and so I would keep clicking and read a little bit more” (P6).

### Access to information on a lot of topics (breadth of topics)
- “[It would help if the platform had], like, a more robust portfolio of different like classes and articles” (P4).

### Consistent care or support from the same people over time on the digital platform
- “The sleep coach that I am talking to now. She’s the same one I’ve talked to every single time...[It’s important to have continuity], especially just like to not have to answer the same questions over and over again, like they just kind of know who I am, looking for me, my style, and just more get to the care rather than have to do the basic information each session” (P3).

### Proactive outreach from the digital resource (pushes content to me; provider reaches out to me)
- “One thing I like about the Baby Center or a lot of the articles I get from other providers is that they’re just in the email, and I don’t have to go anywhere” (P7).
Others said that they trusted digital content that was reviewed by medical professionals (Pilot P3) or had a “provider stamp of approval” (P9). A couple of participants were looking for digital resources that provided information from the people who conducted the research (P8) and that included “the latest research and peer reviewed evaluation” (P3).

In interviews, participants explained that access to free digital health services enables users to consume more health resources and spend more time interacting with health care providers than during in-person appointments:

> [When there are] no limit on appointments...suppose I forgot something and I want another appointment and I can do it today. I don’t have to wait for another appointment. [P2]

They also accessed types of resources that they valued but would not use if there was an out-of-pocket cost:

> So I think I just wouldn’t have gotten what I needed [in-person] because I have two other children, and I didn’t [get what I needed] with them. Just, like you know, Google things or Pinterest, or talk to friends, and that’s it. But because this service was free to me I felt like “well, it’s there, and I might as well use it,” so I’ve taken advantage of it. And so things like a sleep consultant I probably wouldn’t have paid for. But it was just so nice to have a sounding board...So yeah, I think just having services there that I wouldn’t have made the effort to use before, but because they’re just sitting there on my phone, I might as well, and it’s free to me. [P3]

Participants highlighted that free digital resources are particularly important as the cost of in-person services is very high and they were looking for a cheaper alternative:

> Free resources—that’s big, since in person visits are so expensive. [P5]

Interview participants also wanted to interact with digital health content and people who provided information and support without judgment. A participant explained that it is easier to receive nonjudgmental care from a digital health care provider as the person only knows the information that is being shared in the moment and cannot be biased by previous interactions or conditions. Another participant explained that she did not want to discuss her baby’s sleep issues with her in-person pediatrician as she was worried that the physician would judge her as a bad mother. It felt safer to explore the problem with the web-based provider, with whom she did not have an ongoing relationship (Pilot P4).

Interview participants shared anecdotes illustrating the accessibility of web-based providers and described connecting with these providers at night and on weekends or around their work or family schedules:

> Whereas in person, they’re always busy. So there’s some waiting time...If I had concerns, I want to consult with somebody...[it’s] very helpful where I can just find someone to talk to within the week, sometimes even the same day...Being able to get in touch with someone quickly during pregnancy and even postpartum has been super helpful. [P5]

> There was one time where I had a concern and it was 2AM and I reached out to a practitioner over the phone, it might have been with Maven or it might have been with Telehealth, and [I had] flexibility with getting help at abnormal times of day. [P8]

In general, the importance of digital health platform features was consistent by race, parity, and mental health. Differences emerged for free resources, which were more important to respondents without a mental health history compared with those with a mental health history (\(P=.02\)), and consistent care from the same people over time on the digital platform (\(P=.01\)) and access to information on a lot of topics (\(P=.02\)) were more important for Hispanic and people of racial and ethnic minorities respondents than for non-Hispanic White respondents.

For both pregnant and postpartum survey respondents, the 2 least important features were care or content that fit with their culture and identity and proactive outreach from the digital resources. These features were selected as extremely important by less than 20% of respondents. In interviews, participants described experiences on digital health platforms that were enhanced by resources and support that were respectful of and relevant to their culture or identity. When specifically asked about the importance of digital health resources that “take their whole identity into account,” participants consistently interpreted this to be about race, ethnicity, and gender or sexual identity, and participants from non–historically marginalized populations tended to report that inclusion was not relevant for them. This emerged in comments such as “Personally, I’m a woman, heterosexual, so I fit in fine, more than fine” (Pilot P1) and “[Health care is] not hard for me to navigate as a straight, White woman” (Pilot P3). However, as they shared anecdotes about their use of digital health platforms, they described experiences that were meaningfully inclusive (or noninclusive) related to other characteristics, such as their lifestyle (eg, family structure, work choices, and how they cared for their child) or religious practices. A participant appreciated that a nutritionist took the time to accommodate the fact that she kept kosher and “went above and beyond to research kosher supplements and make sure they were appropriate” for her to take (Pilot P2), and a working mother described her appreciation for resources that recognized her more limited availability to be with her children:

> "The [online doctor] knew Indian culture. So they knew Indian body like how our body reacts after [giving birth]. We are different than other people. So by giving specific things or a suggestion to Indians that is specific to my body, like after delivery, Indians don’t drink too much water. They understand, but my [in-person] doctor will say, drink four litre five litre today. I know so but one of the doctor on Maven when I talk, she said, I know the Indian people don’t drink too much water just after delivery, so I understand that. So if you want to have less water, so you can have a coconut water instead of normal water that will increase the hydration. So that kind of suggestion I don’t get from normal doctor” (P2).
I’m probably in the majority, for most of the like, you know, bubbles you would fill in of race, gender, like I’m not a minority in any of those, but I think that everyone was just very respectful...maybe because they got to just like learn a little bit about me. [P3]

People of racial and ethnic minorities participants appreciated when there were racially diverse providers on the platform. Even though the participants did not necessarily choose to interact with a member of their ethnicity or race, they valued the presence of diversity:

I felt included throughout the process. I think even seeing the diversity of the people you can choose for a specific topic also helps just, like, feel more included, like just her background. I am Mexican American. So I was born in the US but Mexican background. And so just seeing the diversity on the team was important to me. [P8]

Discussion

Principal Findings in Relation to Prior Research

This mixed methods study found that the reasons why perinatal people use digital resources are consistent with previous research. During pregnancy, our survey and interview participants were highly interested in fetal development [10,11,16,18,20,21], reassurance about what is normal [5,16,17,38], and childbirth [10,11,20,21,39], although in our study, the latter topic was not among the top reasons for use. Unlike other studies, we found less interest in health and nutrition during pregnancy. During the postpartum period, our results were concordant with those of previous research with regard to users having a high interest in feeding, especially breastfeeding; developmental milestones; and the baby’s health [18,19,21]. Although interest in infant sleep is also common in the literature [18,19], we did not explicitly ask about this. However, this need is consistent with our overall finding that respondents were looking for information about caring for their baby and with anecdotes in our interviews that centered on infant sleep when participants discussed wanting to know what is normal, reaching out to digital providers at night, and receiving nonjudgmental support. We found an especially high interest in using digital resources for breastfeeding help among respondents with a mental health history (17/20, 85%), which is consistent with studies showing an association between maternal anxiety and breastfeeding outcomes [40-42]. Aligning with findings from content analyses of perinatal forums, top interests included baby-related topics and pain during pregnancy [17,19], but we found less interest in using digital resources for the health of the birthing person, and we did not ask about relationships (a common topic in web-based perinatal forums [17,19]) as this did not emerge as a key interest during the formative interviews. In addition to finding many of the same known reasons for using digital resources, we found that using these resources to help manage anxiety or depression was commonly selected as extremely important (55/147, 37.4% during pregnancy and 45/110, 40.9% during the postpartum period), especially for people of racial and ethnic minorities during pregnancy (21/35, 60%).

Our survey identified that, during the postpartum period, reasons for using digital resources related to the health of the birthing person were ranked lower than reasons related to obtaining information or help about the baby. This aligns with findings that mothers tend to focus on their babies and deprioritize their own needs [43]. However, there are physical and emotional challenges during the fourth trimester that often go unaddressed and can negatively affect maternal and child outcomes [44,45]. Contributing to underuse is a misalignment between the issues being addressed by providers and the birthing person’s needs, discomfort with discussing “embarrassing” issues with providers and feeling judged by them, and not knowing where to access information [43,46,47]. Digital health resources provide an opportunity for birthing people to be more in control of when, how, and for which needs they access self-care resources. Even though self-care may not be the primary priority for using digital health resources, making these supports available is valuable for those times when the birthing person is ready and interested in using them.

Emerging from both our surveys and interviews was the preference for using digital health resources to access providers. The characteristics that make digitally based providers helpful are differentiators from in-person care, with providers on platforms being reported as spending more time, focusing on issues and questions that matter to the user, and providing support quickly and conveniently [48-50]. Although study participants were explicitly asked about what is important to them when using digital health resources in general, they all had access to Maven, which offers access to a wide range of provider services. Study participants may have been more likely to express the importance of digitally based providers as they had the opportunity to use them during their perinatal stage. Users of digital health services who do not have access to digitally based providers may not identify them as important as they have not had the opportunity to experience their value. Although our results may not replicate those among digital health users who have not had access to these providers, this does not mean that digitally based providers are not an important part of what should be offered in digital health. Rather, it is an opportunity to meet a need that people may not realize they have.

Generally, the needs and preferences for perinatal digital resource use did not show much variation by perinatal phase (pregnancy vs postpartum), parity, demographics, or health characteristics. The least important reasons for use were the same during pregnancy and the postpartum period: help with healthy eating and being physically active (and, for the postpartum period, help with losing weight), connecting with a community of people in the same perinatal stage, and obtaining recommendations of things to buy to care for the birthing person or baby. Platform features were ranked in generally the same order during pregnancy and the postpartum period. However, there seems to be a difference in the overall importance of information during pregnancy versus the postpartum period, with reasons for using digital resources being selected as extremely important by a greater percentage of respondents during pregnancy than post partum. During pregnancy, the only reasons for using digital resources that differed by race were...

(page number not for citation purposes)
non–pregnancy-related (help with managing mental health and physical health problems), which may reflect gaps in in-person care for people of racial and ethnic minorities [51,52]. In interviews, we found a difference in participants who said that care or content that fits with their cultural, racial, or ethnic identity was important to them, with people of racial and ethnic minorities describing the value of being able to access providers with a shared identity or who provided culturally relevant support, whereas non-Hispanic White participants tended to say that this was not relevant to them. We were surprised that we did not find this difference in the surveys. A possible reason for this discrepancy is that our survey analysis focused on “extremely important” responses, and it may be that culturally relevant support is important but not extremely important. This would align with comments in the interviews about liking that providers of the same race were available even if they did not choose to use these providers.

This study included a national sample from the United States. Although our sample underrepresented people who identify as Black and Hispanic and lower-income people, it includes a significant portion of sustained users of digital resources (based on their completion of questionnaires on the Maven platform at multiple time points throughout pregnancy and the postpartum period), which is valuable as they represent people who will often use digital resources and have the potential to be significantly helped and supported by them. However, future research should also explore these topics among lower-frequency users to identify and understand barriers or deficiencies in the resources that may be contributing to reduced use.

This study adds to existing research by linking survey responses to other pregnancy, health, and demographic data about the respondents. Psychological states and mental health, especially perinatal anxiety, in relation to digital use are understudied [20], as are race and ethnicity. This formative research found only minor differences in digital resource needs and preferences across several user characteristics, including perinatal phase, parity, demographics, and mental and chronic health conditions. If this finding holds up in additional research, it has implications for the design of digital resources as it suggests that it may be appropriate to cover the same high-level perinatal topics for users across these groups. However, additional research is needed to better understand whether the content within these topics needs to be tailored to different populations. For example, future research could find that, although it is appropriate to include resources on childbirth for all users, there may be a need for more information about birthing centers in resources targeting Black pregnant people. Additional insights that are needed to improve the relevance and impact of these resources include understanding the use of the internet by nonbirthing partners [20] and the impact of use on clinical outcomes and user satisfaction [51]. There is also an opportunity to develop a standardized set of methods and metrics for assessing perinatal digital resources [4].

Limitations
This study has some limitations. First, the generalizability of these results is limited as all survey and interview participants had access to private insurance, the sample had a relatively high income, and Hispanic and Black respondents were underrepresented. Second, there was a high amount of missingness within our race and ethnicity data from respondents selecting that they prefer not to provide this information (17/110, 15.5% and 35/147, 23.8% for postpartum and pregnancy survey respondents, respectively). This missingness may limit the reliability of our results regarding differences in digital needs by race. Finally, not all survey respondents completed the Maven questionnaires, and those who did not complete at least one Maven questionnaire were excluded from the analyses of the survey. This potentially biased the sample toward heavier users of digital resources, although this creates an opportunity to understand use needs among this segment of users.

Data Availability
Owing to the sensitive nature of the questions asked in this study, respondents were assured that raw data would remain confidential but may be shared upon request.

Conflicts of Interest
NH, AB, AA, and HRJ are employed by Maven Clinic. NH, AA, and HRJ have equity in Maven Clinic.

Abstract

Background: Suicide rates in the United States have increased recently among Black men. To address this public health crisis, smartphone-based ecological momentary assessment (EMA) platforms are a promising way to collect dynamic, real-time data that can help improve suicide prevention efforts. Despite the promise of this methodology, little is known about its suitability in detecting experiences related to suicidal thoughts and behavior (STB) among Black men.

Objective: This study aims to clarify the acceptability and feasibility of using smartphone-based EMA through a pilot study that assesses the user experience among Black men.

Methods: We recruited Black men aged 18 years and older using the MyChart patient portal messaging (the patient-facing side of the Epic electronic medical record system) or outpatient provider referrals. Eligible participants self-identified as Black men with a previous history of STB and ownership of an Android or iOS smartphone. Eligible participants completed a 7-day smartphone-based EMA study. They received a prompt 4 times per day to complete a brief survey detailing their STB, as well as proximal risk factors, such as depression, social isolation, and feeling like a burden to others. At the conclusion of each day, participants also received a daily diary survey detailing their sleep quality and their daily experiences of everyday discrimination. Participants completed a semistructured exit interview of 60-90 minutes at the study’s conclusion.

Results: In total, 10 participants completed 166 EMA surveys and 39 daily diary entries. A total of 4 of the 10 participants completed 75% (21/28) or more of the EMA surveys, while 9 (90%) out of 10 completed 25% (7/28) or more. The average completion rate of all surveys was 58% (20.3/35), with a minimum of 17% (6/35) and maximum of 100% (35/35). A total of 4 (40%) out of 10 participants completed daily diary entries for the full pilot study. No safety-related incidents were reported. On average, participants took 2.08 minutes to complete EMA prompts and 2.72 minutes for daily diary surveys. Our qualitative results generally affirm the acceptability and feasibility of the study procedures, but the participants noted difficulties with the technology and the redundancy of the survey questions. Emerging themes also addressed issues such as reduced EMA survey compliance and diminished mood related to deficit-framed questions related to suicide.
Conclusions: Findings from this study will be used to clarify the suitability of EMA for Black men. Overall, our EMA pilot study demonstrated mixed feasibility and acceptability when delivered through smartphone-based apps to Black men. Specific recommendations are provided for managing safety within these study designs and for refinements in future intervention and implementation science research.

Introduction
Suicide among Black Americans is a critical public health priority that requires immediate attention. Studies have shown that suicide rates among this population are increasing and that Black men, in particular, are at a higher risk of suicide-related mortality [1,2]. It is crucial for public health efforts to prioritize suicide prevention in the Black community and address the systemic issues that contribute to mental health disparities [1,2]. Epidemiological data reveal that Black men die by suicide at rates 4 to 6 times greater than Black women and that suicide is the third leading cause of death for young Black men [2,3]. While nationwide suicide rates provide a broader perspective on this alarming public health issue, delving into state-specific data, such as in Maryland between 2016 and 2020, reveal a localized increase in suicide death for Black Americans, compared to their White counterparts and highlights the urgent need for tailored research priorities [4]. The COVID-19 pandemic further exacerbated these alarming trends, with Black Marylanders experiencing an uptick in suicide deaths during the initial lockdown periods in the United States [5]. These national and state-specific trends highlight the pressing need to address more robust approaches to suicide prevention, emphasizing the importance of ensuring equitable access to support and resources for all communities.

Mental health disorders, such as depression and substance use, are known risk factors for suicide among Black Americans [6,7], but recent research also highlights racism and associated contextual stressors as important, but underresearched, explanatory risk factors for suicidal thoughts and behaviors (STB) among Black adults [8-10]. Previous studies have demonstrated the significant impact of racism and associated daily stressors on mental health outcomes, including depression, anxiety, sleep disturbances, and posttraumatic stress disorder (PTSD), among Black individuals [11-15]. However, the emerging research highlights the need to examine the specific ways in which racism contributes to STB among this population. Further research in this area is crucial to identify effective prevention strategies that can reduce the impact of racism and mitigate the rising trend of suicide completion among Black adults.

Black Americans also face significant barriers in accessing mental health care due to stigma, systemic lack of access to services, and cultural mistrust [16-19]. Although Black men are approximately 30% more likely to report having a mental health condition compared to non-Hispanic White individuals [20], they also have significantly lower percentages of mental health-related visits prior to a suicide attempt than men of other racial and ethnic backgrounds and Black women [21,22]. In addition, traditional clinical records used to assess suicide risk and prevention often rely on distal and static measures of risk, such as prior diagnoses and family history, which may overlook the dynamic interplay of proximal factors that contribute to STB and patient-provider synergy. Consequentially, while Black Americans face considerable obstacles in accessing mental health care, these disparities are particularly pronounced among Black men, highlighting the urgency of addressing these disparities and adopting approaches to assess more proximal aspects of suicide risk and prevention.

Smartphone-based ecological momentary assessment (EMA) platforms are one such approach to collect dynamic, real-time data and encompass a range of different active and passive information, including, but not limited to, spatial trajectories (via GPS), physical mobility patterns (via accelerometer), social networks and social dynamics (via call and text logs and Bluetooth), and EMA surveys [23-25]. Understanding dynamic risk in suicide prevention efforts is important since decades of previous research have shown that single, static risk factors often add little to our understanding of who is at elevated risk and when [26]. More real-time data on STB may also provide key information about when to intervene with potential just-in-time interventions.

Although participant burden, noncompliance, and reactivity to the protocol measures have been cited as potential limitations to EMA approaches, studies using this methodology to assess STB demonstrate a favorable median response rate of 70%, suggesting feasibility [25,27-30]. These studies highlight the potential of EMA as a tool for capturing the complexity and variability of STB, ultimately aiding efforts to improve mental health outcomes. Specifically, one systematic review of EMA studies found suicidality fluctuates considerably over short periods of time and that those with higher levels of overall suicidality also have more fluctuations [27]. This review also noted risk factors such as negative affect, hopelessness, burdensomeness, and sleep characteristics that impacted suicidality [27]. In a sample of psychiatric inpatients, a separate study discovered that the use of real-time data collections significantly enhanced the accuracy of predictions for suicide attempts post-discharge [31]. Despite the promise of this methodology for the study and prevention of suicide [25,29,32], there has been no study, to date, that uses this approach to assess experiences among Black men at critical periods for early
intervention [26]. Black men face daily societal and cultural stressors that may contribute to their heightened risk of suicide, including but not limited to, systemic and interpersonal racism, economic disparities, and limited access to mental health resources [8,33,34]. To address this gap, additional research is needed to clarify the efficacy of EMA monitoring as a suicide prevention tool for this at-risk population.

Methods

Eligibility and Recruitment Procedures

We recruited adult Black or African American men (18 years of age or older) with a lifetime history of suicidal ideation or attempt residing in Maryland counties where mobile crisis support was available. To be eligible, participants had to (1) own a smartphone and (2) not be present with active psychosis or cognitive deficits. We used two recruitment approaches: (1) providing recruitment information to eligible, active patients via the Johns Hopkins Health MyChart, the web-based patient portal of the Epic electronic medical record system that allows for health communication between patients and health care providers and (2) clinician referral. Participants who met the eligibility criteria through either of these approaches were referred to the study coordinator and were required to complete a screening survey to confirm their interest and eligibility.

Ethical Considerations

The study was approved by the institutional review boards of Johns Hopkins Bloomberg School of Public Health (IRB 00013672). All participants were provided detailed information about the study procedures and expectations, risks, and benefits as part of the informed consent process conducted by a research coordinator.

Baseline Survey

We asked enrolled participants to complete a brief baseline assessment including demographics and psychosocial measures associated with affective, gender, and race-specific factors associated with STB, such as anger, sadness, attributional style, and racial identity. A complete list of baseline measures is described elsewhere. During the informed consent process, participants received an overview of the MetricWire smartphone app from the study coordinator. The study coordinator also determined the county in which the participant resided, in order to align our safety protocol with mobile health crisis units in their area. After completion of the baseline survey, we asked participants to download the MetricWire app onto their personal smartphones for the duration of the study. The MetricWire app is available for both iOS and Android smartphone platforms at no cost in the Apple App Store (Apple Inc) or Google Play Store (Google), respectively. Examples of the user interface of the MetricWire app are presented in Figure 1.

Figure 1. Screenshot of suicidal ideation and intensity questions on the ecological momentary assessment user interface. CSSR: Columbia Suicide Severity Rating Scale.

EMA and Daily Diary Data Collection Procedures

This study used the MetricWire app to deliver daily EMA surveys to participants at 4 time points between 10 AM and 6 PM. Each of the prompts was designed to occur at least 2 hours after the previous prompt and included 3 push notification reminders at 20, 40, and 55 minutes after the initial prompt. If the participant did not complete the EMA survey within 60 minutes, it was marked as incomplete. The EMA surveys were designed to be brief and take no more than 3 minutes to complete to reduce respondent burden. To capture instances of racism-related stressors occurring outside of the random EMA survey prompts, participants were allowed to record event-driven entries detailing their daily experiences (see Figure 2).
We administered a brief daily diary survey via the MetricWire app once per day to assess participants’ everyday experiences, including sleep-related impairment and quality, as well as their daily experiences with racism-related stress. The daily diary was prompted each day at 8 PM. This survey was not designed to capture momentary instances but rather to provide a more comprehensive picture of participants’ daily experiences.

**Exit Interview**

After the 7-day data collection period, each participant underwent a qualitative semistructured exit interview conducted by the study team. The interviews probed participants on issues such as question difficulty and clarity, potential revisions to question prompts, and overall satisfaction with the study protocol and EMA surveys. Verbatim transcripts of the recorded interviews were produced and analyzed to evaluate the feasibility and effectiveness of the study protocol.

**Participant Incentives**

To encourage higher EMA survey completion rates, participants were eligible to receive up to US $110 throughout the study duration. The incentive was incrementally phased, with participants receiving US $10 after completing the baseline survey, US $20 for completing 20% (7/35) of all surveys, US $50 for completing 50% (17.5/35) of all surveys, and US $80 for completing 80% (28/35) of all surveys. We offered an additional US $20 for the completion of the exit interview.

**Safety Protocols**

Upon enrollment, we provided participants with a document containing information about local and national mental health resources, including suicide crisis hotlines, to support their well-being throughout the study. To ensure participant safety during the data collection period, we implemented a 3-tiered safety protocol. Moderate risk, which is defined as any suicidal ideations (“Have you had thoughts of killing yourself?”), since the last assessment, but without any plan or intent, resulted in a notification to the participant guiding them to the online support groups and community-based mental health services and urging them to seek support. Elevated risk, defined as suicidal ideation with intent or a plan within the last 24 hours (“Have you planned out how you would do it?” or “When you thought about making yourself not alive anymore, did you think that this was something you might actually do?”), resulted in the same notification that was given to participants with moderate risk and participants will be asked if they would like to handle the matter themselves or if they would like us to contact a mobile crisis response unit in their area on their behalf. Acute risk, defined as suicidal ideation with an action since the last assessment ("Did you do anything to make yourself not alive anymore or kill yourself?"), resulted in a call to the participant’s closest mobile crisis response unit made by a member of the study team on the participant’s behalf. To protect participant privacy, data were not stored on their smartphones. Instead, survey response data were automatically synced to the MetricWire servers when participants were connected to the internet.
internet, and encrypted response data were stored until the next connection. These servers were continuously backed up.

To provide additional support, all research personnel interacting with participants received training in psychological first aid to assist with identifying any mental health needs. EMA responses were closely monitored by the study coordinator and regular updates were provided during biweekly research team meetings between January 2022 and May 2023.

Quantitative and Qualitative Data Analysis

To measure the acceptability and feasibility of the EMA method, we tracked four key metrics using Excel (Microsoft): (1) the proportion of eligible patients who enrolled in the study, (2) the percentage of completed EMA sessions out of the total number of scheduled sessions, (3) the number of safety-related incidents reported to mobile health crisis support teams, and (4) the average time taken to complete the EMA surveys.

Semistructured exit interviews were audio recorded and transcribed verbatim by the research team. The transcripts were then imported into Dedoose (version 8; Sociocultural Research Consultants, LLC) qualitative data analysis software for analysis. A deductive coding framework was used based on previous conceptual definitions related to implementation science. The research team independently reviewed the transcripts and generated a preliminary codebook based on a priori concepts. These concepts focused on prevailing definitions of acceptability, feasibility, adoption, and fidelity to the EMA methodology.

Results

Demographics

Participants ranged from 18 to 34 years of age, with an average age of 27 (SD 5.31) years. The majority (4/10, 40%) of our sample had completed a high school degree, followed by an associate or bachelor’s degree (n=2, 20%), while some completed high school (n=1, 10%), college (n=2, 20%), and a master’s degree (n=1, 10%). Participants lived across 3 counties in Maryland, including Baltimore, Anne Arundel, and Howard. Furthermore, participants identified as a spectrum of sexual orientations, including heterosexual (n=3, 30%), gay (n=2, 20%), bisexual (n=1, 10%), pansexual (n=2, 20%), and questioning (n=1, 10%). One participant chose not to disclose his sexual orientation.

Feasibility of EMA and Daily Diary

The MyChart recruitment service identified and sent study information to 744 active patients residing in Maryland. A total of 58 individuals completed our interest survey. Of those, 53 (91%) were attributed to the MyChart recruitment service. Three submissions were from clinician referrals and 2 were from community outreach events. Out of the 58 individuals completing the interest survey, 10 (17%) participants were enrolled in the EMA study. The primary reasons for exclusion after completing the interest survey were active psychosis (n=19) and no history of suicidal thoughts or behavior (n=10). A total of 7 individuals were excluded because they reported having no mental health care provider.

The 10 enrolled participants completed 166 EMA surveys and 39 daily diary entries. A total of 4 (40%) out of 10 participants completed 75% (21/28) or more of the EMA surveys. The average completion rate of all surveys was 58% (20.3/35), with a minimum of 17% (6/35), and maximum of 100% (35/35). A total of 4 (40%) out of 10 participants completed at least 5 out of 7 daily diary entries. The response rate for each day of the week ranged from 64% (3.2 surveys submitted on average; day 1) to 54% (2.7 surveys submitted on average; days 6 and 7). All 10 participants completed qualitative exit interviews at the conclusion of the study. There were no safety-related incidents that required mobile health crisis service response teams. On average, participants took 2 minutes and 5 seconds to complete EMA surveys and 2 minutes and 43 seconds to complete daily diary surveys.

Qualitative Findings From Exit Interviews

After coding, several key themes arose, including the study implementation, the iatrogenic effects of repeated suicidality assessments, and strategies to improve usability and effectiveness in suicide-related smartphone app development for Black men. We present key details and findings on these themes as follows.

Study Implementation

Table 1 shows representative quotes that illustrate participant perspectives on adoption, acceptability, and feasibility to the study protocol.
Table 1. Qualitative codes and selected quotations related to implementation of smartphone-based ecological momentary assessment study.

<tbody>
<tr>
<td>Acceptability</td>
<td>• “They’re good questions. It makes sense. It’s exactly the information that you’d be looking for.” [Participant 1]</td>
<td>• “The only thing that I can really think of as far as that is the hours...Maybe they’re asleep, maybe they’re working etc., etc.” [Participant 1]</td>
</tr>
<tr>
<td></td>
<td>• “I like how it did call my therapist, because I finally set up a meeting with her. But she, you know, was like, ‘Hey, um, you know, come in contact with me, because I know you’re not doing well.’ And I was like, ‘Yeah, that’s fair.’” [Participant 2]</td>
<td>• “I thought it shouldn’t have been the same questions. It got boring and repetitive and seemed like more of a hassle than something that was going to help me, because it’s annoying now, because it’s the same questions.” [Participant 5]</td>
</tr>
<tr>
<td></td>
<td>• “I thought the questions were pretty straightforward.” [Participant 4]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• “I think for the most part, it was good, it was self-explanatory. It was easy to get to.” [Participant 5]</td>
<td></td>
</tr>
<tr>
<td>Feasibility</td>
<td>• “What were your opinions regarding you know, how many surveys you got per day?” [Moderator]</td>
<td>• “The wording was, yeah, as I was saying before, it was very, extremely clinical, which I mean, you’re not really supposed to be beating around the bush as far as the stuff is concerned.” [Participant 1]</td>
</tr>
<tr>
<td></td>
<td>• “Um, that was fine. I was. I’m not sure if you remember, but I was a bit wary beforehand. I was worried that it might be a little bit too many, but no, it was fine. The amount was perfectly okay. The timing was fine too. Yeah, the timing was definitely fine as well.” [Participant 1]</td>
<td>• Regarding racial stress record: “I really don’t like the sound of my voice...like, ugh, don’t like that, and eventually just stopped doing them. Because it’s just like, it’s easier to like, write things down. I guess.” [Participant 2]</td>
</tr>
<tr>
<td></td>
<td>• “The only thing that I can really think of as far as that is the hours but as I had mentioned, before we even started this, anyone who’s downloading this resource is probably doing it with the intention on actually utilizing it. So I can’t really see someone actively like disregarding the surveys, unless they either don’t notice them or, well, yeah, unless they don’t notice them or somehow it slips past their schedule. Maybe they’re asleep, maybe they’re working etc., etc.” [Participant 1]</td>
<td>• “Sometimes you miss an alert and yeah and that would be like, all day, that was my main focus, like oh my God, I got to remember my survey or whatever.” [Participant 5]</td>
</tr>
<tr>
<td>Fidelity</td>
<td>• Prompts to complete surveys: “It was good, because some days I will remember, I have to take the survey so such and such time but other days, I wouldn’t to remember. I’m glad they, the prompts you know, were there.” [Participant 6]</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Fidelity</td>
<td>• Timing of prompts: “I’m not sure if you remember, but I was a bit wary beforehand. I was worried that it might be a little bit too many, but no, it was fine. The amount was perfectly okay. The timing was fine too. Yeah, the timing was definitely fine as well.” [Participant 1]</td>
<td>“One of the things that was a little annoying was like oh, it would crash on me a lot. So I would have to re-open it, but when I would re-open it, it would take me right back to the question that it crashed on me on. So, I was like, ‘Oh, okay, that was convenient.’” [Participant 4]</td>
</tr>
<tr>
<td></td>
<td>• Completing racial stress record in a predominantly Black neighborhood: “I normally don’t go through racial stuff, like I’m in a neighborhood is predominately Black. I see one White person a day, maybe.” [Participant 5]</td>
<td>• “it seemed like every time I tried to open the app, it wouldn’t even open, like sometimes it...ugh like it was so frustrating, so I just wouldn’t try to do it for a while.” [Participant 6]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Lack of use due to app issues: “I didn’t always have like issues as far as that’s concerned, I didn’t really use it very often, explicitly, because around the time that I was doing the, well, around the time that I was, you know, taking part in this study, it was out of work.” [Participant 1]</td>
</tr>
<tr>
<td>Appropriateness</td>
<td>• Intention influenced by number of prompts: “It’s not like, something like a text or the person will later call me and be like, ‘Hey, did you see my text?’ I’ll probably completely forget it exists, which I think is what I did for like a lot of the surveys.” [Participant 2]</td>
<td>N/A</td>

<td>N/A</td>
</tr>
<tr>
<td></td>
<td>• “I think that the first couple of questions are pretty intense ones. So, what was interesting for me at first—which I was having like a very good week, so the questions were a little bit jarring almost, if you’re like, in the middle of a good day, and then you get those questions.” [Participant 8]</td>
<td>N/A</td>
</tr>
</tbody>
</table>

*Note: N/A: not applicable.*
Overall, participants found the frequency and timing of the EMA survey prompts to be appropriate. One participant commented that the questions provided “exactly the information needed,” while another appreciated the reminder to contact their therapist. Participants generally found the questions straightforward and easy to understand, and the survey itself was considered self-explanatory and easy to access. Participant I noted that they were initially concerned about the number of prompts, but ultimately found them to be manageable:

I’m not sure if you remember, but I was a bit wary beforehand. I was worried that it might be a little bit too many, but no, it was fine. The amount was perfectly okay. The timing was fine too.

However, some participants reported feeling that the racial stress record and daily diary questions regarding discrimination may not have been relevant to their daily experiences.

I normally don’t go through racial stuff, like I’m in a neighborhood that is predominantly Black. I see one White person a day, maybe. [Participant 5]

Our study identified some challenges related to technology issues that impacted the fidelity of our study implementation and, ultimately, participants’ ability to complete the surveys in a timely manner. Participants identified app crashes as a significant issue, which led to frustration and difficulty in completing the surveys.

One of the things that was a little annoying was like oh, it would crash on me a lot. So I would have to re-open it, but when I would re-open it, it would take me right back to the question that it crashed on me on. So, I was like, “Oh, okay, that was convenient.” [Participant 4]

This issue not only caused inconvenience but also resulted in participants potentially losing progress on their survey responses. Consequently, this problem may have discouraged some participants from continuing with the study.

Influence of Mood on EMA Compliance

The narratives shared by the participants highlighted the possibility of diminished effect resulting from frequent evaluations of suicidality, which could potentially exacerbate negative mental health outcomes. Participants’ accounts of their study experience suggest that depressed mood prior to a notification to complete a survey may impact compliance with suicide-related assessments. Overall, as stated by I participant, “during moments where I already wasn’t feeling too great, it exacerbated things a bit.” Further, another participant in the study described how their survey compliance can be influenced by their mood:

It’s sort of like a reflex for like, whenever something bounces on my phone, and I’m like, not in a good mood, I immediately, like, swipe it [get rid of the notification]

Participant 2 noted that repeated assessments of suicidality could increase their awareness of passive suicidal thoughts, stating, “Not really trigger me, but be like, oh, yeah, I am, like, passively suicidal 99% of the time.” Another participant noted in his interview that he did not complete the last day of the trial due to an anniversary of a loved one’s death:

It was an emotional day and I didn’t want to continue because my responses would have changed drastically. I didn’t want nobody to look at me differently...I didn’t want to put myself in an uncomfortable position.

This response further cements the idea that response rates may be influenced by low mood. Several participants provided feedback on the survey questions, suggesting that shorter surveys may be more effective in assessing suicidality. They noted that if they responded with a positive mood score, assessed by the Patient Health Questionnaire-2 item measure (PHQ-2), it likely indicated they were doing well and not feeling suicidal. Multiple participants suggested that gauging mood before asking directly about suicide may improve the effectiveness of the survey.

Those questions are pretty good. But I would probably, like I’d probably try and, like keep the survey shorter...So maybe like gauge the mood before asking like, “Hey, are you going to kill yourself?”

Because if I’m at like, 3, then the answer is like, it’s no, it’s, it’s gonna be no, you know, because I’m in like, a pretty good place. [Participant 2]

Given our study’s focus on suicide risk assessment, a significant portion of the survey questions pertained to assessing proximal or momentary risk for self-harm. Unfortunately, these questions were predominantly framed from a negative or deficit-oriented perspective, such as “Have you thought about killing yourself since the last prompt?” Several participants pointed out that this focus on negative experiences was contributing to their mood states and recommended that the survey be balanced with more positive questions.

It seems like everything was about if I have a terrible day...there should have been some questions that show record of your good days, too. [Participant 5]

Recommendations to Improve Usability and Effectiveness

As part of the qualitative exit interview, participants were asked to provide feedback and suggestions for the future use of the app. In relation to the app’s accessibility, several participants suggested incorporating features that would promote ease of use. Specifically, participants mentioned that a dark mode would be beneficial, as the bright white background of the app was uncomfortable for some. In addition, participants suggested incorporating a text-to-speech feature that would read the survey questions aloud to make it easier for individuals with visual impairments or reading difficulties.

To encourage better participation and compliance, some participants suggested that a more flexible schedule would better align with their daily routines and lifestyles. Some participants pointed out that they are less inclined to fill out surveys when they are occupied with other social activities. As a result, participants suggested a schedule that can be customized according to their personal needs and circumstances.
I guess, maybe if I could like, sort of choose my own schedule...like put it at times where I know that I'm going to be like, on my phone, or like, in my bed...I'm probably going to be in my bed not doing anything else, like probably playing a game on my phone. So I'll tell myself, “Hey, you have no excuse, fill this out so that they know you haven't, like died.” But, if it’s like, in the middle of me, like going to the mall with my friends, I'm most definitely not going to stop and be like, “Hold on everybody, I have to fill this out” I'm just gonna forget about it. [Participant 2]

Participants provided various suggestions for enhancing the interactivity of the smartphone-based app, including incorporating a journaling component to allow them to document their thoughts in written form. Participant 2 described the potential benefit of such a feature, stating that it could provide a private space for them to express their emotions and thoughts more freely, without the fear of judgment or negative consequences.

I was thinking, maybe something where, you know, if you're not feeling that bad, you can just write down something...And knowing that it's going to medical professionals, I probably will be as kind of open as I am in my journal.

Additionally, other participants expressed interest in in-app features that would allow for personalized coping strategies, such as guided breathing exercises or links to mental health resources. These in-app features were seen as potential tools to promote engagement with the app and ultimately improve mental health outcomes. Finally, participants recommended that the survey include questions that allow for a more comprehensive and nuanced picture of their mood and well-being, and that these questions should be presented before questions pertaining to suicide risk to “ease into the heavier stuff,” as suggested by participant 1.

**Discussion**

**Principal Findings**

Our study aimed to assess the feasibility of using smartphone-based EMA to evaluate suicidality in real time among individuals in a high-risk sample of Black men. During the interviews, most participants generally reported that the frequency and timing of the prompts and reminders were suitable for the project and their daily lives. The results indicate that this approach shows promise for future research in this population. The results also suggested that while suicide-related smartphone apps have the potential to be effective tools for suicide prevention, they need to be developed and implemented with care. Even though the completion rate for EMA surveys was not optimal, we are encouraged by the high level of compliance with the daily diary entries. The study also did not pose any safety concerns, and the completion time for the surveys was found to be relatively short. Participants reported that the questions were generally relevant to their daily experiences and easy to understand. Additionally, the user feature that allowed for open-ended audio recordings was found to be useful in capturing daily experiences of racism, which is an important factor that could contribute to suicidality in this population. Finally, the qualitative findings from exit interviews suggest that the study procedures were perceived by participants to be acceptable and feasible.

Despite the promising results, the study revealed that the compliance rate was lower than in other studies not focused on Black men that leveraged EMA approaches to assess suicide risk [25,28]. One possible reason for this finding is that participants encountered technological issues and cited them as reasons for disengagement from the study. Participants noted redundancy in survey questions, which can lead to survey fatigue and reduced engagement. This redundancy might have contributed to the lower completion rates observed in the study. Moreover, the frequency of prompts may have contributed to the overall low compliance rate. The participants recommended fewer prompts and more flexibility in timing to enhance compliance.

Our findings also highlight the need for careful consideration of the potential harms of repeated assessments of suicidality, which focuses on a negative framing of mental well-being, and the need for the development of personalized interventions to mitigate any negative effects. Specifically, participant narratives from our qualitative exit interviews suggest that individuals experiencing negative moods may be less likely to engage with suicide-related assessments delivered via smartphone app notifications. Additionally, respondents felt that the EMA survey questionnaire could be more balanced by including both questions that assessed suicide risk and positive emotions as protective factors. One such measure, the Reasons for Living Inventory (RLI), was developed to identify factors that serve as deterrents against suicidal behavior. This inventory assesses positive emotions that support an individual’s decision to avoid death by suicide, should such thoughts emerge. Including measures, such as the RLI, that ground Black men to life is vital for addressing mental health challenges and fostering well-being for this demographic. By understanding how to balance the benefits of suicide-related assessments with their potentially harmful impact, scholars will be more equipped to identify protective factors and develop tailored interventions that are more likely to be used by Black men.

Our findings have important implications for the use of EMA among Black men. Smartphone-based methods, such as EMA and daily diaries, offer a unique opportunity to assess and evaluate suicide risk in real time. This approach represents a significant advancement in capturing momentary phenomena that could aid in suicide prevention, such as (1) characterizing dynamic mood changes over a short time span, (2) untangling stressful and racialized daily experiences, and (3) transmitting critical health information to health care providers to support care management. By using this approach, researchers can gain a more nuanced understanding of the experiences of high-risk populations and provide timely culturally relevant interventions to prevent suicide [23,24,32,33].

Moreover, researchers should be aware of certain populations that may be cautious to participate in research, such as Black men, particularly when it involves the explicit tracking and reporting of their daily experiences. This hesitancy can be
ration, given the history of systemic exploitation of Black communities in biomedical research [36]. Therefore, it is important for researchers to acknowledge and address these historical injustices to build trust and facilitate participation among these populations. Only by taking these steps can researchers ensure that their work is ethical, respectful, and ultimately beneficial to the communities they seek to serve [19,37,38].

Smartphone-based suicide prevention is also increasingly becoming a viable approach for combating rising suicide rates, especially among young adults. The prevalence of health-related internet searches via smartphones, as evidenced by the high percentage of people who are 18-29 and 30-49 years of age and who use their phones for medical information, suggests that smartphones can be effective tools for suicide prevention. Additionally, the fact that Black and Hispanic Americans use their phones for medical information more frequently than White non-Hispanic Americans suggests that smartphone-based interventions may be especially important in addressing suicide risk in communities that experience higher levels of stigma and barriers to accessing traditional health care resources [39]. By leveraging the widespread use of smartphones, suicide prevention efforts can reach a larger and more diverse population, potentially reducing the burden of suicide on individuals, families, and communities.

Limitations
There are several potential limitations to our study that should be noted. First, our primary recruitment method was through MyChart messaging, which may have limited the pool of potential participants to those who are more likely to have additional physical comorbidities. The recruitment approach may have influenced the response rate, since participants may not have had the same motivation to respond to an interest survey, compared to a direct referral from a medical professional. Second, all participants were required to own a smartphone, which may have excluded individuals who did not have access to this technology. Additionally, we excluded Black men with active psychosis, which may have further limited the diversity of our sample. Given the potential for overdiagnosis of psychosis in underserved communities [40], it is possible that we also excluded potentially eligible individuals. Our study was also geographically restricted to Black men receiving health care in Baltimore, Maryland, and its surrounding counties. Future studies should consider additional venues and settings to recruit Black men who are not engaged in psychiatric care, including but not limited to social media, advocacy groups, and peer-led and community-based organizations. Finally, our study involved a relatively small number of participants, with 9 eligible participants completing the EMA surveys. This limited sample size may not fully represent the diversity and complexity of experiences among Black men and can affect the generalizability of findings to a larger population. Future studies should expand from our preliminary findings with a sufficient sample size to statistically investigate predictors of low compliance and user uptake.

Conclusions
This study is the first to our knowledge to address critical gaps in suicide research by incorporating EMA to improve the care for Black men who are at risk of suicide. Using EMA may be an important tool to help stem challenges to the timely assessment of suicide among Black men, who comprise the largest percentage of deaths by suicide (81%) within the Black community [4]. Our findings highlight how acceptable and feasible this method is for this high-priority population, as well as potential approaches to improve its fit.

Our study provides critical insights into the use of smartphones to capture real-time data for assessing the mental and emotional health of individuals in high-risk clinical samples of Black men. Our results highlight the suitability of EMA using smartphone-based approaches for studying sensitive topics related to suicide in vulnerable populations. Furthermore, the findings shed light on the next steps for creating more equitable suicide prevention approaches, including identifying areas of missing data and the cultural acceptability of smartphone-based tools for health promotion. However, further research is necessary to expand these tools to assess structural racism and other racialized factors that influence Black men’s daily lives.

Abstract

Background: Approximately 80% of primary school children in the United States and Europe experience glue ear, which may impair hearing at a critical time for speech acquisition and social development. A web-based app, DigiBel, has been developed primarily to identify individuals with conductive hearing impairment who may benefit from the temporary use of bone-conduction assistive technology in the community.

Objective: This preliminary study aims to determine the screening accuracy and usability of DigiBel self-assessed air-conduction (AC) pure tone audiometry in adult volunteers with simulated hearing impairment prior to formal clinical validation.

Methods: Healthy adults, each with 1 ear plugged, underwent automated AC pure tone audiometry (reference test) and DigiBel audiometry in quiet community settings. Threshold measurements were compared across 6 tone frequencies and DigiBel test-retest reliability was calculated. The accuracy of DigiBel for detecting more than 20 dB of hearing impairment was assessed. A total of 30 adults (30 unplugged ears and 30 plugged ears) completed both audiometry tests.

Results: DigiBel had 100% sensitivity (95% CI 87.23-100) and 72.73% (95% CI 54.48-86.70) specificity in detecting hearing impairment. Threshold mean bias was insignificant except at 4000 and 8000 Hz where a small but significant overestimation of threshold measurement was identified. All 24 participants completing feedback rated the DigiBel test as good or excellent and 21 (88%) participants agreed or strongly agreed that they would be able to do the test at home without help.

Conclusions: This study supports the potential use of DigiBel as a screening tool for hearing impairment. The findings will be used to improve the software further prior to undertaking a formal clinical trial of AC and bone-conduction audiometry in individuals with suspected conductive hearing impairment.

Introduction

Over 5% of the world’s population, approximately 430 million people worldwide, have disabling hearing loss; 34 million of these are children [1]. The main causes of hearing loss in adulthood are age-related hearing loss, noise-related hearing loss, and hearing loss due to chronic otitis media. In children, the most common cause of hearing impairment is otitis media with effusion, also known as “glue ear”. Approximately 80% of primary school children in the United States and Europe experience glue ear [2]. In contrast to most forms of adult hearing loss, hearing impairment in children with glue ear fluctuates. Serial testing is often required to detect and manage the condition to mitigate its adverse impact on social development. Children in low- and middle-income countries, families experiencing socioeconomic deprivation, and disadvantaged populations are disproportionately affected by conductive hearing loss caused by glue ear and its complications, or from damage to the eardrum as seen in chronic tympanic perforations or chronic serous otitis media [3,4]. Since delayed recognition and management of childhood hearing impairment have long-term consequences for socialization and educational attainment, screening audiometry is recommended in primary school [5]. However, population screening programs are hindered by cost, standardization, requirement for staff training, false-positive referrals, and poor data capture [6,7]. Even where available, school screening may miss children with fluctuating hearing loss due to glue ears. Additionally, several year groups have missed screening during the COVID pandemic [8]. These children may face months of impaired hearing before diagnosis and management due to backlogs in audiology and specialist services.

Hearing thresholds are assessed using pure tone audiometry (PTA) with air-conduction (AC) headphones and bone-conduction (BC) transducers. This usually requires specialist equipment and trained clinicians. Automated audiometry and, more recently, validated self-testing hearing software apps, may improve the accessibility of screening and threshold audiometry testing, particularly in rural areas. The DigiBel web app is a recently developed Class 1 CE marked medical device that enables self-testing of AC and BC hearing levels. Like some other audiometry apps, it is suitable for community use in adults and children without clinical support. DigiBel has the novel facility to undertake BC audiometry with the same transducer used in a BC hearing assistance kit (BC headphones with Bluetooth-connected microphone, Raspberry Pi, Cambridge, United Kingdom). This could identify children who may benefit from this assistive technology while waiting for diagnosis, spontaneous resolution, or definitive management of their glue ear [9].

The purpose of this study of DigiBel audiometry is to determine the app’s sensitivity and specificity for detecting simulated conductive hearing impairment of more than 20 dB and to identify software modifications required prior to formal trials in a clinical population. Given the long protocol of testing or retesting and the requirement for usability feedback to inform improvement in the app design, this preliminary study involved healthy adult volunteers rather than children.

Methods

Overview

Healthy adult volunteers from the community without a previous history of hearing impairment were invited to participate in this comparative study of automated PTA and DigiBel audiometry. After receiving an explanation of the study, participants provided verbal consent to proceed to audiometry testing. Each participant was assigned a unique study identification number; no personal identifiable information was recorded.

Testing was undertaken in community settings such as participants’ homes and classrooms by nonaudiologist technicians. Prior to testing, each volunteer was instructed to place a foam earplug firmly into their left auditory canal and requested not to adjust it until testing was complete. This simulated a conductive hearing loss in the plugged ear, making each ear an independent entity for the purpose of statistical analysis and providing a range of hearing levels.

The reference automated AC PTA and the index DigiBel audiometry test were undertaken sequentially in random order. DigiBel audiometry for 4 frequencies was repeated immediately after the initial test, to assess within-session test-retest (TRT) reliability. After completing both audiometry tests, each volunteer was asked to complete a feedback questionnaire covering test preference and usability (Multimedia Appendix 1).

Automated Pure Tone Audiometry—The Gold-Standard Reference Test

Automated PTA was undertaken using an Oscilla (Oscilla A/S Aarhus Denmark) USB300 audiometer with TDH-39 headphones. The modified Hughson-Westlake algorithm was used for determining the reference AC audiometric threshold [10]. After an initial explanation by the technician and a conditioning test at 1000 Hz, thresholds were recorded at 2000, 4000, 8000, 1000, 500, and 250 Hz in accordance with British Society of Audiology recommendations [11]. The hearing threshold criterion for each frequency was determined as the lowest intensity at which participants accurately signaled 2 confirmations out of 3 presentations. The number of false positive responses was manually recorded.

The DigiBel Index Test

DigiBel has been laboratory and biologically calibrated (Institute of Sound and Vibration Research, University of Southampton, United Kingdom; and Chears-audiology, Royston, United Kingdom) to run specifically on any model iPad tablet (Apple) with Sennheiser HD 400S AC headphones (Wedemark, Germany).

A pretest embedded video provides instructions for use and a checklist ensures that the iPad volume is on maximum and the headphones are fitted correctly. Noise sampling, using the inbuilt Sennheiser headphone microphone, ensures that the ambient noise level is less than 40 dB prior to testing. Testing can be paused and restarted at any stage if the ambient noise level changes unexpectedly or interruptions occur. Configurable
settings include a choice of warble or pure tone, test frequencies, ambient noise setting, and child or adult version of the test.

The user taps a central animated button on the iPad display when they hear the tone (Figure 1A). A conditioning step requires the user to accurately tap the button on hearing a random onset suprathreshold tone at 1000 Hz before testing can begin. During testing, the onset of the tone is randomized from 0 to 3 seconds after the appearance of the response button to avoid a predictable response pattern. The tone stops in response to the tap and a psychophysical staircase algorithm starting from 60 dB (10 dB down, 5 dB up) is followed in a 2 down, 1 up rule, requiring 5 reversals dependent on the user’s input. The final threshold is calculated as the mean of the final 3 reversal thresholds. Once completed, a standard audiometry graph and the number of false positive responses are displayed (Figure 1B). The user can choose to repeat testing or undertake BC testing to determine the functional effect on hearing levels.

Figure 1. (A) DigiBel test interface and (B) DigiBel audiometry graph.

For this study, DigiBel AC PTA was undertaken in the sequence 2000, 4000, 8000, 1000, 500, and 250 Hz and retested in the sequence 2000, 4000, 8000, and 500 Hz using the adult test version.

Statistics
Data were analyzed in R (version 4.1.2; R Foundation for Statistical Computing) [12,13]. Accuracy and TRT reliability were assessed through Bland-Altman analysis, a statistical approach enabling analysis of the agreement between 2 measurement methods by assessing their mean differences (mean bias) and upper and lower limits of agreement (SD 1.96). Qualitative appraisal of mixed effects model 2-way intraclass correlation coefficients (ICCs) between the threshold measurements from each device was based on conventional standards with moderate, good, and excellent agreement indicated by an ICC of ≥0.50, ≥0.75, and ≥0.90, respectively [14]. The correlation between calculated bias and mean threshold values was analyzed using Pearson correlation coefficients (PCCs). The percentages of DigiBel threshold measurements lying within 10 dB of both the reference test and the repeated DigiBel test were calculated [15,16]. Statistical significance was calculated for the mean bias where confidence intervals did not cross zero, and for ICC and PCCs where \( P < 0.05 \). To assess diagnostic efficacy, sensitivity and specificity for detection of hearing thresholds above 20 Hz were calculated, using automated PTA as the reference. The Student t test was used to compare the number of false positive responses for each test. Throughout, magnitudes were reported as the mean (SD) unless otherwise stated.

Ethical Considerations
The study adhered to the tenets of the Declaration of Helsinki and the protocol was approved by the Quality and Safety Committee of Cambridge University Hospitals National Health Service Foundation Trust as part of a service improvement project. The Quality and Safety Committee at Cambridge University Hospitals considered that formal ethics committee approval was not required for this no-risk service improvement study in a healthy, adult population and opined that verbal consent was sufficient in these circumstances to prevent the collection of patient identifiable information (approval for
Service Evaluation Project – PRN9288; dated April 11, 2023). No other demographic information other than age was recorded to maintain anonymity for this service improvement study. No compensation was offered for participating in the study.

**Results**

**Participant Characteristics**

A total of 32 healthy participants agreed to take part, but 2 participants were excluded due to malfunction of the reference automated PTA test. The 30 participants who completed both the reference and index tests were 21-66 (mean 27.9, SD 10.3) years. TRT data were collected from 29 participants (one volunteer left early due to time constraints). Feedback forms were completed by 24 participants (Figure 2).

**Figure 2.** Participant flow diagram.

**Accuracy and Reliability of DigiBel**

Across the 6 tested frequencies, threshold hearing levels of DigiBel compared with automated PTA gave an ICC of above 0.75 (good or excellent agreement) and \( P < .001 \) in every trial (Table 1; Multimedia Appendices 2 and 3). The mean lower limit of agreement (LOA) was –17.04 dB (SD 2.12 dB) and the mean upper LOA was 20.39 dB (SD 3.41 dB). No significant bias was apparent except at 4000 and 8000 Hz where a small but statistically significant bias was apparent (2.62 and 4.60 dB, respectively), with DigiBel providing systematically higher threshold results at those frequencies (Figure 3). An agreeable level of threshold difference in audiometry assessments has previously been defined as 10 dB; 263 out of 360 (73%) of DigiBel threshold measurements were within this standard [16]. There was a significant positive PCC between the measurement bias and mean at 500 (\( P < .001 \)), 1000 (\( P = .005 \)), 2000 (\( P < .001 \)), and 4000 Hz (\( P < .001 \)) test frequencies.

\(^a\)LLoA: lower limit of agreement.
\(^b\)ULoA: upper limit of agreement.
\(^c\)ICC: intraclass correlation coefficient.
\(^d\)PCC: Pearson correlation coefficient (calculated for the relationship between measurement bias and mean for each frequency).
\(^e\)Comparison of threshold values (in dB) using Bland-Altman statistics and ICCs between DigiBel and standard automated PTA and DigiBel test and retest.
\(^f\)N/A: not applicable.

In TRT comparisons, ICC was above 0.90 (excellent) at all tested frequencies: 500, 2000, 4000, and 8000 Hz (Table 1). No statistically significant mean bias was exhibited at any frequency. The mean lower LOA was –13.99 dB (SD 2.34 dB); the mean upper LOA was 15.76 dB (SD 2.20 dB). Overall, 85% of TRT thresholds were within 10 dB of each other.

A mean of 3.57 (SD 4.68) false positive responses were recorded during reference testing and 11.43 (SD 7.12) during the first DigiBel test \((P<.001)\).
Sensitivity and Specificity

The sensitivity and specificity of DigiBel for detecting 20 dB hearing loss at each frequency are shown in Table 2. When applied to the 4 frequencies used for screening (250, 1000, 2000, and 4000 Hz), DigiBel had 100% sensitivity (95% CI 87.23-100) and 72.73% (95% CI 54.48-86.70) specificity for detecting 20 dB hearing loss in adults in a quiet setting.

Screening frequencies (250, 1000, 2000, and 4000)

100.00 (87.23 to 100.00) | 72.73 (54.48 to 86.70)

Usability

Out of the 24 participants, 21 (88%) participants, while completing the questionnaire, did not regularly use digital health apps. All 24 participants rated DigiBel either good (15/24, 63% of participants) or excellent (9/24, 38% of participants); (7/24, 29% participants preferred the DigiBel test; 6/24, 25% participants preferred the standard test; and 11/24, 46% participants gave no test preference). A total of 21 (88%) participants agreed or strongly agreed that they would be confident to use DigiBel at home without help. The most common qualitative feedback given to the question “what is the best thing about the app?” was that it was easy or intuitive to use (17/24, 71% of participants). Answering “what is the worst thing about the app?” the commonest complaint was that the test was too long or boring (10/24, 42% of participants). One participant commented on environmental noise leaks through the headphones (Multimedia Appendix 1).

Discussion

Principal Findings

In 30 healthy adults with simulated unilateral conductive hearing impairment, DigiBel’s screening sensitivity and specificity were 100% (95% CI 87.2-100) and 72.73% (95% CI 54.45-86.7), respectively. The hearing threshold measurement mean bias between DigiBel and automated AC PTA was not significant except at 4000 and 8000 Hz, where it reached statistical significance (2.62 and 4.60 dB higher than the reference, respectively).

At least 5 validated downloadable apps enable automated AC audiometry, several of which support self-testing without clinician involvement [17]. Two apps, uHear (Unitron Ltd) and ShoeBOX (SHOEBOX Ltd) for iOS, include a BC audiometry facility [18,19]. uHear has been calibrated for use with commercial in-ear Apple headphones and ShoeBOX uses purpose-built audiometry headphones. Discussion

Principal Findings

In 30 healthy adults with simulated unilateral conductive hearing impairment, DigiBel’s screening sensitivity and specificity were 100% (95% CI 87.2-100) and 72.73% (95% CI 54.45-86.7), respectively. The hearing threshold measurement mean bias between DigiBel and automated AC PTA was not significant except at 4000 and 8000 Hz, where it reached statistical significance (2.62 and 4.60 dB higher than the reference, respectively).

At least 5 validated downloadable apps enable automated AC audiometry, several of which support self-testing without clinician involvement [17]. Two apps, uHear (Unitron Ltd) and ShoeBOX (SHOEBOX Ltd) for iOS, include a BC audiometry facility [18,19]. uHear has been calibrated for use with commercial in-ear Apple headphones and ShoeBOX uses purpose-built audiometry headphones. DigiBel is not yet commercialized but its potential advantage is its calibration to use affordable (retail price US $41, equivalent to €39), lightweight, and wipe-clean Sennheiser HD 400S AC headphones. DigiBel supports the use of Raspberry Pi BC headphones (retail price US $28, equivalent to €26) for BC audiometry which may quantify the potential benefit from their use (with a paired microphone) as an assistive technology.

DigiBel’s screening sensitivity and specificity for hearing impairment (more than 20 dB) is comparable to previous studies of both uHear (98.2%–100% sensitivity and 60.0–82.1 specificity) and ShoeBOX (91.2%–93.3% and specificity of 57.8%–94.5%) [18–22]. In this study comparing the threshold measurements of DigiBel to automated AC PTA in 30 individuals, there was a significant positive correlation between the mean bias and the mean threshold measurement at 500, 1000, 2000, and 4000 Hz frequencies, resulting in an overestimation of hearing ability at normal hearing levels and an underestimation of hearing ability in ears with subnormal hearing. This was particularly evident at 2000 Hz testing and may have resulted in the lower specificity demonstrated at this frequency. This is likely to reflect the sound output characteristic of the AC headphones and will require software corrections prior to future clinical studies. Overall, 73% of threshold measurements with DigiBel were within 10 dB of standard PTA; previous studies of ShoeBOX have found over 90% of measurements were within this range [23]. The comparatively poor performance of DigiBel for this metric may be due to environmental noise leakage through the Sennheiser headphones, a disadvantage of their comfort.

Masking of the unplugged ear was not used for either automated PTA or DigiBel because this facility is unlikely to be used by nontrained observers in community settings. A minority of participants in this study had a simulated intra-aural threshold difference exceeding 40 dB. It is possible that intra-aural transmission may have affected threshold values in these individuals, but this would be expected to affect both tests similarly.

The Hughson-Westlake algorithm and other adaptive methods are widely used to assess audiometric threshold, more recently, machine learning techniques have been developed [24]. To our knowledge, DigiBel is the only app to apply a staircase-reversal technique to audiometry, although it is commonly used for visual threshold testing [25]. In this study, the number of false positive participant responses was substantially higher with

https://formative.jmir.org/2024/1/e51770
DigiBel than standard testing. This may be due to the higher number of stimulus presentations compared with the ascending method used in standard automated PTA. The sensitivity of the iPad screen to a tap compared with the standard audiometer’s hand-held responder may be an additional factor. There was no evidence in this study that the higher false positive rate translated into a systematic overestimation of hearing ability.

All participants rated DigiBel as good or excellent, but 42% (n=10) of participants complained that the test took too long or was boring. Test duration was not measured during this study, but threshold testing for 6 frequencies is expected to take approximately 13 minutes with DigiBel, several minutes longer than standard automated PTA, primarily due to its staircase-reversal algorithm. Study participants had performed retesting which may have contributed to the perceived length of testing. The children’s version of the app has cartoons designed to increase interest but, even so, the test duration of threshold audiometry may limit its usability in young children. The DigiBel screening test of 4 frequencies takes approximately 3 minutes and may prove more feasible in this, its target population.

To simulate a range of hearing thresholds in the participant cohort, an earplug was used. This is a major limitation of the study because the effectiveness of the earplug may have altered during testing and earplugs may not accurately mimic genuine hearing impairment. Although this study indicates that DigiBel has acceptable accuracy for detecting simulated hearing impairment in healthy adult volunteers, these results are not generalizable and software corrections are required prior to clinical use.

This preliminary study confirms that the DigiBel app is an acceptable and easy-to-use self-testing web-based tool that accurately detects more than 20 dB of simulated hearing impairment in adults. Minor modifications to the 1000, 2000, and 4000 Hz frequency-specific normalization factors used in the software algorithm which converts sound pressure levels to hearing level are required to ensure uniformity of sound output and accuracy across the range of hearing abilities. A study, conducted in primary school children attending a hospital audiology clinic, is underway to assess the accuracy of DigiBel in identifying conductive hearing impairment. Additionally, the innovative concept behind DigiBel will be tested: its ability to identify those children who could benefit from the temporary use of a BC hearing assistance kit for use at school and home, and the impact this has on quality of life (using a parent- or patient-reported outcome measure questionnaire) while waiting for specialist care.

Conclusions
The World Health Organization identifies hearing loss as a major global health issue, with two-thirds of people with severe hearing loss living in low and middle countries with poor access both to hearing testing (audiometry) or conventional hearing aids. It can affect many aspects of life such as education, employment, and communication, and result in social isolation.

Several software apps like DigiBel, studied here, have been developed to enable individuals to test their own hearing in the community. Uniquely, DigiBel has the additional potential to identify individuals with hearing loss who could derive immediate hearing support from an affordable and rechargeable bone-conduction hearing assistance kit while waiting for specialist care.

This initial study of DigiBel provides confirmation that the app is easy to use and accurate at detecting simulated hearing impairment. It identifies some software corrections that may improve its accuracy and lays the groundwork for future clinical studies to assess DigiBel’s performance in children and adults with hearing impairment.

Abstract

Background: Poor sleep hygiene persists in college students today, despite its heavy implications on adolescent development and academic performance. Although sleep patterns in undergraduates have been broadly investigated, no study has exclusively assessed the sleep patterns of premedical undergraduate students. A gap also exists in the knowledge of how students perceive their sleep patterns compared to their actual sleep patterns.

Objective: This study aims to address 2 research questions: What are the sleep patterns of premedical undergraduate students? Would the proposed study protocol be feasible to examine the perception of sleep quality and promote sleep behavioral changes in premedical undergraduate students?

Methods: An anonymous survey was conducted with premedical students in the Medical Science Baccalaureate program at an R1: doctoral university in the Midwest United States to investigate their sleep habits and understand their demographics. The survey consisted of both Pittsburg Sleep Quality Index (PSQI) questionnaire items (1-9) and participant demographic questions. To examine the proposed protocol feasibility, we recruited 5 students from the survey pool for addressing the perception of sleep quality and changes. These participants followed a 2-week protocol wearing Fitbit Inspire 2 watches and underwent preassessments, midassessments, and postassessments. Participants completed daily reflections and semistructured interviews along with PSQI questionnaires during assessments.

Results: According to 103 survey responses, premedical students slept an average of 7.1 hours per night. Only a quarter (26/103) of the participants experienced good sleep quality (PSQI<5), although there was no significant difference (P=.11) in the proportions of good (PSQI<5) versus poor sleepers (PSQI≥5) across cohorts. When students perceived no problem at all in their sleep quality, 50% (14/28) of them actually had poor sleep quality. Among the larger proportion of students who perceived sleep quality as only a slight problem, 26% (11/43) of them presented poor sleep quality. High stress levels were associated with poor sleep quality. This study reveals Fitbit as a beneficial tool in raising sleep awareness. Participants highlighted Fitbit elements that aid in comprehension such as being able to visualize their sleep stage breakdown and receive an overview of their sleep pattern by simply looking at their Fitbit sleep scores. In terms of protocol evaluation, participants believed that assessments were conducted within the expected duration, and they did not have a strong opinion about the frequency of survey administration. However, Fitbit was found to provide notable variation daily, leading to missing data. Moreover, the Fitbit app’s feature description was vague and could lead to confusion.
Conclusions: Poor sleep quality experienced by unaware premedical students points to a need for raising sleep awareness and developing effective interventions. Future work should refine our study protocol based on lessons learned and health behavior theories and use Fitbit as an informatics solution to promote healthy sleep behaviors.

Introduction
Sleep health has been recognized as an unresolved public health concern since 2006 [1]. Although sleep plays a vital role in adolescent health and development, poor sleep patterns continue to be associated with college students. A 2015 study showed that 70%-96% of college students sleep less than the recommended 8 hours on weeknights [2,3]. With the heavy prevalence of sleep deprivation, it is important to recognize the detrimental effects it can have. Starting with cognitive processing, poor sleep has been shown to have negative effects on working memory, attention span, and speed of processing [4]. With poor sleep, our bodies can also experience impaired immune function, more susceptibility to illnesses, increased risk of stress, and decreased physical functions [5]. In addition, emotional dysregulation and lower levels of subjective well-being can be observed [6]. As a result, students experience a consequential effect on their academic performance [7]. It is therefore imperative to understand and discuss the sleep patterns of adolescents, especially college students, in order to aid them with tools that can help avoid these consequences.

Additionally, it is possible that students who may appear to receive an adequate amount of sleep can experience poor sleep due to bad sleep quality. Sleep quality refers to both quantitative aspects of sleep such as duration, sleep latency, and number of arousals, and qualitative aspects such as depth and restfulness of sleep according to a 1998 Psychiatry and Research publication [8]. Poor sleep quality refers to the struggle of falling asleep or maintaining sleep. A recent 2022 study clarifies this definition by adding the component of individuals’ self-satisfaction with their sleep as another part of sleep quality [9]. A previous survey on college undergraduates found that only 34.1% of students displayed good sleep quality based on Pittsburg Sleep Quality Index (PSQI) scores [10]. The PSQI is a self-rated questionnaire that serves as a standard tool for measuring sleep quality [8]. The responses to questionnaire items allow researchers to determine a global PSQI score, which helps distinguish between good-quality and poor-quality sleepers. A PSQI score smaller than 5 (<5) signifies good sleep quality, whereas a PSQI score equal to or larger than 5 (≥5) indicates poor sleep quality. However, to diagnostically study sleep, polysomnography (PSG) can be conducted, which involves recording brainwaves, oxygen level in the blood, respiration rate, and physical movements to diagnose sleep disorders [11]. PSG is used to understand the sleep patterns of patients and why there might be disruptions [12].

A recent study on the sleep quality of college students explored the determinants of sleep quality [13], interventions for improving sleep quality, overall demographics of sleep patterns, and associations of poor sleep quality with health problems. Some studies [7,14] have approached the understanding of sleep through a comparison of different college majors. One such major or a group of students that is of interest to us are students who are premedicine (premedical) majors or undergraduate students on the prehealth track. However, there is limited exploration looking specifically at the sleep patterns of premedical undergraduate students (premedical students hereafter). Previous research in this area has largely been centered on the sleep quality of students who are in a medical school or graduate medical education program and focused on sleep-related disorders among them [15-19]. Numerous studies have measured the sleep patterns of medical students but have not focused on understanding the patterns [20-33]. To date, only 1 study has tested medical students on their sleep knowledge and has found a disconnect between their understanding of sleep facts and actual sleep quality [34]. This led to the focus of our study on the sleep quality perception of premedical students.

A student’s perception of his or her sleep habits can give us insights into whether perception influences sleep behaviors and quality. Many prior studies [35-38] have looked at sleep state misperception. This concept discusses how there is a disconnect between the amount of sleep people think they get versus their actual duration of sleep. Research on sleep state misperception has primarily been conducted on people dealing with varying mental health conditions or sleep disorders [35-38]. In this manner, our research focused on the effect of sleep quality perception on sleep patterns, which considers overall sleep quality rather than just duration, in a relatively healthy population comprised of premedical students. Literature shows that in medical students, perception of stress can have an impact on their well-being [39], while another study has confirmed that there is a positive effect of education on sleep in undergraduates [40]. However, there is a gap in the literature in terms of understanding how premedical students perceive their sleep versus their actual sleep patterns. Although one study comes close to answering this question by examining the beliefs of sleep hygiene in medical students compared to their actual sleep practices [41], the behavior of premedical undergraduates is yet to be explored and understood.

Current validation studies suggest that while PSG remains the gold standard, Fitbit is capable of monitoring various sleep parameters that do not significantly deviate from PSG measurements [42-44]. The overall objective of our research was to understand the sleep patterns of premedical students and create interventions to promote positive behavioral changes. Our pilot study focuses on answering the following 2 research
questions (RQs). What are the sleep patterns of premedical undergraduate students (RQ1)? Would the study protocol be feasible to examine the perception of sleep quality and promote sleep behavioral changes in premedical undergraduate students (RQ2)?

**Methods**

**Setting**

This study was conducted with premedical students from a Medical Sciences Baccalaureate Program (MSBP) at the University of Cincinnati, an R1: doctoral university and an undergraduate College of Medicine in the Midwest United States. The MSBP is a program designed to help premedical students prepare for professional graduate schools in the health care field. The 4-year program consists of 376 students as of October 2022.

**Study Design**

To address RQ1, a “Well-being and Sleep Survey” (the well-being survey hereafter) was distributed to collect subjective sleep patterns. To address RQ2, a small group of participants (MSBP premedical students) were recruited to evaluate whether the study protocol (Figure 1) was feasible and could generate valid data for analysis. Specifically, the participants put on the Fitbit Inspire 2 wearable watch to monitor their sleep patterns. These participants were then invited to a semistructured interview to understand their Fitbit app experience. As shown in Figure 1, during the 2-week pilot study period, participants progressed through preassessment (week 0), midassessment (week 1), and postassessment (week 2) periods. The well-being survey was filled out by participants at all 3 fixed time points. During week 0, a semistructured interview was conducted assessing participants about their typical sleep habits and their previous experience with wearable devices. Participants at this point were also prompted to fill out a form daily, reflecting their thoughts regarding the Fitbit sleep score they received the night before. On week 1, a midassessment was performed in which the participants were asked to speak about their previous week’s experience with the aid of the daily reflections they had previously filled for days 1-7. In order to prompt the participants, researchers displayed a line chart of the 7 responses gathered from participants’ daily forms to project their sleep score trends over the week. Researchers also listed all participants’ free-text responses so that they could elaborate specifically about their sleep corresponding to certain dates. Lastly, in week 2, participants reviewed the daily reflections for days 8-14, which was followed by a semistructured interview.
**Figure 1.** Flowchart of the study protocol tested on 5 premedical participants during the 2-week pilot study with Fitbit Inspire 2. Week 0 started with preassessment, conducted in person at the University of Cincinnati Medical Sciences building. Week 1 midassessment and Week 2 postassessment were conducted virtually through Microsoft Teams meeting. The data collection was conducted in 2 cycles. Participants 1, 2, and 3 began the 2-week protocol in the last week of July 2022 and finished in the second week of August 2022. Participants 4 and 5 began the 2-week protocol in the first week of September 2022 and finished in the third week of September 2022. All of the participants had varying start dates during this time frame, but each participant was available for 10 weekdays and 4 weekend days during the duration of the 2-week data collection. PGHD: patient-generated health data; PSQI: Pittsburgh Sleep Quality Index.

**Ethics Approval**

This study was reviewed and approved by the University of Cincinnati Institutional Review Board (approval 2021-1119) and determined as not human subject research due to its collection on de-identified data and the focus on quality improvement. This institutional review board determination resulted in the avoidance of collecting detailed student demographics such as sex and age and the deidentification of all participant information in the data.
Participant Recruitment
The survey participants were recruited on a voluntary basis via email and GroupMe messages through the research team’s professional and personal network. The small group of participants for the protocol evaluation was selected from the survey participants as a convenience sample. This study was expected to target 100 survey participants and 5 protocol evaluation participants.

Data Collection
The well-being survey was distributed among all cohorts (years 1, 2, 3, and 4 students) of the MSBP program (N=376). The survey consisted of PSQI items (1-9) adjusted to items (1-11) to accommodate the web-based survey format due to some combined line items in the original paper format, requiring different lines in the web-based survey. The response components combined to calculate a global PSQI score (with a Cronbach α of .83) [8], which suggests a high degree of internal consistency. These items were followed by a few questions assessing students’ demographics and their perception of their sleep quality. The well-being survey was created in Microsoft forms with survey questions as listed in Table 1. For the protocol evaluation, 5 students were selected from the well-being survey pool. In addition to the sleep patterns collected from the self-reported PSQI survey and the objective Fitbit wearables, these 5 participants’ feedback on the protocol was collected through semistructured interviews. The interview was recorded and conducted on a virtual platform and further analyzed thematically [45]. For the Fitbit data collection, 5 Fitbit Inspire 2 watches were deployed—one for each participant. Fitbit data were collected by linking the watch to the participant’s Fitbit web account. During the semistructured interview in the midassessment, the participants were instructed to log into their account on Fitbit.com. Next, they were asked to navigate to “Settings,” select “Data Export,” and then click on “Request Data.” This generated an email request to the participant to “Confirm Export Request.” Finally, after confirmation, the participant received a downloaded data zip file with JSON files containing complete archive data. The participants were then prompted to email the zip file to the researcher. This process was again repeated during the postassessment. Table 1 identifies each question sequentially, as it was presented in the web-based Microsoft form, as well as categorizes it as either a PSQI question or a demographic question. PSQI questions are directly derived from PSQI questionnaire items (1-9), which are adjusted to items 1-11 in our survey to accommodate the web-based format as compared to the original PSQI questionnaire paper format. The description lists exactly how the questions were asked to premedical MSBP students. The response type specifies whether survey participants responded to the question by inputting free text or selecting their answers on the Likert scale or multiple choice.

aPSQI: Pittsburg Sleep Quality Index.
bMSBP: Medical Sciences Baccalaureate Program.

Survey Data Analysis

After MSBP premedical students completed the well-being survey, the responses were analyzed as follows. First, the PSQI items (questions 1-11) were scored based on PSQI scoring guidelines. Then, a global PSQI score was assigned to each survey participant. Next, 3 analyses were made: (1) comparing student distributions with good PSQI scores (<5) versus poor PSQI scores (≥5) categorized by each cohort, (2) detecting the consistency between the perception of sleep quality and the PSQI score levels, and (3) finding the PSQI score differences on the perception of stress effect levels. Statistical analyses were performed to test the distribution homogeneity of each cohort using the chi-square test. The consistency between the perception of sleep quality and PSQI score will be tested using Cohen κ by grouping PSQI scores into corresponding sleep quality levels. For comparing the global PSQI score differences between stress effect levels, global PSQI scores were first treated as a continuous variable and the equality of medians on each group was tested using the Kruskal-Wallis test (nonparametric equivalent test of 1-way analysis of variance) to show any statistical difference. Furthermore, the post hoc Dwass-Steel-Critchlow-Fligner multiple comparisons test was applied to show the pairwise comparisons if at least one group median was significantly different from others.
Protocol Evaluation

The protocol evaluation was 2-fold. First, each assessment had an expected duration to avoid overwhelming the participants. The expected durations of the preassessments, midassessments, and postassessments were 30 minutes, 30 minutes, and 60 minutes, respectively. The postassessment was longer due to the semistructured interview. Second, the semistructured interview collected the participants’ feedback on the study protocol in 4 areas: (1) duration of the 3 (pre, mid, and post) assessments, (2) frequency of administering the well-being surveys, (3) completeness of Fitbit data, and (4) other suggestions. An additional analysis was conducted to assess the degree to which Fitbit data aligns with the self-reported data obtained through surveys by using Pearson correlation coefficients where $>|0.7|$ is strong correlation, $[0.3]-[0.7]$ is moderate correlation, and $<[0.7]$ is poor correlation (of note, the vertical lines present the absolute value sign).

Results

Survey Responses and Analysis Results

The survey responses ($n=103$) demonstrated that premedical MSBP students sleep an average of 7.1 hours each night with 81.3% habitual sleep efficiency (average hours slept versus hours spent in bed, as defined in PSQI). Those who experienced trouble sleeping commonly expressed reasons such as not being able to sleep within 30 minutes, waking up in the middle of the night or early morning, anxiety, stress, and a restless mind. Among the cohorts (Figure 2), no significant difference was found in the median PSQI scores as indicated by the Kruskal-Wallis test at a .05 significant level ($P=.11$). Similarly, the proportion of students who had good versus poor sleep was not significantly different as indicated by the chi-square test ($P=.48$). This concludes that the distributions have no significant differences in the good or bad PSQI scores among the student cohorts. It is worth noting that the response rates of the survey for the first-, second-, third-, and fourth-year cohorts were 38% (33/88), 23.4% (25/107), 23% (20/86), and 26% (25/95), respectively. Further, the same analysis was applied to the categorical variables collected in the survey data (Multimedia Appendix 1), including 2 non-PSQI variables (perceived sleep quality and perceived stress). The only significant difference was that the first-year students tended to take medicines to help themselves to sleep unlike the other cohorts ($P=.03$). However, there was no significant difference between the low frequency group (less than once a week and no medicine) and the high frequency group (once a week or more). To demonstrate the consistency between the perceived sleep quality and the PSQI scores, we assumed that students who perceived “no problem at all” will receive PSQI global scores <5, those who perceived “only a very slight problem” will receive PSQI global scores of 5-7, those who perceived “somewhat of a problem” will receive PSQI global scores of 8-10, and those who perceived “a very big problem” will receive PSQI global scores ≥11. The Cohen $\kappa$ (with 1 being a perfect consistency) showed that participants’ perceived sleep quality only had a slight consistency with the PSQI scores ($\kappa=0.19$). Table 2 shows the contingency of these 2 variables with an overpositive tendency from participants, that is, the bigger the problem the participants perceived in their sleep quality, the poorer the PSQI score they would receive. However, the table shows some inconsistencies. When participants perceived no problem at all in their sleep quality, 50% (14/28) of them actually had a nonoptimal PSQI score. When the participants thought there was only a very slight problem in their sleep, about a quarter of them (11/43, 26%) had a poor PSQI score. When the participants appeared to recognize that they had somewhat of a problem (or a big one) in their sleep, the majority of them had nonoptimal PSQI scores. Finally, the comparisons between perceived stress impact and median global PSQI scores in each perceived stress level were analyzed (Figure 3). The Kruskal-Wallis test shows there is at least one median that is significantly different ($P<.001$) from others at the .05 significant level. The post hoc Dwass-Steel-Critchlow-Fligner multiple comparisons was applied and showed that the students who perceived “a very big problem” on the stress effect had significantly greater PSQI scores than the students who perceived “no problem at all” ($P=.048$) and “only a very slight problem” ($P<.001$). Similarly, for the students who perceived “somewhat of a problem,” the stress effect was significantly greater than that in students who perceived “only a very slight problem” ($P=.001$) but not significantly different from the “no problem at all” stress level (Table 3). This indicates that participants’ perceived stress effects have high correlation with their PSQI scores, but it may not be the only effect at play.

Process Evaluation and Participant Feedback

Overall, the participants reported the Fitbit app as a helpful tool in understanding their sleep. They were especially excited to visualize their sleep stage breakdown and obtain an overview of their sleep by simply looking at their Fitbit sleep score. The participants' feedback on the study protocol was summarized in the following 4 areas.

First, all assessments were conducted in the expected duration, that is, 30 minutes for the preassessment and midassessment and 60 minutes for the postassessment. The web-based mode of midassessments and postassessments did not create any barriers to the data collection. The feedback also revealed that the interview component in all 3 assessments was effective and served different purposes. Specifically, the interview in the preassessment made the participants think about their previous experiences regarding sleep and patient-generated health data devices. The midassessment interview, which reviewed daily reflections at a glance, invoked awareness among participants. The interview in the postassessment was the most comprehensive as it gathered thoughts on daily reflections and assessed Fitbit data comprehension. The administered questionnaires in preassessments, midassessments, and postassessments, as shown in Figure 1, had a 100% response rate because participants were required to complete it during the semistructured interview. The global PSQI scores for 5 participants across the 2 weeks are shown in Figure S1 in Multimedia Appendix 2. The daily reflections also had a 100% response rate, as several reminder emails were sent out to ensure data collection.

Second, the participants did not have a strong opinion about the frequency of the well-being survey administration (3 times over a 2-week period in this study). However, the survey scores did not display much variation or clear trends. Although this can be due to the small group of participants (n=5), it may be more ideal to conduct the survey with more spaced durations.

Third, the Fitbit data provided notable variation daily and was able to grasp all 14 days well for the most part. Some participants experienced cases during which Fitbit would sense bed and wake time but would not be able to provide detailed analytics on the sleep stages or on the sleep score. For these participants, some of the issues included wearing the Fitbit too snug or loose or wearing the Fitbit only right before going to bed. In other cases, participants simply appeared to forget to put on their Fitbit watch after removing it for charging, leading to a void of data points. The participants were fairly adherent to completing daily reflections on time and found that a daily email reminder from the research team helped greatly with this task.

Lastly, the participants identified that the Fitbit app tends to provide vague descriptions. For example, the biggest concern raised was not being able to understand how the sleep score was calculated. This made participants question the score’s reliability and accuracy. Similarly, some participants highlighted redundancy of information (sleep stage condensed cycling), whereas others suggested presenting information in a more visually appealing manner (pie chart to see sleep stage breakdown), individualized manner (suggesting sleep recommendations based on score trends), and sleep score explainability (being specific as to why a score may have dropped/raised on a day-by-day basis).

Finally, the degree to which Fitbit data aligns with the PSQI self-reported data obtained through surveys was assessed. Overall, across the 2-week period, there was a moderately negative correlation (r=−0.598) calculated from the data shown in Table S1 of Multimedia Appendix 2. In context, this means high Fitbit scores, indicating good sleep, were correlated with low global PSQI scores, also indicating good quality of sleep. Week 1 had a strong negative correlation (r=−0.87) compared to Week 2, which had a moderate negative correlation (r=−0.648).

Discussion

Principal Findings

This study presents the sleep patterns of premedical students through a sleep and well-being survey and evaluates a study protocol in preparation for a large-scale study. The survey showed that although the participants did have an average of 7 hours of sleep in general, only a quarter of them had good sleep quality. There was no difference in sleep quality among the student cohorts. Furthermore, there was an inconsistency between the perceived sleep quality by the students versus what their PSQI scores reflected. The poor sleep quality experienced by unaware students points to the need for self-monitoring through wearables such as Fitbit devices to increase sleep quality awareness. Lastly, a comparison of stress effect on sleep with PSQI scores establishes that sleep is not the only dominant factor in PSQI. The participants who perceived stress to play no role in their sleep still displayed a wide range of PSQI scores. Our findings show that the study protocol is highly feasible in terms of assessment durations and interview effectiveness. The usage of Fitbit devices did increase participants’ awareness.
regarding their sleep based on the qualitative feedback, along with their overall understanding of sleep factors. Participants keeping track of their sleep via daily reflections also aided in their cognizance. Based on the feedback, the study protocol can be improved by extending the duration, educating individuals about the Fitbit-wearing behaviors, and increasing the sleep score interpretability.

In assessing how the Fitbit sleep score data align with the global PSQI scores, we found a moderate negative correlation. This makes sense because higher Fitbit scores, suggesting good sleep, aligned with lower global PSQI scores, which indicates good sleep quality. Therefore, achieving moderate to high correlation displays a good potential for Fitbit sleep scores to serve as a proxy for PSQI global scores. Although week 1 gathered a stronger correlation than week 2, we believe that this result may be due to greater missing data in week 2, either from fatigue or nonadherence.

**Implications**

Our study shows that only 25.2% (26/103) of the participating premedical students had good sleep quality, as indicated by the PSQI scores. This proportion is lower than that (34.1%) previously reported among college students in general [10]. This leads us to a possible inference that premedical students may have sleep patterns different from those of college students overall. Our study also introduces a new direction, in which sleep patterns are not only measured but further analyzed to determine discrepancies between perception versus actual sleep quality. Prior studies [17,46] looking at sleep patterns in medical school students or undergraduate college students in general could also benefit from this approach and take their sleep analysis to the next step. For example, a 2016 study conducted on undergraduates at the University of California explored relations between sleep and mental health in individuals with healthy sleep habits [17]. Hence, further understanding the sleep perceptions of these healthy students could be used to create a benchmark to which other types of sleepers can be measured relatively. Another application could include a longitudinal study, similar to the one proposed by the University of South Wales in Australia [46]. This 5-year study provides insights into the mental health of medical students, with sleep being one of the factors measured via Fitbit. By incorporating the concept of sleep and well-being perceptions, the longitudinal approach may provide a better understanding of whether perceptions stay consistent or change over time.

The increase in awareness regarding sleep due to Fitbit usage mentioned by the participants also opens an area for possible interventions. As previous literature has reported, when individuals are educated in a personally relevant manner, their awareness leads to behavior change [47-49]. An important component of behavior change is self-efficacy, which is the perception of one’s ability to achieve certain outcomes [50-52]. Hence, interventions can begin with Fitbit usage to increase participant awareness regarding why they need to make a change, establish how certain health behaviors will lead to expected outcomes, and then provide ways for participants to reach those outcomes [53,54]. Conversely, I study has tested a habit loop model, which is based on cue, routine, and reward [55]. The Fitbit usage behavior in terms of the habit loop model can be as follows: trust in Fitbit accuracy of physical and sleep data (cue), intensity of Fitbit use (routine), and adjustment of physical and sleep behaviors (reward). Although this study shows that trust in Fitbit produced little changes in sleep and health behaviors, future studies should be built upon this foundation to examine the potential behavioral change through the supplementation of educational information to participants.

In the evaluation of the protocol itself, there were inconsistencies in obtaining sleep scores from Fitbit at times. A pre-existing measure during this study was placing instructions in the daily reflection reminder email to contact the research team immediately if they received no score in order for the research team to troubleshoot. Some other troubleshooting measures could help ensure participants wear their Fitbit at all times. For example, the study team can propose a standardized charging time that prompts participants to remove and charge their Fitbits during our week 1 midassessment session and wear the Fitbit again at the conclusion of the meeting. This can prevent participants from forgetting to wear their Fitbits during the study period. Not all participants explored all the features of Fitbit’s sleep interface. This points to the need to give participants a tutorial about the various types of analytical information available that participants can browse through to understand their sleep patterns. Finally, for the Fitbit data retrieval process, researchers asked the participants to download their data from the Fitbit.com website in week 1 and week 2 assessments. This proved to be a time-consuming process; therefore, the protocol was updated to begin data download at the beginning of the assessment meeting, which allowed the download to be finished by the end of the meeting. These lessons learned help to refine our study protocol and will lead to higher data quality in our large-scale study.

**Limitations**

This study is limited in several ways. First, the assessment was conducted with premedical students from a single program in a single institution. Hence, it is possible that the findings were limited to the student demographics in our institution. Additionally, the well-being survey administered in this study did not ask for their sex, race, or age due to the constraints in the institutional review board protocol. Thus, this analysis does not demonstrate whether demographic factors are linked with certain sleep patterns. Moreover, this study did not consider the academic performance of the participants and its relationship with sleep patterns. Demographic information and academic performance will be collected in our future studies with an updated institutional review board protocol. Next, we only recruited 5 students via convenience sampling for protocol evaluation. Small sample sizes introduce the possibility of skewed opinions. However, it should be noted that the goal of this study was to test the protocol rather than any hypothesis. Additionally, the Fitbit usage habits demonstrated by the pilot study group point to the need to improve the Fitbit usage protocol. For example, students were advised to always wear their Fitbits except while charging. However, some students after charging their Fitbit forgot to wear it overnight, thereby leading to nonadherence. Another instance involved a participant using the “sleep now” function offered by the watch to track their cognizance. Based on the feedback, the study protocol can be improved by extending the duration, educating individuals about the Fitbit-wearing behaviors, and increasing the sleep score interpretability.
sleep, even though the participants were not instructed on that feature’s use. Using that function did dysregulate the visualization data, which returned to normal once the participant was asked to terminate the function’s usage.

**Future Work**

With the findings gathered from this pilot study, we hope to expand to a larger experiment within the MSBP and expand to premedical programs at other institutions. We hope to address sleep quality discrepancies and determine a feasible solution for sleep hygiene improvement in premedical students. Another future work involves the calculation of Fitbit sleep scores especially when the sleep data are collected but the sleep score is missing. In this study, we tried to explore how the Fitbit score was calculated and attempted to assess trends. Fitbit informs everyone that their sleep score is devised from 3 pieces of information: time asleep and awake, deep and rapid eye movement sleep, and sleeping heart rate and restlessness. However, it is unclear how exactly the sleep score values are formed. Therefore, it was difficult to generate actionable information. Hence, this topic should be further explored to determine whether sleep scores are indeed valid measures of sleep.

**Conclusions**

We conducted a pilot study to understand the sleep patterns of premedical undergraduate students and evaluated the study protocol. The survey results showed a generally lower sleep quality for this student population and posited a gap between the perceived sleep quality versus PSQI-measured sleep quality. This gap may be solved by the awareness raised by Fitbit usage. We will revise the study protocol based on the lessons learned and health behavior theories and conduct a large-scale experiment to use Fitbit as an informatics solution to promote healthy sleep behaviors.

**Acknowledgments**

This research did not receive any funding. We thank Dr Anil Menon, Director of the Medical Sciences Baccalaureate Program at the University of Cincinnati College of Medicine, for supporting the implementation of this study along with the student tribunal for the recruitment efforts. In addition, we thank Dr Claudia Rebola, Co-Principal Investigator of the WorkWell project, for providing Fitbit watches for data collection.

Background: Perinatal depression (depression during pregnancy or the first year postpartum) affects 10%-25% of perinatal individuals, with a higher risk among youths aged <25 years. The Mothers and Babies Course (MB) is an evidence-based intervention for the prevention of perinatal depression, grounded in cognitive behavioral therapy, attachment theory, and psychoeducation.

Objective: We developed a digital adaptation of MB (Interactive Maternal Group for Information and Emotional Support [IMAGINE]) and evaluated it in a pre-post mixed methods pilot among young perinatal people in the United States.

Methods: IMAGINE was a structured digital group of up to 7 participants, with scheduled MB content and open discussion for 12 weeks, facilitated by a social worker. Scheduled content included asynchronous SMS text messages, graphics, prerecorded videos, mood polls, and optional weekly synchronous video calls. Eligible participants were pregnant or ≤80 days postpartum, aged 16 to 24 years, had access to a smartphone, spoke English, and had a Patient Health Questionnaire score <10. Participants were recruited throughout the United States from August 2020 to January 2021 through paid social media ads, in-person outreach at clinics, and respondent-driven sampling. Participants completed quantitative questionnaires at enrollment and 3 months, and qualitative interviews at 3 months. We determined uptake, acceptability (by Acceptability of Intervention Measure score), and utility (by use of cognitive behavioral therapy skills). We compared depression symptoms (by Patient Health Questionnaire score), social support (by abbreviated Social Support Behavior score), and perceived stress (by Perceived Stress Score) between enrollment and follow-up by paired 2-tailed t test.

Results: Among 68 individuals who contacted this study, 22 were screened, 13 were eligible, and 10 enrolled, for an uptake of 76.9%. Furthermore, 4 (40%) participants were pregnant at enrollment. Participants had a median age of 17.9 (IQR 17.4-21.7) years, 6 (67%) identified as Black, 5 (56%) Latinx, and 6 (67%) using Medicaid health insurance. Further, 9 (90%) participants completed follow-up. Among these, the mean acceptability score was 4.3 out of 5 (SD 0.6) and all participants said they would recommend IMAGINE to a friend. Participants reported using a median of 7 of 11 skills (IQR 5-7 skills) at least half the days. We found no significant changes in depression symptoms, perceived stress, or social support. Qualitatively, participants reported one-to-one support from the facilitator, connection with other parents, and regular mood reflection were especially helpful aspects
of the intervention. Additionally, participants reported that the intervention normalized their mental health challenges, improved their ability to manage their mood, and increased their openness to mental health care.

**Conclusions:** This pilot study provides promising evidence of the acceptability and utility of IMAGINE among perinatal youths. Our study’s small sample size did not detect changes in clinical outcomes; our findings suggest IMAGINE warrants larger-scale evaluation.

**Introduction**
Perinatal depression, defined as depression during pregnancy or up to 1 year after childbirth, affects an estimated 10%-25% of birthing people in the United States [1,2]. Untreated, perinatal depression can have long-term negative impacts on birthing parents and newborns, including elevated risk of suicide [3], preterm birth [4], low birth weight [5], and impaired infant attachment [6]. Young parents (aged 15 to 24 years), those with low income, and people of color experience elevated risks of perinatal depression [7,8].

Despite many programs aimed at reducing the incidence of adolescent pregnancy in the United States, nearly 23% of all pregnancies occurred in people aged 15 to 24 years in 2020 [9]. Young parents are more likely to have risk factors that place them at greater risk for perinatal depression, including unplanned pregnancy, social isolation, and intersecting social determinants of health [10,11]. Many barriers to mental health care exist for perinatal youths, including lack of financial resources to pay for treatment, lack of access to or money for transportation, and difficulty finding childcare and missing work to attend appointments [8]. Young parents are therefore a key group needing innovative and tailored perinatal mental health support.

Evidence-based interventions have been developed to prevent and treat perinatal depression. The Mothers and Babies Course (MB) is a cognitive behavioral therapy (CBT) program developed for low-income racial minority women in the United States [12]. MB can be delivered to individuals or groups and is focused on building participants’ skills in modifying their thoughts, social contact, and pleasant activities. Further, 4 randomized controlled trials of the MB program found it reduced depressive symptoms in the perinatal period, and it has been rolled out at scale in the United States through home visiting programs [13-18]. MB has been recognized by the US Preventive Services Task Force as an evidence-based intervention that should be recommended for individuals at high risk of perinatal depression [19]. Despite these advances, there are barriers to accessing interventions such as MB, due to regional provider shortages, lack of transportation and childcare, clients’ difficulty committing to a prespecified time to attend sessions, and experienced or internalized stigma of seeking mental health care [20]. These barriers may be higher among those at the highest risk of perinatal depression, and barriers were further exacerbated by the COVID-19 pandemic and consequent physical distancing protocols [21-24].

Mobile phones can be used to offer more accessible mental health support to young parents (known as mobile health [mHealth]). mHealth interventions have shown promising results in improving perinatal mental health [25-30], and young people in the United States are an ideal audience for such programs: nearly all Americans aged 18 to 29 years own a phone, and 96% own a smartphone [31]. mHealth can eliminate the need to travel to appointments, and asynchronous mHealth programs allow patients to access care within their schedules, which can be especially helpful to parents [32]. Group mHealth interventions allow new parents to connect with and share ideas with peers, which can lower feelings of social isolation and increase social support and mental well-being [33].

We developed a digital adaptation of MB for the prevention of perinatal depression in youths, named Interactive Maternal Group for Information and Emotional Support (IMAGINE) [34]. In this paper, we present a mixed methods evaluation of a pilot study of the IMAGINE intervention, assessing the uptake, acceptability, and utility of IMAGINE.

**Methods**

**Study Design**
We conducted a single-arm pilot study with pre-post mixed methods evaluation.

**Study Population and Recruitment**
Participants were eligible to participate in the IMAGINE pilot if they were: pregnant or ≤180 days postpartum, aged 16 to 24 years during pregnancy, had daily access to a smartphone, and were comfortable conducting study visits and reading and responding to social media messages in English. Individuals who exhibited elevated depression symptoms at screening (Patient Health Questionnaire [PHQ-9] score ≥10 [35]) were excluded and referred to individual clinical care.

Participants were recruited between August 2020 and January 2021, through 3 main methods. First, study information was shared through paid, targeted advertisements on Instagram and Facebook throughout the United States. Specific parameters used to target participants were: female sex, aged 16 to 25 years, located anywhere in the United States. Second, this study’s team identified health care providers and community-based organizations in several cities in the United States (Seattle, WA; Olympia, WA; Philadelphia, PA; and Temple, TX) and provided materials for staff at these organizations to promote this study by distributing flyers. Finally, we used respondent-driven
sampling [36] to encourage participants who enrolled in this study to invite their peers to participate; a financial incentive of US $20 was offered to the referring participant if their referred peer enrolled.

Potential participants who learned about this study through any method contacted this study by phone call, text message, email, Instagram message, or by sending a message through this study’s website. Study staff then contacted potential participants to conduct eligibility screening by phone or video call. If participants were ineligible due to elevated depression symptoms at screening, study staff shared the National Crisis Line phone number and offered support to find treatment near their location. This study’s team psychiatrist was available to support linkage with resources.

Informed Consent
Informed consent was obtained by study staff for screening and enrollment. Participants provided verbal consent to participate in eligibility screening. Eligible participants provided written consent for study enrollment, using a web-based consent form on REDCap (Research Electronic Data Capture; Vanderbilt University) [37].

Study Visit Schedule
Participants enrolling in the IMAGINE pilot attended 2 study visits by video call: enrollment and 3-month follow-up after completion of the intervention. Quantitative data were collected at enrollment and follow-up using a REDCap web-based questionnaire. Qualitative interviews were additionally conducted at follow-up.

Intervention
The IMAGINE intervention was a facilitated digital group adaptation of the evidence-based MB program [12], developed through a human-centered design process described elsewhere [34]. MB content focuses on engagement in pleasant activities, healthy thinking, and social support, and is grounded in CBT, attachment theory, and psychoeducation. IMAGINE was delivered using the messaging platform, Slack (Slack Technologies, Salesforce Inc.), to groups of up to 10 participants, facilitated by a member of this study’s team with Master’s-level training as a social worker. Groups ran for approximately 12 weeks. Participants were grouped based on the timing of enrollment: groups were filled sequentially as participants enrolled. Guided by our formative work [34], the intervention consisted of multimedia adaptation of MB content, delivered through 5 components. First, MB session content was delivered asynchronously, through short SMS text messages, summary graphics, and prerecorded videos sent approximately 4 times per week. Messages were designed to promote group discussion or personal reflection. Participants were encouraged, but not required, to participate in group discussions by sending messages and reacting to other participants’ messages, at a time that was convenient for them. Second, an automated “mood poll” was sent to each participant individually 3 times per week, prompting the participant to reflect on their mood, activities, thoughts, and social contacts. Third, the facilitator was available for individual messaging through Slack. This was used for the facilitator to answer questions and send messages when a participant showed low engagement in other parts of the intervention. Fourth, participants could send messages on topics beyond the MB curriculum, through separate Slack “channels” (parallel conversations all members had access to): “ask an expert,” where participants could send questions for members of this study’s team with expertise in obstetrics and psychiatry; “random,” where participants could share any content; and “references,” where the facilitator posted graphics summarizing intervention content and links to resources. Fifth, in addition to asynchronous messaging content, the facilitator held a weekly 1-hour synchronous group video call, using the videoconferencing platform, Zoom (Zoom Video Communications, Qumu Corporation). Participation in the call was optional, to reduce barriers to participation due to scheduling and attendance challenges. No new content was delivered on the call, but participants could ask questions, share experiences, and receive support from the facilitator and other group members. Intervention content was developed in advance of the intervention and manually sent by the facilitator, except for mood polls, which were automatically scheduled within Slack. The facilitator could exercise discretion in message pacing based on participant feedback and questions during the intervention period. All 5 elements of the intervention were considered to be active components in engaging MB’s mechanism of action.

Quantitative Data Collection
Recruitment Log
A spreadsheet was used by study staff to record participants who contacted the IMAGINE study and their completion of eligibility screening.

Screening Questionnaire
Screening was completed verbally by phone or video call and responses were entered by study staff into an electronic questionnaire using REDCap, hosted at the University of Washington [37]. The screening questionnaire ascertained pregnancy status, age, access to a smartphone, comfort in English, and depression symptoms by PHQ9.

Enrollment Questionnaire
Enrollment of eligible participants was conducted either immediately following consent or at a separate scheduled visit, based on participant preference. The enrollment questionnaire was administered using REDCap by study staff through Zoom or phone calls. If conducted by video call, study staff screen-shared the REDCap questionnaire and read each question aloud so the participant could see and hear the questions and responses; data were entered by study staff. The enrollment questionnaire ascertained demographic characteristics and technology access. It also included an abbreviated 12-item version of the Social Support Behavior (SSB) instrument [38] to ascertain social support (score range 5-60). We used an abbreviated version of SSB to reduce the burden of data collection on participants. This version of the SSB has not been psychometrically validated. We used the Perceived Stress Score (PSS-4) instrument [39] to ascertain perceived stress (score range of 0-16). This instrument has previously been used in MB studies and is recommended for comparability [40,41].
Instrument reliability was previously reported as Cronbach $\alpha$ .72 [39].

**Follow-Up Questionnaire**

A follow-up visit was conducted at 3 months. The week after the completion of the IMAGINE intervention, a member of this study’s team other than the group facilitator contacted participants and arranged a follow-up study visit, conducted via Zoom video conference. The follow-up electronic questionnaire was administered using REDCap and assessed pregnancy status, PHQ9, abbreviated 12-item SSB, PSS-4, and acceptability of IMAGINE via the Acceptability of Intervention Measure (AIM) [42]. The AIM scale is a Likert scale questions with possible responses scored 1-5: completely disagree, disagree, neither agree nor disagree, agree, and strongly agree. The score is calculated as the mean numerical value of the responses across the 4 items. Instrument internal consistency and validity were previously reported as Cronbach $\alpha$.85 and confirmatory factor analysis loadings 0.75-0.89 [42]. Participants were also asked how often they had used key CBT skills over the past month, using a Likert scale with possible responses: not at all, a few times, half the days, most of the days, and every day. The following questions were asked about mood tracking, engaging in pleasant activities, overcoming obstacles to engage in pleasant activities, thought interruption to reduce harmful thoughts, designated worry time to reduce harmful thoughts, time projection to imagine a better time in the future, self-instruction, positive contact with others, soliciting positive support from others, and using assertive communication. These questions were modeled on the core CBT components of the MB program [17]. If a participant reported the use of a skill, they were asked how helpful the skill was, using a Likert scale with possible responses: not helpful at all, somewhat helpful, or very helpful. Study staff screen-shared the REDCap questionnaire, as in the enrollment visit.

**Engagement data**

We quantitatively assessed engagement in the different components of IMAGINE. Messaging data from all Slack channels was exported as an HTML file. Message counts for each group member were determined by searching for each member’s username and counting the number of occurrences in the file. Completion of automated mood polls was determined based on reports from the Polly tool within Slack that was used to send polls. Attendance of each group member in Zoom calls was recorded by the facilitator.

**Quantitative Data Analysis**

We calculated descriptive measures of uptake, acceptability, and utility. Uptake was defined as the percentage of screened, eligible participants who enrolled in the intervention. Acceptability was determined based on self-report responses to the AIM. Utility was defined as the percentage of participants who reported using each CBT skill discussed in MB at least half the time. Additionally, among those who used each skill at least half the time, the percentage of participants who found it to be helpful was calculated.

We determined pre-post change in indicators of mental wellness. Depression symptoms were determined by PHQ9 score, calculated according to instrument guidelines, with a possible range of 0-27. Social support was calculated using the abbreviated SSB, as the sum score over all questions referring to family support and separately those referring to friend support. The mean and SD for each score were summarized for each time point. Scores at the 2 time-points were compared by paired 2-tailed t test. RStudio (version 2023.06.0+421; Posit) was used for all data analysis.

**Qualitative Data Collection**

Qualitative In-Depth Interviews (IDIs) were conducted with all study participants at the 3-month follow-up visit. IDIs were conducted virtually over Zoom using a semistructured interview guide designed by this study’s team. The guide explored participants’ experience in the intervention, utility and potential improvements to each component of the intervention, level of engagement with intervention content, barriers to participation, and recommended improvements for future intervention implementations.

**Qualitative Data Analysis**

We conducted a thematic analysis of IDIs using a mixture of inductive coding driven by themes emerging from the transcripts and deductive coding based on themes from the interview guide. Qualitative analysis focused on the perceived acceptability and mental health impact of the IMAGINE intervention as well as recommendations for future iterations. First, 3 members of this study’s team (KR, EW, and AG) read all transcripts and separately developed initial codebooks based on themes that emerged from the transcripts and were explored in the interview guide. Initial codebooks were compared and discussed to create an agreed-upon combined codebook. Transcripts were then coded by 2 analysts (EW and AG) using Dedoose (Sociocultural Research Consultants, LLC) software [43]. Disagreements between analysts were resolved through discussion.

**Ethical Considerations**

The IMAGINE study was approved by the University of Washington Institutional Review Board (STUDY00008278). All participants provided informed consent for eligibility screening, exposure to the intervention, and data collection. Waivers were obtained for written documentation of informed consent and parental consent for adolescents younger than 18 years.

**Results**

**Participant Flow and Intervention Uptake**

Figure 1 summarizes participant flow from contacting this study to completing screening, enrolling in this study, and completing follow-up. In total, 68 individuals contacted this study between October 16, 2020, and January 29, 2021. Of these, 22 were assessed for eligibility, while 46 individuals did not complete screening due to challenges scheduling screening calls or participants declining to complete screening. Of the 22 who were assessed, 13 were eligible and 9 were ineligible, most (n=7, 77.8%) due to elevated depression scores warranted referral to individual care. In total, 3 eligible participants declined participation and 10 eligible participants were enrolled
in the pilot, for an uptake of 76.9% (10/13 eligible participants). Participants were divided into 2 intervention groups: 7 in group 1 (active December 2020 to February 2021) and 3 in group 2 (active February to May 2021). While groups could be up to 10 participants, we elected to initiate the first group when 7 participants had been enrolled to minimize participants’ wait, while recruitment of the remaining participants continued. Of the 10 study participants, 9 completed the 3-month follow-up questionnaire and IDI.

**Figure 1.** Participant flow. PHQ-9: Patient Health Questionnaire.

**Participant Demographic Characteristics**

Demographic characteristics of enrolled participants are summarized in Table 1. All participants identified as female, and the median age was 17.9 (IQR 17.4-21.7) years. Of 9 participants who provided their race or ethnicity, 6 (67%) identified as Black, 5 (56%) identified as Latinx, 1 identified as an unlisted category, and 2 (22%) identified as White. Further, 4 (40%) participants were bilingual and 5 (50%) had completed at least a high school diploma or general education development. In total, 4 (40%) participants were pregnant at the time of this study and 6 (67%) used Medicaid health insurance. All but one of the participants reported that they were stably housed.

### Intervention Acceptability and Utility

#### Quantitative Assessment

Among the 9 participants who completed follow-up, we found a mean acceptability score of 4.3 out of 5 (SD 0.6) on the AIM questionnaire. All participants reported that they would recommend IMAGINE to a friend. When asked about the use of core CBT skills covered in MB, all participants reported engaging in “playing with baby,” “contact with others,” and “talking to/contacting someone who has been a positive support for self and baby” skills during at least half the days in the prior month (Table 2). The majority reported using the following skills at least half the days: “mood tracking” (n=6, 66.7%), “engaging in pleasant activities” (n=6, 66.7%), “overcoming obstacles to doing pleasant activities” (n=6, 66.7%), “thought interruption to reduce harmful thoughts” (n=5, 55.6%), “using time projection to imagine a better time in the future” (n=6, 66.7%), and “using self-instruction to give oneself helpful directions” (n=7, 77.8%). When asked about the helpfulness of each skill, 100% of participants who used them (n=9) reported they were helpful (Table 2). Of the 11 skills we asked about, participants reported using a median of 7 (IQR 5-7) skills at least half the days.

We also analyzed participant engagement in the intervention. Figure 2 summarizes 3 measures of engagement: the number of SMS text messages sent on all Slack channels over the course of the intervention, the proportion of video calls attended, and the proportion of mood polls completed. Participants sent a median of 12 (IQR 11-15.8) messages during the 12-week intervention period, attended a median of 9.7% (IQR 0%-45.8%)
of the weekly video calls, and responded to a median of 32% (IQR 14.5%-47%) of the mood polls. Levels of engagement, particularly messaging, generally decreased over time but increased at intervention close (Multimedia Appendix 1).

\textsuperscript{b}Among those who reported using the skill; includes “somewhat helpful” and “very helpful” responses.

\textsuperscript{c}Responses to this question asked for the number of new people who met who can provide support. This n represents the number of those who met at least 1 new support person.

Figure 2. Participant engagement in the intervention.

Qualitative Assessment

IDIs explored the acceptability and perceived utility of IMAGINE. Participants highlighted several aspects of the intervention that were especially well-received (Textbox 1). Support from both the facilitator and other participants was viewed as beneficial. Most participants (n=8) reported valuing the connection with the facilitator and feeling that they could go to them for guidance and support. Participants (n=7) highlighted that support from other young parents in the program normalized and validated their experiences; several participants spoke about the value of connecting with others in similar situations to them. Mood polls were mentioned by all 9 participants as an impactful component of the intervention, with participants valuing the opportunity to reflect on their emotional state. In total, 2 participants highlighted the value of the intervention’s flexibility, both that the asynchronous design allowed them to access content at a time and pace that worked best for them, and that the facilitator made adaptations to respond to participant needs during intervention delivery.
In-Depth Interview themes related to intervention acceptability.

Support from the study facilitator

- When I had something come up or just anything, like, I would just talk to her, or if I had a question, I would talk to her. I asked her the question, and she would like answer the best way that she could or stuff. And I was just like, that's really helpful.
  [Participant 5, aged 21 y, postpartum]
- I had a kind of Facetime with her one time, just us, because the other girls weren’t able to make it. But that was very - I really appreciated that. It was kind of something that I didn't know that I needed, but she willing to like, hear me out and ask the right questions for me. So I think that was pretty awesome of her.
  [Participant 7, aged 23 y, pregnant]

Connection with other participants

- Seeing other women, not necessarily the facilitator, but being around the women that are going through the same things that you're going through, like that are also pregnant and just had babies, that makes a difference. That allows the connections that you form are a lot stronger and a lot tighter
  [Participant 9, aged 23 y, postpartum]
- We all went through this together and I felt like we all kind of grew together and, you know, they could, we could all relate to each other. And I didn't really have many mom friends I guess before this.
  [Participant 17, aged 17 y, pregnant]

Mood polls

- Normally you don't really reflect on your day unless you have a bad day. So I just like the way how it got me thinking. ‘Oh, well, I did have a good day but I didn't notice it because it wasn't a bad day’ if that makes sense.
  [Participant 12, aged 23 y, postpartum]
- I think they were helpful just because it was like a second to self-reflect, maybe look in the real world. Sometimes they ask you how you doing but it's kind of difficult to explain to someone, but when you're doing it for yourself, I think it can be a little bit more honest.
  [Participant 7, aged 23 y, pregnant]

Intervention flexibility

- At the beginning I think it started off slow and then she was sending a lot of messages, every day, so I wouldn't get time to read them. I'd have to go back a lot, and then that's something that I told her, and so she slowed down on the number of messages, so she sent them every other day, instead of every single day.
  [Participant 17, aged 17 y, pregnant]
- Having lots of interactions in written form gave everyone an opportunity to share their perspective and their experiences and what works for them, and we didn't all have to be right then and there, like I could look at it at two o'clock in the morning and another girl could look at it at two o'clock in the afternoon.
  [Participant 9, aged 23 y, postpartum]

Mental Wellness

Quantitative Assessment

Summary statistics for mental wellness outcomes are presented in Table 3 and individual participant trajectories are displayed in Multimedia Appendix 2. We compared depression symptoms (by PHQ-9), perceived stress (by PSS-4), and social support (by abbreviated SSB) between enrollment and follow-up. No significant changes in scores were found. At enrollment, the median PHQ-9 score was 4.0 out of 27 (IQR 2.0-5.0), compared with 2.0 (IQR 2.0-3.0) at follow-up ($P=.25$); 6 of 9 participants demonstrated reductions in PHQ-9 scores from baseline to follow-up. Median PSS-4 at enrollment was 8.0 out of 16 (IQR 8.0-10.0) and 9.0 out of 16 (IQR 8.0-10.0) at follow-up ($P=.46$). The median social support score related to participants’ family was 50.0 out of 100 (IQR 42.0-53.0) at enrollment, and 48.5 out of 100 (IQR 47.5-50.5) at follow-up ($P=.11$). The median social support score for friends was 51.0 out of 100 (IQR 47.0-54.0) at enrollment and 50.0 out of 100 (IQR 46.0-53.0) at follow up ($P=.88$).

<sup>a</sup>PHQ-9: Patient Health Questionnaire.

Qualitative Assessment

In IDIs, participants highlighted 3 ways they perceived participating in IMAGINE benefited their mental health (Textbox 2). First, participants (n=5) expressed that being in a group with other young parents normalized and validated their experiences, which helped them feel more connected with others and strengthened their belief that they could make changes to improve their mood. Second, several participants (n=5) noted that they had gained skills in regulating their emotions. Some stated that they still used some of the mood monitoring and management techniques discussed in the program after it had ended. Participants highlighted that they had few opportunities in their day-to-day lives to reflect on their mood and that there was value and ease in reflecting “for yourself” through the digital platform, rather than to another person who may not understand their feelings. Participants also commented that they learned to pay closer attention to emotions in the middle of the spectrum (ie, not crisis or elation), and that helped them monitor when and why their mood changed. Third, several participants (n=6) stated that they would be more open to mental health services in the future after they completed IMAGINE. Some common feedback from participants related to this was that it helped them realize they needed to return to psychotherapy if they had sought it in the past, or for those without prior experience, IMAGINE helped normalize some of the unknown or off-putting aspects of mental health care. It became more familiar to discuss moods and feelings with others, which increased their openness to seeking care.
Textbox 2. In-Depth Interview themes related to mental health impact.

Normalized experiences

- It helped me, like, open up a little more, and realize that I’m not the only person suffering, and that there’s more people like me that I can talk about it with. I don’t have to, you know, suffer by myself.
  [Participant 17, aged 17 y, pregnant]
- [IMAGINE helped me] understand… my emotions right now were normal… Before, I felt like I was broken or I needed to be fixed or there’s something wrong with me and now… there’s nothing wrong with me. [I’m] normal.
  [Participant 9, aged 23 y, postpartum]

Gained emotional regulation tools

- I had a pregnancy before that and it was also a preterm birth. And so, that baby passed away. And so it was really hard for me. I was really depressed, and so I know that if I would have had like the Imagine group it like it would help it would have helped me to manage my, my emotions and stuff.
  [Participant 5, aged 21 y, postpartum]
- I definitely added a handful more tools to my arsenal to be able to calm myself down, stay calm, or not become overwhelmed with everything that’s going on… I’ve been using these - to me they’re like lower tier ways of coping. So it’s like when I’m not at a ten, I’m at like a five, I can use these.
  [Participant 9, aged 23 y, postpartum]
- Reading the mood tree… identifying the stressors… how to regulate it, different forms of communication, just all these different things for your mood and focusing on that. It just helped me to realize taking myself is a priority. And not just my baby and making sure she’s okay but making sure I’m okay as well.
  [Participant 17, aged 17 y, pregnant]

Open to mental health services in the future

- I like to bottle up my anger or my problems and they explode on the wrong person at the wrong time so that being in a group kind of made me realize like I need to go back to counseling. I was already in counseling but I don’t feel like I was taking it as serious but when I sat back and realized… No, I do need to get it together, that’s when I was like, I’mma just go back to counseling.
  [Participant 14, aged 18 y, pregnant]
- When you talk to [my family] about… feeling depressed and you’re not mentally okay they’re, like, “oh that’s not real, it’s fake, it’s all in your head”… And so, [IMAGINE] just helped me to think that there is help, and it is real, and that it’s not just in your head.
  [Participant 5, aged 20 y, postpartum]

Recommended Improvements

IDIs explored participants’ barriers to intervention participation and recommended improvements to IMAGINE. Frequently identified barriers to participation included being too busy, introversion, and low engagement from other members (Textbox 3). Participants (n=7) mentioned being unable to read all the messages or join Zoom meetings because they were working, in school, or busy with parenting responsibilities. Introversion was mentioned by a few participants (n=3), and 1 participant stated that a reason she did not participate in more Zoom calls was the thought that she was expected to be on camera, which she found uncomfortable. Limited engagement from other group members was discussed as a deterrent to engagement: participants (n=6) felt they would have engaged more and benefited more if synchronous and asynchronous conversations had included more voices. In total, 2 participants also reported technology challenges, both of which were resolved.

Participants shared recommendations to address their barriers to engagement (Textbox 3). Several participants (n=8) recommended changes to the frequency and timing of the synchronous Zoom calls to facilitate their attendance. Calls were scheduled each week based on polls with the group to identify the optimal time. Participants suggested that offering calls in the evenings, during the weekends, or announcing the schedule for all calls at the start of the program rather than scheduling them week-by-week could improve attendance. A few participants suggested offering multiple call times each week. Some participants (n=3) also requested more onboarding at the start of the group, including more orientation to the Slack platform and more icebreakers and rapport-building activities with other group members to encourage greater comfort and collective engagement in the group. While IMAGINE was designed to be virtual and COVID-19 restrictions meant in-person contact was not possible at the time, a common piece of feedback (n=7 participants) was to have at least one in-person meeting or offer a hybrid version of IMAGINE to deepen relationship-building with other group members.
Textbox 3. In-Depth Interview themes related to barriers to participation and recommended improvements.

**Barriers**
- **Being busy**
  - I couldn't read or join in on the calls, because I had started back working. [Participant 24, aged 16 y, pregnant]
  - I started working like right after I got into [the study], and I didn't know when I was actually going to be available… Some of the polls or some of the Zooms I wasn’t even able to join, because I work. [Participant 18, aged 19 y, pregnant]
- **Introversion**
  - I’m a shy person. So that’s what, I just want to push myself more to be able to, you know, do more things like this because this is like out of my comfort zone. [Participant 17, aged 17 y, pregnant]
  - Being on video is just not for me. I’m just not gonna keep with this. [Participant 12, aged 23 y, postpartum]
- **Low engagement from other study participants**
  - It would have been better if everybody, you know, responded in and reacted. But it was a good thing to still be able to have somebody there talking to us, even though we weren’t always responding. [Participant 20, aged 18 y, postpartum]
  - I just wish more people participated, because even in the zoom calls like sometimes I would be the only person that would join, or it would just be one or two other moms. [Participant 17, aged 17 y, pregnant]
- **Issues with technology**
  - My phone like we started and it kind of deleted the app so I was just like, whoa. Okay. [Participant 5, aged 21 y, postpartum]
  - I had to switch [cell phones], so I had turned in a phone that I was leasing for Sprint and then I had an old phone, but I couldn’t do certain things on it. Like I couldn’t download a lot of apps because I didn’t have the latest iOS and then, when I got the new phone, I had to wait to switch carriers. It was a lot going on, when I was trying to get a new phone. [Participant 12, aged 23 y, postpartum]

**Recommended improvements**
- **More flexibility for Zoom calls**
  - I didn’t really get to join any of the zoom meetings because I was usually busy… I wish I could have. [Participant 5, aged 21 y, postpartum]
  - If we had more zoom calls like twice a week, that would be really great for me. [Participant 7, aged 23 y, pregnant]
- **Hybrid or in-person meetings**
  - I think that if we have more in person, it would have been better because it's more something that you can engage in more than just being online. [Participant 20, aged 18 y, postpartum]
  - I feel if you were to go in person and meet everyone, I think that’d be great. You get to interact. [Participant 5, aged 21 y, postpartum]
- **More onboarding**
  - At the very end, it was really nice because we were kind of more comfortable with each other, but at the beginning it was, understandably, a little bit awkward. We don’t know each other, but I think we could have benefited with some more icebreakers or some more like getting to know each other, rather than just kind of jumping in and expecting [us] to be open to each other. Because not everybody is willing to, you know, put themselves in that situation where they kind of have to be vulnerable. [Participant 7, aged 23 y, pregnant]
  - Me personally I didn't like the Slack platform just because I'm not really tech savvy I guess you could say, and it was a lot of different components to the app, so it's kinda like I'm still trying to learn how to use it. [Participant 14, aged 18 y, postpartum]
- **Low engagement from other study participants**
  - It would have been better if everybody, you know, responded and reacted. But it was a good thing to still be able to have somebody there talking to us, even though we weren’t always responding. [Participant 20, aged 18 y, postpartum]
  - I just wish more people participated, because even in the zoom calls like sometimes I would be the only person that would join, or it would just be one or two other moms. [Participant 17, aged 17 y, pregnant]

**Discussion**

**Principal Results**

In this mixed methods pilot study, we found that IMAGINE, a novel digital adaptation of the evidence-based MB course, had high acceptability and perceived utility. Uptake of IMAGINE, defined as the proportion of eligible participants who enrolled, was high. However, many individuals who initially contacted this study did not complete the screening process, suggesting these screening procedures presented barriers. These barriers may include the need to arrange a call with study staff to...
complete screening; it is possible the reach would be higher in a lower-barrier delivery model where clients could self-register in the group without arranging a screening call. We also found that a substantial proportion of screened participants were ineligible, most commonly due to elevated PHQ-9 scores. While our study’s focus was on the prevention of perinatal depression, this observation suggests that IMAGINE may also be appealing to individuals who are already experiencing elevated symptoms of depression; this observation is important in considering potential future applications of IMAGINE.

Acceptability scores were high and all participants stated they would recommend IMAGINE to a friend. Quantitative measures of engagement in the intervention, such as frequency of messaging and attendance of video calls, demonstrated low-moderate engagement. Nevertheless, most CBT approaches discussed in the IMAGINE intervention were used frequently and reported to be useful by the majority of participants. Qualitatively, participants reported one-to-one support from the facilitator, connection with other parents, and regular opportunities to reflect on their mood through mood polls were especially helpful aspects of the intervention. Additionally, participants reported that the intervention normalized their mental health challenges, improved their ability to manage their mood, and increased their openness to mental health care. We found no significant changes in depression scores, perceived stress, or perceived social support, although our study’s small sample size was not powered to detect changes in these outcomes.

Participants also made recommendations for improvements to the IMAGINE intervention in future iterations, including more opportunities for synchronous connection with other group members, additional rapport-building activities, and further simplification of message content.

Comparison With Prior Work

Our findings add to a small but growing body of literature on the use of digital interventions to prevent perinatal depression. While several studies have found that internet-delivered CBT is effective in the treatment of depression, including in the perinatal period [28,44-49], digital interventions for the prevention of perinatal depression have been less well studied [30,50].

Our findings are consistent with data from in-person MB. The levels of CBT skill use that IMAGINE participants reported were similar to that reported in a cluster randomized trial of in-person MB [51]: 66% (n=6) of IMAGINE participants reported that they engaged in pleasant activities and 100% (N=9) talked to or contacted someone who has been a positive support, compared with 78% and 80% respectively in Tandon et al’s [51] study previously adapted MB to a self-guided web-based format with informational pages, audio and video clips, and worksheets that follow MB modules in English and Spanish. A pilot randomized trial of the intervention, named Mothers and Babies Online Course, found nonsignificant improvement in depression symptoms; this study’s power was limited by sample size and the authors commented that facilitator guidance may improve uptake and efficacy [25,52]. The IMAGINE intervention differs from the Mothers and Babies Online Course in its inclusion of a facilitator and group delivery format, both of which were viewed as helpful components by participants in our pilot. Our findings of high acceptability, low-moderate engagement in intervention content, and high perceived utility are consistent with those of Barrera et al [25], suggesting digital delivery of MB with and without facilitation is a promising strategy that warrants further evaluation.

Strengths and Limitations

Our study has several strengths. The IMAGINE intervention was developed through systematic adaptation of the evidence-based MB course that prioritized fidelity to core MB components while adapting to participants’ design recommendations [34]. Our recruitment strategy feasibly reached potential participants across the country. Our evaluation is strengthened by including measures of CBT skill use that align with the mechanism of MB and were used in previous MB studies, allowing comparison of our findings with other MB studies. Furthermore, our study explored the experiences of young perinatal people, whose often marginalized perspectives are critical to developing responsive interventions. Guided by the principles of human-centered design [53], we collected in-depth insights from users before and after our pilot to drive future iteration and improvement of the intervention.

The primary limitations of our study are its small sample size and nonrandomized design. This study was not powered to evaluate the intervention’s effect on mental health outcomes, and pre-post comparisons are susceptible to confounding by changes over time that are not attributable to the intervention. Additionally, recruitment was primarily through Facebook and Instagram, which were selected for participants who were already using social media platforms and may be more open to a digital intervention. Due to resource constraints for this pilot study, our eligibility criteria included the ability to read and write in English, which systematically excluded non-English speakers, whose needs may differ. Future evaluations should address the limitations of this study by achieving a larger sample size, employing a randomized design, recruiting from nonsocial media sources, and developing translations in additional languages, particularly Spanish, in which MB materials already exist.

Conclusions

This pilot study provides promising evidence of the acceptability and utility of a digital group adaptation of MB among perinatal youths. These findings support further development and evaluation of the IMAGINE intervention to increase access to evidence-based interventions for the prevention of perinatal depression. Future iterations of IMAGINE will incorporate user recommendations from this study and use randomized powered evaluations to test clinical impact.
Acknowledgments

The authors gratefully acknowledge IMAGINE study participants and recruitment partners. This study was funded by a grant from the Technology and Adolescent Mental Wellness program at the University of Wisconsin-Madison. This study was also supported by the National Institutes of Health (grant K18MH122978) and the University of Washington Behavioral Research Center for HIV (BIRCH), a National Institute of Mental Health–funded program (P30 MH123248). Benefits, Recruitment, Dropout, and Acceptability of the Strength Back Digital Health Intervention for Patients Undergoing Spinal Surgery: Nonrandomized, Qualitative, and Quantitative Pilot Feasibility Study

Abstract

Background: Patients undergoing spinal surgery report high levels of insecurity, pain, stress, and anxiety before and after surgery. Unfortunately, there is no guarantee that surgery will resolve all issues; postsurgical recovery often entails moderate to severe postoperative pain, and some patients undergoing spinal surgery do not experience (long-term) pain relief after surgery. Therefore, focusing on sustainable coping skills and resilience is crucial for these patients. A digital health intervention based on acceptance and commitment therapy (ACT) and positive psychology (PP) was developed to enhance psychological flexibility and well-being and reduce postsurgical pain.

Objective: The objective of this study was 3-fold: to explore the potential benefits for patients undergoing spinal surgery of the digital ACT and PP intervention Strength Back (research question [RQ] 1), explore the feasibility of a future randomized controlled trial in terms of recruitment and dropout (RQ 2), and assess the acceptability of Strength Back by patients undergoing spinal surgery (RQ 3).

Methods: We used a nonrandomized experimental design with an intervention group (n=17) and a control group (n=20). To explore the potential benefits of the intervention, participants in both groups filled out questionnaires before and after surgery. These questionnaires included measurements of pain intensity (Numeric Pain Rating Scale), pain interference (Multidimensional Pain Inventory), anxiety and depression (Hospital Anxiety and Depression Scale), valued living (Engaged Living Scale), psychological flexibility (Psychological Inflexibility in Pain Scale), and mental well-being (Mental Health Continuum–Short Form). Semistructured interviews combined with log data and scores on the Twente Engagement With eHealth Technologies Scale were used to assess the acceptability of the intervention.

Results: A significant improvement over time in emotional (V=99; P=.03) and overall (V=55; P=.004) well-being (Mental Health Continuum–Short Form) was observed only in the intervention group. In addition, the intervention group showed a significantly larger decline in pain intensity (Numeric Pain Rating Scale) than did the control group (U=75; P=.003). Of the available weekly modules on average 80% (12/15) was completed by patients undergoing spinal fusion and 67% (6/9) was completed by patients undergoing decompression surgery. A total of 68% (17/25) of the participants used the intervention until the final interview. Most participants (15/17, 88%) in the intervention group would recommend the intervention to future patients.
Conclusions: This pilot feasibility study showed that combining ACT and PP in a digital health intervention is promising for patients undergoing spinal surgery as the content was accepted by most of the participants and (larger) improvements in pain intensity and well-being were observed in the intervention group. A digital intervention for patients undergoing (spinal) surgery can use teachable moments, when patients are open to learning more about the surgery and rehabilitation afterward. A larger randomized controlled trial is now warranted.

Introduction

Background

Patients undergoing spinal surgery report high levels of physical complaints as well as insecurity, pain, low well-being, stress, and anxiety before and after surgery [1-3]. Postsurgical recovery often entails moderate to severe postoperative pain, and approximately 20% to 30% of patients undergoing spinal surgery do not experience (long-term) pain relief after surgery [3,4]. This results in a longer hospital stay, higher health care costs, longer physical and mental recovery, delayed return to work, and the potential development of chronic pain. The potential transition from postoperative pain to chronic pain is a major issue as chronic pain affects many aspects of a patient’s life, such as work; physical, emotional, and social well-being; and quality of life [5,6].

Mental factors such as cognition, emotions, and expectations play a significant role in the experience of pain [7]. The fear-avoidance model explains the trajectory from acute to chronic pain through fear and catastrophizing, which is the tendency to enlarge the threat of pain and a feeling of helplessness, leading to an increase in pain avoidance as a dominant coping strategy [8]. Pain avoidance then leads to a less active lifestyle, thereby worsening rather than relieving pain. High levels of catastrophizing and fear have been found to predict higher levels of (postoperative) pain and pain chronicity and a lower quality of life in patients who undergo surgery [4,9-11]. In addition, realistic expectation management is key as unrealistic or unfulfilled expectations about surgery and preoperative stress may lead to the experience of higher levels of postoperative pain [12-18]. This link between mental factors and expectation management with postoperative outcomes shows that psychological preparation before surgery is essential to improve recovery after surgery.

Although the potential benefits of psychological preparation before surgery have long been known [19], a more recent meta-analysis of psychological preparation techniques before surgery could not find strong evidence from high-quality research to verify these claims [20]. Potentially, interventions that focus on promoting adaptive coping skills and reducing maladaptive emotion regulation skills are more promising. Smith and Zautra [21] and Sturgeon and Zautra [22] found, for example, evidence that coping strategies such as (pain) acceptance, engaging in beneficial social interactions, and experiencing a value-based purpose in life have the potential to improve mental well-being and promote resilience in the face of (chronic) pain. Sustainable resilience to (chronic) pain requires skills promoting adaptation and mental health in the long term [22]. In other words, adaptation to different contexts and circumstances requires (psychological) flexibility and a long-term focus. In the context of pain, psychological flexibility implies that painful sensations, feelings, and thoughts are accepted as opposed to avoided and that attention shifts toward personally valued goals [23]. For patients undergoing spinal surgery, psychological flexibility enables them to cope with the fluctuating circumstances surrounding surgery (eg, insecurity, fear, and pain) in a flexible rather than rigid manner. Being able to accept negative emotions or sensations such as pain and insecurity in the face of surgery might prevent catastrophizing, fear, and avoidance behavior.

Psychological flexibility is the aim of acceptance and commitment therapy (ACT) [24]. ACT is based on the relational frame theory and focuses on performing value-based activities in life even in the face of insecurity and adversity [24]. In a similar way, positive psychology (PP) is the scientific study of well-being and optimal functioning, focusing on human flourishing instead of reducing the risk factors for psychopathology and malfunctioning. PP involves topics such as strengths, virtues, meaning, happiness, gratitude, compassion, resilience, and flourishing [25]. ACT and PP can help experience a value-based purpose in life, promote resilience, and improve mental well-being. Mental well-being comprises positive emotional, psychological, and social functioning [26]. The presence of higher levels of these 3 dimensions of well-being is an indicator of flourishing [26-28]. Promoting positive resources and skills that contribute to successful adaptation and (mental) health are the aims of PP interventions (PPIs) [25,29]. PPIs and ACT have been found to be effective in the treatment of chronic pain [30-35], improving affect and functional ability after knee surgery [21], and quicker cessation of pain and opioid use in veterans after orthopedic surgery [36]. In summary, PP and ACT could potentially benefit patients undergoing spinal surgery in terms of physical (eg, pain) and psychological (eg, well-being) factors.

In the context of surgery, digital health interventions can be used to aid patients during their recovery process [37]. These interventions can be used to improve postoperative outcomes by supporting healthy lifestyle behavior change before and after surgery [38,39] and to improve medication adherence [40,41]. Digital health interventions can also better prepare patients for surgery or shorten postoperative recovery through behavioral modification, patient monitoring, or protocol adherence [42-45].
Behavioral modification can also be applied to promote a healthy lifestyle. This is important as healthy lifestyle behavior changes before and after orthopedic surgery, such as increased preoperative physical activity or smoking cessation, have been associated with improved postoperative bone healing [46] and wound healing [47], quicker recovery times, and reduced pain scores [48]. Moreover, patients undergoing surgery who engage with digital health interventions show better medication adherence, better adherence to discharge instructions, greater patient satisfaction, improved clinic attendance, lower readmission, and less emergency department visits after surgery [49]. van der Meij et al [50] found in their review that, in most studies, perioperative digital health interventions improved clinical patient-related outcomes compared with face-to-face perioperative care alone for patients who had undergone various forms of surgery. This shows the potential of digital health interventions to improve perioperative care in addition to face-to-face meetings with professionals.

Despite the clear potential of ACT and PPIs for mental well-being and long-term resilience, they have not yet been used to develop interventions targeting psychological flexibility in patients undergoing spinal surgery. In addition, seeing the potential of digital health interventions in the context of surgery, this form also seems promising for patients undergoing spinal surgery. For this reason, a digital health intervention called Strength Back [51] was developed. Strength Back aims to increase psychological flexibility and well-being and improve postoperative recovery in patients undergoing spinal surgery. This intervention, developed through cocreation with different stakeholders, contains procedural information, pain education, and PPI and ACT exercises.

**Objectives**

Although the intervention is based on a scientific, theoretical framework, the effects and impact of the intervention need to be proven to be able to implement it in an evidence-based health care setting. This requires a collection of evidence, such as through a randomized controlled trial (RCT). As an RCT is complex and expensive, preparation and insights in advance into the required parameters, such as measures, recruitment, and dropout numbers, are essential to perform a thorough RCT. In light of the aforementioned research on PP and ACT in other target populations, several outcome measures covering physical and psychological factors need to be explored as potential benefits of this intervention. In addition, in an RCT, the best possible version of the intervention needs to be tested. This is in line with the recommendation of the Medical Research Council of first testing and refining an intervention to ensure it is acceptable to successfully evaluate whether it is effective [52]. In addition, to reduce psychological and practical barriers and maximize acceptability, it is important to understand and accommodate patients’ views [53]. As of yet, it is unknown how patients undergoing spinal surgery value the intervention Strength Back in terms of acceptability, potential benefits, and feasibility in a real-life setting and what the required parameters for a future RCT would be. Therefore, the objective of this study was 3-fold: to explore the potential benefits for patients undergoing spinal surgery of the digital ACT and PPI Strength Back (research question [RQ] 1), explore the feasibility of a future RCT in terms of recruitment and dropout (RQ 2), and assess the acceptability of Strength Back by patients undergoing spinal surgery (RQ 3).

**Methods**

**Study Design**

This was a nonrandomized pilot study, a subset of feasibility studies as described by Eldridge et al [54]. Our study design included an intervention group and a historic control group (Figure 1). We used a historic control group as the development of the intervention was still ongoing and the target population was small. The participants in the control group received care as usual. In addition to receiving care as usual, the participants in the intervention group were given access to the digital health intervention Strength Back. To test the acceptability of the intervention, individual interviews were conducted with the participants in the intervention group. Both groups filled out a questionnaire before (pretest time point) and after (posttest time point) surgery.

![Figure 1. Study design and timeline for individual participants (patients undergoing spinal surgery) in the control and intervention groups of this pilot feasibility study.](https://formative.jmir.org/2024/1/e54600/figure1.png)
As suggested by Orsmond and Cohn [55], we used a combination of qualitative and quantitative measures in this feasibility study. We aimed to include 20 participants in our control group and 20 participants in our intervention group, which is in line with the study by Billingham et al [56], who found a median sample size of 36 in their review of feasibility studies.

**Participants**

Patients undergoing decompression or spinal fusion surgery were eligible for inclusion in either the control or intervention group of this study. Patients undergoing spinal surgery other than decompression or spinal fusion surgery (e.g., patients with hernias or patients of oncology) were excluded. Other inclusion criteria were age of >18 years, proficiency in Dutch, and an email address. Participants in the intervention group needed an Android or iOS smartphone or tablet at home and had to be willing to use a digital health intervention both before and after surgery.

All participants in this study were recruited through purposive sampling at an orthopedic center in the Netherlands. The participants in the historic control group were recruited between February 2020 and July 2020. The participants in the intervention group were recruited between September 2020 and February 2021.

**Conditions**

**Care as Usual**

The historic control group received care as usual. They were provided with brochures containing information about their diagnosis, surgical procedure, surgery preparation, physical guidelines during recovery, contact information, and possible complications. In addition, usual care consisted of several appointments besides the surgery itself: an intake and a preoperative screening before surgery, a consultation by phone 10 days after surgery, and a physical checkup at the orthopedic center 6 weeks (both surgery types) and 12 weeks (spinal fusion surgery) after surgery.

**Strength Back Digital Health Intervention**

In addition to care as usual, participants in the intervention group were given access to the *Strength Back* digital health intervention (see Figure 2 for screenshots). The content of this app was developed through a process of cocreation. The stakeholders involved in this process were patients who had undergone spinal surgery, orthopedic surgeons, a physical therapist, a nurse practitioner, a research coordinator, and several nurses. The content of the intervention was based on the results of interviews and focus group sessions with the aforementioned stakeholders (patients and health care professionals) combined with ACT and PP exercises. Multimedia Appendices 1 to 3 of this publication and our previous publication on the cocreation of *Strength Back* [51] provide more details on the developmental process.
The intervention consisted of 13 information modules, which were continuously available, and 6 to 12 weekly modules. Participants did not receive personal messages from a health care professional. The contact information of the orthopedic clinic was provided in the intervention, making sure participants could contact a health care professional in case of any questions.

The information modules of the intervention were based on existing brochures and leaflets of the orthopedic center (Multimedia Appendix 1).

In addition, to support them during recovery, intervention participants received 6 to 12 weekly modules. These modules were timed: participants received 3 modules in the 4 weeks before surgery and 6 or 12 weekly modules after surgery depending on the type of surgery they had undergone. In total, 6 weekly modules were provided for patients undergoing decompression surgery, and 12 weekly modules were provided for patients undergoing spinal fusion, matching the expected recovery time after surgery as suggested by the orthopedic center (Multimedia Appendices 2 and 3).

During the intervention, participants received automated reminders every time a new weekly module was available. This was voluntary and could be turned on or off by the participants.

The digital health intervention was downloaded by the participants themselves using a step-by-step guide provided by the researcher.

**Procedure of Data Collection**

For both conditions, patients received a leaflet from their personal health care professional (ie, orthopedic surgeon, specialized physical therapist, or advanced nurse practitioner) explaining this study during their visit to the orthopedic center and were subsequently contacted by phone by the researcher. When patients agreed to take part in the study, their email address was collected, after which they received an information email with a link to the first web-based questionnaire (through Qualtrics [Qualtrics International Inc]; pretest assessment). We chose this specific moment for the pretest assessment to clarify the current and most up-to-date picture of the preoperative situation. In the questionnaire, the participants first had to
provide active informed consent to continue. Participants in both the control and intervention groups filled out this questionnaire (pretest assessment; Figure 1).

A total of 3 months after surgery, participants in both groups received an invitation by email to fill in the posttest questionnaire. At this time, it was expected that (nearly) all participants were in the final phase of their recovery process. We chose this specific moment to collect the data, when the recovery situation had stabilized. At this point, the participants in the intervention group were contacted by the principal investigator (AH) to make an appointment for an interview to assess how they valued the intervention. These semistructured interviews were conducted between January 2021 and June 2021 by 2 researchers (AH and LM). Owing to the COVID-19 pandemic, interviews were conducted via telephone. The interviews were audio recorded and lasted between 30 and 60 minutes.

The recruitment and dropout numbers in the intervention group were explored in this study to provide insights into what is needed for the recruitment process of a future RCT to reach the desired power.

Materials

Regarding RQ 1 (potential benefits), the questionnaires contained several outcome measures (ie, pain intensity and interference, anxiety, depression, psychological inflexibility, valued living, and mental well-being). These potential benefits were measured at the pre- and posttest time points for both the control and intervention groups.

Pain intensity was measured using the Numeric Pain Rating Scale (NRS). For the NRS, participants were asked to circle the number (0-10) that best described their experience of pain in the last week in general and in the last week at worst. The questions asked were as follows: “Please indicate the average intensity of your pain in the last week” and “Please indicate the intensity of your pain at the worst moments in the last week.” A higher score indicates a higher intensity of pain. The NRS is considered a valid, reliable, and appropriate pain rating scale for use in clinical practice, with good sensitivity [57].

Pain interference was measured using the pain interference subscale of the Multidimensional Pain Inventory (MPI) [58]. This subscale consists of 11 items measuring to what degree pain influences the daily life of a respondent, with total mean scores ranging from 0 to 6. A higher score indicates a higher degree of pain interference. The subscale showed good reliability in our study population, with a Cronbach α of .874.

Anxiety and depression were measured using the Hospital Anxiety and Depression Scale (HADS) [59]. Both the anxiety and depression subscales consist of 7 items with scores ranging from 0 to 21. A higher score indicates a higher degree of anxiety or depression. Both subscales showed good reliability, with a Cronbach α of .874 for the anxiety subscale and .789 for the depression subscale.

Psychological inflexibility was measured using the Psychological Inflexibility in Pain Scale (PIPS) [60]. The 2 subscales measure avoidance and cognitive fusion, concepts derived from the theoretical framework of ACT [24]. As the cognitive fusion subscale showed low reliability in our study population with a Cronbach α of .524, only the total score of the PIPS was used in this study. This total score had good reliability, with a Cronbach α of .893. A higher score indicates more inflexibility with pain (ie, lower acceptance and higher cognitive fusion).

Value-based living was measured using the “Valued living” subscale of the Engaged Living Scale (ELS; Trompetter et al [61]), which covers the concept of “valued living”—recognizing personal values and undertaking committed actions that are congruent with these values. The “Valued living” subscale consists of 10 items and uses a 5-point scale, with scores ranging from 10 to 50. A higher score indicates a higher degree of valued living. This subscale of the ELS showed high reliability, with a Cronbach α of .917.

Mental well-being was measured using the Mental Health Continuum–Short Form [62] on three dimensions: (1) emotional well-being, defined as positive feelings (3 items); (2) psychological well-being, described as individual functioning (eg, environmental mastery and purpose in life; 6 items); and (3) social well-being, measuring functioning in community life (eg, social contribution and social acceptance; 5 items). The mean scores per subscale range from 0 to 5, with a higher score indicating a higher degree of emotional, psychological, or social well-being. The total score (Cronbach α=.930) as well as that of the different subscales (emotional: Cronbach α=.930; psychological: Cronbach α=.874; social: Cronbach α=.799) showed good reliability, with a high Cronbach α in our study population.

Regarding RQ 2 (recruitment and dropout), we kept an overview in Microsoft Excel (Microsoft Corp) of the recruitment and dropout numbers in the intervention group in this study.

Regarding RQ 3 (acceptability), the scheme used for the interviews consisted of 2 parts. The first part of the interview started with questions on the intervention in general (eg, topics on layout and user-friendliness based on the Mobile App Rating Scale [63]). The second part continued by discussing the content of the modules (Multimedia Appendix 1) followed by the exercises in the weekly modules (Multimedia Appendix 2) as topics. Engagement with the intervention was measured using the Twente Engagement With eHealth Technologies Scale (TWEETS) [64]. This scale of 9 items comprises 3 subscales: behavioral, cognitive, and affective engagement. In this study, the total score, with a Cronbach α of .883, was used. In addition, the automated logs from the system were analyzed to see when participants opened which weekly module. The information modules were continuously available (before and after surgery), and activity in these modules was not recorded in the automated logs.

Data Analysis

All statistical analyses were conducted using SPSS (version 26.0; IBM Corp). For the exploratory aim of this study, full cases provide the most valuable information. Therefore, only full-case analyses were conducted. In addition, as the quantitative data were used to generate a general picture of
between-group differences, no imputation techniques were used. When participants filled out the pre- or posttest assessment more than once, the first completed test was used for the analysis.

For RQ 1 (potential benefits), between-group differences were assessed using nonparametric Mann-Whitney $U$ tests because of the small sample size and nonnormal distribution of the data. First, between-group differences were analyzed at baseline using the Mann-Whitney $U$ test. Second, within-group differences were analyzed for both groups between the pre- and posttest assessment using a Wilcoxon signed rank test. The effect sizes were calculated using the Cohen $d$: \( \frac{\text{mean at the posttest assessment} - \text{mean at the pretest assessment}}{\text{SD}} \). When the SD of both moments differed, the mean SD of the pre- and posttest assessments was calculated and used. Values for the Cohen $d$ of 0.2 were considered a small effect size, 0.5 was considered a medium effect size, and values of $\geq 0.8$ were considered a large effect size.

Third, between-group differences were analyzed by comparing the pre- and posttest difference scores of both groups (Mann-Whitney $U$ test). All statistical tests were 2 sided. $P$ values of $<.05$ were considered statistically significant. As this was a feasibility pilot study, the results were considered exploratory, and no correction for multiple testing was performed.

For RQ 2 (recruitment and dropout), we analyzed the recruitment and dropout numbers of the intervention group in this study. For the analysis, we looked at the number of approached patients, the number of patients who consented to participate in the study, and the time span in which all these patients were approached. Dropout was defined as agreeing to participate in the study but not downloading the intervention, not filling out the pretest questionnaire, or not filling out the posttest questionnaire.

For RQ 3 (acceptability), interview data were collected, and the audio recordings were transcribed verbatim. For the analysis, the transcripts of all interviews were read and reread by 2 researchers (AH and LM) to familiarize themselves with the data. Subsequently, the transcripts were open coded by both researchers independently, followed by a discussion to reach a consensus regarding the coding. As a next step, both researchers sorted the codes into several groups. A deductive coding approach was used based on the topics on the interview scheme combined with an inductive approach for important content within these topics. For the coding and analysis process, the ATLAS.ti software (version 9.0; ATLAS.ti Scientific Software Development GmbH) was used.

**Ethical Considerations**

Ethics approval was granted by the Medical Ethical Committee of the Radboud University Medical Centre in Nijmegen (2019-5608) and the Ethics Committee of the Faculty of Behavioural, Management, and Social Sciences of the University of Twente (191080). The study is registered at the repository of the University of Twente for processing of personal data (AVG Register; WBP18ME0048).

Participants in both the control group and the intervention group filled out a questionnaire before and after surgery. When patients agreed to take part in the study, they received a link to the first questionnaire, in which they had to provide active informed consent to continue.

All human participant data were deidentified before analysis. Study participants received no compensation for their inclusion in the study.

**Results**

**Sample**

Figure 3 shows an overview of the inclusion of participants in the intervention and control groups. A total of 25 patients agreed to participate in the intervention group, of whom 3 (12%) participants did not fill out the pretest questionnaire; the reason for this is unknown. Therefore, a total of 22 participants filled out the pretest questionnaire. After filling out the pretest questionnaire, 9% (2/22) of the participants failed to download the intervention to their phones. Therefore, a total of 20 participants started using the intervention (20/35, 57% of the approached patients). Before the posttest questionnaire, 15% (3/20) of the patients discontinued their participation. This resulted in a total of 17 participants filling out the pre- and posttest questionnaires. All these participants (17/17, 100%) also took part in a telephone interview.
A total of 31 patients were approached by phone to participate in the control group. This resulted in 71% (22/31) of these participants completing the pretest questionnaire. A total of 9% (2/22) of these participants did not complete the posttest questionnaire without giving a reason. In total, 9% (2/22) of the participants started the posttest questionnaire but only partially completed it. This resulted in a control group of 20 participants, of whom 18 (90%) completed the entire pre- and posttest questionnaires.

The participant characteristics at baseline are presented in Table 1. The Mann-Whitney U test revealed no substantial differences between the intervention and control groups in terms of these characteristics.
Table 1. Participant characteristics at baseline by group.

**RQ 1: What Are the Potential Benefits for Patients Undergoing Spinal Surgery of a Digital ACT and PPI?**

First, between-group differences were analyzed at baseline (Mann-Whitney *U* test). The total score on the PIPS was significantly higher in the control group (*U*=262.5; *P*=.004). Other measures did not differ significantly between both groups at baseline.

Second, within-group differences were analyzed for both groups between the pre- and posttest assessments (Wilcoxon signed rank test; see Table 2 for the results). When looking at the differences between the pre- and posttest assessment, it should be taken into account that both groups had undergone surgery, which is an intervention by itself. Both groups showed significant improvement in the NRS (pain intensity week average and week worst), HADS anxiety subscale, HADS depression subscale, pain interference subscale of the MPI, and total score on the PIPS between the pre- and posttest time points. The score on the valued living scale of the ELS did not significantly change over time in either of the 2 groups. In the control group, the subscores as well as the total score on the Mental Health Continuum–Short Form did not differ significantly between the pre- and posttest time points. In the intervention group, the total score (*V*=99; *P*=.03 as well as the score on emotional well-being (*V*=55; *P*=.004) increased significantly over time.

<sup>a</sup>PIPS: Psychological Inflexibility in Pain Scale.
<sup>b</sup>NRS: Numeric Pain Rating Scale.
<sup>c</sup>HADS: Hospital Anxiety and Depression Scale.
<sup>d</sup>ELS: Engaged Living Scale.
<sup>e</sup>MHC-SF: Mental Health Continuum–Short Form.
<sup>f</sup>MPI: Multidimensional Pain Inventory.
Third, between-group differences were analyzed by comparing the pre- and posttest difference scores of both groups (Mann-Whitney U test). A significant difference was found in the weekly average NRS score between the intervention and control groups (U=75; P=.003), showing a significantly larger decline in pain intensity in the intervention group.

RQ 2: What Is the Feasibility of a Future RCT in Terms of Recruitment and Dropout Rates?

To determine the feasibility of a future RCT, recruitment, dropout rates, and dropout characteristics were examined. Over a period of 5 months, a total of 35 patients were approached by phone to participate in the intervention group (Figure 3). In total, 51% (18/35) of the approached patients did not want to participate and did not start with or dropped out of the intervention. Of these 18 patients, 14 (78%) were female and 14 (78%) underwent decompression surgery. Most of the dropouts did so before the intervention started as they did not want to participate in the study (10/18, 56%, of whom 9/10, 90% were female; age range 19-79 years). Most of the additional 44% (8/18) of dropouts did so at the pretest (3/8, 38%) or posttest (3/8, 38%) time points, and only 25% (2/8) of these participants dropped out because of nonadherence as they did fill out the pretest questionnaire but did not download the intervention. Of these 2 nonadherers, 1 (50%) was male and 1 (50%) was female; both underwent decompression surgery, and both were aged >65 years.

RQ 3: What Is the Acceptability of a Digital ACT and PPI Called “Strength Back” by Patients Undergoing Spinal Surgery?

Overview

Individual semistructured interviews were conducted with all 17 participants in the intervention group. The results of these interviews are described in 3 sections: general impression of the intervention, content of the intervention, and suggestions for improvement. Subsequently, engagement with the intervention is discussed by combining input from the interviews, log data, and the scores on the TWEETS [64].

General Impression of the Intervention

The general impression of the intervention can be described in terms of added value, recommendation, ease of use, repeated answers, feedback, and notifications.

Most of the participants (15/17, 88%) felt that the intervention had at least some added value in terms of support and as a source of information. PT3 stated the following:

*It did make me realize that the surgery was not a thing to take too lightly, that I could experience a relapse, so it did comfort me to know that in advance* [PT8]

Of the 17 participants who were interviewed, 2 (12%; PT4 and PT5) stated that the intervention did not have any added value for them. For instance, PT5 stated the following:

*The information from the physician was enough for me, but it might be helpful for other patients* [PT5]

A total of 12% (2/17) of the participants (PT4 and PT8) stated that they found the intervention to be too fluffy or vague and not suitable for them as they did not experience any pain or ups and downs.

When comparing the intervention with the paper brochure that patients normally receive from the hospital, some participants stated that either one would have been fine (eg, PT1 and PT9), whereas others stated that they preferred the intervention as the information was always nearby and, therefore, more accessible than a paper brochure that might get lost (eg, PT2, PT5, and PT6). Some participants stated that they had looked on the internet for information as well but preferred the information in the intervention as this was tailored to their own hospital and, therefore, also more reliable.

Similarly, 88% (15/17) of the participants stated that they would recommend the intervention; one participant (PT4) would not recommend it as it did not offer him anything additional to a paper brochure, and with another participant (PT12), this topic was not discussed. Participants mainly stated that they would recommend the intervention as it helped them prepare for surgery and enabled them to read and reread important information.

Participants indicated that the intervention was easy to use. A total of 12% (2/17) of the participants (PT5 and PT18) mentioned some minor layout suggestions, but the main consensus was that the intervention was easy to download and use, had a nice layout, and contained text in clear language. The functionality of previous answers (eg, preoperative answers on valuable activities to do after surgery) being repeated in later modules was appreciated by the participants:

*Nice to read what I had filled in previously and to see, on a later date that I was doing better when I answered a similar question* [PT3]

As the intervention only provided general information and no personal feedback from a professional, participants were asked whether they had missed this. Several participants (5/17, 29%) indicated that they did miss this personal feedback during the intervention or in general during recovery. This preferred feedback ranged from the ability to click on a help button (PT15) or the possibility of contacting someone for more information (PT1) to reaching out to someone guiding the intervention to reduce the amount of psychological content (PT11 and PT16) or feeling insecure and missing a contact person to consult (PT7).

Owing to an error, participants did not correctly receive a notification every time a new weekly module was available. Participants (6/17, 35%) indicated that receiving a notification
made them use the intervention more. They would have liked to receive the reminder every week, stating that they would have used the intervention more if they had.

Content of the Intervention
During the interview, all separate components of the intervention (Multimedia Appendices 1 and 2) were discussed with the participants. These elements were clustered as preparation and peer support, hospital information, and positive psychology and ACT content.

Preparation and Peer Support
Almost all participants (14/17, 82%) appreciated the videos of the nursing ward and the surgery room. These participants stated that they found watching the videos informative and comforting. One of the participants who did not appreciate the videos (PT11) stated the following:

*It might be comforting for little children, but as an adult you know what a hospital looks like and what will happen.* [PT11]

The practical tips from previous patients were valued by most participants (11/17, 65%). In total, 24% (4/17) of the participants did not see or remember this element, and 12% (2/17) of the participants would have liked to see more tips. The module describing the fluctuating recovery process was not remembered by several participants (8/17, 47%) but was valued greatly by those who did remember it:

*I could really recognize myself in the text, having had pain for so long myself.* [PT14]

*It really resembled the reality.* [PT18]

Participants reacted with mixed feelings to the quotes of previous patients. In total, 12% (2/17) of the participants (PT1 and PT16) stated that it might benefit other people but it was not for them. Several participants (7/17, 41%) could not remember the module (PT2, PT8, and PT15) or did not find it interesting (PT4, PT9, PT11, and PT13). These participants stated that they wanted to do things their own way and were not interested in the stories of other patients. Other participants (8/17, 47%) found the quotes valuable, recognizable, and comforting.

Hospital Information
The information on the spinal condition and on the surgical procedure was appreciated by the participants. Some stated that it was clearer than what the physician had told them or that it was nice to be able to read and reread it in the intervention, whereas other participants stated that it had no added value to them as the information resembled that of the paper brochure. The information on physical therapy did not match reality for some participants (3/17, 18%), but the discharge criteria were useful to see before surgery. In total, 18% (3/17) of the participants (PT1, PT4, and PT9) thought that the physical guidelines in the intervention had no added value as they were also available in the paper brochure. Another 18% (3/17) of the participants (PT11, PT15, and PT18) liked the fact that the physical guidelines were in the intervention but would have preferred them to be more specific or elaborate. The other participants (11/17, 65%) found the physical guidelines in the intervention pleasant, useful, and supportive. Most participants (11/17, 65%) appreciated the pain medication module. The other participants (6/17, 35%) liked the fact that the physical guidelines were in the intervention but would have preferred them to be more specific or elaborate. The other participants (11/17, 65%) found the physical guidelines in the intervention pleasant, useful, and supportive.

PP and ACT Content
The PP and ACT content in the intervention evoked the strongest opinions in the participants (Table 3). Several participants (5/17, 29%) stated that the amount of psychological content in the intervention was too high and made them less engaged with the intervention (like or use it less):

*The amount of psychological content was too much for me. I wasn’t raised that way and it doesn’t appeal to me. It almost made me stop using the intervention all together.* [PT17]
Table 3. Participants’ opinions on the positive psychology and acceptance and commitment therapy content of the intervention ranked in order of most to least appreciated exercise (n=17).

</tbody>
</table>

The potential relaxing effect of the mindfulness exercises was not experienced by 12% (2/17) of the participants (PT3 and PT9) even though they did do the exercises. Other participants (4/17, 24%) stated that the exercises were not for them as they already knew the techniques (eg, from yoga) but suggested that they might benefit other patients. The least appreciated exercise was writing a letter to themselves to support themselves in difficult times during recovery. Exercises focusing on values and positive statements were the most appreciated by the participants. Table 3 provides a more detailed overview.

Suggestions for Improvement

Overview

The participants also gave some suggestions for improvement. For instance, PT1, PT2, PT6, and PT15 stated that the information in the intervention was sometimes too elaborate and could have been more concise. Some suggestions about the usability of the intervention were mentioned (eg, on where to position the menu of the intervention or to enlarge the font size for older participants). Several participants would have liked the intervention to have less psychological content (eg, PT4, PT12, and PT15) or at least have the option to influence the amount of these exercises or content while using the intervention (eg, PT17). Other points of interest were the need for more specific physical guidelines (eg, PT11), more physical (therapy) exercises (PT18), and information about returning to work (PT17).

Engagement With the Intervention

Engagement with the intervention is described through the topics usage, reasons for not using, and number of modules, as discussed in the interviews, together with scores on the TWEETS and log data.

In the interviews, some participants (3/17, 18%) mentioned that they mainly used the intervention before surgery, and PT1 even used it almost daily before surgery. Other participants primarily used the intervention after surgery (eg, “almost daily to check the physical guidelines” [PT2 and PT11]), especially the first few weeks after surgery, when they were more restricted in movements and were in bed for most of the day (eg, PT9, PT12, PT14, and PT17). These participants stated that, as their recovery—and, therefore, their mobility—progressed, their use of the intervention declined.
I noticed that the more I recovered, the less I used the app. [PT9]

Other participants used the intervention both before and after surgery (eg, PT18 and PT3):

I must have read the entire app at least 10 times, I only missed one weekly module because I got COVID. [PT3]

Interestingly, all participants stated that the fact that they received a new module every week helped them use the intervention more often, as did viewing the other content of the intervention while filling out the weekly module.

Reasons for not using the intervention (more) were the lack of automatic notifications or reminders (eg, PT16), feeling no pain postoperatively, feeling that pain management was the main focus of the intervention (PT11), or lack of interest in the (large amount of) psychological content (eg, PT9, PT11, PT16, and PT17).

Most participants (12/17, 71%) felt that the number of modules was correct. The other 29% (5/17) of the participants stated that fewer modules would have sufficed, especially in the later weeks after surgery.

The mean total score of all participants in the intervention group on the TWEETS was 2.6 out of a possible 4 (SD 0.7), which is more than the average answering option of the scale (65% of the maximum score). The highest-scoring items on the TWEETS were “Strength Back is easy to use” and “Strength Back helps me to get more insight into my preparation before surgery and recovery after surgery” with an average score of 2.9 and 3.1, respectively. The lowest-scoring items on the TWEETS were “Strength Back is part of my daily routine” with an average score of 1.9 and “Strength Back fits me as a person” with an average score of 2.1.

A total of 15 weekly modules were offered to the patients undergoing spinal fusion (6/17, 35%). Log data of these patients showed that the average number of weekly modules completed was 10.2 out of 15 (SD 3.9; Table 4). The least completed weekly modules were POST-6, POST-7, and POST-12 (2/6, 33% in all cases). All patients undergoing spinal fusion completed the weekly POST-2 and POST-3 modules.

**Discussion**

**Principal Findings**

The objective of this study was 3-fold: to explore the potential benefits for patients undergoing spinal surgery of the digital ACT and PPI Strength Back (RQ 1), explore the feasibility of a future RCT in terms of recruitment and dropout (RQ 2), and assess the acceptability of Strength Back by patients undergoing spinal surgery (RQ 3).

The focus of this study was to explore the potential benefits of the intervention and not to determine its effectiveness. The latter should be the focus of a future RCT including more participants and allowing for more robust statements. Nonetheless, this study does show that Strength Back seems promising as pain intensity decreased more in the intervention group than in the control group and emotional well-being as well as overall well-being improved in the intervention group but not in the control group (RQ 1). This is in line with research in patients with chronic pain showing beneficial effects of ACT and PPIs compared with a control group on pain intensity and emotional functioning [65,66], in the treatment of chronic pain [30-35], in improving affect and functional ability after knee surgery [21], and in quicker cessation of pain and opioid use in veterans after orthopedic surgery [36].

Contrary to our expectations, no differences between the groups were observed in improvement in pain interference and psychological flexibility. Possibly, the effect of the ACT and PPI content shows through in the significantly larger decline in pain intensity in the intervention group. It is reasonable to suppose that a decline in pain intensity also helps prevent pain interference with daily activities and improve psychological flexibility. However, the sample size may have been too small, or the effect of surgery may have been so massive that these effects did not appear in this study. Moreover, in the intervention group as well as the control group, valued living and psychological and social well-being were almost the same at the pre- and posttest time points. The amount of ACT and PPI content may have been too small to influence valued living or psychological and social well-being. It is also possible that these effects only occur in the longer term. Living more accordingly to one’s values, resulting in enhanced psychological and social well-being, may only start later in the recovery process and not immediately after surgery.

In terms of recruitment and dropout rates, a future RCT seems feasible (RQ 2). A large proportion of the approached patients wanted to participate in the study, and once they started with the intervention, almost all participants used it until the posttest assessment and final interview. The willingness to use a digital health intervention seemed quite high in our study compared with in previous studies [67,68]. It seems that, once participants started the intervention in this study, they saw its value and kept using it over a longer period. In line with other research [69], patients stated that receiving notifications improved their use of the intervention. The dropout numbers found in this study were low and correspond to those of a recent RCT on PP exercises for patients with chronic pain [66]. However, to recruit a larger number of participants for an RCT, multiple hospitals or orthopedic centers should be included as there are a limited number of potential participants in a single facility. Interestingly, almost all the patients who were approached and did not want to participate in our study were female. Perhaps this group needs more attention during recruitment to explore their reasons for not wanting to participate.

The vast majority of participants in the intervention group were positive about the digital health intervention and would recommend it to future patients (RQ 3). The scores on the
TWEETS indicated a moderate to above-moderate engagement with the intervention, which was in line with log data showing that participants completed on average approximately 75% of the available weekly modules. The information modules containing videos of the surgery room and nursing ward, practical tips from previous patients, physical activity guidelines, and pain medication were the most appreciated by participants. The PP and ACT content evoked the strongest opinions in the participants, with a small minority indicating that they preferred no psychological content at all, whereas most of the participants saw added value in a number of specific exercises. Although the development of the intervention was based on a participatory design process and most participants appreciated the content, others felt that the focus was too much on mental health, whereas they experienced their issues as physical. At the same time, to increase the effectiveness of the intervention on the ACT- and PP-related outcomes, even more psychoeducation and exercises might be needed. In addition, the current version of Strength Back focuses on certain elements of ACT, whereas it may be necessary to address all ACT processes to achieve optimal benefits for patients undergoing spinal surgery. Indeed, Carr et al [29] found in their meta-analysis of PPIs that interventions were more effective when they contained multiple PPIs, were of longer duration, and contained more sessions. This poses a dilemma for the further development of this intervention. Information on the psychological content of the intervention before inclusion and tailoring the content and dose of the intervention to individual patients might further improve acceptance of the PP exercises, as suggested by previous research [70-72]. In a future version of Strength Back, patients could be introduced with a few of the most appreciated ACT and PP exercises and from there on be given the possibility to determine the amount of ACT and PP content themselves. This might reduce the potential effect on some patients who opt for a lower amount of ACT and PP content but might increase overall adherence to and acceptance of the intervention.

Our results question what the most appropriate primary outcome is for a subsequent RCT. As the intervention is based on ACT and PP, it makes sense to choose a measure corresponding to this content, such as well-being or pain interference. However, our feasibility study shows that the intervention and control groups particularly differed in improvement in pain intensity, which is an outcome that is important to patients but not directly targeted within the intervention. Perhaps targeting both pain intensity and increasing well-being might be the best option for sustainable resilience in patients undergoing spinal surgery. This is in line with previous research proposing a balanced, complaint and strength-oriented approach to reach sustainable mental health [73].

Second, attention should be paid to what the appropriate process measurements in a subsequent RCT would have to be. On the basis of the content and assumed working mechanism of this intervention, we propose psychological flexibility as a process measure in a future RCT. Nonetheless, we would not advise using the PIPS to measure this concept as we found low reliability in our study. Other studies have found similar issues with this scale and have recommended only interpreting it as a whole [74] or only using the avoidance subscale [75]. In addition, the PIPS measures inflexibility and not flexibility, which does not fit as well with the focus of ACT and PP. Perhaps the Personalized Psychological Flexibility Index [76] is a suitable alternative measure of psychological flexibility for a future RCT. In addition, we propose pain interference as a process measure in a future RCT, measured using the MPI subscale of pain interference. In addition, the ELS might be used in a future RCT to measure engaged living, including valued living.

The final discussion point relates to the length and timing of the intervention. The current intervention starts before surgery and lasts 6 to 12 weeks after surgery (for decompression and spinal fusion surgery, respectively). This was regarded positively by most participants, and from both the interviews and log data, we learned that most participants were already active in the intervention before surgery. This focus on pre- and postoperative timing is supported by a recent systematic review on perioperative psychological interventions that found that interventions (also) delivered after surgery tended to be more effective for postsurgical pain and disability than interventions delivered (only) before surgery [77]. It seems that, while waiting for surgery, patients are quite eager to learn more about the surgery and rehabilitation afterward. An intervention such as Strength Back can take advantage of these “teachable moments” [39] by providing content that participants may not have found or chosen themselves but that is known to help them in the recovery process. The duration of our intervention is in line with a recent review on perioperative psychological interventions for patients undergoing spinal fusion showing a reduction in pain and disability starting from immediately after surgery up to 3 months [78].

Strengths of This Study

The high recruitment and relatively low dropout rates were a strength of this study. In addition, qualitative data were collected through individual interviews with almost all the users of the intervention. This yielded crucial information on the value of the intervention and the reasons behind participants’ use of the intervention. Using multiple methods combining qualitative data with log data and quantitative data retrieved through the questionnaires provided a complete picture of the value of the intervention. Therefore, this research design is close to a convergent parallel mixed methods design [79]. Another strength of this study is the underlying theoretical framework of the intervention. As this is lacking for many digital health interventions, there are calls for further research to enhance the scope and use of this technology [80,81]. The design of digital interventions should be anchored in behavior change theories to optimally engage patients in the intervention and behavior change [82,83]. In a review of 85 studies using the Behavior Change Support Systems by Oinas-Kukkonen and Harjumaa [82], less than half referred to theories of behavior change, but those that did were uniformly successful [84]. Clearly, a sound theoretical base for digital health interventions is warranted for optimal behavior change and effectiveness.

Limitations of This Study

As all participants underwent surgery, which is an intervention by itself, we wanted to see in this study what the digital health
intervention might add to the effect of the surgery. An exploratory design regarding outcome measures was used to see which potential benefits could be achieved for patients undergoing spinal surgery. Owing to this exploratory design and the small sample size, more and larger effects of the intervention were not expected to be found in this study. In addition, no correction for multiple testing was performed in this study, and thus, conclusions can only be drawn with caution. Therefore, the preliminary findings of this study need to be replicated in a future larger study.

This study used a historic control group. A future RCT should use a design in which the intervention group and the control group run parallel in time and participants are assigned to them randomly.

In this study, log data were gathered on modules in which participants answered questions. For a future study, we would recommend registering every log-in and activity of users instead of only activities in which participants provide answers. We now see certain patterns in the use of participants, but more data are needed to further investigate use of and engagement with the intervention.

Previous hospital experience, preexisting comorbidities, patient technology readiness, health literacy, and ward factors such as staffing were not measured in this study. As these factors may influence how prepared patients are and what their capability is to engage with the intervention, they should be considered in a future RCT.

Conclusions
This study shows that combining ACT and PP in a digital health intervention is promising for patients undergoing spinal surgery as the content was accepted by most of the participants and (larger) improvements in pain intensity and well-being were found in the intervention group. A digital intervention for patients undergoing (spinal) surgery can use teachable moments, when patients are open to learning more about the surgery and rehabilitation afterward, to also provide patients with content that they may not have found or chosen themselves but that is known to help them in the recovery process.

Acknowledgments
The authors would like to thank all the participating patients as well as Leonie Olde Keizer-Spanjer, Leid de Vries-Gerritsen, Mark Havinga, and their colleagues at (Orthopedic Centre Oost Nederland) OCON for their help and contribution during this study. This work was supported by an educational grant from the Dutch Ministry of Education, Culture, and Science provided by the Saxion University of Applied Sciences. The funding body had no role in the study design; collection, analysis, or interpretation of the data; writing of the report; or the decision to submit the paper for publication.

Data Availability
The data sets analyzed during this study are not publicly available because of the exploratory and mixed methods nature of the study, but they are available from the corresponding author upon reasonable request.

Authors' Contributions
AVDH was responsible for conceptualization, methodology, validation, formal analysis (qualitative and quantitative data), investigation, data curation, visualization, writing—original draft, project administration, and funding acquisition. LM was responsible for validation, formal analysis (qualitative data), investigation, and writing—review and editing. Abstract

Background: Recent survivors of intimate partner violence (IPV) and sexual assault (SA) are at a high risk for traumatic stress and alcohol misuse. IPV and SA survivors face barriers to services for traumatic stress and alcohol misuse and have low service utilization rates. One way to increase access to services for this population is the use of web-based screening, brief intervention, and referral to treatment (SBIRT), an evidence-informed approach for early identification of traumatic stress and alcohol and drug misuse and connecting individuals to treatment.

Objective: This study aims to assess the usability and acceptability of a web-based SBIRT called CHAT (Choices For Your Health After Trauma) tailored to address traumatic stress and alcohol misuse following past-year IPV, SA, or both.

Methods: Phase 1 involved gathering feedback about usability and acceptability from focus groups with victim service professionals (22/52, 42%) and interviews with past-year survivors of IPV, SA, or both (13/52, 25%). Phase 2 involved gathering feedback about the acceptability of an adapted version of CHAT in an additional sample of recent survivors (17/52, 33%). Survey data on history of IPV and SA, posttraumatic stress disorder symptoms, alcohol and drug use, and service use were collected from survivors in both phases to characterize the samples. Qualitative content and thematic analyses of the interviews and focus group data were conducted using a coding template analysis comprising 6 a priori themes (usability, visual design, user engagement, content, therapeutic persuasiveness, and therapeutic alliance).

Results: Six themes emerged during the focus groups and interviews related to CHAT: usability, visual design, user engagement, content, therapeutic persuasiveness, and therapeutic alliance. Phase 1 providers and survivors viewed CHAT as acceptable, easy to understand, and helpful. Participants reported that the intervention could facilitate higher engagement in this population as the web-based modality is anonymous, easily accessible, and brief. Participants offered helpful suggestions for improving CHAT by updating images, increasing content personalization, reducing text, and making users aware that the intervention is confidential. The recommendations of phase 1 participants were incorporated into CHAT. Phase 2 survivors viewed the revised intervention and found it highly acceptable (mean 4.1 out of 5, SD 1.29). A total of 4 themes encapsulated participant’s favorite aspects of CHAT: (1) content and features, (2) accessible and easy to use, (3) education, and (4) personalization. Six survivors denied disliking any aspect. The themes on recommended changes included content and features, brevity, personalization, and language access. Participants provided dissemination recommendations.
Conclusions: Overall, CHAT was acceptable among victim service professionals and survivors. Positive reactions to CHAT show promise for future research investigating the efficacy and potential benefit of CHAT when integrated into services for people with traumatic stress and alcohol misuse after recent IPV and SA.

Introduction

Background

Sexual assault (SA) and intimate partner violence (IPV) remain major public health concerns for both women and men. In the United States, an estimated 43.6% of women and 24.8% of men experience some form of contact sexual violence in their lifetime, and 21.3% of women and 2.6% of men report being a survivor of attempted or completed rape [1]. Furthermore, more than one-third of women (36.4%) and men (33.6%) in the United States have experienced contact sexual violence, physical violence, or stalking by an intimate partner [1]. Individuals whose gender identity is transgender, gender queer, or nonbinary experience higher rates of SA and IPV compared with cisgender individuals [2,3]. Survivors of IPV and SA are at high risk for traumatic stress symptoms and alcohol misuse (ie, >4 drinks per day or 14 drinks per week for men and >3 drinks per day or 7 drinks per week for women) [4-6]. Although evidence-based treatments for traumatic stress and alcohol misuse exist, survivors of recent IPV and SA receive related services at low rates [7-9] and face many barriers to engaging in treatment [10]. Screening, brief intervention, and referral to treatment (SBIRT) is an evidence-based approach for identifying and reducing alcohol misuse, and web-based delivery shows promise in decreasing alcohol use, addressing barriers, and increasing treatment engagement among survivors of IPV and SA [11,12]. This study examined the usability of a web-based SBIRT intervention for traumatic stress and alcohol misuse tailored to recent survivors of IPV and SA.

Traumatic Stress and Related Alcohol Misuse Among Survivors of IPV and SA

Survivors of IPV and SA are at a high risk for traumatic stress and alcohol misuse [4-6]. A nationally representative study revealed that, when accounting for sociodemographic factors such as age, ethnicity, marital status, income, and education, people who experienced IPV in the past year were more likely to have problematic use of alcohol in the past year [13]. The effect of recent IPV remained for alcohol use even when accounting for past-year mood and anxiety disorders, lifetime personality disorders, and IPV perpetration. Among a national sample of lifetime female survivors of SA, the current prevalence of alcohol use disorder (AUD) ranged from 5% to 20% depending on the type of rape (ie, forced rape, incapacitated rape, or combined type) [6], and more than half of the people who receive an SA medical forensic examination report alcohol misuse [14]. Symptoms of traumatic stress are also high after recent IPV and SA, with 57% of the lifetime survivors of IPV [15] and 74% of the past-month survivors of SA [5] reporting traumatic stress symptoms.

Self-medication or using alcohol to cope with trauma-related distress is theorized to account for high rates of alcohol misuse among survivors of IPV and SA [16-18]. Existing research supports the self-medication hypothesis among survivors of IPV and SA. The negative sequelae of exposure to IPV and SA, including posttraumatic stress disorder (PTSD), depression, and other mental health difficulties, serve as mediating factors linking IPV and SA to increased alcohol use, consistent with the self-medication hypothesis [16,17]. Qualitative data also point to alcohol use as means to cope with the emotional distress of IPV [19]. Similarly, longitudinal evidence suggests that traumatic stress symptoms predict subsequent increase in alcohol use [16].

Aligned with the self-medication hypothesis, the motivational model of alcohol use suggests that people make decisions about drinking based on the expected positive consequences (eg, avoid negative affect) and negative consequences (eg, approach positive affect) [20]. Among people with SA or IPV histories, negative affect from trauma-related distress increases the likelihood of using alcohol to cope [21,22]. Thus, increasing motivation to reduce alcohol use and teaching alternative coping strategies to use during periods of negative affect, particularly in response to trauma-related distress, recently after exposure to IPV and SA could have a substantial impact on decreasing the development and sustainment of alcohol misuse. In addition, the empowerment model, which is often applied to interventions for survivors of SA, highlights the importance of aligning a survivor’s long-term goals with their behaviors in trauma recovery [23]. Therefore, aligned with the empowerment process model, empowering survivors by giving power and control over choices about their health [24] and helping survivors to identify how their values align with their current alcohol use could enhance the likelihood of reducing use after IPV and SA.

Mental Health Service Use for Traumatic Stress and Alcohol Misuse Among Survivors of IPV and SA

Interventions that are effective at addressing traumatic stress and co-occurring alcohol misuse are available. For example, COPE (Concurrent Treatment of PTSD and Substance Use Disorders Using Prolonged Exposure) [25] and Seeking Safety [26] are effective integrated treatments for addressing traumatic stress and alcohol misuse simultaneously. In addition, traumatic stress treatment alone (ie, Cognitive Processing Therapy) has been shown to reduce alcohol and other substance use among survivors of SA [27]. Finally, a psychoeducational video shown to survivors of recent SA during a forensic examination was...
found to be an effective early intervention to reduce the risk of alcohol misuse among recent survivors with a previous history of exposure to SA [28]. Although numerous treatment options for traumatic stress and alcohol misuse are available, survivors of IPV and SA face barriers to accessing treatment for these conditions. Despite high rates of alcohol misuse among survivors, it is estimated that only 20%-35% of survivors seek medical, psychiatric, or mental health services [29,30], with an even smaller subset seeking treatment for substance use disorders. People in abusive partner relationships may be hindered by their partner from seeking treatment, may not have independent financial resources, or may be subject to exacerbated violence or retribution for seeking treatment [31]. Furthermore, survivors of IPV and SA may not disclose their alcohol misuse to service providers as active substance use can be an exclusion criterion for accessing safe housing in zero-tolerance IPV shelters [19].

Additional barriers to treatment engagement include the lack of available mental health and substance use resources in the community, limited transportation particularly for rural residents, stigma associated with behavioral health service utilization, immigration status for undocumented survivors, and a lack of culturally sensitive services [19,31]. Stigma and discrimination associated with intersecting racial, ethnic, gender, and sexual identities can create additional obstacles to receiving care [32,33]. Furthermore, research highlights the potential for further harm when survivors seek services owing to limited training and awareness of IPV and SA-related issues among staff, which may increase fears that survivors will not be believed or will be blamed for the IPV or SA [10]. Staff in substance use disorder treatment settings report feeling ill-equipped to identify and address IPV [30]. In addition, even for survivors who access victim-related services, treatment services for alcohol misuse are typically not integrated within these settings [34], leaving a critical care gap for survivors of IPV and SA with alcohol misuse.

**Use of SBIRT for Alcohol and Drug Misuse**

SBIRT is a public health–based approach to screening for alcohol misuse, assessing the level of risk, and providing an appropriate intervention that can include no intervention, brief motivational interviewing, or referral to AUD treatment [35]. SBIRT has been effectively extended to address the screening, intervention, and referral to treatment needs of survivors of trauma with alcohol misuse, known as T-SBIRT. This approach has shown promise in elevating the rates of referrals for survivors of trauma experiencing alcohol misuse to specialized mental health services [36]. SBIRT has shown efficacy in reducing alcohol use and has been applied across a range of clinical and community settings, including primary care clinics, emergency departments, outpatient medical settings, and employee assistance programs [37].

In recent years, there has been an increase in efforts to adapt SBIRT to electronic health technologies (eg, computer, web, and phone based) because it may increase disclosure of alcohol misuse owing to increased comfort and decrease provider barriers to screening and providing brief interventions [38]. However, limited research has examined web-based SBIRT as an early intervention among survivors of IPV and SA. A randomized controlled trial of a web-based SBIRT intervention for identifying and addressing IPV among women who used substances, Women Initiating New Goals of Safety, was developed and increased survivors’ likelihood of seeking follow-up care for IPV and reduced drug use at a 3-month follow-up [12]. Similarly, Brief Spousal Assault Form for the Evaluation of Risk [11], a web-based intervention for co-occurring substance use and IPV was feasible and acceptable among a sample of women presenting to the emergency department. Safe and Healthy Experiences is another computerized SBIRT intervention specific for alcohol misuse delivered on an iPad tailored for female Veterans who have lifetime experiences of SA seeking services in primary care [39]. Results from these studies support that SBIRT delivered via eHealth is feasible and acceptable; however, preliminary efficacy results on substance use outcomes were mixed.

These existing interventions are limited because they are not specific to recent IPV, SA, alcohol misuse, or traumatic stress. SBIRT may be advantageous in the months after IPV and SA because this is a period when there is a risk for patterns of alcohol misuse to intensify because of elevated trauma-related stress [5]. SBIRT was developed for use in medical settings, such as emergency care centers, clinics, and primary care, with the intention of reaching people who are at a high risk for alcohol misuse. However, most recent survivors, who would be appropriate for SBIRT given the high-risk period for alcohol misuse, do not receive related medical care [14,40,41]. Although some limited studies have identified early interventions for survivors of recent IPV and SA, there is no consensus on the best approach to early intervention following recent SA and IPV [42]. To address gaps in service provision and research, we developed a web-based SBIRT called CHAT (Choices For Your Health After Trauma), which is compatible for use on a smartphone and, therefore, has the potential to be disseminated in a variety of community settings and on social media, increasing reach. CHAT is tailored for recent survivors of IPV and SA and provides SBIRT primarily for alcohol misuse, while also screening and offering psychoeducation about traumatic stress and drug use, which commonly co-occur with alcohol misuse among survivors of SA [14,41]. The SBIRT intervention is based on the motivational model of alcohol use [20], self-medication theory [16], and the empowerment model [23] and applies principles of motivational interviewing to reduce motives to drink alcohol and increase valued living, particularly when experiencing negative affect, which are theoretical and empirically supported intervention targets for alcohol misuse. CHAT follows the core SBIRT model components. First, the intervention provides psychoeducation about alcohol use specific to IPV and SA. Next, screening and assessment of alcohol misuse, drug use, and traumatic stress symptoms are completed by administering brief validated, standardized measures (ie, Alcohol Use Disorder Identification Test–Concise, AUDIT-C [43], item 2 from the National Institute of Drug Abuse–Modified Assist [44], and the Primary Care PTSD Screen for DSM-5 [45]). Next, participants receive personalized feedback about trauma symptoms, coping with traumatic stress symptoms (eg, self-blame and nightmares), drinking quantity, recommended drinking limits, money spent on alcohol and drugs, and the
impact of drinking and drugs on recovery from IPV and SA adapted from the National Institute on Alcohol Abuse and Alcoholism Rethinking Drinking [46]. In addition, brief exercises aimed at increasing motivation and healthy alternatives to alcohol use, including value identification, readiness to change ruler, goal setting, identification of coping skills, and social support adapted from Brief Spousal Assault Form for the Evaluation of Risk [11]. Finally, a personalized printable plan with all psychoeducational information and personalized goals created when using the intervention is provided with numerous referrals in the local community for traumatic stress or alcohol or drug-related services. Throughout the intervention, users are provided feedback on their responses and provided tailored recommendations for care (eg, “Your reactions are common and natural responses to violence. If these reactions are bothering you, it might be time to try therapy or other services. We will provide you with a list of providers at the end.”).

Empowerment is an essential component of recovery after IPV and SA as increased agency and control over one’s choices is associated with improved mental health outcomes [47]. Therefore, throughout the intervention, empowering imagery and themes are integrated. For example, aligned with the empowerment process model, the intervention emphasizes the importance of personal choice and autonomy and places survivors in control by providing options (eg, choices for personal goals that range from abstinence to a smaller reduction amount or choosing to not set a goal). Furthermore, by providing the intervention in a web-based format, the intervention is survivor led and self-paced, which is intended to enhance feelings of agency and choice throughout the intervention.

This Study

IPV and SA remain highly prevalent [1-3]. Unfortunately, there is a strong bidirectional association of IPV and SA with traumatic stress and alcohol misuse [4-6]. However, many survivors of IPV and SA do not engage in the services needed for traumatic stress and alcohol misuse because of several access barriers. One avenue for addressing barriers and increasing access for this population is the use of web-based SBIRT for traumatic stress and alcohol misuse, which incorporates tailored IPV and SA content. The purpose of this study was to examine the usability and acceptability of a web-based SBIRT intervention (CHAT) designed for recent survivors of IPV and SA, adapted from previous web-based SBIRT applications [11], among a sample of victim service professionals (VSPs) within IPV and SA advocacy centers and survivors of IPV and SA. Usability testing for web-based interventions refers to formal evaluation for use within the population of interest to identify methods to receive feedback that improves the design and addresses errors in the application [48]. Testing usability of eHealth interventions using a combination of quantitative and qualitative methods is crucial for obtaining adequate feedback to improve and tailor web-based interventions for use in specific populations [48].

This study had 2 phases. The first phase involved refining CHAT by making iterative adaptations based on feedback about usability and acceptability gathered from VSPs in focus groups and people who have experienced recent IPV and SA in individual interviews. After making iterative adaptations to the intervention, the second phase was to gather feedback about the acceptability of the adapted version of CHAT in an additional sample of people who have experienced recent IPV and SA.

Methods

Ethical Considerations

The institutional review board (IRB) at the Medical University of South Carolina (Pro00080368) approved this study. Informed consent was obtained from all survivors before their participation in the study. A Waiver of Consent was issued by the IRB for VSPs, and all VSPs were made aware of the risk to loss of confidentiality before participating in focus groups. The provider and survivor participants in both phases were assigned a random ID to protect their anonymity. Providers were compensated with US $25 Amazon gift cards for participation in focus groups. Phase 1 survivors received US $75 Amazon gift cards as compensation. Phase 2 survivors received US $50 Amazon gift cards as compensation. Transcriptions of focus groups were deidentified and stored in a secure location.

SBIRT Development and Design

CHAT was created on REDCap (Research Electronic Data Capture; Vanderbilt University) [49], a secure application for creating and managing surveys, that is hosted on the Medical University of South Carolina server. We chose to create CHAT on REDCap for several reasons, including low cost, accessibility among several institutions, ability to limit privileges to potential future providers and agencies interested in the intervention to help maintain the confidentiality of users, interventions that allow for personalizing intervention content such as branching and piping logic, ability to embed videos and photos into content, and available distribution methods (eg, links, URL codes, and email). We also selected REDCap because it is compatible with use on smartphones, which is a promising approach for reaching survivors of IPV and SA given the numerous barriers to accessing formal services [50].

CHAT was based on previous SBIRT interventions for survivors of traumatic events, including an SBIRT intervention for IPV and alcohol use (Brief Spousal Assault Form for the Evaluation of Risk [11] and National Institute on Alcohol Abuse and Alcoholism Rethinking Drinking [46]). The SBIRT intervention is based on the motivational model of alcohol use [20], self-medication theory [16], and the empowerment model [23] and applies principles of motivational interviewing to reduce motives to drink alcohol and increase valued living, particularly when experiencing negative affect, which are theoretical and empirically supported intervention targets for alcohol misuse. The SBIRT intervention, “CHAT” involves (1) psychoeducation about alcohol and drug use specific to IPV and SA; (2) screening and assessment for alcohol misuse, AUD, drug use, and traumatic stress symptoms using standardized measures; (3) personalized feedback about drinking quantity, recommended drinking limits, impact of drinking and drugs on recovery from SA, and money spent on alcohol and drugs; and (4) brief exercises aimed at increasing motivation and healthy alternatives to alcohol use, including value identification, readiness to change ruler, goal setting, identification of coping skills, and...
social support. The intervention concludes with a personalized plan and lists national and local referrals to IPV, SA, and substance use agencies. It takes approximately 20 minutes to complete. At the beginning of CHAT, users select whether they would like to view female, male, or gender nonbinary content, and branching logic provides images and drinking recommendations tailored to their preference. Piping logic is also used to personalize the intervention in several ways, including providing feedback about the quantity of the user’s alcohol use compared with recommended limits, relating the user’s reasons for drinking to potential long-term consequences (eg, “Making healthy choices about alcohol use helps me to take good care of my children”; response options range from strongly disagree to strongly agree), integrating the top values the user initially selects into motivational exercises at the end of the intervention, and providing them with a plan at the end that summarizes their selections throughout the intervention.

Phase 1: Refinement

Participants

Phase 1 included 2 samples. The first sample comprised adult VSPs (22/52, 42%) who were employed at 1 of 2 local nonprofit agencies that serve people who have experienced IPV and SA and completed semistructured focus groups. The VSPs included master-level clinical providers (9/22, 41%) and victim advocates who did not have a degree in counseling (12/22, 55%); educational level of 1 participant was unknown. The average experience of working with survivors of IPV and SA was 6.95 (SD 8.4) years and ranged from 4 months to 30 years. The second sample included adult survivors of past-year SA or physical IPV who drank alcohol (13/52, 25%).

Alcohol use was selected as an inclusion criterion because it is the most common substance used among survivors of IPV and SA and is the primary focus of intervention; however, participants could also use drugs as CHAT includes content on drug use after IPV and SA. Participants who used drugs were also permitted to be included in the sample; however, this was not required. The survivors were asked to complete a web-based screener to determine study eligibility. There were no exclusion criteria other than inability or unwillingness of the participant to provide informed consent.

Procedure

For phase 1, a total of 3 focus groups with 7 to 8 VSPs in each group took place at the agencies. Study flyers and email invitations to participate in the study were sent to all staff at an SA advocacy program and a nonprofit for IPV. VSPs completed a paper-based survey before the interview about demographics and experiences of treating survivors as well as an additional survey completed after the interview focused on assessing perceptions of CHAT. Survey data were entered into REDCap by 2 research assistants and checked for accuracy. Overall, 69.2% (9/13) of the survivors were recruited from the community using social media advertisements and flyers to participate. Four participants were recruited from an outpatient mental health clinic that served survivors of crime. After obtaining informed consent, interviews with survivors (13/52, 25%) were conducted in person in an outpatient clinic that served survivors of crime or over a secure web-based video platform. Baseline surveys administered on REDCap were completed before conducting the interview, and a brief second survey was administered after the interview to assess perceptions of CHAT. The interviewers and focus group moderators included 1 clinical psychologist and 2 master-level service providers.

Quantitative Measures

Demographics and Background Information

Self-report surveys were used to collect demographic and background variables from survivors and VSPs. VSPs were asked to indicate the percentage of time per week they provided services related to alcohol misuse and the type of evidence-based treatment they provided (ie, “Do you provide any of the following evidence-based treatments for PTSD and/or alcohol use in your agency?”).

Mental Health Self-Report Measures

Phase 1 survivors were administered measures of exposure to IPV and SA, traumatic stress symptoms, alcohol and drug use, and treatment utilization.

SA Victimization and IPV

SA exposure among phase 1 survivors was assessed using 2 items adapted from the Trauma History Questionnaire [50]: “Has anyone ever made you have intercourse or oral or anal sex against your will?” and “Has anyone ever touched private parts of your body, or made you touch theirs, under force or threat?” Physical IPV exposure among phase 1 and 2 survivors was assessed using an item from the HITS (Hurt, Insult, Threaten, Scream Measure; eg, Has a partner ever physically hurt you?) [51]. Survivors were asked to indicate if the IPV and SA events occurred in the lifetime or the past year.

1. PTSD Checklist for DSM-5 (PCL-5) [52]: The traumatic stress symptoms associated with the most distressing incident of IPV or SA among phase 1 survivors were assessed using the 20-item PCL-5. Items are rated on a 5-point scale ranging from 0 (not at all) to 4 (extremely), and a total score is created with higher scores indicating greater traumatic stress symptoms. PCL-5 scores >31 indicated clinically relevant traumatic stress symptoms [43]. Internal consistency was excellent for the PCL-5 for the phase 1 sample (Cronbach α=.92).

2. AUDIT-C [43]: The 3-item AUDIT-C was used to identify alcohol misuse. Survivors responded to 3-items about alcohol use (eg, How often do you have a drink containing alcohol?), with response options ranging from 0 (ie, never/no) to 4 (ie, ≥4 times a week/daily or almost daily). Responses were summed, and scores of ≥3 for women and ≥4 for men were used to indicate alcohol misuse. Internal consistency was good for the AUDIT-C for the phase 1 sample (Cronbach α=.91).

Qualitative Measures

To assess factors related to perceptions of the intervention created to address substance misuse, a semistructured focus group discussion and qualitative interview was developed. The term interpersonal violence was defined (ie, “Interpersonal violence included physical, sexual, and emotional abuse.”)
violence means physical or sexual violence such as sexual assault or domestic violence.”) for survivors and VSP participants at the start of the interview. Next, the web-based SBIRT intervention was described to survivors and VSP participants as a self-help intervention for substance use after IPV and SA.

The interview consisted of asking survivors and VSP participants up to 4 questions as they looked at each content area of the intervention, including “What are you thinking about as you look at this page?,” “What do you like about this page?,” “What don’t you like about this page?,” and “How can we make this more interesting?” Issues related to errors in branching, options, or presentation of content were noted by the interviewer. Follow-up probes were used to clarify information provided whenever necessary. After viewing CHAT, survivors and VSP participants were asked about usefulness (eg, “Do you think this would be useful, why or why not?”; “Do you think other people with use it, why or why not?”; and “Is this something that you think people should be told about shortly after they speak to a provider about experiencing interpersonal violence, why or why not?”).

**Data Analysis**

Descriptive statistics were computed (ie, mean and SD) for participant age, PCL-5 scores, and AUDIT-C scores. Rates of past-year and lifetime exposure to IPV and SA, race, gender, and previous service use were aggregated. Clinical psychologists with expertise in qualitative methods conducted qualitative analyses.

The interviews and focus group discussions were audio-recorded and transcribed verbatim by an IRB-approved third party. Data from qualitative interviews were organized using coding template analysis [53], applying thematic and content analysis approaches using 6 themes outlined by Baumel et al [54] to examine the quality and usability of mobile apps, including usability, visual design, user engagement, content, therapeutic persuasiveness, and therapeutic alliance. Using a deductive coding strategy not only allowed for examination of themes proposed in existing usability literature but also allowed for the development of inductive categories that emerged through coding [55].

A clinical psychologist with expertise in substance use intervention development and qualitative analysis examined each line of the transcripts and mapped participant’s responses to the coding template [55,56]. More than 1 code could be applied. A second coder, who was also a clinical psychologist with expertise in interpersonal violence and substance use, reviewed responses against the coding template. Interrater discrepancies were discussed and resolved by 2 independent coders. NVivo software (version 11.1; QSR International) was used for data management and analysis. Demographics and background variables were computed using SPSS (version 27; IBM Corp [57]).

Results from formative usability trials have shown that 80% of usability issues can be identified with a sample of at least 5 people involved in usability testing [58,59]. Thus, this study was suitably powered to assess usability.

**Phase 2: Acceptability**

**Participants**

The phase 2 sample included adult survivors of past-year SA, physical IPV, or both who drank alcohol (17/52, 33%). The inclusion criteria for the survivor sample of phase 2 mirrored the inclusion criteria for survivors in phase 1.

**Procedures**

For phase 2, survivors were recruited through Facebook advertisements (14/17, 82%), through Craigslist advertisements (1/17, 6%), and from an outpatient clinic that served survivors of crime (2/17, 12%). Phase 2 survivors completed the study remotely using their own devices to complete study surveys and CHAT. They completed a baseline survey on REDCap comprising questions about demographics, IPV and SA exposure, and alcohol use. Next, the survivors completed CHAT and a survey on acceptability of the intervention.

**Measures**

Demographics, descriptive characteristics, exposure to IPV and SA, alcohol misuse, and traumatic stress were gathered from phase 2 survivors using the same validated measures as in phase 1 (PCL-5, AUDIT-C, HITS, and Trauma History Questionnaire items). Internal consistency was fair for the AUDIT-C (Cronbach α=.70) and PTSD Checklist (Cronbach α=.80) in the phase 2 sample. Phase 2 survivors were also asked whether they needed care for past-year SA, IPV, alcohol use, or drug use (eg, In the past year, did you ever want or need help with any alcohol use concerns?). The following additional measures were collected from phase 2 participants:

1. **Daily Drinking Questionnaire** [60]: The Daily Drinking Questionnaire was used to assess the number of standard drinks consumed per week by phase 2 survivors (eg, “On a typical Monday, I had _ drinks.”). The mean weekly drinks were calculated.

2. **Acceptability of Intervention Measure** [61]: After viewing the web-based SBIRT intervention, phase 2 survivors completed the 4-item Acceptability of Intervention Measure. Items were rated on a 5-point scale (1=completely disagree to 5=completely agree) and averaged. Phase 2 survivors were also asked open-ended survey questions about most-liked aspects of the intervention, least-liked aspects of the intervention, and dissemination recommendations (ie, What would be the best way to inform people about the tool?).

**Analyses**

Descriptive statistics were computed in the same way as in phase 1. Participant’s brief responses to open-ended questions were coded into representative themes and subthemes. Previous research indicates that a sample size of at least 10 should suffice for acceptability testing [62]. Therefore, the phase 2 sample size had sufficient power to assess acceptability.

### Phase 1: Refinement Qualitative Results

#### Participant Demographics

VSPs (22/52, 42%) experience working with survivors ranged from 4 months to 30 years, and the average experience of working with survivors was 6.95 (SD 8.4) years. Two-thirds (13/22, 59%) of the participants had experience providing services to individuals engaging in alcohol misuse. Table 1 shows the demographics of the VSPs. Overall, 85% (11/13) of the phase 1 survivors reported lifetime exposure to both SA and physical IPV, and 31% (4/13) of the survivors reported both types of exposure in the past year. Phase 1 survivors reported a high prevalence of alcohol misuse, traumatic stress symptoms, and previous substance use and mental health service use (Table 1).

Theme 1: Usability

Both survivors and providers rated the usability of CHAT very positively overall. VSPs and survivors reported that the intervention was easy to use and self-explanatory, stating it was “straight to the point,” “short, sweet, and user friendly,” and “clear and concise.” A survivor specifically mentioned the following:

It's easy to navigate, easy to understand, and it's pretty much just a self-analysis.

VSPs provided similar feedback about the usability of CHAT, with VSPs from 2 of the 3 focus groups stating positive comments. Specifically, VSPs made comments that CHAT was “very easy to understand.”
**Theme 2: Visual Design**

This theme describes the appearance of CHAT, including observations about the text, font size, pictures, colors, and look and feel of the activities within the application. Survivors discussed visual design slightly more than the providers, as visual design was the most discussed topic for survivors and the second most discussed topic (after content) for providers. Survivors made comments about visual design such as follows:

> I like this. It kinda breaks down everything and gives you visual points to look at. Like you immediately go to what you are experiencing.

> I really like the diagram because it shows what you are doing...Drinking more than the single day limit.

Another survivor described the follows:

> Picture is good too. Shows people drinking, gathering like it’s fun in a way, but reading those kind of wake up calls. Like it’s not really fun.

In all VSP focus groups, the visual design of the intervention was discussed, with most comments about visual design being positive and only a few constructive recommendations about changes to visual design. Specifically, some comments that VSPs made on visual design included “I think the graphic is good,” “I like the colors,” and “I like this whole visual.” Recommendations about visual design included changing font sizes or adding pictures.

**Theme 3: User Engagement**

The theme, user engagement, describes how well the participant was able to engage with the application including how interactive and personalized the VSP and survivor participants felt that the intervention was. This included the users’ ability to engage in the activities embedded within the intervention and how often they felt that they would engage. More than half of the survivors commented on their potential engagement in the intervention, stating that they would be very willing to engage and that they would engage in the intervention often. Specifically, 1 survivor noted, “I would definitely use it. It’s easier.” Survivors also mentioned that they would be more likely to engage with the intervention than with people personally, as 1 survivor stated the following:

> I feel like people would use it because it’d help. You may not even want to talk to your close people who are close to you. You may just want to be anonymous, and you probably would feel more comfortable with this.

Another survivor said the following:

> I guess it would be the ideal thing for somebody who didn’t want to come in and talk to anybody, and just wanna do it on...just looking for information on their own, looking for help on their own.

In all the focus groups of VSPs, it was discussed that the survivors they worked with, as well as themselves, would engage with the intervention very frequently and that the intervention was easy to use. Specifically, 1 provider stated the following:

> Wow! You can pull it up on any device. I would literally use this all the time [with different clients]

Another provider stated the following:

> It’s so great that the whole thing takes about 15 minutes. That’s nice.

In describing ways that a patient might engage, a provider stated the following:

> That’s really cool that you are able to print this off and put it on your fridge.

**Theme 4: Content**

This theme described the quality and appropriateness of the content presented during the intervention. All survivors and VSPs in each focus group made positive statements about the intervention, stating that it was rooted in evidence, appropriate for themselves or their patients, and contained information that was often relevant to patients. Specifically, 1 survivor stated the following:

> I think it really hits all the points. It even has God in here which is really something people don’t mention.

Another survivor stated the following:

> I actually wouldn’t add anything. I love this information.

Throughout the interviews, survivors made comments about specific content that they found relevant or that they thought was important to include. In addition, VSPs discussed mostly positive comments about the content, with just a few suggestions or examples to add. For example, 1 VSP noted the strength in content by stating the following:

> I love how there are so many short snippets. I thought those were all pretty powerful points.

Another VSP discussed the comprehensive nature of the content by mentioning the following:

> I like that it is fairly all-encompassing. I like that there are positive reasons and then neutral reasons.

**Theme 5: Therapeutic Persuasiveness**

Therapeutic persuasiveness included comments regarding the suitability of the content provided by the intervention and whether the provider or survivor would see the content as useful in addressing substance use or trauma. All survivors described therapeutic persuasiveness and noted that the intervention would be useful in addressing these topics among survivors. Specifically, 1 survivor noted the following:

> It makes you evaluate your life and see things that you maybe didn’t see while you were drinking or why you were drinking. It makes you really think about what you are doing.

Another survivor described the following:

> It helps you realize how much you really are drinking. I like it because it lets you know that [values] are important and can be accomplished by changing your substance use problem. This helps you put things into
All VSP focus groups included positive comments about the therapeutic persuasiveness of the intervention. One provider described the therapeutic persuasiveness of the intervention by stating the following:

*I really like the statistics. They kind of make you feel like you’re not the only one experiencing this. It’s okay that this is happening, it’s not something to be ashamed of, it’s something to deal with. It speaks to a lot of people.*

**Theme 6: Therapeutic Alliance**

This theme describes whether users thought that the intervention provided support that could mirror, support, and take the place of human contact provided by an actual provider as well as whether they saw it as a resource to bolster ongoing therapy. Approximately half of the survivors discussed the therapeutic alliance gained by the intervention, with 1 survivor stating the following:

*I love that the tool is helpful but also shows the places you can go to for actual, real help with your problems. Both are good.*

VSPs in all 3 focus groups discussed this theme and described that the intervention would support the concepts taught in therapy and would serve as a useful addition to therapy. Specifically, 1 provider mentioned the following:

*They can share the information without anybody knowing their situation. Because most times they really don’t want to share. So to be able to use this, versus verbalize it and have somebody judge them, that is much easier.*

In addition, each VSP focus group discussed information on how to integrate the intervention into practice. For example, 1 VSP mentioned the following:

*We get so many clients that have alcohol and drug histories. It’ll take several sessions for me to really get them to a point where they realize they are drinking/using drugs too much. But I feel like this [intervention] can get them to that point a lot quicker, where they’re more likely to at least think about [substance use] earlier on.*

VSPs in each focus group also reported that this intervention would be helpful throughout treatment and potentially at different points for different clients. For example, 1 VSP described the following:

*Honestly, it depends on what stage of change the client is in. Like, if they’re like “I’m not an addict or an alcoholic, I’m not going to listen to anything you say.”*

Another VSP stated the following:

*This [intervention] could be part of the assessment process. They come in for their mental health assessment, ask them to get there 20 minutes early to fill this out just to screen, then give them the tool to use if needed.*

**Revised Intervention Content Aligned With Results**

Iterative changes to CHAT were made based on user experience during usability testing including fixing errors noted with logic branching, piping, spelling, grammar, increasing font size, and changing images based on participant suggestions. In addition, a page encouraging user to take 5 slow breaths was added based on VSPs’ suggestion that content may increase stress and adding breathing could help users engage with the intervention. Furthermore, options for gender-based content and language around recommended drinking limits and sex were adapted based on VSP recommendations. Gender-based content options were to view images of women, men, or nonbinary content. Drinking limits were explained based on biological sex because current recommended drinking limits are based on sex assigned at birth owing to physiological differences that change the way alcohol affects the body (eg, For people assigned female sex at birth, drinking more than 3 drinks on any day or 7 drinks per week is “at risk” or “heavy drinking.”).

**Phase 2: Demographics and Qualitative Results Regarding Acceptability**

**Overview**

Phase 2 survivors also reported high levels of alcohol use, traumatic stress symptoms, and previous substance use and mental health services use. In phase 2, 59% (10/17) of the survivors reported both types of exposure in their lifetime, and one quarter (4/17, 23%) of the survivors endorsed past-year SA and physical IPV. Phase 2 survivors endorsed high levels of alcohol use with an average AUDIT-C score of 6.88. More than one-third (6/17, 35%) of phase 2 survivors self-reported needing care for alcohol misuse, and one-quarter (4/17, 23%) self-reported needing care for drug use. A total of 17 survivors recruited through social media and the community viewed the web-based intervention and completed surveys. On a 5-point scale (1=completely disagree to 5=completely agree), survivor participants agreed that the intervention was, on average, acceptable (mean 4.1, SD 1.29).

**Qualitative Results**

Phase 2 participants’ (17/52, 32%) favorite aspects of the intervention were encapsulated by 4 themes: content and features (6/17, 35%) such as encouraging messages, focus on reduction rather than abstinence, and ability to download a personal plan; accessibility and ease of use (6/17, 35%); psychosocial education (3/17, 18%) about alcohol, IPV, and SA; and personalization (4/17, 23%). For example, 1 survivor wrote the following:

*I liked that it made a personalized plan just for me whereas in a group setting it’s geared more towards everyone.*

Approximately one-third (6/17, 35%) of the survivors denied disliking any aspect of the intervention. The aspects of CHAT that could be improved were encapsulated by 3 themes: content and features (6/17, 35%), including increased focus on broader mental health, describing prevalence of IPV and SA in a more sensitive manner, increased brevity, and increased...
personalization; connection to immediate services (4/17, 23%); and language access (1/17, 6%). Survivors suggested 5 dissemination methods: calls, emails, and texts (2/17, 12%), podcasts (1/17, 6%), posters and flyers (1/17, 6%), social media advertisements (10/17, 58%), websites (2/17, 12%), and referrals when seeking help for IPV, SA, or substance use (3/17, 18%). For example, 1 participant offered the following suggestion for dissemination:

If anyone entering a behavioral center, drug rehabilitation center, or any mental health office showing signs of sexual trauma or substance use, the tool could be suggested to them by a medical health provider and implemented through a computer at home or cell phone. If they don’t have a cellphone or computer at home, hopefully counties can provide the computer for them to complete the tool. Social media is always a good way to promote tools to help mental health, advertisements are how I found Better Help. I have found a lot of online counseling through Google as well.

**Revised Intervention Content Based on Phase 2 Results**

Iterative changes were made to the web-based intervention in response to participants’ suggestions (Figure 1). Images of the intervention were also updated, and images that were displayed were updated to match the preferred gender-based content selected by users at the beginning of the intervention. To improve brevity, we removed assessment of AUD symptoms and focused solely on alcohol misuse with the 3-item AUDIT-C [55]. In traditional SBIRT, the full AUDIT is used and people who report risky alcohol misuse receive brief intervention focused on reducing use and people who report more severe levels of alcohol misuse are referred to treatment. We decided to provide brief intervention and referral options based on alcohol misuse (rather than the full AUDIT) because the time after recent IPV and SA is a high-risk time for the escalation of substance use, and this minimizes the chance that we fail to provide treatment options to someone who could benefit from AUD treatment. In addition, to further personalize the intervention content to users’ drinking goals, additional content on harm reduction skills was added. Increased personalized feedback based on symptoms endorsed on the Primary Care PTSD Screen for DSM-5 was increased in the revised intervention to further interweave education about self-medication and links between alcohol misuse and traumatic stress. Finally, additional piping was used to incorporate more information about the users’ values as they relate to alcohol use. Words were also reduced for length and increased readability.

**Figure 1.** Final images of CHAT (Choices For Your Health After Trauma).
Discussion

Primary Findings

Survivors of IPV and SA report elevated rates of traumatic stress and alcohol misuse [4-6]. However, <35% recent survivors of IPV and SA seek services for mental health [29,30]. Higher levels of substance use are related to lower service use among survivors of recent trauma [7], which points to the importance of providing services for alcohol use recently after trauma exposure. This is especially important among recent survivors of IPV and SA given their uniquely high risk for alcohol misuse and drug use in this acute period [14,41]. We conducted an investigation of the usability and acceptability of a web-based SBIRT intervention for traumatic stress and alcohol misuse following an IPV and SA. Focus groups were conducted with IPV and SA service providers, and interviews were conducted with recent survivors of with the aim of gathering recommendations to improve the usability of the intervention. Following adaptation of the intervention based on this feedback, we examined the acceptability of the adapted SBIRT intervention in a second sample of recent survivors. Overall, our results suggested that service providers and recent survivors viewed the intervention as acceptable (as indicated by high ratings on the acceptability of intervention measure) and beneficial to integrate into services (as indicated by the qualitative feedback provided by VSPs and survivors). In this study, both providers and survivors commented that the intervention content was useful in addressing traumatic stress and alcohol misuse, including evaluating one’s alcohol use patterns in the context of trauma. It may be important to address the link between IPV and SA-related distress and alcohol use [16]. Although historically IPV and SA and alcohol use services have operated independently, our findings are in line with recommendations for integrated approaches that address trauma and alcohol misuse simultaneously [36,63,64].

Individuals with greater alcohol misuse may be less likely to seek care following IPV and SA [65], indicating the importance of addressing substance use–related barriers to service access. Some survivors in this study indicated that they would be more likely to engage with the intervention (rather than speak with another person) given the anonymity. This suggests that delivery of a self-directed, web-based SBIRT intervention may help circumvent common service barriers among survivors of IPV and SA related to shame, fear of the consequences of disclosure, and anticipatory stigma [10,66]. In addition, web-based delivery of SBIRT may help with barriers in clinical settings related to time constraints and staff availability [67] given the ease of access (ie, ability to use on any device), empowering content (eg, self-paced and power to decide what goals to select), and brevity (<20 minutes to complete) of the intervention. It will be important for future research to determine whether web-based SBIRT can help address some of these barriers to care if adopted into practice and to determine the most effective way of integrating this intervention into existing clinical practice.

It is imperative that the SBIRT intervention is delivered in a nonstigmatizing manner given the highly stigmatized nature of IPV, SA [68], and alcohol misuse [69]. Indeed, several survivors and providers in this study discussed the importance of ensuring that the content of the intervention is nonjudgmental and culturally sensitive. The high acceptability ratings of CHAT and previous SBIRT research [11] indicate that integrated interventions for trauma and substance misuse following recent IPV and SA can be delivered in a sensitive manner to address the important treatment needs of this population. It is crucial for future researchers developing interventions for survivors of IPV and SA to be mindful of using inclusive and nonjudgmental language. This may include explicit statements that the survivor is not to blame for the violence they have experienced, destigmatizing alcohol-involved SA by sharing statistics about the common nature of this type of assault, etc. Useful suggestions regarding design and content were made by the service providers and survivors that inform preferences for the web-based SBIRT intervention following IPV and SA focused on alcohol misuse. The intervention was modified in accordance with this feedback. The results underscored the significance of conducting usability testing with both providers and survivors. Neglecting to consider user perspectives and preferences is a key factor contributing to the low utilization of mobile mental health interventions [70,71]. Consistent with previous research indicating that privacy is an important concern for users of mobile health interventions [71], several providers and survivors in this study also discussed the need to ensure confidentiality. Therefore, interventions developed for this population may benefit from explicitly addressing issues of confidentiality. Finally, we examined the acceptability of the revised version of CHAT in a sample of recent survivors in phase 2 of this study. Research supports the effectiveness of early interventions in reducing trauma-related symptoms [72]; however, accessing health care in the weeks following assault is uncommon [73]. The current web-based SBIRT intervention was developed to address gaps in service provision after recent IPV and SA when risk for alcohol misuse and drug use is heightened owing to trauma-related distress. Survivors found the revised intervention to be acceptable and noted the personalization of the intervention as being important. Personalized care and delivery of individualized treatments is a priority for mental health care to improve the effectiveness of evidence-based interventions [74]. CHAT is an example of how a web-based SBIRT intervention can be personalized, and future research is needed to evaluate the effectiveness of this intervention in addressing needs related to substance use following IPV and SA. Taken together, our results support that, in general, recent survivors find it acceptable to be provided web-based SBIRT.

Strengths and Limitations

The strengths of this investigation include gathering feedback from both VSPs and survivors that informed revisions of the web-based SBIRT intervention. Furthermore, the intervention included multiple substances, and the motivational content of the SBIRT intervention was personalized to refer to the substances reported by survivors (ie, alcohol use, drug use, or substance use for use of both alcohol and drugs). The high acceptability of the web-based SBIRT intervention in this study encourages examination of its efficacy in future research trials. However, the sample sizes across the 2 study phases were small, and future research with larger sample sizes is needed to test
the feasibility of the web-based intervention. Inclusion criteria for survivors in this study were based on reporting of alcohol misuse. Overall, 69% (9/13) of phase 1 survivors reported drug use, with the most common drug used being marijuana (6/13, 46%). Thus, it is possible that the findings would differ if survivors were recruited based on reporting drug use. Future research should compare the acceptability, feasibility, and efficacy of the interventions among survivors reporting various types of substance use. In addition, future research may test whether allowing people who use multiple substances to select a specific substance for the motivational interventions as in the Brief Spousal Assault Form for the Evaluation of Risk intervention in the study by Choo et al [11] would improve outcomes. It is also important to note that SBIRT is most effective for people who report alcohol misuse but do not yet meet the criteria for AUD. As many recent survivors of IPV and SA may already meet the AUD or PTSD criteria before the recent trauma, the SBIRT intervention may have limited utility as an early intervention for those individuals.

It should be noted that most survivors included in this study identified as female individuals, White, and not Hispanic, and sexual orientation information was not collected. Individuals with marginalized identities based on race, ethnicity, sexual orientation, gender, and immigration status experience additional barriers to accessing services following IPV and SA [10,33,73]. In addition, experiences of identity-based stigma and discrimination may contribute to substance use [75] and exacerbate trauma-related distress following interpersonal violence [76]. Thus, it is imperative for future research to examine the usability, acceptability, and efficacy of the SBIRT intervention among survivors with diverse intersecting identities and consider experiences of stigma and marginalization. Furthermore, given the gender differences in female and male exposure to IPV and SA as well as barriers to service engagement, this study should be replicated with greater male representation in the sample. Participation was also limited to English-speaking individuals as the intervention was only available in English, and future revisions of the intervention should address language as a barrier.

All service professionals included in this study provided services within IPV and SA advocacy centers, and therefore, future evaluation of the intervention should be conducted with providers in other types of settings (eg, primary care, emergency department, and law enforcement). Furthermore, although the intervention was not designed for a single outlet for dissemination, a strength of the intervention is its flexible nature and ability to be disseminated in a wide range of settings (ie, advocacy centers, web-based forums, and emergency departments). This may increase the reach of the intervention to survivors of IPV and SA in the community who do not seek formal services. The findings in phase 2 provided crucial data to inform better ways to reach survivors and disseminate the SBIRT intervention broadly on social media and should be tested for effectiveness in reaching survivors with lower levels of service use in future research. Further implementation research is needed to understand how to integrate CHAT into specific settings (eg, rape advocacy centers). Although SBIRT is intended to be an early intervention that addresses traumatic stress symptoms and alcohol misuse and prevents the development of AUD or PTSD (because the recent months following IPV and SA are a heightened period of risk for AUD and PTSD to develop), it is possible that CHAT could also benefit nonrecent survivors. Future research should expand to apply the SBIRT model to nonrecent survivors and examine whether a broader application is beneficial. In addition, the web-based intervention had limitations in terms of referral and treatment owing to its brevity. Moreover, it lacked a follow-up mechanism to assist individuals in overcoming barriers to accessing referrals. This is a weakness of the current SBIRT intervention. Future research should focus on increasing the robustness of the referral to treatment component. Adding a support person to follow-up with intervention users might be an important component for future development [77]. For example, 1 survivor participant recommended, “Definitely follow ups, like a call, would help.”

In conclusion, results from this study among VSPs and survivors support the usability and acceptability of a web-based SBIRT intervention designed for traumatic stress and alcohol misuse among recent survivors of IPV and SA. Future research should include samples with greater diversity and address the barriers related to English language proficiency. Overall, the findings encourage future examinations of the efficacy of web-based SBIRT for co-occurring traumatic stress and alcohol misuse among recent survivors.

Abstract

Background: Measurement of sodium intake in hospitalized patients is critical for their care. In this study, artificial intelligence (AI)–based imaging was performed to determine sodium intake in these patients.

Objective: The applicability of a diet management system was evaluated using AI-based imaging to assess the sodium content of diets prescribed for hospitalized patients.

Methods: Based on the information on the already investigated nutrients and quantity of food, consumed sodium was analyzed through photographs obtained before and after a meal. We used a hybrid model that first leveraged the capabilities of the You Only Look Once, version 4 (YOLOv4) architecture for the detection of food and dish areas in images. Following this initial detection, 2 distinct approaches were adopted for further classification: a custom ResNet-101 model and a hyperspectral imaging-based technique. These methodologies focused on accurate classification and estimation of the food quantity and sodium amount, respectively. The 24-hour urine sodium (UNa) value was measured as a reference for evaluating the sodium intake.

Results: Results were analyzed using complete data from 25 participants out of the total 54 enrolled individuals. The median sodium intake calculated by the AI algorithm (AI-Na) was determined to be 2022.7 mg per day/person (adjusted by administered fluids). A significant correlation was observed between AI-Na and 24-hour UNa, while there was a notable disparity between them. A regression analysis, considering patient characteristics (eg, gender, age, renal function, the use of diuretics, and administered fluids) yielded a formula accounting for the interaction between AI-Na and 24-hour UNa. Consequently, it was concluded that AI-Na holds clinical significance in estimating salt intake for hospitalized patients using images without the need for 24-hour UNa measurements. The degree of correlation between AI-Na and 24-hour UNa was found to vary depending on the use of diuretics.

Conclusions: This study highlights the potential of AI-based imaging for determining sodium intake in hospitalized patients.

Introduction

Overview
A low-salt diet is prescribed for patients with cardiovascular, kidney, or liver diseases. In these patients, sodium intake regulation is essential. High salt intake is a key modifiable risk factor for these diseases. Thus, monitoring the dietary salt intake of patients provides patients and clinicians with valuable information on dietary salt reduction advice [1].

For therapeutic purposes, the salt intake of hospitalized patients is assessed either indirectly by the prescription order of diet and food consumption questionnaires or directly from repeated 24-hour urinary sodium (UNa) excretion collections [2]. However, these methods have several limitations. Discrepancy with the prescribed diet order, the actual food intake of patients may vary because of poor compliance. Inaccurate answers provided during questionnaire surveys may result in biased results. Direct access to repeated 24-hour UNa collection, which is the standard method of salt intake marking, is an inconvenient and costly process because samples are to be sent to a laboratory, and flame photometry is typically required [3]. Furthermore, this method is inherently impractical because of the dependence on patient compliance and variability between collections.

For inpatients, a quick evaluation of salt intake would enable real-time advice and subsequent application to the next diet regimen. Therefore, a tool to objectively quantify a patient’s dietary intake and repetitively evaluate the sodium content of the diet of hospitalized patients is required.

Artificial intelligence (AI) technology has enabled image-based analyses of nutrition and ingredients. Picture-to-Amount, a deep learning architecture using a cross-modal image-to-text retrieval system, can predict the number of ingredients in a given food image [4]. Technology-assisted dietary assessment relies on AI to accurately group food pictures and measure food credit by assessing a cellphone food record [5]. AI models for dietary assessment have been verified for reproducibility and validity. A large-scale population survey verified the accuracy of one such AI model for nutrient analysis [6]. Carter et al [7] conducted a study to compare the nutritional intake recorded in the smartphone app called “My Meal Mate” and the nutritional intake using the 24-hour recall method. Ahmed et al [8] divided participants of their study into 2 groups, namely a meal diary group and a tablet application use, and compared their nutrient intakes [8]. A fully automatic monitoring system of nutrient intake by hospitalized patients was presented for medical use by processing Red Green Blue (RGB) depth image pairs before and after meal consumption using AI-based estimation [9]. However, most studies have focused on classifying food or identifying the content of protein, fats, and carbohydrates, whereas studies on specific nutrients such as salt are scarce. To further improve the assessment and monitoring of the salt content of inpatients’ diets, the validation of accurate estimation of the diet and consumption of salt by patients is still required.

Objectives
We evaluated whether sodium intake could be determined through AI methods using food photographs and known nutrition information in hospitalized patients. We also determined if it is significant to compare sodium intake with 24-hour UNa, which is the gold standard for measuring sodium intake.

Methods
Study Design and Population
This single-center prospective study was conducted from August to November 2021 and involved 54 hospitalized patients, recruited from the hospitalist-run acute care unit as well as nephrology and urology departments. The following criteria were used for inclusion: (1) adult patients aged 19 years or older, (2) patients who agreed to take photographs before and after meals, and (3) patients who were prescribed 10 g of salt (4 g of sodium) in their diet. Patients who were unable to eat because of conditions such as respiratory arrest requiring tracheal intubation, cardiac arrest, acute coronary syndrome or life-threatening arrhythmias, failure of more than 2 organs, recent trauma, or burns of the neck and face were excluded. People with alcohol addiction and pregnant patients were also excluded. Previous medical history, demographics, and laboratory data were retrieved from electronic medical records.

Nutrient Information and Acquisition of Food Images
A novel and dedicated image database was developed because models pretrained using the data of different regions and countries could not be used. Hence, curating a local food data set was necessary, particularly for measuring sodium intake in hospitalized patients. A 3-month diet was predetermined before the study was initiated. The Seoul National University Bundang Hospital Nutrition Department provided all the meals and laboratory data were retrieved from electronic medical records.

Food Image Analysis—Sodium Intake Measurement with AI (AI-Na)

We used the hybrid model for sodium intake measurement based on food image analysis. This model incorporates the You Only Look Once, version 4 (YOLOv4) model’s detection of the image areas and uses 2 classification approaches—Custom-101 and Hyperspectral imaging—to predict the food quantity estimation for sodium amount (Figure 3A and 3B). YOLOv4 has been used in several previous studies to detect and classify the food and dish areas in the images [10,11]. Multidish images were generated by cropped images using the boundary-box area to create a data set containing images with different sizes. Figure 3 shows data generated after converting single images into multidish images. A data set for a convolutional neural network with one kind of food was placed in dishes of different shapes. Then, all the food images were rotated to different angles, and the light and sharpness of these images were adjusted (Figure 3B). For the estimation of food quantity from the images, we predominantly used convolutional neural networks, with ResNet-101 being our primary model of choice. In our pursuit to select the optimal classification model, several alternative architectures were also evaluated. This included experimenting with models such as MobileNetV2, ResNet-18, Wide-ResNet-50, and InceptionV3. After rigorous testing and evaluation, ResNet-101 demonstrated superior performance, affirming its selection for our research objectives. The amount of food remaining was estimated, and the calorie and nutrition contents were estimated [12,13]. The food photographs were color-based images, and a hyperspectral image was used to clarify the differences between colors and improve image quality. Hyperspectral images have rich information and show superior performance when used for feature identification based on pixel intensity [14,15]. In our study, we used Custom-MST++ to facilitate the conversion of standard RGB images into hyperspectral images. Although a conventional RGB image is composed of 3 channels (ie, red, green, and blue), the reconstructed hyperspectral image boasts an enhanced structure, encompassing 31 distinct bands. This transition from a trichannel format to a multiband representation allows for a more nuanced and detailed analysis, critical for our research objectives. The following steps must be performed when using hyperspectral analysis...
images for estimating food quantity: (1) reconstruction of the hyperspectral image from the RGB image, (2) preprocessing of the hyperspectral image thus obtained, (3) calculation of the pixel intensity per spectral band, and (4) classification with of the food quantity using random-forest regression of food quantity. Therefore, by using the aforementioned method and procedures, the types and quantities of food that the patients consumed were classified and estimated from the food images. In our research, our foremost goal was to devise an algorithm capable of estimating sodium intake solely from images. Initially, our challenge was to accurately discern the volume or weight of the food items depicted in these images. Leveraging cutting-edge AI methodologies, we crafted a model adept at both recognizing and quantifying various food items. As part of this implementation process, we used information regarding the selected menu’s nutrients, type of food, and amount of food based on the protocol of the hospital nutrition department. Once we established the food quantity, we cross-referenced it with the nutritional data pertinent to the identified items. By combining this food quantity data with the nutritional profiles, our algorithm adeptly calculated the sodium proportion in the given dishes, ultimately yielding the sodium intake value, which we have denoted as AI-Na (unadjusted). Subsequent adjustments were made to the algorithm by subtracting sodium content from administered fluids, resulting in a refined AI-Na (adjusted; Figure 2).

Figure 3. Sodium intake measurement using the artificial intelligence–based method. (A) Data generated after converting single images into multidish images; (B) Dataset for the convolutional neural network. ’Q’ denotes quantity in the classification of food classes by portion size.

The 24-Hour UNa Collection as a Reference Value for Sodium Intake

The gold standard for estimating dietary sodium intake is the 24-hour UNa value [16]. Participants were asked to collect all urine during a 24-hour period, starting with the first urine sample on the morning of the day when they took the food photos and concluding with the second urine sample on the following morning. The urine aliquots were stored at –20 °C before transportation to the certified laboratory. An ion-selective electrode method (Modular DPE chemistry; Roche Diagnostics) was used to measure urinary sodium and potassium levels. The urinary creatinine (UCr) level was measured using the Jaffe reaction (kinetic colorimetric assay; Roche Diagnostics). The urine samples were excluded if any of the following were observed: (1) total volume of urine during the 24-hour period was <500 cc, (2) UCr was <0.6 g/day in men and <0.4 g/day in women, and (3) the self-reported spillage was more than 30 cc [17,18].

Statistical Analysis

The Mann-Whitney test and Brand–Altman method were performed to determine the extent to which the AI-Na values matched the 24-hour UNa as reference values. However, because diuretics affect the 24-hour UNa, we divided the participants into diuretic and nondiuretic groups for the analysis. As kidney function can also affect the 24-hour UNa, a regression equation using sodium intake, 24-hour UNa, and estimated glomerular filtration rate (eGFR) was developed, and an interaction term was used to evaluate the role of diuretics. The interaction term was used rather than the dose, depending on the use of diuretics, as the sample was too small to evaluate the relationship between diuretic dose and 24-hour UNa. In the baseline characteristics of the study population, continuous variables were expressed as median values, and categorical variables were described as frequencies and percentages. We considered 2-sided P values <.05 to be statistically significant. Statistical analyses were performed using the R 4.1.0 (R foundation for Statistical Computing).

Ethical Considerations

The study followed the general treatment policy for the underlying disease, and patients did not go beyond the scope of the standard treatment, except for capturing photographs of the prescribed meal. The study protocol complied with the Declaration of Helsinki and was approved by the Institutional Review Board of the Seoul National University Bundang Hospital (B2108-701-302). Written informed consent was obtained from all the patients.
Results

Estimating Sodium Intake From Food Images—Quantifying Results of Food Quantity Estimation

We collected 20,000 images for food quantity estimation and 1500 hospital images with sodium amount metadata. Table 1 and Table 2 show the results of food area detection and classification. In the context of our research, when we refer to YOLO versions, such as YOLOv3, YOLOv3-tiny, YOLOv3-tiny3l, YOLOv4, and YOLOv4-tiny, an important part of the highlight is that our choice of YOLOv4 signifies our preference for the best training and testing mean average precision among these versions. The decision was made after rigorous evaluation and comparative analysis, ensuring optimal performance for our specific use case. Moreover, similar to choosing the ResNet-101 architecture for its distinct advantages in certain applications, we used 5 alternative CNN models to get the best accuracy of classification. ResNet-101 got the highest \( F_1 \)-score and a lower train and validation loss in 50 epochs. Training and validation losses quantify the model’s prediction error. Lower values indicate higher accuracy and better generalization to new data. These losses are measured as dimensionless quantities derived from the chosen loss function, such as cross-entropy for classification tasks. Epoch count, such as the 50 used in our experiments, represents the total number of times the learning algorithm processes the entire data set, a critical factor in optimizing the model’s learning curve and preventing overfitting or underfitting.

Of the 54 participants enrolled in this study, 11 withdrew their consent because they could not wait for the photographs to be taken before the meal and because their general health deteriorated. Seven participants were excluded due to incomplete urine collection, and 11 were excluded due to inaccurate urine collection based on the 24-hour UCr value. Finally, the data of the 25 selected participants were analyzed (Figure 4).

The median age was 64 (IQR 53-74) years, and 68% (n=17) were men. The median values of serum creatinine and serum sodium were 1.0 (IQR 0.8-1.6) mg/dl and 138 (IQR 135.0-140.0) mEq/ml, respectively. The baseline characteristics of the study participants are presented in Table 3. Because the use of diuretics affects 24-hour UNa—the standard of sodium intake evaluation—the baseline characteristics were classified accordingly (Table 3). A total of 10 participants were treated with saline and parenteral nutrients. Because sodium in these fluids affects the 24-hour UNa, total intake was calculated by adding the amount of sodium administered (AI-Na [adjusted]).

The median sodium intake (AI-Na [unadjusted]) was estimated to be 1756.5 (IQR 1266.6-2273.2) mg when using the AI algorithm; further, the sodium in the fluids was included, resulting in a total sodium intake of 2227.2 (IQR 1936.2-2564.4) mg (Table 3). The 24-hour UNa was determined to be 2783.0 (IQR 1955.0-4922.0) mg. Depending on the effect of the diuretics, the value of 24-hour UNa varied and was 2599.0 (IQR 1771.0-4922.0) mg and 2921.0 (IQR 2231.0-4059.5) mg for the nondiuretic and diuretic groups, respectively (Table 4).

We compared the AI-estimated sodium intake values with those of 24-hour UNa and analyzed the degree of concordance and difference between the two.

The Disparity and Accordance Analysis Between Sodium Intake by Image-Sodium and 24-Hour UNa

The sodium intake was measured using the 2 aforementioned methods, and it was 2022.7 mg in AI-Na (adjusted) and 2783.0 mg in 24-hour UNa, and the statistical significance was 0.02, indicating a statistically significant difference. Considering the effect of diuretics on UNa, the participants were divided into 2 groups: diuretic and nondiuretic, and no significant difference was noted between the 2 groups (Table 5).

Interaction Model Using Regression Analysis

The difference between the 2 test values could be attributed to factors that affect 24-hour UNa excretion in a real-world setting, such as the use of diuretics as well as the patient’s gender, age, and renal function; this prompted us to derive a formula considering the aforementioned factors. The eGFR value using the Chronic Kidney Disease Epidemiology Collaboration equation was used as a variable, and the following regression equation was obtained using the interaction term for diuretics because gender, age, and renal function can all be calculated using eGFR (Table 6).

24h-UNa = 0.535 * AI-Na [adjusted] - 2292.009 * I (diuretics) + 1.280 * AI-Na [adjusted] * I (diuretics) + 22.102 * eGFR

24h-UNa = 2.355 * AI-Na [adjusted] + 22.102 * eGFR - 2292.009 (diuretic group)

24h-UNa = 0.535 * AI-Na [adjusted] + 22.102 * eGFR (nondiuretic group)

In this equation, “I” is the interaction term.
In this regression equation, the AI-Na (adjusted) and 24-hour UNa exhibited a strong relationship. Additionally, eGFR was significantly related to 24-hour UNa. Because the impact of the eGFR value on the 24-hour UNa is the same regardless of the use of diuretics, which was negligible in this equation, it can be assumed that 2.355 times the total sodium input (AI-Na [adjusted]) corresponds to 24-hour UNa in the diuretic group, and 0.535 of the AI-Na corresponds to the measured 24-hour UNa in the nondiuretic group.

Table 6. Linear regression with the interaction term between sodium intake calculated by the artificial intelligence algorithm (AI-Na; adjusted) and 24-hour urine sodium (UNa) excretion (adjusted $R^2=0.739$; $F=18.7$; $P<0.001$).

**Discussion**

**Principal Findings**

Our study may be the first study that compared an AI-based method with 24-hour UNa for measuring sodium intake in a real clinical field. Although the AI-Na and 24-hour UNa values were not the same, the various factors that affect the 24-hour UNa value, such as age, sex, renal function, diuretics, and even the underlying disease, cannot be ignored when using real-world data. Therefore, the 2 methods were worth evaluating using regression. The AI-Na values can be clinically considered as a significant indicator of sodium intake, although there were differences based on whether diuretics were used. Therefore, food images can be used to measure sodium intake to some extent, but this method is still inaccurate.

We calculated the sodium amounts in each test image as ground truth and used them for the AI sodium amount prediction model. Food amount served as one of the input values for Sodium amount prediction, as we used a multi-input fixture to predict sodium amount prediction and 24-hour UNa amount prediction using the collected data set from the hospital. As we collected metadata, it included food quantity, sodium amount, food classes, food intake, and patient information. The AI-based method predicted salt or sodium amount in food based on our multitask method.

Concerns regarding sodium intake have led to the development of several sodium measurement methods [16,19,20]. Numerous methods for measuring sodium intakes are available, ranging from 24-hour UNa, the most objective method, to single or multitask method.

Table 6. Linear regression with the interaction term between sodium intake calculated by the artificial intelligence algorithm (AI-Na; adjusted) and 24-hour urine sodium (UNa) excretion (adjusted $R^2=0.739$; $F=18.7$; $P<0.001$).

reference. Additionally, because the aforementioned study focused on the method of analyzing food photos, the experimental setting of this study did not reflect that of a real-world clinical one. Our study, on the other hand, considered several variables of an actual clinical environment and showed that salt intake measured by a photo-based AI algorithm had a significant relationship with the gold standard of sodium intake (ie, 24-hour UNa), thereby demonstrating that AI-Na value establishes the foundation for clinical use.

Accurately measuring food intake in hospitalized patients is crucial for determining their nutritional status, disease progression, or treatment option selection. However, traditional methods for evaluating food intake, such as visual estimation of the entire or 75% of the amount and patients’ subjective evaluations, often result in inaccuracies and an overestimation of up to 15% [23,24]. Therefore, a convenient and semiautomated digital method for food intake evaluation is required, and AI-based food photographs are expected to fulfill this need.

Strengths and Limitations
Our study’s strength lies in its evaluation of sodium intake in actual inpatients using cutting-edge technologies, food photos, and AI-based techniques as well as a comparison with established standards. Various variables of a real clinical setting were considered in this study, demonstrating the potential clinical usefulness of using AI in this domain. This study had some limitations. First, the sample size considered in this study was small. If more patients were enrolled, it would be possible to derive a more accurate formula using different variables. The second limitation was the inaccurate estimation of the food amount during food intake measurement. In addition to considering 24-hour UNa, it would have been useful if the food’s weight was considered both before and after consumption along with the corresponding nutrients. Third, the method proposed in this study failed to account for the potential loss of sodium during cooking and trimming processes, which may have further impacted the accuracy of the results.

Although we presented hyperspectral image reconstruction and employed a machine learning model for estimating food quantity, it is important to note that our approach did not directly detect sodium amounts from food images. Instead, it demonstrated a robust correlation between hyperspectral images and sodium amount estimation. This correlation provides a promising foundation for future research focused on refining methods for predicting sodium content.

In summary, our study aimed to incorporate AI into the clinical field; however, owing to limitations associated with AI, incomplete nutritional information, and the diversity of real-world treatments, comprehensive research planning is necessary for clinical use.

Conclusions
The method of measuring sodium intake using food photos was found to be inconsistent as compared with 24-hour UNa, which is widely used in clinical settings. However, the study results have clinical significance because variables of a real-world clinical setting, such as gender, age, diuretics, and fluid treatment, were considered. The findings also suggest that the formula derived in this study may not provide accurate estimates of the absolute sodium intake. However, if additional data are collected, it may be possible to develop a more useful formula in the future.

Acknowledgments
This study was supported by Seoul National Bundang University Hospital (grant 14-2021-0052).

Data Availability
The data set used in this research consists of food images and nutrition information. The data set is publicly available on AI Hub, a repository for AI-related data sets, maintained by the National AI Research and Development Agency of Korea. The data set can be accessed on AI Hub [25].

Authors' Contributions
SK designed the study. JR and SK contributed to the conceptualization and methodology. YL, JHO, SK, JHC, HSP, JL, ESK, NHK, and JES contributed to data collection and validation. Abstract

Background: As large language models (LLMs) are becoming increasingly integrated into different aspects of health care, questions about the implications for medical academic literature have begun to emerge. Key aspects such as authenticity in academic writing are at stake with artificial intelligence (AI) generating highly linguistically accurate and grammatically sound texts.

Objective: The objective of this study is to compare human-written with AI-generated scientific literature in orthopedics and sports medicine.

Methods: Five original abstracts were selected from the PubMed database. These abstracts were subsequently rewritten with the assistance of 2 LLMs with different degrees of proficiency. Subsequently, researchers with varying degrees of expertise and with different areas of specialization were asked to rank the abstracts according to linguistic and methodological parameters. Finally, researchers had to classify the articles as AI generated or human written.

Results: Neither the researchers nor the AI-detection software could successfully identify the AI-generated texts. Furthermore, the criteria previously suggested in the literature did not correlate with whether the researchers deemed a text to be AI generated or whether they judged the article correctly based on these parameters.

Conclusions: The primary finding of this study was that researchers were unable to distinguish between LLM-generated and human-written texts. However, due to the small sample size, it is not possible to generalize the results of this study. As is the case with any tool used in academic research, the potential to cause harm can be mitigated by relying on the transparency and integrity of the researchers. With scientific integrity at stake, further research with a similar study design should be conducted to determine the magnitude of this issue.

**Introduction**

Artificial intelligence (AI) is perhaps best defined as an algorithmic mechanism applied to machines, whereby solving challenges requires little to no human interaction [1]. Differentiating human-made and AI-generated work is becoming increasingly difficult with the rapid technological advancement of deep learning [2]. Deep learning is based on the replication of human thinking and the brain’s structure [3]. With the vast potential benefit that AI might bring to the table, extensive research has been conducted in the last decade with the purpose of finding potential solutions for health care–related problems [4]. The field of orthopedics, for example, might greatly benefit from AI image recognition capabilities to assist in the diagnosis of fractures or skin lesions. Other benefits can be drawn from AI’s capacity to analyze massive amounts of clinical information, which in turn presents benefits in clinical decision-making, risk assessment, and the generation of individualized care plans [5]. That is why an exponential increase in research on the topic of AI in the field of orthopedics has been noted, which has led to a subsequent increase in reviews trying to summarize the findings and give out recommendations [4].

Orthopedic sports medicine is the subspecialty of orthopedics that deals with pathologic conditions of the musculoskeletal system that arise from the practice of sports. This includes the prevention, diagnosis, and treatment of diseases. A particular challenge of sports medicine lies in the willingness of athletes to return to performance in a timely manner [4]. Through the use of deep neural networks, AI can assist specialists in various aspects of management. AI has shown to be especially advantageous for the diagnosis of fractures based on plain radiographs and computed tomography, with reviews reporting high accuracy, sensitivity, and specificity for the evaluation of plain radiographs [6] and computed tomography images [7]. With the evolution of convolutional neural networks and the increased capacity to integrate large amounts of written information, the patient’s medical records could serve as a basis for determining an individualized care plan as well as for making predictions for the best future course of treatment [8].

The influence of large language models (LLMs) on research in the field of orthopedics and sports medicine has not yet been well studied. AI is commonly used by researchers to help organize thought processes, obtain feedback, edit their work, and present their citations in the requested format. Consequently, AI has made academic work much more efficient [9]. However, considering that some of the most impactful journals allow the use of AI in composing or editing scientific texts, there are some ethical reservations regarding the authenticity and credibility of academic work [2]. Furthermore, some journals are actively involved in the development of tools to spot AI-generated texts [10]. In the light of this, the line where scientific research becomes fraudulent with regards to the use of AI must be determined. Different journals have adopted different guidelines for the use of AI.

The aim of this qualitative analysis is to determine the possibility that human researchers and AI-detection platforms can detect AI-generated texts. For this purpose, 4 researchers were recruited to participate in this study. As well as this, an AI-detection platform was used to assist in this endeavor.

**Methods**

This study adopted a similar method to previously conducted research on the matter [10].

**Recruitment**

For the purposes of the study, 4 participants were recruited. Two senior researchers in the fields of orthopedics and qualitative research, as well as 2 junior researchers in the same fields, expressed their interest in the subject at hand. All researchers were informed about the study’s objectives. The inclusion criteria for senior researchers were more than 10 years of research experience and having a doctoral degree in their field. Junior researchers were defined as students or physicians who had commenced their first project in the last 2 years.

**Ethical Considerations**

Due to the noninterventional nature of this study, as well as the anonymization of the included participants, local institutional and regulatory bodies did not require ethical approval. The methodology of the study and data collection were in line with the Geneva conventions. Informed consent was obtained from all participants involved in this study. The privacy and confidentiality of the involved participants has been protected by anonymizing their responses. No compensation was given to the participating individuals.

**Selection of Literature**

After searching PubMed for relevant material, 5 abstracts about meniscal injuries were selected for inclusion in the study [11-15]. The search strategy included the word “meniscus.” Subsequently, the first 5 articles published in reputable first quartile (Q1) or second quartile (Q2) journals were chosen to ensure the high quality of the articles. Abstracts that did not meet the criteria were excluded. This choice was made based on the fact that abstracts usually present a general overview of the topic at hand and communicate the main objectives of the paper. Although some treatment modalities are commonly applied to meniscal injuries, it is often impossible to completely restore the meniscal architecture, especially when the injury occurs in the middle, less vascularized portion [16]. Selecting meniscal injuries as a topic was, therefore, agreed upon by the research team as it is a common pathologic condition [17] and an area of extensive research [18].

**Involving AI**

Abstracts selected in the previous step were then rewritten by 2 AI platforms. One platform was the commonly used and extensively developed ChatGPT 3.4 (OpenAI) and the other was You.com. Using the instruction “rewrite the following in perfect academic English,” 5 new abstracts were generated by each AI. In the subsequent step, the command “write five abstracts on meniscal injuries” was used and 10 further abstracts were generated.
Randomization
The 25 resulting abstracts included the 5 original versions that were written by humans, the 5 rewritten versions that were generated by each AI, and the 5 newly generated versions that were composed by each AI platform. The abstracts were numbered from 1 to 25. These numbers were subsequently randomized using Microsoft Excel and the assigned abstracts were presented as a sheaf in the resulting order.

Evaluation
Evaluation of the abstracts was carried out using 2 methods. The first method of evaluation involved researchers with varying specialties and at different stages of their academic careers, while the second was based on the use of AI-detection software.

Participants were then asked to evaluate all the resulting abstracts using parameters that are commonly used for peer review. Suggested criteria that might aid in differentiating human-written from AI-generated literature included nuance, style, and originality [10]. Subtle phrasing and word choice might also be giveaways. A rating scale from 1 (very bad) to 5 (very good) was used for each parameter.

Participants were additionally asked whether they thought that the abstract was generated by a newer-generation AI, a more-developed AI, or a human. A short explanation was provided by each participant.

User Statistics
Descriptive statistics were used to investigate the correlation between the degree of academic experience and the number of correctly identified abstracts on one hand and between the previously mentioned parameters (eg, originality, grammatical soundness) and the correct identification of abstracts on the other. Furthermore, the correlation between the parameters and a researcher’s classification of an abstract was investigated. Interrater reliability was assessed by comparing the assessment of different articles by the same researcher, on the levels of both correct identification and assessed parameters. Intrarater reliability was assessed by comparing the assessments of different evaluators for both previously mentioned parameters.

The Mann-Whitney U test, the Wilcoxon W test, the Z test, and the asymptotic significance (2-tailed) P value were determined.

Results
The results of the analysis are presented in Tables 1-3. Further descriptive statistics are presented in Multimedia Appendix 1.

Discussion

Principal Results

The primary results of the study indicate that neither AI-detection software nor human critical appraisal can reliably distinguish AI-generated texts from human-written work. Regarding human detection of AI-generated texts, neither clinical experience nor area of expertise played a role in the evaluation of the presented material. The secondary results of the study indicate that criteria suggested by prior research, such as originality, style, and nuance, did not correlate with whether the researchers identified a text correctly or not. Furthermore, none of the criteria correlated with whether researchers judged a text as human written or AI generated. The qualitative analysis of the written answers did not provide any new insights on the subject in question. However, the junior orthopedic researcher was able to correctly identify texts according to the objectivity parameter. Whether this was due to correct interpretation or chance is unclear. Perhaps future studies with larger sample sizes can help in shedding light on this matter. Selecting the evaluators might have impacted the results of the study. Although the researchers were proficient published authors, English was not their primary language and this might have led to the inability to correctly identify the abstracts. However, the impact of this study is not reduced, as one might argue that scientific literature consumption is not restricted to researchers with English as their mother tongue. Furthermore, reading and publishing in English is becoming common practice, especially if research is considered to be relevant on the international level.

Comparison With Prior Work

Although AI is an evolutionary technology that presents an enormous potential for future research applications, the results of this study and previous studies with similar methodologies are alarming. AI seems to have reached human-level writing skills, which in combination with its easy accessibility is able to threaten academic integrity. The findings of this analysis contradict previous claims for the ability to detect manuscripts generated by AI through model-agnostic and distribution-agnostic features. Even though nonmalicious applications of AI, including grammatical corrections, reference style adjustment, and thought-process organization, represent plausible uses of AI models, potential fraudulent uses include the generation of complete texts from a simple command. Examples of malicious AI use might also include the rewriting of entire texts, as shown in this study. AI-generated texts can also be passed through AI-detection software by malicious users, who would then use the texts that passed the examination, making it even more difficult to subsequently detect fraudulent use.

Besides the ability to falsify results, AI presents researchers with the capacity to present false results in a plausible manner. This also applies to inaccurate findings being reported confidently, which may be a misrepresentation that could lead to confusion, especially if the results are presented to unexperienced peers. Therefore, fact-checking the AI-generated statements and references will be essential when relying on such tools. AI also the capacity to generate images that can be used in the presentation of results. In the area of orthopedic surgery, AI has already been proven to recognize patterns associated with multiple types of fractures. Combined with its image-generation capacity, AI models will be able to create radiographic representations of fractures that are of no true scientific value but can be used to alter the results of a study.

Additionally, with the ever-increasing human inability to distinguish AI- and human-generated work, new rules must be written to ensure the scientific integrity of every published paper. Suggestions have included an increase in transparency in the design of AI models, as well as complete transparency in the use of AI by authors. This includes where and how LLMs were used in scientific projects.

Understanding the algorithms of these programs might aid in conceiving new and better programs to counteract fraud in its many forms. In an article in the journal Nature, the company Turnitin was reported to have incorporate AI-detection software.

Finally, and perhaps most importantly, the integrity of research is the most important aspect of the evolving discussion around the use of AI. Many previously conducted cross-examinations of academic publications revealed that research data obtained from prestigious academic institutions and published in equally prestigious academic journals were falsified. Whether these findings were intentionally corrupted or were errors of data collection is of little significance compared to the effects they might have on clinical and academic work. Thus, one can say that AI is just a tool, and its potential to cause good or harm is derived from individual motivations, experience level, and integrity. Calls to completely ban AI from academic endeavors are, in the eyes of the authors, exaggerated, and future fraud can be minimized by optimizing self-regulatory mechanisms and AI-detection models. As well as this, the authors of this paper agree that detection of academic fraud is a responsibility of editors and journals, as a letter to Nature previously suggested. However, the central role of researchers cannot be overemphasized.

Limitations

Limitations of this study include the inability to trace AI use in the original articles included in this study. However, we assumed that if AI were used, it would have been reported in the methodology or declarations sections. A second limitation of this study is that English is not the native language of the assessors. However, all the involved researchers have deep levels of proficiency, having published prior research in English. A third limitation is the small sample size of examined individuals and AI-recognition software, which does not allow us to draw definite conclusions on the matter at hand. However, as LLMs in the field of AI become more sophisticated, the recommendations that were made by previous authors and mentioned in this paper will still hold. The final limitation of this study is that a subset of articles dealing with meniscal injuries was chosen from the immense field of orthopedics. This is particularly important when considering the “hot topic” subset.
Conclusions
The statistical and qualitative analysis of the presented material showed that researchers were unable to differentiate human-written from AI-generated texts. Furthermore, the secondary finding of this study was that previously suggested criteria, such as originality and comprehension, did not aid in the differentiation of human-written and LLM-generated texts. Both findings show that humans and AI-detection software currently fail to properly identify the use of LLMs in the academic literature.

Furthermore, one can only speculate about the amount of undisclosed AI use in the academic literature. However, with the ever-increasing sophistication of LLMs, the integrity of future projects will be entirely dependent on scientists’ attitudes, as AI can serve as a facilitator and accelerator in publishing but can also be used with malicious intent. With regard to replicating this study, the authors strongly recommend that a larger sample size of articles with a larger number of researchers should be considered.

Abstract

Background: Emergency departments play a pivotal role in the US health care system, with high use rates and inherent stress placed on patients, patient care, and clinicians. The impact of the emergency department environment on the health and well-being of emergency residents and nurses can be seen in worsening rates of burnout and cardiovascular health. Research on clinician health has historically been completed outside of clinical areas and not personalized to the individual. The expansion of digital technology, specifically wearable devices, may enhance the ability to understand how health care environments impact clinicians.

Objective: The primary objective of this pilot study was to assess the feasibility and acceptability of using wearable devices to measure and record physiologic data from emergency nurses and resident physicians. Understanding strategies that are accepted and used by clinicians is critical prior to launching larger investigations aimed at improving outcomes.

Methods: This was a longitudinal pilot study conducted at an academic, urban, level 1 trauma center. A total of 20 participants, including emergency medicine resident physicians and nurses, were equipped with a wearable device (WHOOP band) and access to a mobile health platform for 6 weeks. Baseline surveys assessed burnout, mental health, and expectations of the device and experience. Participants provided open-ended feedback on the device and platform, contributing to the assessment of acceptance, adoption, and use of the wearable device. Secondary measures explored early signs and variations in heart rate variability, sleep, recovery, burnout, and mental health assessments.

Results: Of the 20 participants, 10 consistently used the wearable device. Feedback highlighted varying experiences with the device, with a preference for more common wearables like the Apple Watch or Fitbit. Resident physicians demonstrated higher engagement with the device and platform as compared with nurses. Baseline mental health assessments indicated mild anxiety and depressive symptoms among participants. The Professional Fulfillment Index revealed low professional fulfillment, moderate workplace exhaustion, and interpersonal disengagement.

Conclusions: This pilot study underscores the potential of wearable devices in monitoring emergency clinicians’ physiologic data but reveals challenges related to device preferences and engagement. The key takeaway is the necessity to optimize device and platform design for clinician use. Larger, randomized trials are recommended to further explore and refine strategies for leveraging wearable technology to support the well-being of the emergency workforce.

(JMIR Form Res 2024;8:e51569) doi:10.2196/51569

https://formative.jmir.org/2024/1/e51569
Introduction

Emergency departments (EDs) are a critical and frequently used resource within the US health care infrastructure (1 in 5 adults are treated in an ED annually) [1,2]. EDs are stressful environments [3-6]. Research has demonstrated the negative impact of the physical ED environment on patients [7-10], yet less is known about the effects on the health and well-being of the clinicians working within these EDs. Burnout and cardiovascular (CV) health remain threats to ED clinicians, their careers, and patient care [11-14]. Research on clinician health and burnout has historically been limited by retrospective studies which are often conducted outside of work. The rapid growth of digital technology, such as wearable devices and remote monitoring [15-17], offers new opportunities and challenges to investigate clinician health within health care environments and spaces.

Multiple occupational hazards have been attributed to the practice of emergency medicine (EM) [18], EM clinicians have a 20% higher morbidity due to coronary artery disease, motor vehicle accidents, and impaired reproductive health [19-22]. Clinicians working night shifts, an essential practice in EM, have less restorative sleep, elevated blood pressure, and lower heart rate variability (HRV) [19,23-26]. Before the pandemic, the prevalence of stress, exhaustion, and burnout was alarmingly high in EM [27,28]. COVID-19 worsened these factors, resulting in workforce depletion, and making this an urgent and critical area of focus underscored by the Surgeon General and National Academy of Medicine [14,29].

A gap exists in understanding how clinicians identify and prioritize their health within the workplace. High-performance athletics provides a potential analogous framework whereby athletes track physiologic data (HRV, physical activity, and sleep) to guide their daily performance. There is an unrealized opportunity space for clinicians to understand and enhance care delivery and career longevity (reduce burnout and CV disease). Technological advancements provide a potentially unobtrusive and personalized method to collect individual data using wearable devices. Wearable device use has grown in popularity, with over 30% of Americans reporting they can obtain device ownership [30]. These wearable devices are typically wrist-worn and provide methods to measure health data such as step count, heart rate, and sleep [15]. What is less known, is if these devices and associated platforms are appealing to clinicians and can provide actionable insights to help inform strategies to support the workforce.

The objective of this study was to pilot test and evaluate the feasibility and acceptability of a wearable device and associated platform to measure and record emergency nurse and resident physician physiologic measures while they provide emergency care. This was a pilot study, investigating early barriers and facilitators to using these devices within health care settings for emergency nurses and residents.

Methods

Overview

Eligible EM resident physicians and emergency nurses included those providing 20 or more hours of patient care per week, having regular access to a smartphone, and providing consent to where a wrist-worn wearable device (WHOOP band [31]). Participants were recruited via email, completed informed consent, and were given a wrist-worn wearable device. Consenting participants completed a baseline survey assessing burnout and mental health (depression and anxiety), asked about their expectations of the study, and followed for 6 weeks. Validated instruments included the Patient Health Questionnaire (PHQ-8), General Anxiety Disorder (GAD-7), and the Professional Fulfillment Index (PFI) [32-36]. Over the 6 weeks, patients were also given access to a web-based platform that allowed participants to see their own physiologic data, access basic coaching videos, and connect to other users on the platform (Arena Strive [37]). At the completion of 6 weeks, participants were asked to complete a final survey exploring the feasibility and acceptability of the approach. Participants were also asked to provide free text commentary on the general approach and the specific device. The primary outcomes were use of the wearable device, acceptance of the device, and adoption of the device. Secondary measures included burnout, mental health symptoms, and physiologic measures recorded by the device including HRV and sleep.

Ethical Considerations

This was a longitudinal pilot feasibility study conducted at an urban, academic, level 1 trauma center in the northeastern United States. This study was reviewed and approved by the University of Pennsylvania Institutional Review Board (850371). All eligible participants completed informed consent forms and were informed that all data would be deidentified and aggregated for analysis. Participants received the wearable device at no cost and could keep the device following the completion of the study.

Data Analysis

Analysis was conducted using Stata SE (version 18; StataCorp). Descriptive statistics were used to summarize participant demographics and well-being survey results which included the PHQ-8, GAD-7, and the PFI. Single-sample 2-tailed t tests were used to investigate exploratory differences in physiologic measures.

Results

This was a pilot feasibility study and thus was not powered to detect individual health outcomes. A total of 20 participants were enrolled (13/20, 65% were female), 12 were EM resident physicians and 8 were emergency nurses. Of the 20 participants, 10 participants routinely wore the wearable device (6 resident physicians and 4 nurses).
Participants completing baseline mental health assessments reported mild anxiety as measured by the GAD-7 (mean score 5.07, SD 3.7), with 85% (n=17) reporting minimal or mild anxiety. Participants also reported mild depressive symptoms as measured by the PHQ-8 (mean 5.73, SD 2.9), with half reporting mild depressive symptoms. Participants completed the PFI to evaluate burnout and fulfillment. Individuals reported low professional fulfillment (mean 49.4, SD 16.9) moderate workplace exhaustion (mean 57.1, SD 24.4), and moderate interpersonal disengagement (mean 44.7, SD 20.1). Participants were asked via survey to comment on their early thoughts and goals with the pilot and the device. Notable themes emerged reflecting (1) technological features (eg, seeking a device with a watch face), (2) ways to integrate data into their personal lives and clinical roles, and (3) increasing self-awareness of the objective measures of stress related to clinical care.

Among participants who used the band consistently for 6 weeks, variation existed in their experience with the wearable and the data it generated. None of the participants were very likely to recommend the device to others. Two participants found the data interaction helpful and useful and overall, none commented on the platform being easy to use. When asked specifically, participants noted the band to be obtrusive given its lack of daily use features (eg, watch face and activity data) and odd charging mechanics. Several participants did comment positively that the data output and data generated was useful and empowering but needed to be collected using a more user-friendly design such as the more commonly used Apple Watch or FitBit. Participants sought the same application using these devices and expressed enthusiasm for those.

Of the 10 users who routinely used the device, we saw early variation in physiologic measures related to HRV, stress, and sleep (Table 1; Figures 1 and 2). While statistically significant differences are identified here, this remained a pilot study in feasibility, user input, and data collection methods. Early insights from these data suggest differences across roles between resident physicians and nurses, as well as across sex.

Discussion

Principal Findings

The physical and mental toll facing clinicians working in the ED continues to grow. Emergency nurses and resident physicians face a number of challenges impacting their health including, but not limited to, ED crowding, boarding, workplace violence, shifting schedules, and rising patient acuity. In the wake of the COVID-19 pandemic, an emphasis on supporting the workforce remains a priority. The evolving landscape of digital technology, including wearable devices, offers new opportunities for individuals to monitor their own health and potentially proactively identify physical or mental strain. This pilot study begins to examine if and how wearable devices can be used for emergency clinicians.

First, we found mixed enthusiasm for this approach given low interest in completing exit surveys and ongoing data interaction. It appears from this early feasibility study that resident physicians may be more engaged with this strategy and data collection method. Nurses in this pilot tended to be less engaged with the data tracking and follow-up mechanisms. Resident physicians were, in general, more enthusiastic before, during, and after the period ended. Though small in size, this pilot study does shed some initial interest from emergency clinicians and understanding key physiologic metrics such as sleep and physical activity. Key data insights remain physical activity as measured by step count, amount and quality of sleep, and HRV, which is an established physiologic measure relating to CV health [38]. The next steps to build on this pilot study included bringing it to a larger scale and designing it for nurse and physician preferences which we have learned to date.

The key finding of this pilot study is that the type of device and platform must be optimized for clinician use. In this study, we used a high-performance athletics device, which is designed primarily for physiologic measures [39]. This device does not have some traditional features that the average person may be accustomed to including a clock and the ability to send or receive messages. More traditional and popular bands such as the Apple Watch or Fitbit offer participants data tracking with features such as message-sending capability and a watch. These features are important when designing for scale, but were not previously known until we pilot-tested it, as other studies in more controlled environments have used the same device [39,40], underscoring the need to optimize design over technological capacity. The high-performance athletic band used in this pilot study offered a longer battery life and the ability to charge while wearing the device, which seemed less important to participants in this study. Future work needs to leverage the existing devices that clinicians wear in their everyday lives and incorporate those devices into this approach.

Finally, these devices and remote surveys highlight the persistent and real variation in professional disengagement, exhaustion, and burnout. In this small cohort, we do not identify significant amounts of anxiety or depression in screening assessments. We do note some variation and physiologic measures across resin physicians and nurses as well as differences across individuals who identify as male vs female. These differences though statistically significant, represent only a small sample size, and follow-up studies need to be scaled at larger populations. Specific interests should investigate physiologic measures such as heart rate, HRV, and sleep.

Limitations

This study has several limitations. This was a single-center pilot study and had a small sample size, which was intentional by design. We see glimpses toward mechanisms to optimize digtal technology and workforce sustainment. The signals identified
Here represent only early pilot findings, and inherently there is also selection bias in individuals who opted to wear the band and complete surveys. Less is known about individuals who do not want to be part of this pilot, and future studies will need to be larger, randomized, and for a longer duration. Nonetheless, the study is among the first to begin to investigate the feasibility of using digital technology to support emergency physicians and nurses by helping them identify physiologic variations in their own health. The study represents the pilot beginnings to help identify proactive and much-needed new methods to mitigate strain that is related to physical and mental health.

**Conclusion**

This pilot study of emergency nurses and resident physicians investigating wearable devices to capture physiologic data from a cohort represents early signals toward feasible and acceptable programs. This pilot study identifies opportunities and interest in these mechanisms and a need to leverage more consumer-facing and potentially less sophisticated wearable devices for emergency clinicians. These methods can be further explored and larger, randomized trials can be conducted to investigate these strategies and how we support the workforce.

Abstract

Background: Cognitive behavioral therapy (CBT) is effective in treating anxiety disorders. Accessibility to CBT has been limited in Japan due to the shortage of therapists. While an open-source e-learning system can be used to create a simple internet-based cognitive behavioral therapy (ICBT) program, the safety and outpatient acceptance of this treatment approach have not been explored in Japan.

Objective: The aim of this study was to investigate whether outpatients with anxiety disorders could accept and successfully complete the ICBT program with guidance by CBT therapists when implementing therapeutic modules and CBT tasks. Due to being in the initial phase of a novel treatment in Japan, this study was intended for verification with a small sample size.

Methods: In total, 6 adults, including 4 male participants and 2 female participants, were enrolled in a single-arm trial. The intervention involved guided ICBT comprising 12 sessions, including CBT text, comprehension confirmation tests, and explanatory videos about cognitive behavioral models, accessible through a website. The therapist guided the participants in accessing the ICBT program and answering their questions using a chat tool. The primary outcome was anxiety severity assessed using the State-Trait Anxiety Inventory-Trait. Secondary outcomes included the Panic Disorder Severity Scale, Liebowitz Social Anxiety Scale (LSAS), Beck Anxiety Inventory (BAI), Patient Health Questionnaire–9, Generalized Anxiety Disorder–7, and Working Alliance Inventory–Short Form (WAI-SF). Statistical analyses were performed using paired 2-tailed \( t \) tests to assess the changes in clinical symptoms. The total WAI-SF score at the final session was used to evaluate the therapeutic alliance. For statistical analyses, mean changes for total State-Trait Anxiety Inventory-Trait, BAI, Panic Disorder Severity Scale, LSAS, Patient Health Questionnaire–9, and Generalized Anxiety Disorder–7 scores were analyzed using the paired 2-tailed \( t \) test. The 2-sided significance level for hypothesis testing was set at 5%, and 2-sided 95% CIs were calculated.

Results: Most participants diligently engaged with the ICBT program. No adverse events were reported. The mean total scores for the primary outcome decreased by 11.0 (SD 9.6) points (95% CI –22.2 to 0.20; Hedges \( g = 0.95 \)), but it was not statistically significant.
Introduction

Anxiety disorders such as social anxiety disorder (SAD) and panic disorder (PD) involve prolonged and significant anxiety, leading to substantial impairment in daily functioning. In Japan, the 12-month prevalence of anxiety disorders is 5.3%, making them the most commonly diagnosed mental disorders [1]. Cognitive behavioral therapy (CBT) has been proven to be effective in treating anxiety disorders, particularly SAD and PD [2,3]. As per the clinical guidelines [4,5], CBT is the primary treatment option for patients with SAD or PD. However, CBT has rarely been integrated into the Japanese psychiatric clinical practice. The limited availability of CBT therapists and high implementation costs have been major obstacles significantly impacting the accessibility of CBT [6,7]. According to a 2018 report, the implementation rate of CBT in Japanese psychiatric clinics was 6.2% [7]. When CBT is applied, it is rarely based on an evidence-based cognitive behavioral model. In most CBT practices, therapists independently select and combine CBT techniques [7].

Since the latter half of the 1990s, self-help CBT programs have been provided in rural areas via the internet. CBT delivered through the internet is known as internet-based cognitive behavioral therapy (ICBT) [8]. In the ICBT approach, therapists guide patients via phone or email to enhance their treatment experience. Previous studies of guided ICBT have demonstrated significant therapeutic effects on anxiety disorders. According to 2 systematic reviews with meta-analyses, guided ICBT is likely as effective as face-to-face CBT [9,10]. Most studies of guided ICBT in these reviews were conducted in Europe, particularly, Northern Europe [10-13]. Due to the varying internet infrastructure and ICT literacy across different countries, evidence from clinical trials in Eastern countries is crucial.

Recently, several studies on ICBT with treatment programs adapted to specific cultures have been conducted in China, Korea, and Pakistan, yielding results supporting the effectiveness of ICBT [14-16]. Although some culturally adapted ICBT programs for mental disorders have begun to emerge in Japan [17-20], there is a lack of evidence of clinical trials that specifically target anxiety disorders [21]. A previous single-arm study in Japan demonstrated the feasibility of CBT via videoconference as another remote format for 20 adults with SAD or PD [22]. In this study, remote therapists provided individual CBT in real time. The results indicated that Japanese individuals with anxiety disorders find remote interventions preferable and readily acceptable. However, in the guided ICBT format, the absence of face-to-face interaction with the therapist is fundamental, and it is anticipated that the treatment experience may qualitatively differ, potentially leading to less favorable patient acceptance and treatment responses.

To carefully assess the feasibility of guided ICBT, a novel treatment in Japan, we conducted a rigorously controlled clinical trial with a small sample size, monitoring for the risk of deterioration and unexpected adverse events. The participants’ guided ICBT experiences were also summarized in a brief case series included as Multimedia Appendix 1.

Methods

Study Design

This prospective single-arm open trial was conducted between September 2019 and March 2020 at 2 university hospitals and a psychiatric clinic in Japan. Patients with PD or SAD were recruited between September and November 2019 through posters and leaflets placed at medical institutions in the 2 prefectures and on the university’s home page. The participants continued to receive treatment from general medical practitioners during the study period, and their authorization was obtained before enrollment. Personal IDs and passwords to the treatment program and chat tools were provided to participants.

Ethical Considerations

This study project and the present clinical trial protocol adhered to the Ethical Guidelines for Medical and Biological Research Involving Human Subjects in Japan [23]. This study was approved by the institutional review board of Chiba University Hospital (G2019004). Written informed consent was obtained from all participants after they were thoroughly informed of the study protocol. No compensation was provided for participating in the research, although the guided ICBT was provided for...
free. This pilot single-arm trial was registered at the University Hospital Medical Information Network Clinical Trials Registry (UMIN0000038118).

Recruitment

Figure 1 illustrates the flow of participants throughout the study. Initially, 8 patients were recruited in the study. The screening through psychological assessments was conducted by 3 clinical psychologists (SS, KM, and SH), and it was ultimately confirmed by 2 physicians (HI and ES) whether the participants met the diagnostic criteria of the *Diagnostic and Statistical Manual of Mental Disorder, Fifth Edition* [24]. After the screening, 2 patients were excluded either because they did not meet the inclusion criteria or because of pending cancellations as part of the participant management process. In total, 6 patients underwent a baseline assessment and were subsequently enrolled in the study. Following enrollment, 1 patient disagreed with the exposure in session 6 during the intervention. Notably, there were no dropouts in this trial, and no adverse events were reported during treatment. Of the 6 patients, 5 (83%) successfully completed the treatment modules and participated in the telephonic posttreatment assessment conducted by an independent assessor. One patient with PD who could not be assessed over the phone received all symptom rating scales via mail except for the Panic Disorder Severity Scale (PDSS).

Figure 1. Participant flow.

Inclusion Criteria

Inclusion criteria were (1) age between 18 and 65 years, (2) a primary diagnosis of PD or SAD according to the Mini-International Neuropsychiatric Interview [25], (3) moderate symptoms of PD or SAD: PDSS total score >9 or Liebowitz Social Anxiety Scale (LSAS) total score >70 [26-29], and (4) the ability to send emails and access the e-learning system.

Exclusion Criteria

Exclusion criteria were (1) psychosis and bipolar disorder, (2) current high risk of suicide, (3) substance abuse or dependence diagnosed within the past 12 months (antisocial personality disorder), and (4) IQ<80 measured by the Japanese Adult Rating Test [30].

Primary Outcome Measure

The primary outcome was a change in anxiety symptoms assessed using the Japanese version of the State-Trait Anxiety Inventory-Trait (STAI-T) [31]. The STAI-T is a self-reported scale comprising 40 items that quantitatively measures anxiety and can be evaluated using 2 scales [32]. The STAI-T comprises 20 items rated on a 4-point scale, and the total score ranges from 20 to 80, divided into 5 levels (I=very low, II=low, III=normal, IV=high, and V=very high). The validity and reliability of the Japanese version of the STAI-T have been demonstrated [33].

Secondary Outcome Measures

In addition to the primary outcome, several secondary outcomes with established reliability and validity were selected based on the research objectives. The Beck Anxiety Inventory (BAI) was
used to quantify comprehensive anxiety symptoms [34]. The BAI is a 21-question multiple-choice self-report inventory used to assess anxiety severity [34,35]. Other secondary outcome measures included the PDSS for participants with a primary PD diagnosis [26,27] and the LSAS for those with a primary SAD diagnosis [28,29].

The PDSS is a 7-item clinical interview rating scale that evaluates the core PD characteristics and demonstrates good psychometric properties [36]. As the PDSS is meant to be administered by professionals knowledgeable of the clinical manifestations of PD, an independent assessor (SH) was used to conduct and interpret this scale. The treatment response and remission rates were calculated using the LSAS and PDSS. For SAD, treatment response was defined as a 31% or greater reduction in the total LSAS score, and remission was defined as a final LSAS score of ≤36 [29]. For PD, treatment response was defined as a 40% or greater reduction in the total PDSS score, and remission was defined as a final PDSS score of ≤5 [37].

The participants also assessed the psychological bond between therapists and participants using the Working Alliance Inventory–Short Form (WAI-SF) [38], depressive symptoms using the Patient Health Questionnaire–9 (PHQ-9) [39,40], and generalized anxiety symptoms using the Generalized Anxiety Disorder–7 (GAD-7) [39,41]. The WAI-SF assesses the strength of the therapeutic alliance between the therapist and patient through 12 items rated on a scale of 1 (never) to 7 (always). The total score ranges from 12 to 84, reflecting the overall strength of the therapeutic bond between the therapist and patient.

Both the PHQ-9 and GAD-7 were scored on a 4-point scale (0=none, 1=a few days, 2=more than half, and 3=almost daily). The PHQ-9 scores range from 0 to 27, with the cutoff value for clinically significant depressive symptoms set at 10. Symptomatological was categorized as follows: 0–4=none, 5–9=mild, 10–14=moderate, 15–19=moderate to severe, and 20–27=severe depressive state. The Japanese version of the PHQ-9 has demonstrated adequate validity [40]. GAD-7 scores range from 0 to 21, with a cutoff value for clinically significant generalized anxiety set at 10. Symptomatological was defined as follows: 0–4=none, 5–9=mild, 10–14=moderate, and 15–21=severe general anxiety. The GAD-7 has demonstrated good reliability and validity [42].

**Intervention**

We developed ICBT programs based on the Clark and Wells [43] model for SAD and Seki and Shimizu’s model for PD [44]. Each ICBT program consisted of 12 modules. Therapeutic guidance was provided by a clinical psychologist (KM) with extensive experience in face-to-face CBT for patients with PD and SAD. The therapist, a clinical psychologist with a PhD, had completed the CBT training course [45]. After each session, the therapist conducted peer supervision with the third author. The intervention involved guided ICBT comprising 12 sessions, including CBT text, comprehension confirmation tests, and explanatory videos about cognitive behavioral models, accessible through a website. The therapist guided the participants in accessing the ICBT program and answering their questions using a chat tool.

The ICBT program for PD included the following modules: guidance for ICBT program (session 0), psychological education and case conceptualization (week 1), review of safe behaviors (week 2), modification of self-image (week 3), attention shift training (week 4), behavioral experiments with internal sensory exposure (week 5), staged exposure (week 6 and 7), intervention on memory of the first panic attack (week 8), examination of others’ interpretations of panic attacks (week 9), stop dwelling on the panic attacks (week 10), reconstruction of remaining beliefs (schema work; week 11), and relapse prevention (week 12).

The ICBT program for SAD included the following modules: guidance for ICBT program (session 0), psychological education and case conceptualization (week 1), examination of safety behavior (week 2), video feedback (week 3), attention shift training (week 4), behavioral experiment 1 (week 5), behavioral experiment 2 (week 6), creation of anxiety hierarchy form and graded exposure (week 7), validating negatively rated expectations (week 8), stop dwelling on things (week 9), rewriting the meaning of memories linked to self-image (week 10), reconstruction of remaining beliefs (schema work; week 11), and relapse prevention (week 12).

The participants in this study were generally instructed not to initiate, discontinue, or modify their pharmacotherapy after the intervention. The participants were required to inform the research team if there were any changes to their medication regimen.

**Hardware and Software**

The participants used personal PCs, tablet PCs, or smartphones. The software used included LearningBox (Tatsuno Information System Co) and MediLine (ShareMedical Co), a medical chat service for delivering ICBT. LearningBox is an e-learning system enabling administrators to create and manage educational materials, handle member groups, and record and assess grades. Although e-learning systems store and manage user results, they do not include personal or sensitive information. MediLine is a medical chat service (medical social networking service) designed to replace email and phone calls. It incorporates robust encryption to prevent military-level information leaks and operates in a double-encrypted state, following the Japanese government guidelines. End-to-end encryption is performed in real time on the server during communication, and temporary memory is used in the terminal. The lectures for each CBT session were recorded as video footage, uploaded to YouTube [46,47], and shared with the participants.

**Data Setting**

SH was responsible for collecting outcomes at baseline (week 1) and postintervention (week 12). The collected data were registered on a server and managed by the Data Management Office of Chiba University Hospital.

**Statistical Analysis**

Statistical analyses were conducted according to the intention-to-treat principle by a team of statistical analysts (YI, YO, and YK). For screening assessments at baseline, summary
statistics were generated, including proportions for categorical data and means and SDs for continuous variables. All outcomes that could be expressed as continuous variables were analyzed using paired 2-tailed t tests before and after the intervention. Specifically, total STAI-T, BAI, PDSS, LSAS, PHQ-9, and GAD-7 scores were analyzed. The 2-sided significance level for hypothesis testing was set at 5%, and 2-sided 95% CIs were calculated. The total WAI-SF score, which measures the strength of the therapeutic alliance, was submitted as a raw score after the completion of ICBT. One male participant with PD did not submit PDSS data after the intervention. Imputation of missing values was not performed.

### Results

#### Demographic Data and Clinical Characteristics

In total, 6 participants (4 male participants and 2 female participants) with a mean age of 41 (SD 8.2; range 26-51) years were enrolled in the clinical trial. Table 1 shows the demographic data and the participants’ clinical characteristics. All participants continued their pharmacotherapy during the trial with specific medications such as paroxetine hydrochloride hydrate (n=3), venlafaxine hydrochloride (n=1), sertraline hydrochloride (n=1), and a combination of sertraline hydrochloride and ezilam (n=1). The participants’ estimated IQs tended to be higher than the mean (110, SD 4.2).

#### Adverse Events

No mental or physical adverse events were reported after the intervention.

#### Evaluation Outcomes

Table 2 provides a detailed overview of the outcomes. In the primary outcome, the mean total score on the STAI-T decreased by 11.0 (SD 9.6) points, although this did not reach statistical significance (95% CI –22.2 to 0.20; P=.05; Hedges g=0.95). However, several secondary outcomes demonstrated significant improvements. The mean total BAI score significantly decreased by 15.7 (SD 12.1) points (95% CI –28.4 to –3.0; P=.03; Hedges g=1.24). The mean total PDSS score also decreased significantly, by 12.0 (SD 4.2) points (95% CI –50.1 to 26.1; P=.16; Hedges g=1.79). Furthermore, the mean total LSAS score significantly decreased by 32.0 (SD 11.1) points (95% CI –59.7 to –4.3; P=.04; Hedges g=1.38).

*aSTAI-T: State-Trait Anxiety Inventory-Trait.

*bBAI: Beck Anxiety Inventory.

*cPDSS: Panic Disorder Severity Scale.

*dLSAS: Liebowitz Social Anxiety Scale.

*ePHQ-9: Patient Health Questionnaire–9.

*fGAD-7: Generalized Anxiety Disorder–7.

Regarding depressive symptoms, the mean total PHQ-9 score decreased from 12.5 (SD 5.61) to 8.7 (SD 4.47) points, but the reduction was not statistically significant (95% CI –9.3 to 1.6; \( P = .13; \) Hedges \( g = 0.68 \)). Similarly, for generalized anxiety symptoms, the mean total GAD-7 score decreased from 9.17 (SD 6.85) to 6.0 (SD 4.74) points, but the reduction was not statistically significant (95% CI –9.8 to 3.5; \( P = .27; \) Hedges \( g = 0.55 \)).

At the postintervention assessment (week 12), the treatment response rates were 67% (n=2) for PD and 67% (n=2) for SAD. The remission rates were 67% (n=2) for PD and 33% (n=1) for SAD.

Acceptance of Guided ICBT

Of the 4 male participants, 3 completed all treatment modules. These 3 participants completed the treatment without asking questions to the therapist and were able to understand the content and execute therapeutic tasks independently. A female participant with SAD avoided even minimal communication with therapists through chat tools due to severe social anxiety symptoms. While she accepted the self-help format of CBT, the chat with the therapist itself became burdensome rather than beneficial. A female participant with PD and fear of panic attack reported being encouraged by the therapist’s empathy and encouragement. A male participant with PD self-discontinued the treatment module and subsequently lost contact with the therapist. He frequently struggled to control his emotions, making it challenging to address his concerns effectively. For a brief case series of guided ICBT, please refer to Multimedia Appendix 1.

Discussion

Principal Results

This study explored the feasibility of guided ICBT in outpatients with PD and SAD in Japan. In total, 5 of the 6 participants successfully completed all modules, and no adverse events were reported throughout the study period. While anxiety symptoms decreased in most patients after the intervention, with a substantial effect size, the primary outcome (STAI-T) did not show a significant difference. However, significant improvements were observed in the secondary outcome, as measured by the BAI. Our results suggest that guided ICBT has a positive impact on anxiety symptoms, as evidenced by the notable changes in BAI scores. Most participants diligently engaged with the ICBT programs. Meanwhile, patients who considered themselves to have enough understood the materials understood the materials hardly contacted the therapists.

Limitations

When interpreting our study, it is important to consider the following limitations. First, the small sample size prevented us from determining whether the findings were due to a type II (\( \beta \)) error. Second, this was a single-arm trial without a control group. More robust and statistically rigorous results could be obtained through a clinical randomized controlled trial in which the sample size is determined based on the effect sizes observed in our study. A randomized controlled trial in Japan would allow for better investigation of the effectiveness of ICBT in Japanese patients with anxiety disorders.

Additionally, we did not assess the extent to which the participants implemented ICBT program strategies in their daily lives. While the therapist encourages participants to practice what they learned through chat tools, phone calls, and in-person interactions, patients might face challenges in implementing these changes or coping with symptoms [48]. In this study, patients with PD had difficulty applying learned techniques in daily life. Future studies should evaluate the impact of practice on symptom improvement to gain a more comprehensive understanding of the therapeutic processes.

Comparison With Prior Work

Our results showed that participants engaged in video lectures explaining the treatment modules, potentially enhancing their understanding and motivation for treatment. Despite the small sample size, guided ICBT with these lecture videos showed significant effectiveness as reflected in a treatment response rate of 67% (n=4) and a remission rate of 50% (n=3). These
results are consistent with a representative meta-analysis examining treatment response predictors in 1162 patients undergoing ICBT [9]. The reduction in the total score on the primary symptom rating scales before and after the trial, along with the effect size, underscored the efficacy of guided ICBT that incorporated lecture videos. Notably, the within-group effect sizes for the primary symptoms in this study (Hedges g=1.38 for LSAS and 1.79 for PDSS) were as substantial as those observed in previous representative studies [49-51].

In this study, the dropout rate was 17% (1 of 6 participants), which is comparable to face-to-face CBT (26%) [52]. In contrast, another study of guided ICBT reported an average dropout rate of 32% for depression [53]. Notably, one dropout from our trial was a male patient with a significantly lower therapeutic alliance score (12 points on the WAI-SF total score). Consistent with previous studies on dropout predictors, patients with low therapeutic alliance scores tended to drop out [54]. When the therapeutic alliance is weak, therapists and patients should engage in discussions regarding treatment goals and tasks. However, rebuilding therapeutic alliances in guided ICBT contexts may be more challenging than in face-to-face contexts.

Participants with anxiety disorders might willingly participate in CBT programs but may not always practice cognitive behavioral skills [8]. For instance, one participant with PD (participant 5) experienced severe panic symptoms related to employment status. Conversely, some patients demonstrate independent therapeutic progress without extensive therapist interactions. Overall, our findings align with the existing research, indicating that severe anxiety, coexisting depression, and low socioeconomic status are associated with poor outcomes [55]. Please refer to Multimedia Appendix 1 for details regarding each participant’s treatment course.

In the case of SAD, all 3 participants successfully applied the acquired skills to their daily lives. However, none of the participants with SAD used a communication tool with their therapist. This suggests that using a chat tool may be burdensome for individuals with social anxiety, potentially reducing the accessibility of ICBT, as these patients often dislike high-intensity communication. However, the therapists’ guidance may have encouraged them to engage in self-help activities [56]. For patients with social anxiety who find it challenging to ask questions or express their thoughts, therapists could consider expressing their ability to provide answers as needed instead of engaging in routine email interactions.

It is worth noting that even patients with social anxiety who avoid chatting may still be willing to receive treatment, as indicated by a guided ICBT trial conducted in China, in which patients with SAD completed more modules of the treatment program than the nonclinical group [15]. However, if the symptoms are severe, patients may struggle to practice cognitive behavioral skills independently in their daily lives. Participants who showed symptom improvement had relatively high social functioning, continued employment, and direct community involvement (participants 1, 2, 4, and 6).

Conversely, patients with severe disorders (participant 3) and those resistant to exposure-mediated interventions (participant 5) may require a significant amount of therapeutic attention. For instance, individual face-to-face CBT might be a more suitable option for someone like participant 3, who has SAD. Similarly, for participant 5, a personalized face-to-face CBT approach in which the therapist helps analyze the gains and losses of exposure and safety behaviors and demonstrates internal sensory exposure techniques could be beneficial. Clinicians and therapists who are going to conduct CBT should consider disclosing treatment modules to patients and assess the level of support required before providing ICBT.

Conclusions
Guided ICBT may be a feasibility treatment approach for patients with PD and SAD in Japan. If the patients have high motivation and the ability to understand and practice treatment modules, supports might not be strictly necessary during the treatment from the CBT therapist. The empathetic words from the therapist and encouragement for program implementation may assist some patients in overcoming fear and engaging in the assigned tasks.

Abstract

Background: Digital tools may support people to self-manage their heart failure (HF). Having previously outlined the human-centered design development of a digital tool to support self-care of HF, the next step was to pilot the tool over a period of time to establish people’s acceptance of it in practice.

Objective: This study aims to conduct an observational pilot study to examine the usability, adherence, and feasibility of a digital health tool for HF within the Irish health care system.

Methods: A total of 19 participants with HF were provided with a digital tool comprising a mobile app and the Fitbit Charge 4 and Aria Air smart scales for a period of 6 months. Changes to their self-care were assessed before and after the study with the 9-item European HF Self-care Behavior Scale (EHFScBS) and the Minnesota Living with HF Questionnaire (MLwHFQ) using a Wilcoxon signed rank test. After the study, 3 usability questionnaires were implemented and descriptively analyzed: the System Usability Scale (SUS), Wearable Technology Motivation Scale (WTMS), and Comfort Rating Scale (CRS). Participants also undertook a semistructured interview regarding their experiences with the digital tool. Interviews were analyzed deductively using the Theoretical Domains Framework.

Results: Participants wore their devices for an average of 86.2% of the days in the 6-month testing period ranging from 40.6% to 98%. Although improvements in the EHFScBS and MLwHFQ were seen, these changes were not significant (P=.10 and P=.70, respectively, where P>.03, after a Bonferroni correction). SUS results suggest that the usability of this system was not acceptable with a median score of 58.8 (IQR 55.0-60.0; range 45.0-67.5). Participants demonstrated a strong motivation to use the system according to the WTMS (median 6.0, IQR 5.0-7.0; range 1.0-7.0), whereas the Fitbit was considered very comfortable as demonstrated by the low CRS results (median 0.0, IQR 0.0-0.0; range 0.0-2.0). According to participant interviews, the digital tool supported self-management through increased knowledge, improved awareness, decision-making, and confidence in their own data, and improving their social support through a feeling of comfort in being watched.

Conclusions: The digital health tool demonstrated high levels of adherence and acceptance among participants. Although the SUS results suggest low usability, this may be explained by participants uncertainty that they were using it fully, rather than it being unusable, especially given the experiences documented in their interviews. The digital tool targeted key self-management behaviors and feelings of social support. However, a number of changes to the tool, and the health service, are required before it
can be implemented at scale. A full-scale feasibility trial conducted at a wider level is required to fully determine its potential effectiveness and wider implementation needs.

Introduction

Heart failure (HF) is a major global cause of disability associated with high morbidity and mortality, frequent hospitalization, high health care costs, impaired functional status, and poor quality of life [1-3]. Defined as “a clinical syndrome with symptoms and/or signs caused by a structural and/or functional cardiac abnormality and corroborated by elevated natriuretic peptide levels and/or objective evidence of pulmonary or systemic congestion” [4], symptoms include shortness of breath (dyspnea), fatigue, pulmonary edema, and a reduced ability to complete activities of daily living [2]. Self-care behaviors are critical components of the long-term management of HF [3,5-8]. Self-care is an overarching concept formed of the key concepts of (1) self-care maintenance (eg, taking or adjusting medication as prescribed, engaging in physical activity, and adhering to a healthy diet), (2) self-care monitoring (eg, regular weighing), and (3) self-care management (eg, changing diuretic dose in response to symptoms) [5]. Adequate self-care requires patients to understand what they need to do, have the skills to implement advice given to them, and adjust their behaviors according to how they feel and their symptoms. This is a complex, multicomponent set of behaviors that is constantly evolving, which can result in patients finding it difficult to successfully undertake [2,3,9,10].

Consequently, recent years have seen growing interest in the development of new and novel ways to support patients in their self-care behaviors. In particular, digital health options have begun to be widely used as the ubiquitous use of smartphone apps, and wearable devices appear to be adopted to support health care [3,11]. Used independently, or in combination, such digital health tools (DHTs) may support patients to monitor key behaviors, support improved autonomy in their own care, and provide pathways for patients and health care professionals (HCPs) to communicate [2,9]. However, despite the promise of DHTs in the management of HF, results regarding its potential effectiveness are mixed [3,12,13]. The pace of development of digital tools has resulted in them only being tested in small numbers or over a short duration, and critically, these tools are rarely developed with clear clinical or patient perspectives embedded within them [3]. Recently, the use of human-centered design approaches has led to the successful development of digital health technologies designed to support chronic disease management [14]. As such, implementing a human-centered design approach to the development of DHTs designed to promote self-care behaviors in patients with HF may positively influence the impact their condition has on their quality of life.

Therefore, we used a human-centered design process, as described in the International Organization for Standardization 9241-210:2019 regulations [15], to design and develop a DHT to support effective self-care behaviors in people with HF over a medium-term duration of 6 months to test for the potential of participant fatigue with the DHT (ie, reduced usage over time, poor acceptability, etc). The full process and approach taken were previously outlined in detail elsewhere and pilot-tested over a 2 week period [16]. Specifically, a consumer grade device was used to understand whether such ubiquitous tools can be used to empower people with HF to self-monitor their condition, bridging the gap between them and their clinicians. However, this tool required a more robust assessment of the longitudinal impact on self-care behaviors. Additionally, we wished to get an initial indication of its potential use from the perspective of the HCPs. Therefore, the aim of this study was to conduct a 6-month observational pilot test of this DHT in practice to examine its usability and the participant’s adherence to the system.

Methods

Recruitment

Participants were recruited from a private hospital in Dublin, Ireland, between July and October 2021 and had previously been diagnosed with HF. Purposive sampling was used using the patient lists of Beacon Hospital Cardiology to facilitate the assessment of the acceptability and usability of the DHT. Participants were deemed eligible if they could provide written informed consent; were previously diagnosed with HF; were under the care of Beacon Hospital Cardiology (aged ≥18 years); were under New York Heart Association classification 1-3; were open to the use of technology in the promotion of HF self-care; had access to an internet connection or mobile data; and were intellectually, visually, and auditorily capable of communicating with the investigator and understanding and complying with the requirements of the study. Participants were deemed ineligible if they were medically unstable or undergoing medical treatment judged not to be medically compatible by the investigator (eg, undergoing treatment for cancer), or if they had any skin condition that may affect the integrity of their skin when wearing the activity tracker. Participants (n=43) were approached directly by the members of the cardiology team to determine their interest and eligibility in the study.

Ethical Considerations

The study received ethical approval from the Beacon Hospital Research Ethics Committee (BEA0114 and BEA0151), and written informed consent was obtained from all participants.
before commencing the study. No financial compensation was provided to participants taking part.

Digital Health Tool

The DHT used in this study was designed using human-centered design steps and included behavior change techniques, as previously outlined in detail by Johnston et al [16]. Briefly, the system was designed to comprise a cross-platform (iOS or Android) mobile app capable of linking to a consumer activity tracker and smart scales, specifically, the Fitbit Charge 4 and Aria Air smart scales (information also available in [17]). The mobile app was broadly divided into five sections: (1) advice, (2) symptom reporting, (3) activity tracker and scale data (exercise, weight, heart rate, and sleep), (4) medication reminders, and (5) other vital sign tracking—all targeted through the inclusion of specific behavior change techniques (Figure 1) [16,17]. During the design of this DHT, an initial prototype was trialed with participants with HF for a period of 2 weeks, where positive feedback and adherence were seen [16]. The system was considered easy to use, positively affected their motivation to engage in key self-care behaviors, provided them with skills and perceived knowledge that made them more aware of the importance of self-care behaviors, positively influenced their confidence, and facilitated help seeking. After this, aspects of the system that needed to be improved were identified. These changes were implemented before deployment in this longer study. Specifically, the scaling in the app was adjusted to support larger fonts, the ability to input decimal points for vital signs was inputted, screens were not allowed to take a time-out while videos were playing, the information button was made more visible, technical issues surrounding daily data were addressed, and the ability to visualize within day heart rate data was implemented [16].

Figure 1. Screenshots from the mobile app detailing the main menu, advice section, symptom report, and screens [16].

Study Methods

The recruited participants were invited to an initial setup session at the hospital (Figure 2). Demographic data such as age, sex, and the highest level of education were collected at the beginning of the session. The participants then completed the 9-item European HF Self-care Behavior Scale (EHFScBS) [18,19] and the Minnesota Living with HF Questionnaire (MLwHFQ) [20,21] to evaluate self-care behaviors in patients with HF and the effect of HF treatments on the quality of life. Following a setup and familiarization session with WJ (approximately 40 minutes), participants were asked to use the system as part of their usual daily routine for the following 6 months. Depending on their recruitment date, participants were using the DHT for a 6-month period between July 2021 and April 2022. During this period, patients were asked to wear the Fitbit Charge 4 activity tracker on their wrist, take their weight every morning using the Fitbit Aria Air scales, and interact with the developed mobile app. A check-in symptom questionnaire was completed once a month [16]. This same questionnaire was also triggered to be sent to participants once any of their monitored components (ie, heart rate, sleep, weight, or physical activity) changed by 2 SDs from their baseline level in the previous 7 days. In the event that a trigger occurred, the
A questionnaire was sent to participants as an alert in the app, informing them of a change and asking them to complete the questionnaire. The questionnaire was then sent, along with a trigger, to the cardiology team of the Beacon Hospital who would telephone the participant to determine whether any further medical action or intervention was required.

At the end of the 6-month period, individual semistructured interviews were completed over the phone and recorded with each participant. Open-ended questions were used to explore their perceptions of the acceptability, usability, and practicality of the DHT; understand their experiences pertaining to the impact of the DHT on their self-care behaviors; identify usability and user experience issues; and identify aspects that could improve the DHT (Multimedia Appendix 1). Participants also completed 3 usability questionnaires: System Usability Scale (SUS), a questionnaire designed to measure system usability [22]; Wearable Technology Motivation Scale (WTMS), a questionnaire based on the intrinsic needs listed within self-determination theory [23]; and the Comfort Rating Scale (CRS), a questionnaire designed to assess the comfort of wearable devices across the dimensions of emotion, attachment, harm, perceived change, movement, and anxiety [24]. They also repeated the EHFS/CS and MLwHFQ to indicate whether a change in their behaviors or quality of life occurred.

After the completion of the study, semistructured interviews were also conducted with 2 members of the clinical team in Beacon Hospital Cardiology to explore their perceptions of the DHT (Multimedia Appendix 2).

Data Analysis
The recorded interviews were transcribed verbatim and anonymized. The coding of participants’ experiences with the DHT over the 6-month period was done using the Theoretical Domains Framework (TDF). The TDF was used within the development study to map the target behaviors of the tool; thus, it was used as a lens through which to view the usability, adherence, and potential behavior changes noted during this 6-month study. A deductive content analysis was undertaken whereby transcripts were coded according to the components of TDF [25,26] using a critical realist approach. This approach posits that a reality exists independent of our construction of it, while maintaining that our knowledge of it is interpretive, partial, and fallible [27]. In taking this approach, we recognize that our own experiences influence our insights but that we maintain our objective to view the situation as it occurs. To elaborate on our experiences, AK is a research physiotherapist with over 5 years of experience in digital health research and a PhD in behavior change. CB is undertaking a PhD in behavior change, with expertise in the use of the TDF and publications using the same. Together, these experiences influence and enrich their interpretation of the data.

AK coded all transcripts. First, they familiarized themselves with the data by reading and rereading all transcripts and generating initial notes on the data. Meaningful phrases were highlighted and assigned codes according to the domains of the TDF [25,26]. CB then acted as a critical friend to the coding, reviewing 20% of transcripts and providing critical feedback to improve the interpretation of findings and discussion of codes. How these barriers and facilitators align to each of the key skills of self-management was considered to identify areas for further development. Finally, given that only 2 HCPs were interviewed regarding their experiences, information from their transcripts was summarized narratively.

Questionnaire data were analyzed using SPSS Statistics for Mac (version 27; IBM Corp). The questionnaire data were scored using the appropriate standardized procedure for each
questionnaire. The MLwHFQ is scored by summing each of the components, resulting in a score ranging from 0 to 105 (whereby higher scores indicate higher impairment) [20]. The EHFScBS 9-item is scored by reversing the responses to the questionnaire and standardizing them [30]. This results in a score ranging from 0 to 100 (where a higher score indicates good self-care, and <30 is deemed as inadequate) [18]. Changes in results before and after the study were measured using a Wilcoxon signed rank test. The \( P \) value was set at .05; however, this was adjusted with a Bonferroni adjustment whereby \( P < .03 \) was significant. The SUS is scored out of 40 but converted to a 0-100 scale as per the standard procedure, with >68 deemed acceptable and >80 considered excellent [31]. Each item of the CRS is scored from 0 to 20 (where higher scores equate to worse comfort) [24]. The median of the 6-item questionnaire was calculated. Finally, the WTMS is scored by calculating the average score across the different components for each participant, resulting in a score ranging from 0 to 7 (whereby 7 indicates higher intrinsic motivation) [23]. In addition, adherence was determined by identifying the number of days a user wore the Fitbit device throughout the day and recorded their weight.

### Results

#### Participants

A total of 43 people were contacted by the clinicians in the Beacon Hospital to invite them to participate. Of these, 10 (23%) were not contactable, 1 (2%) did not satisfy the inclusion or exclusion criteria, 6 (14%) declined, and 7 (16%) did not use a smartphone. A total of 19 (44%) participants were recruited, of whom 17 completed the poststudy follow-up session (Table 1). One participant withdrew in the middle of the study because of increased health concerns, and 1 participant was unable to be contacted at the end of the study. Results regarding participants acceptability and changes to their self-care routines are based on the 17 who completed the entire study. Participants wore their devices for an average of 86.2% of the days in the testing period ranging from 40.6% to 98% (average of 157 days out of a possible 184 days). Furthermore, participants weighed themselves for an average of 73.7% of the potential testing days, ranging from 4.9% to 100% (average of 134 days out of a possible 184 days).

### Patient-Reported Outcomes

Although improvements in the EHFScBS were seen between baseline and the completion of the study, these changes were not significant \( (P > .03) \; \text{Table 2, Figures 3 and 4}. \) No participants were deemed to have inadequate self-care according to this scale. Similarly, although improvements were seen in the MLwHFQ results, these were not significant. Nonetheless, the median score suggests moderate quality of life, with 7 participants demonstrating good quality scores (41%) and 5 listing poor scores (29%) [32].

Participant Interviews

A total of 13 of the TDF domains were viewed as barriers or facilitators to the self-management of HF, whereas just 1 domain of the TDF did not match data (“optimism”). However, alongside “goals” this domain was not originally mapped to the key behaviors of self-management during the development of the mobile app [16]. A limited number of codes were noted for “goals” and “reinforcement,” suggesting that neither domain plays an important role in the facilitation of self-management in HF; therefore, they were excluded from the analysis. Of the remaining domains, 5 were generally viewed as facilitators of self-management (knowledge; social role and identity; memory, attention, and decision processes; social influences; and behavioral regulation). One (environmental context) was a barrier to self-management, whereas 5 were neither (skills, beliefs about capabilities, beliefs about consequences, intentions, and emotions; Figure 5).

Figure 5. Demonstrated impact of each Theoretical Domains Framework component on self-management of heart failure (green = facilitator, orange = unclear, red = barrier).

Knowledge

Participants noted that the information provided in the mobile app was simple to understand and provided them with a greater general awareness of important elements to them and the management of their heart condition, specifically heart rate and weight. Indeed, people noted that, if anything, the information was too simple and they would have liked more personalized information, information about dietary requirements and blood pressure. Thus, overall, the knowledge provided by the app was considered useful in the management and awareness of their HF.

Well it was very simple to work. It kept me up to date. I kept an eye on my weight every morning which I usedn’t do. And then I would check the heart rate as well and then of course what I found very helpful was the questionnaire that you sent on every month. [P10, male, 80]

From my own personal point of view, blood pressure, since I had open heart surgery, my blood pressure has been very low, so I suffer on a daily basis with light-headedness and all of that. So, I suppose I would have found it useful to know blood pressure readings. [P17, female, 67]

Well, like as I said, it wouldn’t give me what the problem was with me, like the blood flow through the heart, it wasn’t doing that. It’s just monitoring the heart. [P2, male, 74]

Memory, Attention, and Decision Processes

This domain is a complex element that included participants’ memory of completing self-management behaviors and their awareness and understanding of the data provided to them. For
some, they were unclear as to what the green area within the graphs of the mobile app represented; thus, they paid little attention to it. Furthermore, participants remarked that they sometimes forgot to look at the app and thus were passively monitoring themselves. However, participants were positive about the fact that the app provided them with a way to become more aware of their daily patterns. This, they believed, supported their self-management as it helped them to know they were remaining consistent. Specifically, they were comfortable if they went outside of their normal range for 1 or 2 days but knew to contact someone if that became persistent. This suggests that people did not explicitly change their behavior, but simply being aware that everything was “normal” was sufficient for them to feel confident in themselves.

I knew that I would be contacted if there were discrepancies or going outside the zone, so I knew that, but I mean if for example my weight had started to increase, I would have been very aware of checking up on fluid retention and all that sort of thing, yeah. It was good to be able to see that, I wouldn’t, honestly, have been aware, unless my ankles, I’ve never had particular puffiness or anything like that or similar, so, but, I think there was a slight bit of that whenever I was in hospital in October, although it wasn’t obvious, it wasn’t visible but obviously it would have been obvious from a daily weight reading. [P17, female, 67]

Behavioral Regulation
The use of the digital tool facilitated participants to weigh themselves (daily, weekly, or biweekly). This was the most active behavior change that appeared to occur as a result of the system. Some reported being motivated to go for a short walk if they felt that they had not reached enough steps according to what their DHT was; however, overall, people reported not changing anything substantially. As previously mentioned, an awareness of their normal appeared to be the greatest benefit to them. This may be because other features such as monitoring their sleep and heart rate were mostly passive in nature. The components that required the most active engagements (ie, medication adherence and other methods of monitoring) were not used by any participant as they felt that they already had a method to track their medication that worked for them. Essentially, the digital tool appeared to integrate easily into their existing methods of regulating their HF, supporting their ability to monitor their key metrics without requiring too much additional effort on their part.

I’ll certainly keep the Fitbit up…wearing the Fitbit, I will keep that going definitely, so that I can keep an eye on things. I won’t say you can become obsessed with it but it gives you a good handle, I wouldn’t be checking my heart rate every couple of hours or anything like that but every couple of days I would do or if I did something strenuous I would just have a look and see how am I and what I am doing or anything else like that. [P3, male, 68]

Social Influences
Participants continue to rely on HCPs to lead the management of their condition and initiate topics of discussion. Furthermore, they were motivated to join the study as a result of their doctor asking if they were interested in it. Their perception was that if the doctor felt that it might be useful or interesting, then they were happy to participate. Despite this deference to HCPs, some felt that the information from the DHTs would empower them to talk to their doctors about their progress. However, the strongest element of support that they received from the tool was the comfort they gained in knowing they were “being watched.” Participants appreciated the calls that they received from HCPs if the system was triggered. Far from feeling intruded on, they instead felt supported and “minded” from afar, and had no privacy concerns regarding these triggers.

I have to say, I really appreciated it very, very much. I can’t really think of a particular negative. It really helped me and really reassured me because I had two episodes last year where I went into atrial fibrillation and you know I think it was good to know that, you know, if I did go off the baseline and someone contacted me, that they would then offer that I could speak to someone on the cardiac team, because sometimes it’s very difficult to access even your cardiologist, you know? Even getting past the secretary can be very difficult, so that was, yeah, I really liked that. I just felt that, you know, if something did go drastically wrong that someone was there picking up on it. [P17, female, 67]

I think it’s nice the idea that if something goes badly wrong that somebody rings up like a few times my heartbeat has changed and I’ve got phone calls to ask am I ok and trying to figure out why. [P4, male, 64]

Social Role and Identity
Participants perception of themselves and their own identity appeared to facilitate their self-management behaviors. This was closely linked to knowledge and memory, attention, and decision processes. Specifically, being aware of their data and their patterns of behavior sparked participants to reflect on “how lazy I am one day and how much I am doing the next day type of thing.” This suggests that they saw it as important to understand what they can do to help themselves, which was facilitated by the DHT. Furthermore, participants described being diligent about going to the doctor regularly and “doing everything they were saying I should do,” in order to help themselves manage their condition. Thus, they recognized the role that they had to play in their own condition, even if that is being led by the cardiologist.

Skills
Although skills were related to participants’ ability to self-manage, in this study, they were also required to interact with the digital tool in order to do so. Indeed, the biggest barrier to them being able to self-manage with technology was the technology itself. Specifically, for those less familiar with technology, it took them a while to settle into its use. Some
faced issues with syncing and connectivity, for which they required support from family members or members of the study team to overcome. However, as they got used to it, and as problems were solved, they then found that the DHT was an enabler to their self-management as it became one place for them to see all of their information.

Technology, you know it was always a bit beyond me a little bit. So, I thought it worked out fine ….I became a little more comfortable with it. There were a few times alright….and again with the weighing scales, there was a problem and I made contact with one of your colleagues. And simple things like for example on the tablet, I tend to just ….just press the on/off button until the screen goes out you see. [P16, male, 81]

Beliefs About Consequences

The key for this was whether participants believed that there was a link between their self-management behaviors and their HF. For example, 1 participant did not see the relevance of weighing themselves as they could not see how it impacted their HF. In contrast, others were using the app to help support their perception for how they were feeling. In general, people were able to look at their data and explain any discrepancies as a result of their recent behavior; thus, the system appeared to support building this belief. However, it was not always clear how this linked explicitly to their heart condition, as opposed to their overall health.

Well I’ll tell you once or twice it went down [their weight] and I said ‘Oh my God am I not well’ and then the next day is would come back up. Now I am only talking about a pound here or a pound there but if it did go up oh I would, I’d certainly have to watch, cut out maybe eating a bar of chocolate which I eat every so often or a sweet or whatever. I would be aware of it. [P8, female, 81]

Beliefs About Capabilities

Some participants felt they did not possess the skills to get the most out of the DHT. However, their uncertainty was also related to their ability to self-manage themselves in general. One person was wary about traveling in case something went wrong; another simply listed being unmotivated to self-manage.

One person was wary about traveling in case something went wrong; another simply listed being unmotivated to self-manage. However, their uncertainty was also related to other barriers to self-management were typically related to life events, for example, other illness, bereavement, the weather, relaxing their diet while on holidays, and the area where they live. In contrast, others were using the app to help support their perception for how they were feeling. In general, people were able to look at their data and explain any discrepancies as a result of their recent behavior; thus, the system appeared to support building this belief. However, it was not always clear how this linked explicitly to their heart condition, as opposed to their overall health.

Now I am only talking about a pound here or a pound there but if it did go up oh I would, I’d certainly have to watch, cut out maybe eating a bar of chocolate which I eat every so often or a sweet or whatever. I would be aware of it. [P8, female, 81]

Beliefs About Capabilities

Some participants felt they did not possess the skills to get the most out of the DHT. However, their uncertainty was also related to their ability to self-manage themselves in general. One person was wary about traveling in case something went wrong; another simply listed being unmotivated to self-manage.

I probably am not tech-savvy enough to have gotten everything I needed to get from both of those or everything they could give me, and I’m also going to, in the early part of the interview, put my hands up and say that I didn’t probably put enough effort into that. [P18, male, 68]

I feel good at the minute, I feel ok, and everything’s going well, and I’m going swimming, I’m going walking, I don’t feel any different up in the heart. …..I wouldn’t have known all this stuff if I hadn’t of had the monitor on me and the whole lot, so I think with all this it’s good. [P14, male, 64]

Emotion

The biggest change in emotions reported by participants was the confidence they had in managing themselves as a result of the DHT, and the reassurance they received knowing that they were being monitored. A feeling of safety was reported as a result of this. Despite this, some participants reported moments of anxiety or alarm if the DHT sent them a trigger unexpectedly, or if their data were outside of their normal. For one person, it simply took them some time to realize that a certain amount of change was considered normal; thus, it ultimately led to them feeling reassured once they learnt this. Others though would feel guilty if their activity levels were low, or if they were not losing weight.

Well, I am not as fretful now as it was at the beginning and I do think that wearing the Fitbit has been part of that – knowing that there is something there and also the fact that I was contacted on several occasions that my baselines had changed in a few things. [P7, male 54]

It made me anxious because I looked back on a night like that and say well, I can’t see anything that that’s gone terribly astray here. I would like to have known what triggered it. [P9, female, 71]

Environmental Context and Resources

The focus of this domain was on factors within the environment that either supported or hindered participants’ self-management. In relation to the DHT, having to charge the Fitbit was a downside, but not a burden. Issues connecting the scales were a greater burden as it may result in incorrect readings and were difficult for participants to fix. Other elements that acted as barriers to self-management were typically related to life events, for example, other illness, bereavement, the weather, relaxing their diet while on holidays, and the area where they live. In addition, participants’ medication was noted as negatively impacting their sleep or weight. It was unclear whether this was medication specific to their HF or whether it was related to other comorbidities, but regardless, it influenced elements of their self-management behaviors that they were tracking.

I suppose it was a bad time of the year in the sense, by the time I’d get home from work in the evening, it was pitch dark. So, I wasn’t getting out for a walk and that. We only get kind of a half an hour lunch break. So, you didn’t even have time [to exercise]. [P15, female, 55]

Well, weather wise and then, you know; we had an awful lot to do after the funeral, you know… things had to be sorted, well they are not even sorted yet but anyway, you know, things had to be done. [P1, female, 81]

HCP Experiences

The 2 HCPs (1 consultant cardiologist and 1 physiotherapist) were broadly positive around the potential for this DHT to support HF management; however, they felt that this would require a number of changes both to the system itself and to how it is implemented before its utility is realized.
Both HCPs were surprised at the level of “hands-on” work required to manage the DHT and the triggers sent through it. Essentially, they expected that the trigger system would reduce the work of clinicians, whereas, in reality, it simply transferred some of the work to behind the scenes data management, or even increased their work. Specifically, the system of triggers required them to spend a number of hours each week calling participants and following up on those who did not answer. However, as the purpose of this study was to explore the participant perspective, the HCP did not monitor the number of triggers received or the number that resulted in a hospital visit. Nonetheless, it was felt that future iterations of this tool need to set different criteria for when a participant was called or not.

They felt that it was only feasible to recruit participants with greater health and digital literacy, and those who were based locally to support them in the initial setup of the DHT. However, neither of these elements were explicitly listed as inclusion or exclusion criteria within this study. Recruitment was undertaken using a purposive, pragmatic approach whereby participants were recruited from the existing patient list of cardiologists within the Beacon Hospital. The HCPs acknowledged that their perceptions of a person’s awareness of their condition and their ability to use technology were born out of their interactions with these patients and not from objectively measured assessments. In general, they did not approach patients who they considered to be more frail and older, who appeared to have greater anxieties around technology, and who were less aware of their condition.

Ultimately, it was felt that the DHT has great potential, but that it would require significant changes within the health care service if it were to be implemented into practice. Specifically, adjusting the trigger thresholds, altering the protocol for calling people, and ensuring that the HCPs have dedicated time in their schedules to manage these digital data are critical for its progress.

**Discussion**

**Principal Findings**

This 6-month observational study assessed the feasibility and utility of our human-centered designed DHT to evaluate user engagement and observationally evaluate whether it may affect end points such as quality of life and self-care behaviors. Similar to the results of our development paper [16], participants demonstrated high adherence to the DHT and reported increased awareness of their behaviors and increased confidence in themselves. Questionnaires demonstrated that it was a comfortable device and that their motivation to wear the Fitbit was high, although the usability of the DHT was considered poor. However, interviews suggest that this result may be linked to their low confidence regarding the use of technology. Participants were most impressed at the trigger function of the DHT, which provided them with a great sense of safety and comfort.

**Comparison With Previous Research**

Self-care refers to “performing the daily activities that serve to maintain or restore health and well-being, prevent illness, and manage chronic illness” [33] and includes the knowledge, skills, self-efficacy, and attitudes required to effectively manage signs and symptoms as they arise [10]. Similar to previous research, participants in this study reported that they take their medication as prescribed, have lower levels of physical activity than desired, and monitor their weight regularly but not daily [6]. Notably, their awareness of their sleep, weight, activity, and heart rate increased; however, they felt that they did not change anything substantially as the result of this information, while their EHFScBS and MLwHFQ results remain unchanged. This may be because the included participants were not considered adequate in their self-management at the start of the study; thus, it should be questioned whether they needed to change their behavior unless they began feeling unwell. Furthermore, although changes were not significant, this may be the result of the small sample size, and nonetheless, positive changes in both outcome measures were noted. However, it should also be considered whether no changes occurred because participants were not clear as to why they were assessing certain elements. For example, many seemed to feel that monitoring weight was necessary because they needed to lose it, not because they were monitoring water retention, a finding similar to previous research [34]. Furthermore, skill building requires more than information alone and instead should focus on deficits and managing unique situations as they arise [34]. It should be considered whether, by relying on a trigger system, we are removing this skill rather than building it. However, given the complexity of such decisions [34,35], and the relief provided to participants as a result of the triggers, further thought should be given as to how skills can be developed alongside the support provided by triggers.

When we mapped the participant experiences to the elements of the TDF, the domains of knowledge, social influences, and social identity appear to be particularly strong in facilitating self-management. Although the study was meant to improve participants’ own abilities and motivation to integrate behaviors into daily living, according to the results of “social influences,” it is possible that they took part in the study and remained so adherent because of their desire to follow doctors’ wishes. This brings up a persistent issue with self-management and the motivation to complete it. Theories such as self-determination theory posit that people will initiate and maintain a behavior if it supports intrinsic motivation [36]. Participants began to note that they were able to keep an eye on themselves and that it was up to them to manage what they could control, suggesting that there is certain amount of intrinsic motivation generated as a result of being able to monitor themselves, and this is further supported by the results of the WTMS. However, relying on doctors’ advice to participate and adhere to an intervention is externally motivated behavior that risks poor engagement over time [36]. There is a fine balance between following advice in a partnership and following instructions [37,38]. Ultimately, the most effective and valued element of the intervention was the link that participants had with their HCP. Future studies should consider how to train participants to lead conversations.
in this area with their clinicians, so that they are more empowered to conduct effective self-care, rather than simply rely on triggers being sent to them. Furthermore, the emotive elements of self-management appear to have played a strong role in participants’ experience of the study. Specifically, the benefits were confidence and reassurance, whereas guilt and anxiety also prevailed. Previous research has suggested that emotional reactions such as fear or anxiety, which tend to be viewed as maladaptive coping strategies, may also have a positive influence on self-care [39]. Many patients describe action-based strategies such as learning how to “pace” their activities or “listen to their bodies” to help optimize their ability to maintain physical activity [39]. Seeking guidance and advice from trusted sources is an integral component of self-care, and knowing when to ask for help is considered to be a tactical skill [34]. Thus, there is a need to also emphasize other domains such as skills and emotion further so that the identified barriers are targeted for reduction in a future clinical trial.

Important aspects regarding the feasibility of this system were shown in this study. A promising result was the acceptability of the system to participants. Specifically, they noted no issue with comfort, a high motivation to wear it. However, they also noted poor usability according to the SUS. This is likely to be the result of their concern regarding the system and their ability to use it. Nonetheless, they demonstrated high levels of adherence and engagement with the tool compared with other research in HF or the population in general where abandonment is high [40-44], and importantly, they felt great comfort and reassurance that someone was looking out for them. Additionally, almost 50% of those contacted to take part in the study agreed to participate in it, suggesting that there was interest and acceptability in the idea. However, because of the purposive sampling method, it is unclear whether people with lower levels of literacy or higher levels of disease severity will demonstrate the same levels of acceptability. Among a sample of patients with HF, 96% owned a mobile phone and 32% relied on the mobile phone for internet access, searched health information, and reported moderate self-confidence in using mobile apps [3]; thus, the DHT should be tested in a wider population. However, in the future, when expanding this tool for use within multiple settings, the impact on HCPs needs to be considered. Specifically, the requirement for HCPs to monitor the triggers themselves, and follow up with patients, was perceived as an increased burden. In the future, HCPs whose role is to manage patient-driven data insights will be needed, but this will require additional funding and training to be implemented successfully. The volume of data required to train such models effectively was a surprise to the HCPs who had expected the system to be “smarter” than it was, demonstrating that there is a need to set expectations with HCPs in any future feasibility studies. This study was not powered or intended to assess the predictive capacity of the trigger system. Indeed, if comparing it with the Medical Research Council guidelines, this was the test phase required before evaluation [35]. However for future studies, models need to be refined until the thresholds per person are identified. Adjusting the threshold to become more manageable to HCPs should be considered, but within the context that participants valued feeling safe.

Limitations

A key limitation of this study was that no objective assessment of participants’ behavior change (or lack thereof) was assessed. As a pilot study, the objective of this study was not to evaluate participants’ objective behavior change, and indeed, the study was not powered for that. Nonetheless, it limits our assessment of the potential for this DHT to patient perceptions only. Another limiting factor of this work is the recruitment methods employed, which are likely to have limited the generalizability of the findings with regard to representativeness of the sample. Specifically, purposive sampling was used whereby the HCPs contacted those on their list who they believed would be interested and capable of participating. Consequently, without objectively testing for health and digital literacy, the result of this is likely to be a bias toward people who were most likely to be able to use it. For DHTs to be evaluated fully, it must be offered to all, irrespective of their perceived suitability or not. Thus, future iterations of this tool should be trialed in as wide a range of participants as possible to test its ability to respond to patient needs and abilities. Finally, future studies need to assess feasibility more from the perspective of the health care service. Outcomes such as the number of trigger calls sent to the hospital, the time spent managing the data, the time spent by clinicians setting up the DHT with participants, and the number of visits to the clinic compared with the calls logged should be evaluated to better understand the impact of the DHT on the service.

Conclusions

The DHT demonstrated high levels of adherence and acceptance among participants. The DHT targeted key self-management behaviors and feelings of social support. However, a number of changes to the DHT, and the health service, are required before it can be implemented at scale. A full-scale feasibility trial conducted at a wider level is required to fully determine its potential effectiveness and wider implementation needs.

Acknowledgments

The authors would like to thank the participants of this study for their time and commitment to this body of work. This paper was produced as part of IVA5034 ECME research project and supported by the European Union’s INTERREG VA Programme, managed by the Special EU Programmes Body (SEUPB).

Abstract

Background: Electronic learning refers to the use of assistive tools in offline and distance learning environments. It allows students to access learning tools and materials anytime and anywhere. However, distance learning courses depend on several factors that affect the quality of learning, which consequently affect students’ preferences in the settings and tools used to deliver educational materials.

Objective: This study aimed to evaluate students’ preferences for continuing distance learning after the pandemic and to assess the distance educational environment after the pandemic. It also aimed to identify the factors affecting distance learning and evaluate students’ preferences regarding modes of communication with instructors.

Methods: A web-based survey was used to conduct this cross-sectional study. The target participants of this study were students in the doctor of pharmacy program at Unaizah College of Pharmacy, Qassim, Saudi Arabia. All students enrolled from December 2022 to January 2023 received an invitation with a link to the web-based survey.

Results: The survey was completed by 141 students (58 female students and 83 male students). The research results showed that most students (102/141, 72.3%) did not wish to continue distance education for laboratory courses, and 60.3% (85/141) did not wish to continue taking distance team-based learning after the pandemic. Additionally, 83.7% (118/141) of the students indicated that distance courses were simple. More than half of the participants (79/141, 56%) stated that having a camera on during class negatively impacted their learning, and only 29.1% (41/141) of the students stated that nonvisual communication with their fellow students impacted their learning. A large proportion of students (83/141, 58.9%) reported impairment of social engagement on campus, 44% (62/141) in-person interactions during classes, and 73.7% (104/141) were relieved that their classes were not disrupted.

Conclusions: Similar to all types of education, distance learning is characterized by advantages and disadvantages, as reported by students. Students felt that the course material was intelligible, and the distance course was uncomplicated. Moreover, they expressed relief that their studies were not disrupted. However, they also reported the loss of face-to-face contact during courses as the most significant drawback of distance learning versus face-to-face learning, followed by a lack of social connection on campus.

Introduction

In December 2019, unexpected cases of severe respiratory illness were found in Wuhan, the capital city of China’s Hubei province [1]. The World Health Organization recognized a new coronavirus, termed SARS-CoV-2, which caused the outbreak of COVID-19 [2]. The initial COVID-19 instance in Saudi Arabia was detected on March 3, 2020. Consequently, Saudi Arabia placed most of its public and private facilities under lockdown and instituted statewide limits on population movement. Due to the widespread mitigation efforts implemented by several nations, the COVID-19 pandemic disrupted the daily lives of millions of people [3]. On March 8, 2020, the Saudi Arabian government announced a conversion from regular classroom education to distance education. In the following days, all Saudi Arabian colleges and institutions implemented this approach. Saudi Arabia was among the first nations in the Middle East to enforce full quarantine and the urgent switch to distance learning [4].

The use of assistive tools in both offline and distance learning environments is referred to as e-learning [5] and includes synchronous and asynchronous modes. Synchronous distance learning permits live interactions between educators and students through chat and video conferences, while asynchronous distance learning is based on emails and recorded videos [6]. Distance learning can be used in place of, or in addition to, traditional education [5]. Before the pandemic, some colleges had used distance education using learning management systems such as Blackboard (Anthology Inc) and Zoom (Zoom Video Communications, Qumu Corporation). Distance education delivery abruptly and entirely replaced traditional classroom education, resulting in problems such as incomplete examinations and difficulties with courses requiring hands-on training or laboratory activities [4]. After the COVID-19 outbreak forced the closure of universities in Saudi Arabia, the Saudi Ministry of Education created an alternative policy to support distance education and provided public universities with resources to aid distance learning and virtual classrooms. This was done to prevent interruptions in the educational process. Blackboard is a web-based distance learning tool used by universities and other higher education institutions that enables students to continue their studies [7]. It is one of the most widely used web-based platforms and is currently used by all Saudi Arabian universities [8].

Most telecommunications firms in Saudi Arabia (eg, Saudi Telecom Company, Mobily, and Zain Saudi Arabia) aided in efficiently delivering distance learning and health care during the pandemic. These companies offered free data services to the most widely used telehealth and health applications, as well as educational platforms [3]. In addition, the Saudi Ministry of Education introduced distance learning programs to safely and effectively continue the educational process. Within days, all universities, including medical schools, switched to distance mode of education delivery. Medical schools altered their teaching approach as a result of this tremendous, unforeseen shift from traditional learning to an exclusively distance learning environment [9].

The components of distance learning delivery include ease of information access, material distribution, updating, and standardization. Distance learning allows for rapid and easy content revision to achieve learning objectives [10]. Furthermore, it provides several opportunities for students to improve their autonomous learning and enables students to access learning through distance learning tools and materials anytime and anywhere. Moreover, distance education provides excellent opportunities for students to enhance their connection with instructors [11]. Nevertheless, the appropriate conditions are necessary for the creation of a productive learning atmosphere. In addition, the development of technical infrastructure, the purchase and maintenance of tools and equipment, the instruction of human resources, and the production of distance content are costly and time-consuming processes. The institution, administrators, teachers, and students require information technology resources and skills. Poor time management and a lack of self-control have been reported as the 2 major factors affecting students’ perception of distance learning [12].

A lack of in-person, face-to-face interactions in the classroom or workplace characterizes distance learning classes. Interpersonal communication is vital for numerous students and organizations. For instance, in-person interaction with lecturers and group discussions are crucial motivational activities and learning techniques [6]. Team-based learning (TBL) is a small-group, active learning method that incorporates rapid feedback, teamwork, and solo work to help students apply conceptual knowledge [13]. These activities significantly affect students’ class behavior and comprehension of lectures. However, the effectiveness of distance learning courses depends on individual factors, such as the student’s home setting, socioeconomic factors, and the educational level of their parents [6].

Most universities effectively transitioned their teaching operations from traditional to distance learning in response to the pandemic. However, several problems emerged, including poor teaching quality, work overload, lack of accessibility, student nervousness and dissatisfaction, fundamental questions concerning the use of distance education in the future, the requirement for suitable educational staff support and education to handle the inescapable adjustments required for implementing contemporary educational methods in a distance learning setting, and appropriate teacher preparation. Students expressed concern about the ability of distance education to replace human interaction in terms of emotion [14].

COVID-19 affected the reception and delivery of education at all levels [15], with educational authorities in most countries implementing distance learning strategies [11]. However, the sudden conversion to distance learning affected the performance of students and teachers in all learning environments, potentially influencing the efficacy of distance learning. Many academic staff members had no previous experience teaching using distance learning. Students may have been more anxious than usual due to worries regarding infection, timely graduation, finances, and employment, which could have had a detrimental effect on their academic achievement [16]. Synchronized technology enables teachers and pupils to interact “live.”
Particularly under uncertain global conditions, such as pandemics, distance learning can result in more efficient and straightforward access to knowledge [9]. Distance education can also serve as a tool to mitigate social isolation and assist in outbreak control. It also provides a flexibility that allows for learning regardless of location or time, which is essential for education during periods of crisis. In addition, the success of the technical infrastructure at schools and colleges depends on adequate maintenance [17]. This study aims to assess pharmacy students’ perceptions of distance learning and to evaluate the postpandemic distance learning environment. We also try to identify the factors affecting distance learning and to assess the emotions experienced by students during their period of distance education.

Methods

Study Design and Setting

A web-based survey was used to conduct this cross-sectional study. This study’s intended participants were students enrolled in the doctor of pharmacy (PharmD) program at Unaizah College of Pharmacy, Qassim University, Saudi Arabia, during the 2022-2023 academic year. PharmD students and interns who completed 1 year of distance learning during the COVID-19 pandemic using distance learning platforms provided by Qassim University were eligible for this study. The research did not include students who were attending other colleges. In addition, we excluded students who had not completed 1 year of distance learning at the university, similar to first-year students in the PharmD program, since they were not enrolled in the university during the COVID-19 pandemic.

Sample Size

The target population in this study comprised male and female third-year to sixth-year (internship year) PharmD students from Unaizah College of Pharmacy, Qassim University. According to the college’s students’ academic affairs office, the number of enrolled students was 327. Raosoft (Sample Size Calculator; Raosoft, Inc) was used to compute the sample size. With a 50% response rate, a 5% margin of error, and a CI level of 95%, the sample size should not be fewer than 141 students [18].

Study Tool

The questionnaire used in this study was created based on a prior study by Kedraka et al [14], and the authors obtained permission to use the questionnaire. A survey composed of multiple-choice questions was created using a web-based survey creator. That survey consisted of 34 questions assessing attitudes toward distance learning [14]. We slightly modified some questions to comply with the teaching methods used at Unaizah College of Pharmacy. Subject experts validated this modified questionnaire for clarity, understandability, and applicability. The final survey had 6 sections. The first section included 5 questions to assess the necessary abilities of students in meeting learning objectives and measuring progress. Student preferences also play a crucial role in the learning process. The second section comprised 9 questions that could serve as recommendations for developing a distance learning environment and measuring student performance in distance classrooms. Performance is greatly influenced by technical knowledge, comfort level, and attitudes toward using the internet for learning. Using a 5-point scale (1: not at all to 5: very much), we evaluated the opinions of the participants regarding the effectiveness of remote learning in terms of meeting the needs of the course, satisfaction with communication with the instructor, level of interest in the new method of teaching, level of course participation, interactions between students and teachers, and interactions between students. These factors may provide insight into the perceptions of students regarding the distance learning environment.

The third section, which included 4 questions, aimed to assess remote learning quality by identifying influential factors and motivating elements. The fourth section included 4 questions used to assess successful communication between students and teachers in distance courses, recommend steps to enhance interaction, and lessen the isolation associated with distance courses. The fifth section consisted of 6 questions intended to identify elements lost due to the shift from face-to-face interaction to distance learning, improve course delivery, and understand the factors that constitute a successful distance learning experience. Distance learning requires a critical understanding of the effects of interactions on student engagement. The sixth section consisted of 6 questions focusing on the motives and sentiments of the students toward their participation in the educational program. All eligible students were asked to participate in this study, and the questionnaire was disseminated web-based using WhatsApp (WhatsApp LLC).

Ethical Considerations

The ethics permission for this study was granted by Qassim University’s Health Research Ethics Committee in Saudi Arabia (22-17-11). The participation in this study was voluntary and informed consent to take part in this study was obtained at the beginning of the survey and the statements on the anonymity of responses or confidentiality of data were maintained throughout this study. No compensation or reward was offered to this study’s participants.

Statistical Analysis

The data were analyzed and student replies were compiled using SPSS (version 20.0; IBM Corp). The survey results were compiled using descriptive statistics comprising frequencies and percentages. Further reported were the mean scores for male and female students.

Results

Demographic Data

The survey was completed by 141 students (female: n=58, 41%; male: n=83, 58.9%) from the Unaizah College of Pharmacy. The greatest number of participants were recruited from the fifth year (51/141, 36.2%), followed by the third year (36/141, 25.5%), fourth year (30/141, 21.3 %), and sixth year (24/141, 17%).
Preference for Continuing Distance Education After the Pandemic

As shown in Table 1, most of the students (102/141, 72.3%) were unwilling to continue distance education (male: 50/83, 60.2%; female: 52/58, 89.6%; not at all or a little) after the pandemic for courses that included laboratory activities. In contrast, the majority of the students, 68% (96/141), had a favorable view regarding the continuation of distance education for elective courses (male: 53/83, 63.8%; female: 43/58, 74.1%; much or very much). Regarding TBL examinations, the majority of students, 60.3% (85/141), did not wish to continue taking distance examinations after the pandemic (male: 38/83, 45.8%; female: 47/58, 81%).

Regarding lectures, less than half of the students (63/141, 44.6%) did not wish to continue taking the lectures via distance platforms (male: 36/83, 43.4%; female: 27/58, 46.5%). Approximately 46.8% (66/141) of students wished to continue receiving their education distance for seminars (male: 41/83, 49.4%; female: 25/58, 43.1%).

### Table 1. Pharmacy students’ preference for continuing distance education after the pandemic.

</table>

Assessment of the Distance Educational Environment

As shown in Table 2, most participants had positive opinions regarding the former’s educational potential of the distance versus the conventional learning environment. Male students exhibited a more favorable attitude (higher average) compared with female students in all statements that assessed the distance learning environment compared to conventional learning on campus. Using a 5-point scale (1: not at all to 5: very much), we evaluated the opinions of the participants regarding the effectiveness of remote learning in terms of meeting the needs of the course (male: 3.5; female: 2.9), satisfaction with communication with the instructor (male: 3.6; female: 3.1), level of interest in the new method of teaching (male: 3.5; female: 2.6), level of course participation (male: 3; female: 2.9), interactions between students and teachers (male: 3.2; female: 2.7), and interactions between students (male: 3; female: 2.8).

Less than half of the students (61/141, 43.3%; male: 39/83, 47%; female: 22/58, 37.9%) believed that the course content was understandable. Additionally, 83.7% (118/141) of the students indicated that taking the course online was simple (male: 70/83, 84.3%; female: 48/58, 82.7%; much or very much). As for developing new skills, 38.3% (54/141) of the students thought that they developed new skills related to distance education (male: 40/83, 48.2%; female: 14/58, 24%).

Factors Affecting e-Learning

As shown in Table 3, more than half of the participants (79/141, 56%) reported that having the camera on during class impacted their learning (male: 49/83, 59%; female: 30/58, 51.7%). Further, only 29.1% (41/141) of the students indicated that nonvisual communication with their fellow students would impact their learning (male: 22/83, 26.5%; female: 19/58, 32.7%). About 29.7% (42/141) of the students reported that the teacher’s insufficient knowledge concerning the handling of the platform impacted distance learning (male: 30/83, 36.1%; female: 12/58, 21%), while 44.6% (63/141) indicated that the inability to cooperate with their fellow students would affect distance learning (male: 44/83, 53%; female: 19/58, 32.7%).

Preferred Modes of Communication With Instructors

As shown in Table 4, the participants’ preferred method of communication was the course chat (96/141, 68%; male: 59/83, 71.1%; female: 37/58, 63.8%). The second preferred method of communication for male students was a microphone (47/83, 56.6%), followed by face-to-face communication in the classroom (47/83, 56.6%) and groups on Zoom (37/83, 44.6%) throughout the course. The second preferred method of communication for female students was face-to-face communication in the classroom (36/58, 62%), followed by groups on Blackboard or Zoom (26/58, 44.8%). The least preferred option was a microphone (25/58, 43.1%).

Traditional Education Components not Present in Distance Learning

As shown in Table 5, a large proportion of students, 58.9% (83/141), reported impaired social engagement around the campus (male: 45/83, 54.2%; female: 38/58, 65.5%), while 45.4% (64/141) of the students reported that they missed their classmates (male: 36/83, 43%; female: 28/58, 48.3%), in-person interactions during classes (62/141, 44%; male: 33/83, 39.8%; female: 29/58, 50%), and interactions in the classroom (60/141, 42.5%; male: 31/83, 37.3%; female: 29/58, 50%). Only 31.2% (44/141) of students stated that they missed their professors (male: 27/83, 32.5%; female: 17/58, 29.3%), while 37.5% (53/141) of the students stated that they missed being able to visit the library (male: 21/83, 25.3%; female: 32/58, 55.2%).

Emotions Experienced During Distance Education

As shown in Table 6, a significant majority of the students, 73.7% (104/141), expressed relief that their classes had not been disrupted (male: 59/83, 71.1%; female: 45/58, 77.6%). However, there was still much interest (74/141, 52.5%) in how the studies would go (male: 50/83, 60.2%; female: 24/58, 41.3%), and much enthusiasm among students for their first distance learning experiences (82/141, 58.1%; male: 50/83, 60.2%; female: 32/58, 55.2%). Additionally, the majority of students, 80.1% (113/141; male: 67/83, 80.7%; female: 46/58, 79.3%), liked not having to go to their lessons, whereas only 40.4% (57/141) of students were satisfied that the distance courses would continue (male: 34/83, 40.9%; female: 23/58, 39.6%).

Discussion

Principal Findings

In this study, we attempted to comprehend student opinions, attitudes, and worries regarding distance learning and the barriers and difficulties they faced. Data were gathered through a web-based survey questionnaire between December 2022 and January 2023. The results of our study demonstrate that the participants showed good attitudes to the continued delivery of lectures and elective courses via distance learning. These findings support previous research showing that 63% of students preferred distance learning for the lectures compared to 29% for offline lectures [19]. In contrast, most had negative attitudes toward distance learning for laboratory courses and TBL examinations. These findings support previous research showing that students had negative perceptions of distance learning in many ways of teaching. According to Kedraka et al [14], most of the students at 2 participating universities (University of Patras: 84.1%; Democritus University of Thrace: 98%) did not wish to continue their education for laboratory courses distance beyond the epidemic. A study conducted by Stoian et al [20] reported that 38.8% preferred using face-to-face education, which seemed the most beneficial for their professional development, followed by a distance education rate of 34.3%, then both (face-to-face and distance education) at 27%.

Students’ perceptions of the distance learning environment were positive, with 83.7% (118/141) of the students stating that taking a course through distance learning was easy and 43.3% (61/141) finding the course content understandable. Our findings are in agreement with Bani Hani et al [10], who revealed that more than half of the students participating in the study (615/999) stated they gained the same or even better knowledge than what they gained before the pandemic and around half (458/999) of all the students recognize the university’s e-learning website as available for easy access. A Saudi study [21] showed that 49.2% of students exhibited positive attitudes toward the provided distance learning, and 34% of students identified some barriers to the provision of distance learning.

The majority of participants, 56% (79/141), felt that having a camera on during class had a detrimental influence on their learning. In a survey conducted by Gherheş et al [22], more than half of students claimed that they were unwilling to have their cameras on during distance sessions. Furthermore, 76.5% of participants stated that they did not use webcams when communicating via social media [23]. In contrast, in a study performed by Pullan et al [24], 51% of participants reported that having a camera turned on did not change their ability to engage, while 38% thought that having a camera on improved their engagement.

More than half of the students, 58.9% (83/141), claimed to have impaired social contacts on and around campus, and 44% (62/141) reported having impaired in-person interactions with teachers during class, with 42.5% (60/141) reporting poor interactions in the classroom. These findings support previous research. Muthuprasad et al [25] reported that 60% of respondents agreed with the assertion that contact with the instructor is less effective in distance classrooms as compared to face-to-face classes. Another study [26] revealed that a lack of live communication reduces the effectiveness of distance learning (52.1%). Furthermore, a study by Dodd et al [27]...
revealed that 84.6% of the students found it difficult to interact with other students, teachers 74.6%, and 74.7% reported more difficulty in distance learning than face-to-face.

The preferred method of communication (96/141, 68%) for the students in our study was the course chat, a result that supports earlier studies. Coman et al [28] found that 52.4% of students preferred to communicate with teachers through writing on chat. A study [29] revealed that most students (87.4%) preferred synchronized learning sessions for group discussions. In addition, 61.7% of students disagreed that distance learning provides similar learning satisfaction to classroom learning.

As for feelings, 73.7% (104/141) of students were relieved that their courses had not been interrupted and 58.1% (82/141) had enthusiasm for the new experience. However, there was still much interest, 52.5% (74/141), in how the studies would go in the future. Murphy et al [30] reported that their participants expressed uncertainty (59.5%), anxiety (50.7%), and nervousness (41.2%) regarding the switch to distance courses. In addition, Guse et al [31] revealed in a survey conducted in May 2020 on students that 45.5% of dental students noticed a decline in their excitement to study compared to 30.7% of medical students. Worsening mental health was reported by 36.4% (16/44) and 29.5% (26/88) of dental and medical students, respectively.

As this study was conducted in a single institution, its conclusions may not apply to other Saudi Arabian or global academic institutions. The findings of this study may be used to design a more effective and user-friendly distance course. As the study design is cross-sectional, the results only reflect the situation of distance learning during the data collection.

Conclusions
Similar to all types of education, distance learning is, as reported by the students, characterized by advantages and disadvantages, an understanding of which will aid educational institutions in developing plans for the more effective distribution of instructional materials to students. According to the results, the students felt that the course material was intelligible and that the distance courses were uncomplicated. Moreover, they expressed relief that their studies were not disrupted. These benefits facilitate the design of courses that meet the requirements of students and may lead to advancements in distance learning techniques.

Students in this study identified loss of face-to-face contact during their courses as the greatest drawback of remote education, followed by a lack of social connection on campus. This lack of peer interaction is particularly notable, for it is crucial to understand the importance of peer connection for students. Therefore, these variables should be considered for the improvement of e-learning. In summary, face-to-face communication is an indispensable part of the educational process.

Abstract

Background: The incidence of sexually transmitted infections has been increasing throughout the world. Additionally, substantial changes in emerging adults’ attitudes toward sex and the popularization of premarital sex could further affect the diagnosis and treatment of sexually transmitted infections. With the high acceptability and effectiveness of instant messaging (IM) interventions for health promotion, there is potential for such interventions to improve condom use knowledge and promote safer sex practice.

Objective: The study evaluates the feasibility of a nurse-led IM intervention to promote safer sex practices in emerging adults.

Methods: A 30-minute adaptive IM intervention and a 5-day booster dose of daily messages after 2 weeks through WhatsApp (Meta Platforms, Inc) were conducted with emerging adults in local universities in Hong Kong aged between 18 and 29 years with previous sexual experience. A questionnaire was distributed 1 week after the intervention that measured the consistency in condom use, the change in condom use knowledge and attitudes, and the acceptability of the intervention. The feasibility of the intervention was assessed by Bowen’s feasibility framework.

Results: A total of 20 participants completed the intervention and questionnaire. Results showed (1) high satisfaction level (mean satisfaction score: 9.10/10), (2) high demand of the intervention (retention rate: 95%), (3) smooth implementation of the intervention, (4) high practicality (13/20, 65% of the participants viewed IM to be an effective means of intervention), (5) potential integration of the intervention, and (6) significant mean increase in condom use knowledge and attitudes (mean increase 9.05; \(t_{19}=3.727; 95\%\) CI 3.97-14.13; \(P=.001\)).

Conclusions: The IM intervention was feasible, acceptable, and had potential impacts on improving safer sex practices. These findings will support the future development of IM interventions in the arena of sexual health promotion.

Introduction

Reducing sexually transmitted infections (STIs) has been identified as a global health sector strategy by the World Health Organization (WHO) [1]. The WHO reported that there are more than 1 million STIs acquired every day and that estimated that there are around 374 million new cases each year [2]. Globally, almost 57 million disability-adjusted life years are lost to STIs [2]. Among all STIs, human papillomavirus (HPV) is the most common infection. In severe cases, this will further lead to invasive cervical cancer [3].

In Hong Kong, there was nearly a 3-fold increase in the incidence of diagnosed HIV from 250 cases in 2011 to 725 cases in 2015 [4]. After reaching its peak in 2015, the number of cases gradually decreased to 505 in 2020. A sharp decline in STI cases was noted from 2020 to the third quarter of 2021. However, the decrease could be due to reduced screening or testing during the COVID-19 pandemic. Although no specific data were found in the context of Hong Kong, studies in the United States and Europe showed a relationship between COVID-19 cases and STI-reported cases. Results reflected that the reported cases were much lower than the expected cases in both countries [5,6]. Hence, the situation is still alarming, as the pandemic could have concealed the real size of the population with STI infection.

In addition, the asymptomatic nature of STIs and a substantial change in Hong Kong people’s attitudes toward sex may further delay the diagnosis and treatment of STIs [7]. For instance, premarital sex and high-risk sexual behaviors are becoming more common. According to the Youth Sexuality Study by the Family Planning Association of Hong Kong, the proportion of youth practicing safe sex (use of condoms during sexual intercourse) decreased from 1996 to 2011 [8]. Among male respondents, the number decreased significantly, from 66.4% in 1996 to 21.5% in 2011, while among female respondents, the number decreased gradually from 55.2% in 1996 to 45.4% in 2011 [8]. The AIDS Concern conducted a survey from 2016 to 2017 and also reported that only 16%, 22%, and 29% of young women who had sex with their boyfriends, regular sex partners, and irregular sex partners, respectively, used condoms every time during sex in the past 6 months [9]. The WHO reported a positive relationship between unsafe sex practices and the incidence of STIs [10]. Hence, the burden caused by STIs is avoidable by minimizing unsafe sex, such as having consistent condom use.

A few systematic reviews have demonstrated that mobile health (mHealth) interventions through interactive instant messaging (IM) are effective for improving health behaviors, for example, smoking cessation [11], medication adherence [12], weight management [13], and blood pressure control [14,15]. In the sexual health arena, to the best of our knowledge, no study has yet evaluated the effectiveness of a personalized and brief intervention delivered through IM for enhancing condom use knowledge and attitude, leading to the primary prevention of STIs. In addition, from our experience in evaluating an interactive computer-based intervention in female university students by a multisite randomized controlled trial, the study implementation led us to understand that a specific, personalized, and tailored intervention to cater to sexual activity recommendations and relationship problems is needed [16]. In the Chinese cultural context of pervasive sexual conservatism, it is unclear whether an IM-delivered brief intervention to promote condom use would be acceptable and welcomed by university students. Therefore, the research question of this study is whether an IM-delivered brief intervention by nurses is feasible to educate about safer sex practice among sexually active university students in Hong Kong.

The study aims to investigate the feasibility of an IM-delivered brief intervention to promote safer sex practices among sexually active university students in Hong Kong. The objectives of the study are to design a nurse-led brief intervention based on Information, Motivation, and Behavioral skills (IMB) model of Fisher and Fisher [17] and to investigate the feasibility of an IM intervention for improving safer sex practices using the feasibility framework reported by Bowen et al [18].

Methods

Study Design

The CONSORT (Consolidated Standards of Reporting Trials) eHealth checklist was followed as a reporting guideline to report and appraise the IM-based intervention [19]. Implementation and results of the web-based questionnaire were reported according to the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) checklist [20]. The feasibility study was conducted from August to October 2021.

Recruitment

Subjects were recruited through snowball sampling at local universities between September and November 2021. An electronic flyer was sent through IM (ie, WhatsApp; Meta Platforms, Inc) to inform potential participants about the purpose of the study, participation eligibility, time commitment, and incentives for study participation. The inclusion criteria were being an emerging Chinese adult aged between 18 and 29 years, being able to read Chinese, having a smartphone with WhatsApp installed, and having had sexual activities in the past 12 months. The exclusion criteria were being pregnant, having a psychiatric illness, and having received information related to contraceptives and STIs from universities, hospitals, clinics, or nongovernmental organizations in the past 12 months. The sample selection process is shown in Figure 1. Eligible participants were asked to sign a web-based consent form for study enrollment and were invited to provide 3 available time slots for receiving the 30-minute nurse-led brief intervention.
Figure 1. The flow of participants through the study.

Nurse-Led IM Intervention

**Intervention Development**

The development of the intervention was done by our team, who are experts in the field of sexual health and the development of IM-based interventions. Our nurse-led brief intervention was designed based on the Fisher and Fisher [17] IMB model. A systematic review found that brief interventions designed according to the IMB model were successful in increasing condom use [21]. The model consists of 3 constructs that influence behavioral adherence: that are information, motivation, and behavioral skills [17]. A total of 3 goals were developed accordingly: (1) provide information about STIs and condom use; (2) motivate participants to use condoms with motivational interviewing techniques; and (3) facilitate behavioral skill acquisition to increase condom use, lubricant application, and their purchase.

Regarding the intervention content, we addressed favorable and unfavorable views, including condom use reliability and effectiveness; the pleasure or excitement of condom use; the stigma of condom use; the embarrassment of condom negotiation; condom purchasing; and sexual coercion prevention related to condom use.

**Implementation Process**

A registered nurse who is an expert in sexual health promotion oversaw the intervention delivery throughout the study. The IM conversations were first initiated by providing personalized feedback on the participant’s consistency in condom use, as reported on the baseline survey. Second, further IM engagement explored their reasons for condom use and emphasized their decision to protect themselves by using a condom for the prevention of STIs and pregnancy. Third, the nurse identified the underlying reasons for their consistent and inconsistent condom use and then provided personalized advice, myth clarification, and further motivated participants by emphasizing the importance of condom use at every sex, even with a stable partner. Fourth, continued IM exchanges provided a menu of strategies and conversation techniques to use in condom use negotiations or in verbalizing delaying sex whenever unwanted. Finally, further IM prompts provided support on final tips about safe sex and enhancing self-efficacy for condom use, lubricant use, and its purchase. Overall, the IM messages were phrased in a way to communicate a sense of optimism to use condoms for safety and comfort in the dating relationship. It was conducted in an empathetic, respectful, and nonjudgmental manner. The whole real-time conversation lasted for around 30 minutes through WhatsApp. They were reminded to text the nurse again for any inquiries. A standardized guideline was developed as a reference for the nurse to derive the intervention under the IMB model (Multimedia Appendix 1).

IM was considered for intervention delivery because of its real-time, private, and persuasive nature [22]. IM allows real-time interactions, the use of stickers and emojis, and the delivery of URL links as resources. Also, the personalization of IM conversations is suitable to the needs of those participants, who are passive and sensitive when it comes to sex education. In addition, we provided flexibility for participants to receive the intervention at the most suitable moment; that the intervention time was scheduled after the completion of the baseline questionnaire.

Apart from the 30-minute brief intervention conversations, a booster dose of 5 daily messages was also provided 2 weeks after the brief intervention delivery to further reinforce safer sex knowledge and positive sexual health attitudes. An example of an interaction between the nurse and a participant on WhatsApp is provided in Multimedia Appendix 2.
In order to protect the privacy and confidentiality of the participants during the IM intervention, the messages should not reveal personal identification or other sensitive information, such as HIV status. Only the principal investigator and personnel for data analysis were permitted to access the raw data and study content. All the downloaded messages were stored with passcode protection and will be destroyed after a set period.

**Data Collection**

A baseline questionnaire containing the number of sexual intercourses, the number of protected sexual intercourses in the past 12 months, and the Multidimensional Condom Attitudes Scale (MCAS) was given on the entry of the study (T0). Another questionnaire with the same set of measurements at baseline and questions evaluating acceptability, demand, implementation, practicality, integration, and limited efficacy was distributed 1 week after the completion of the IM intervention (T1). The first author downloaded all the WhatsApp chat data for feasibility evaluation. Incentives of US $18 cash were given for compensating participants for their time and efforts in the study evaluation.

**Demographic Data**

Individual characteristics such as age, sexual orientation, relationship status, and gender of the sex partner were obtained at baseline. A history of childhood sexual abuse experience and sexual health were also asked at baseline to ensure personalized conversation and advice could be made during the intervention. The telephone numbers of the participants were collected to facilitate the delivery of the IM intervention.

**Feasibility Evaluation Criteria**

The feasibility of the brief intervention was investigated according to the recommendations of Bowen et al’s [18] feasibility framework, which includes the focal areas of (1) acceptability, (2) demand, (3) implementation, (4) practicality, (5) integration, and (6) limited efficacy.

**Acceptability**

We examined participants’ perceived appropriateness and satisfaction level with the intervention. Questions included “What is your satisfaction with the intervention on a scale of 1-10?” “Do you think the intervention is appropriate for young adults aged between 18 and 29 years?” “Do you find it embarrassing when discussing sexual health issues during the intervention?” “Do you have any disagreement with the contents?” and “Whether you would recommend the intervention to friends?” Participants could also voice out recommendations for improvement.

**Demand**

We examined the actual use of the intervention, which was reflected in the number of subjects who consented to join the study and its retention rate. All the text messages downloaded were also reviewed for content classification. Participants’ views on their interest in and intention to use were also considered. Questions included “Have you ever asked any questions via the IM app? If yes, is the information useful for you?” and “Will you use the intervention again in the future?”

**Implementation**

We investigated the extent of the intervention that can be successfully delivered to the participants. The number of messages delivered and received was measured. We would be interested to know if the information is appropriate to be understood. Questions such as “Do you have more understanding of condom use?” and “Have you tried to communicate with a sexual partner about condom use?” were asked. In addition, participants’ thoughts on using the intervention through an IM app were also asked to obtain qualitative information. For example, “What do you remember the most?”

**Practicality**

We examined the extent to which the intervention could be carried out by using existing resources. The total number of hours for the whole intervention, including the booster dose, was calculated to estimate the resources needed for implementation. In addition, participants were asked to choose the most effective means of promoting sexual health information to emerging adults.

**Integration**

We investigated the extent to which participants were using the intervention and whether the intervention could be integrated into the current system. The perceived fit with infrastructure, perceived sustainability, and costs to the organization and policy bodies were considered. Questions included “Will you use the intervention again if you come up with any questions about sexual health?” and “What do you think about using IM intervention for sexual health promotion?”

**Limited Efficacy**

We examined whether the intervention could result in a potentially promising outcome and its intended effects. The outcome evaluation was conducted by assessing (1) consistency in condom use and (2) condom use knowledge and attitudes. We compared both outcomes by measuring them before and after the intervention.

Consistency in condom use was measured by the percentage of unprotected sexual intercourse with all partners in the past month. Condom use knowledge and attitudes were measured by the 25-item MCAS. A previous study has shown acceptable validity and reliability in the Chinese population [23]. The Cronbach $\alpha$ of the study was >.7 [23]. It contained 5 domains, including the reliability and effectiveness of condoms, the sexual pleasure associated with condom use, the stigma associated with people proposing or using condoms, embarrassment about negotiating and using condoms, and embarrassment about purchasing condoms [24]. The items were answered on a 7-point Likert-scale, with a total score ranging from 7 to 175. The higher the score, the more positive were knowledge, attitude, norms, and self-efficacy related to condom use.

**Data Analysis**

Descriptive statistics were used to determine the participants’ characteristics. Due to the small sample size of the study, a quantile-quantile plot was used to assess the normality of the distribution. A 2-tailed paired sample $t$ test was done to compare pre- and postintervention performances for outcome measures.
with a normal distribution, while the Wilcoxon signed rank test was used for outcome measures without a normal distribution. The content of all the downloaded messages was screened by the first author, and important data were noted. Another member of the team counterchecked all content extracted from WhatsApp to ensure treatment fidelity [25]. Statistical analysis was conducted using SPSS Statistics (IBM Corp).

**Ethical Considerations**

The study was approved by the Institutional Review Board of the University of Hong Kong/Hospital Authority Hong Kong West Cluster (UW-20-299). Web-based informed consent forms were sent and completed by eligible participants. All messages collected should not reveal personal identification or other sensitive information to protect the privacy and confidentiality of the participants during the IM intervention.

**Results**

**Demographics**

Among the 21 participants who completed the baseline questionnaire, 20 (retention rate=95%) of them completed the T0 and T1 questionnaires. The age of the participants ranged from 18 to 25 years, with a mean age of 22 years. All the participants were university students. In terms of sexual orientation, 16/21 (76%) were heterosexual, and 5/21 (23%) were either bisexual or homosexual. The participants’ characteristics can be seen in Table 1.
Table 1. Characteristics of the participants (n=21).

Feasibility Evaluation Criteria

**Acceptability**

Among the 20 participants, the level of satisfaction was high (mean 9.10, SD 1.25). All of them considered that the intervention was appropriate for emerging adults aged between 18 and 29 years. A total of 19/20 (95%) participants did not feel embarrassed when discussing sexual health issues during the intervention. Participants claimed that through the use of emoji and stickers in WhatsApp, they were able to express their emotions and opinions dynamically, which made them feel more comfortable and casual during the chatting session. No participants disagreed with the content in the chat sessions, and all participants would recommend the intervention to friends. Some of the participants also provided practical recommendations. First, participants suggested the provision of more information on the myths about condom and contraceptive use, condom use decision-making and communication with partners, and the availability of condoms in Hong Kong. In fact, during the booster dose, we received messages to ask further questions related to condom use, STIs, and HPV vaccination, which could be included in the content of future interventions. Second, it was suggested to have a mutual sharing personal sexual health information between participants and the nurse. For instance, sharing of personal experiences and problems encountered in dating relationships or during sexual intercourses. The nurse can further ask about...
individual sexual activities, preferences, and habits. These could make the participants more relatable to the nurse during the intervention and enhance personalized information.

**Demand**

During the recruitment, 39 potential participants were approached, and 21 consented after screening for eligibility and willingness to join the study, with a response rate of 54%. Around 20 of them were retained in the intervention and completed the posttest questionnaire (ie, retention rate of 95%), with only 1 participant lost to follow-up. Among all downloaded messages, the chat session content covered condom use, STIs, HPV vaccination, relationship issues, same-sex activities, refusal of sexual activities, and women’s health checkups. All of them found the message content useful and would use it in the future.

**Implementation**

The chat sessions sent 75 instant messages to each participant on average and received 41 messages from each participant on average with content on lubricant use, contraceptives, STIs, HPV vaccination, and refusal of sexual activities. All participants had a greater understanding of condom use, as reflected in the significant improvement in the MCAS scores. Additionally, 19/20 (95%) tried to communicate with their partners about the use of condoms after the intervention. For qualitative information, we asked participants about the most memorable content. Participants indicated that they particularly remembered the messages about condom use (8/20, 40%) and STIs (7/20, 35%).

**Practicality**

In this study, we had 1 nurse manage all chat sessions, including the 30-minute brief intervention, and 5 daily messages as a booster dose 2 weeks after the brief intervention. The total number of hours spent was around 10 hours. A participant reflected that the response speed during the chat session varied, which might be due to the fact that a nurse had to handle 2 participants at the same time. Nevertheless, 13/20 (65%) of the participants suggested that smartphone apps are an effective way to promote sexual health information, while all of them indicated that mass media (ie, Instagram and Facebook) could be an effective way for promotion.

**Integration**

All participants indicated that they would use the IM intervention again if they came up with any sexual health questions in the future. Participants also claimed that mobile phones are a convenient and comfortable way to receive information about sexual health issues.

**Limited Efficacy**

Due to the small sample size of the study, a quantile-quantile plot was used to assess whether the data set followed a normal distribution (Multimedia Appendix 3). The primary outcome of MCAS showed a normal distribution, and the results of the paired-samples t test showed a significant increase in the total mean score of condoms use knowledge and attitudes measured by MCAS from 124 (SD 10.32) to 133 (SD 11.90; $t_{11}=3.727; P=.001$). The Cohen effect size was large ($d=.81$). The mean increase in the MCAS score was 9.05 (95% CI 3.97-14.13). A total of 3 MCAS subscales showed significant results. There was a mean increase in reliability and effectiveness of condoms ($P=.003$), sexual pleasure associated with condom use ($P<.001$), and embarrassment about purchasing condoms ($P=.03$). On the contrary, stigma associated with people proposing or using condoms and embarrassment about negotiating and using condom were not significant.

</tbody>
</table>

On the other hand, condom use consistency did not show a normal distribution in the normality testing. Therefore, nonparametric testing could be a better representation of the results. The Wilcoxon signed rank test was used to compare the condom use consistency before and after the IM intervention. The increase in the mean score of the condom use consistency was not significant ($Z=-1.41; P=.16$), indicating that the intervention was not effective in improving condom use consistency in the study.

**Discussion**

**Principal Findings**

This study demonstrated that a nurse-led IM-delivered brief intervention is feasible, content-relevant, and acceptable to
sexually active Chinese emerging adults for promoting sexual health. In addition, this study demonstrated preliminary efficacy in promoting greater condom knowledge and more favorable attitudes about condoms. These findings are encouraging since, according to the IMB model, improvements in knowledge and attitude are important precursors to behavior changes [17].

This study is the first to use smartphone IM apps for delivering sex education in Hong Kong. The rapid rise in smartphone use provides an opportunity to use such mHealth technology for important health promotion interventions. The IM-delivered intervention has been reported to be highly acceptable in young people aged between 16 and 29 years in Australia, as it is more personal and informal [26]. It can also engage a larger number of individuals personally for a low cost [26]. Another qualitative study, targeting young people aged between 16 and 24 years in the United Kingdom, found consistent results that the delivery of knowledge through IM is friendly and convenient [27]. The findings are in line with our data that the nurse-delivered text messages were able to engage this particular age group regarding sexual health topics in a comfortable and private manner.

Although there are findings that suggest potential benefits of such interventions, many mHealth interventions were found to have low certainty in the evidence [28]. Also, studies evaluating IM-delivered intervention for improving contraceptive-related outcomes have had mixed results when implemented for primary prevention [29]. A total of 2 studies provided inconceivable effects on sexual health outcomes, such as the percentage of protected sex acts and use of effective contraception, after the delivery of the IM-delivered intervention [30,31]. Another 2 studies showed significant improvements in both reproductive health knowledge and the odds of using condoms in young adults after receiving the IM-delivered intervention [32,33]. Differences in the results could be due to the design and duration of the intervention. In terms of the intervention design, a 2-way interactive component can be more effective in promoting sexual health outcomes [33]. In terms of the intervention duration, it can range from weeks to months [27]. A study suggested that the participants identified redundancies when receiving messages over a long intervention period (ie, 2 years) [30]. Around 20% of the participants in another study in Australia found the 12-weekly messages annoying [26]. Hence, future research on evaluating the IM-delivered interventions in terms of appropriateness of design, optimal intervention length, message delivery frequency, and effectiveness in promoting sexual health knowledge and safe sex practice is necessary.

Our results were analyzed using Bowen et al’s [18] systematic feasibility framework. Condom use knowledge and attitudes were significantly increased. In addition, the results regarding the acceptability of the intervention were perceived to be appropriate according to participants’ needs. Participants were satisfied with the intervention and content. We achieved a retention rate of 95.2%. Most participants showed interest in the intervention, with an average satisfactory score of 9. Also, all of them would recommend the intervention to others. Furthermore, the intervention did not create embarrassment in the discussion due to its private nature. With reflection on the implementation process and results of this feasibility study, we recognized that (1) the IM-delivered intervention was feasible and created no embarrassment during discussions, (2) discussing sexual health issues directly helped to clarify myths, (3) screening for condom use consistency and sexual orientation helped tailor conversations, (4) condom use inconsistency was primarily due to the displeasure of using a condom and alternative contraceptives being used for pregnancy prevention, which also suggested a lack of awareness of STI prevention, and (5) most conversations could use such gender-neutral terms as “they or them” and “partner,” except for discussions of condom or protective barrier practical use tips to fit both heterosexual and lesbian, gay, bisexual, transgender, queer, plus (LGBTQ+) relationships, and (6) using WhatsApp stickers in a conversation helped to create a comfortable atmosphere and establish rapport to facilitate further discussions. This study highlighted the usefulness of using Bowen et al’s [18] framework for systematically evaluating the feasibility of an innovation.

The booster dose stimulated participants’ interest in asking further questions about sexual health-related issues. The booster can not only provide new information to participants but also deliver similar intervention message content to refresh participants’ memories. This helps maintain behavioral changes over time [34]. Previous studies containing booster interventions indicated that participants were able to revisit the content and reinforce their knowledge in these sessions [21,35]. In our booster session, diverse topics such as sexual needs, frequency of sexual activities, delay of sexual intercourse, and STIs were covered. Some participants also raised personal and private questions related to STIs during the booster session. This may indicate that participants needed time to digest the information received initially, which fostered the trust and courage needed to further ask personal questions. Therefore, booster intervention is essential for some participants to assimilate information and share their information at their own pace [27].

Implications

Sex education is essential as a primary prevention strategy for emerging adults due to the underestimation of the risk of unprotected sex [9]. A survey from AIDS Concern found that nearly 40% of surveyed young women underestimated their risk of STIs, while 80% of them were assessed as the high-risk population [9]. Although Hong Kong has a relatively low level of youth sexual activity, recent studies have brought up concerns about the inadequacies of sex education in Hong Kong [36]. Conventional sex education programs or school-based sex education are some common means of promoting condom use in Hong Kong, however, they are still not mandatory. In addition, the teaching hours are largely insufficient. Half of the schools in Hong Kong offered 5 hours or less of sex education in a school year [37]. The conservative culture on sexual health issues also shaped Hong Kong people’s views and attitudes [36]. Although Hong Kong is an internationalized city that accepts cultural diversity and open-mindedness, the general public is still reserved and implicit when it comes to sex education [36]. This study supports the idea that an IM-delivered intervention is potentially effective in filling the gap due to its personalized and proactive delivery mode.

(page number not for citation purposes)
Further efforts should be made to scale up the implementation of the intervention in the community. In total, 1494 messages were sent and received between the nurse and 20 participants during the 30-minute brief intervention and a 5-day booster dose of daily messages 2 weeks later. Also, a participant reflected that the response speed during the chat session varied. The reduced instantaneity may affect the intervention effect. Compared with face-to-face talk and counseling, this intervention was delivered with mHealth technology through free smartphone apps, which were more cost-effective in terms of delivery. We did not conduct a cost-effectiveness analysis in this feasibility study. Previous studies have been done to evaluate the cost-effectiveness of IM interventions targeting smoking cessation [38] and weight management [39]. Smartphone-based interventions using SMS text messaging or IM have demonstrated good cost-effectiveness due to their low cost and scalability. However, a cost-effectiveness assessment on this specific topic has not been done. The main concern of a nurse-led IM intervention could be the requirement of more manpower if it is conducted on a large scale. Having said that, we would suggest developing an intervention manual and training a group of sexual health counselors for implementation efficiency at a large scale. In addition, with the advancement of technology, the training manual can be used for the further development of chatbots, which can assist in intervention delivery automatically. A systematic review reported a significant effect of a chatbot intervention in reducing depression [40]. While a randomized controlled trial also found chatbot intervention to be effective in promoting fertility awareness and preconception health [41]. An intervention protocol with standard answers should be well-designed to maintain a high standard of IM chat session content.

Strengths and Limitations
The strength of the study was in providing a realistic assumption on the feasibility of an IM-delivered brief intervention on promoting safer sex practices in the community. Our evaluation was conducted systematically based on Bowen et al’s [18] framework. The intervention was able to create a friendly, comfortable, nonjudgemental atmosphere that allowed participants to think and ask any questions about sexual health. The participants were also able to gain knowledge and more favorable attitudes about condom use.

The limitation of this study was the small sample size, which might affect the generalizability of the results. In addition, a comparison group was not established, so caution is needed when interpreting its findings. However, it is appropriate to have a small sample size to determine whether the intervention is feasible before carrying out a large-scale study [18]. Additionally, it could be cost-ineffective to increase the sample size without conducting a feasibility study. Another limitation was the short follow-up period. It is very likely to take longer than 2 weeks postintervention to see changes in behavior [21]. Future research with a longer time frame would be able to more fully assess the outcome of this intervention.

Conclusion
An IM-delivered brief intervention was feasible and acceptable. The intervention was also demonstrated to be practical and effective in enhancing participants’ general knowledge and attitudes toward condom use. The intervention was able to minimize embarrassment when discussing sensitive topics. Although intervention implementation can be time-consuming and labor-intensive, the study findings informed IM-based sexual health intervention development or modifications to enhance sexual health promotion among sexually active university students. More research is needed to evaluate the effectiveness and cost-effectiveness of such an intervention at a larger scale with trained counselors and evaluate its long-term effects by using a rigorous design, such as a randomized controlled trial.

Acknowledgments
The authors thank the study participants for their participation. This study is not supported by grants or funding.

Authors’ Contributions
SHLP, AMT, and JYHW conceived the study. JYHW delivered the intervention. SHLP and JYHW analyzed the data. JYHW, AMT, MPW, DYTF, and EPHC provided guidance throughout the study. SHLP wrote the first draft of the manuscript. All authors reviewed the final manuscript.

Abstract

Background: In an aging society such as Japan, where the number of older people continues to increase, providing in-hospital end-of-life care for all deaths, and end-of-life care outside of hospitals, such as at home or in nursing homes, will be difficult. In end-of-life care, monitoring patients is important to understand their condition and predict survival time; this information gives family members and caregivers time to prepare for the end of life. However, with no clear indicators, health care providers must subjectively decide if an older patient is in the end-of-life stage, considering factors such as condition changes and decreased food intake. This complicates decisions for family members, especially during home-based care.

Objective: The purpose of this preliminary retrospective study was to determine whether and how changes in heart rate variability (HRV) indices estimated from ballistocardiography (BCG) occur before the date of death in terminally ill older patients, and ultimately to predict the date of death from the changepoint.

Methods: This retrospective pilot study assessed the medical records of 15 older patients admitted to a special nursing home between August 2019 and December 2021. Patient characteristics and time-domain HRV indices such as the average normal-to-normal (ANN) interval, SD of the normal-to-normal (SDNN) interval, and root mean square of successive differences (RMSSD) from at least 2 months before the date of death were collected. Overall trends of indices were examined by drawing a restricted cubic spline curve. A repeated measures ANOVA was performed to evaluate changes in the indices over the observation period. To explore more detailed changes in HRV, a piecewise regression analysis was conducted to estimate the changepoint of HRV indices.

Results: The 15 patients included 8 men and 7 women with a median age of 93 (IQR 91-96) years. The cubic spline curve showed a gradual decline of indices from approximately 30 days before the patients’ deaths. The repeated measures ANOVA showed that when compared with 8 weeks before death, the ratio of the geometric mean of ANN (0.90, 95% CI 0.84-0.98; P=.005) and RMSSD (0.83, 95% CI 0.70-0.99; P=.03) began to decrease 3 weeks before death. The piecewise regression analysis estimated the changepoints for ANN, SDNN, and RMSSD at –34.5 (95% CI –42.5 to –26.5; P<.001), –33.0 (95% CI –40.9 to –25.1; P<.001), and –35.0 (95% CI –42.3 to –27.7; P<.001) days, respectively, before death.

Conclusions: This preliminary study identified the changepoint of HRV indices before death in older patients at end of life. Although few data were examined, our findings indicated that HRV indices from BCG can be useful for monitoring and predicting
survival time in older patients at end of life. The study and results suggest the potential for more objective and accurate prognostic tools in predicting end-of-life outcomes.

**Introduction**

**Background**

The population of Japan was estimated to be 125 million as of October 1, 2020, and has been declining for 11 consecutive years since 2011 [1]. Meanwhile, the aging rate is increasing, and the number of people aged 65 years and older is estimated at 36 million, accounting for 28.8% of the total population. As the total population declines further, this percentage is expected to continue to increase, reaching approximately 33.3% in 2036 and 38.4% in 2065 [2].

The number of deaths has also increased over the years, exceeding 1 million in 2003 and 1.37 million in 2020. Malignant neoplasms are the leading cause of death, accounting for 27.6% of all deaths, followed by heart disease (15%) and senility (9.6%) [3]. Notably, in 2018, deaths due to senility surpassed cerebrovascular disease and became the third leading cause of death [4], possibly due to the growing number of people aged 90 years and older. The increasing number of deaths among older people creates difficulty in caring for all deaths in hospitals. Therefore, it is expected that end-of-life care outside hospitals will increasingly be provided in nursing homes and at home. In end-of-life care, it is important to monitor patients to understand their condition and predict survival time; this information helps patients anticipate what is to come and gives family members and caregivers time to prepare for the end of life [5,6].

However, this process may be very difficult under conditions when resources are limited, such that medical staff may not be available immediately at home. Furthermore, the physical, spiritual, and psychosocial conditions of older patients at end of life vary [7]. Unnecessary monitoring is also burdensome to patients and should be discouraged. To reduce the burden on patients and families, noninvasive and nonintrusive monitoring systems have been increasingly important, and several studies have demonstrated their usefulness in palliative care [8-10]. While tools to predict the survival of patients with terminal cancer have been developed and many studies have shown their usefulness [11-13], the reliability of these tools in predicting survival time for end-of-life patients without cancer has been questionable, and the tools are considered difficult to use [14,15]. Therefore, we focused on continuous and unobtrusive monitoring of patients using heart rate variability (HRV) indices estimated from ballistocardiography (BCG) obtained from a sheet-type device as a means of monitoring their condition. BCG is a measurement of the vibration signals generated by the ejection of the blood at each cardiac cycle [16], which has been used frequently in recent years to acquire biological signals [17-20]. The advantages of this method are that BCG signals can be obtained by placing a device under a patient’s mattress, making long-term, around-the-clock monitoring possible without attaching electrodes to the patient. The device could also reduce the burden on nurses by allowing them to monitor patients remotely. For example, many recent applied studies have been conducted using BCG to detect hypertension and apnea using HRV indices estimated from BCG signals [21-26]. HRV is a measure of the variation in time between heartbeats, usually recorded by an electrocardiogram (ECG). This variation is related to the autonomic nervous system and reflects a person’s health status [27]. A decrease in HRV generally results in a higher mortality rate [28,29] in patients with myocardial infarction, and HRV has also been demonstrated to be associated with a variety of diseases [30-33]. If the prognosis, including the patient’s survival, can be accurately estimated by HRV indices through noninvasive and noncontact monitoring, this would be beneficial for end-of-life patients, as well as their clinicians, caregivers, and family members, to plan future care and prepare for the end of life.

**Objectives**

The aim of this preliminary retrospective study was to investigate whether there is a changepoint in HRV indices obtained from BCG signals prior to death to predict the survival time in older patients without cancer at end of life.

**Methods**

**Study Design and Patients**

This was a single-center, retrospective pilot study in which all medical records of end-of-life patients (median age 93, IQR 91-96 years) were extracted from one nursing hospital in China. The study included data from 15 patients who were admitted to the facility and died between August 1, 2019, and December 31, 2021. All patients were without cancer. Patients with implanted pacemakers and patients with chronic atrial fibrillation or frequent extrasystoles were excluded. In addition, patients with less than 2 months of data from the date of death were excluded.

**Measurements**

Age and sex were collected as patient characteristics, and the following classical time-domain HRV indices were obtained from a medical database and used for analyses: average normal-to-normal (ANN) interval for each 5-minute segment of HRV recording; SD of all normal-to-normal (SDNN) intervals; and root mean square of successive differences (RMSSD). These HRV indices were collected up to 2 months before the patients’ deaths and used for data analyses.
BCG Sensing Device

The BCG device used in this study is made by Zhejiang Huiyang Technology Co, Ltd; it is a sheet-type device equipped with a highly sensitive motion detection sensor that is placed under pillows or mattresses to continuously measure the patient’s body movements. In addition to HRV indices, this device can measure arousal, sleep, respiratory rate, and bed-withdrawal time. HRV parameters were processed from continuously recorded raw BCG signals at 133 Hz. The BCG signal was preprocessed through filtering and detection of the BCG wave (the J-wave) based on proprietary algorithms. The typical wave form of BCG signals is shown in Figure 1. After detection of J-J wave intervals, ectopic intervals were excluded in time series and formed normal-to-normal intervals. These intervals were used as an alternative to the RR interval (RRI) obtained from ordinary ECGs.

Figure 1. Typical wave form of ballistocardiography signal.

Statistical Analysis

Data are summarized as mean (SD) for continuous variables if the data followed normal distribution and as median (IQR) otherwise. Categorical variables are expressed as numbers and percentages. The time-course changes of HRV indices were examined by drawing a spline chart with a restricted cubic spline model and 3 internal knots fitting each HRV index as a function of time. A repeated measures ANOVA model was conducted to evaluate the within-subject effect, that is, the average of an individual trend of HRV indices over the period for which data were obtained. Since multiple analyses were performed with the reference and the values at each time point, multiplicity was adjusted using the Dunnett-Hsu method. Before analysis, data were natural-log transformed to reduce the right-skewness of the original data, and then daily or weekly averages were calculated for each patient. After analysis, estimates were back-transformed. The results at each time point represent the ratio of the geometric mean of values to reference values. To explore the location of the changepoint of HRV indices over the observation period, a piecewise regression model was used. The regression coefficients were back-transformed; the regression coefficients represent the fold-change for every 10-unit change in the independent variables. The statistical 2-sided significance level was set at .05, and \( P<.05 \) was considered statistically significant. All statistical analyses were conducted using SAS (version 9.4; SAS Institute).

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki (revised in 2013) and the Ethical Guidelines for Medical and Health Research Involving Human Subjects in Japan (revised in 2017). The study received approval from the Research Ethics Committee, Faculty of Medicine, Juntendo University (M19-0287). The committee waived the requirement for informed consent for this retrospective study, as it involved the analysis of existing data. All study data were anonymized, and any identifying information was removed to ensure the complete confidentiality of patients. Only authorized research personnel had access to the collected data, and any publication or presentation of the results strictly maintained the anonymity of the study. Patients were not offered any compensation for their participation in this study.

Results

Patient Characteristics

A summary of patient demographic characteristics is presented in Table 1. The data were obtained from 15 patients aged 90 to 100 years, including 8 men and 7 women. The median age for the entire group was 93 (IQR 91-96) years, and by sex, the median age was 94 (IQR 90-97) years for women and 93 (IQR 91.5-94.5) years for men. The other underlying cardiac diseases of the patients were not a concern; however, only cases with no change in medication during the period were included, resulting in a final study total of 15 patients.

**Time-Course Changes of HRV Indices**

Time-course changes in HRV indices were plotted by spline charts (Figure 2). The x-axis in this figure represents the date of the event as 0 and proceeds backwards from there. As shown in Figure 2, the value for ANN gradually decreased from approximately –60 days to approximately –30 days, but the degree of the trend slightly increased after approximately –30 days until the patients’ deaths. A similar trend was observed in RMSSD and SDNN; however, for SDNN, the values seemed to be constant between –60 days to approximately –30 days. After –30 days, a decreasing trend was observed.
Repeated Measures ANOVA
The results of the repeated measures ANOVA are shown in Table 2. In this analysis, the average of the log-transformed data at 8 weeks before the patients’ deaths was used as a reference and compared to each averaged log-transformed result from 7 weeks to 1 week before death. Then, the estimates were back-transformed in order to represent the results as the ratios to reference. At 3, 2, and 1 week before the patients’ deaths, there were significant decreases in ANN (3 w: 0.90, 95% CI 0.84-0.98; P=.005; 2 w: 0.90, 95% CI 0.84-0.98; P=.004; 1 w: 0.86, 95% CI 0.80-0.93; P<.001) and RMSSD (3 w: 0.83, 95% CI 0.70-0.99; P=.03; 2 w: 0.83, 95% CI 0.70-1.00; P=.04; 1 w: 0.78, 95% CI 0.66-0.93; P=.002) compared to the reference. Although not statistically significant, SDNN began to decrease from 4 weeks, and a statistically significant decrease was observed at 1 week (0.81, 95% CI 0.67-0.97; P=.02) compared to the reference.
Table 2. Repeated measures ANOVA for heart rate variability indices. The values represent ratios of each week’s value to the reference and their corresponding 95% CIs.

<sup>a</sup>These P values represent the results at each time point relative to the reference, that is, the Dunnett-Hsu–adjusted P value.

<sup>b</sup>These P values represent the results for the change in the heart rate variability indices over the entire observation period.

**Changepoint Estimation**

The changepoints in HRV indices were explored by using a piecewise regression model. Results are shown in Table 3. The changepoints for ANN, SDNN, and RMSSD were estimated as occurring at –34.5 (95% CI –42.5 to –26.5), –33.0 (95% CI –40.9 to –25.1), and –35.0 (95% CI –42.3 to –27.7) days, respectively, before the date of the patient’s death at 0. The regression coefficients of the slope for the HRV indices before the changepoint were not statistically significantly different from 0; however, after the changepoint, the coefficients indicated that HRV indices were significantly decreased by a factor of the coefficients for every 10 units of increase in days (ANN: 0.959, 95% CI 0.950-0.968; P<.001; SDNN: 0.930, 95% CI 0.908-0.953; P<.001; RMSSD: 0.925, 95% CI 0.905-0.946; P<.001).

\(^{a}\)The regression coefficient of slope indicates that for every 10-unit increase in days, heart rate variability indices increase or decrease by the value multiplied by the regression coefficient.

\(^{b}\)Values for changepoint represent days before the date of the patient’s death at 0.

**Discussion**

Principal Findings

This preliminary retrospective study aimed to explore the changepoint of HRV indices based on estimates from BCG signals measured over a period of time in older patients at end of life who were residents in a nursing home. Our analysis, conducted by plotting a spline curve, revealed a gradual decline in HRV indices from approximately 30 days before the patients’ deaths. To assess whether this change could be detected statistically, we compared the HRV indices 8 weeks before the date of death with the HRV indices from each week, starting from 7 weeks to 1 week before death, with a repeated measures ANOVA. This analysis found that the ANN and RMSSD values decreased from 3 weeks before the date of death. Furthermore, for a more precise estimation of when the changepoint occurred, we conducted a piecewise regression analysis. This analysis revealed the changepoints for the indices in days before the patients’ deaths for ANN (–34.5, 95% CI –42.5 to –26.5 days), SDNN (–33.0, 95% CI –40.9 to –25.1 days), and RMSSD (–35.0, 95% CI –42.3 to –27.7 days). The results indicate that if the changepoint can be detected during BCG monitoring, it may be possible to predict the survival time from that changepoint: approximately 1 month later. Accurate estimation of the time of death approximately 1 month in advance by continuously monitoring HRV indices obtained from BCG could provide families or health care providers with more time to prepare for end-of-life care. Although our results are from a retrospective study and the sample size was small, to our knowledge, this is the first study to analyze data from long-term monitoring of older patients without cancer at end of life using HRV indices estimated from BCG.

HRV measures the time interval between adjacent heartbeats, that is, the variation in the time interval from R wave to R wave (ie, RRI) on the ECG. HRV indices are a useful noninvasive means of assessing autonomic function. The gold standard for evaluation of HRV indices is to evaluate the RRI on an ECG. However, in recent years, other systems have been developed to acquire BCG signals, most of which come in the form of a mattress or chair [34], and BCG is considered to be a potential substitute for HRV indices [35,36]. Martín-Yebra et al [36] evaluated the JJ, II, KK, and HH intervals of the BCG signal as an alternative to the ECG’s RRI and showed that the JJ interval was almost consistent with the RRI measured simultaneously with BCG. We also analyzed the HRV indices estimated from the JJ intervals of the BCG signal in our study.

The rapid aging of the world’s population and the widespread use of HRV have increased interest in the prognostic value of HRV in older patients, even outside the specific field of cardiology [37]. Kurita et al [38] examined the survival of...
patients based on HRV and blood tests such as serum albumin and C-reactive protein levels at admission among older Japanese individuals in special nursing homes. They reported that there was no statistically significant difference between the death and survival groups in terms of blood test values. However, the SDNN and coefficient of variables of RRI values, which have been suggested to be related to parasympathetic activity, were statistically higher in the survivor group. In another study, which used HRV to predict survival time for terminally ill patients with cancer [39], the length of survival time was shorter in groups with lower SDNN (21.3 ms or less) or higher heart rates (100 or more beats per minute) measured at baseline. Another prospective study using HRV to evaluate the prognostic values for discharge from the hospital in cancer patients compared the high-frequency (HF) and low-frequency components of HRV at admission between patients who were discharged and those who died. In the study, none of the HRV indices were statistically different, but the estimated value of the HF components of HRV as an index reflecting parasympathetic nerve activity (vagal activity), tended to be higher in the discharged group [40]. Since our study also showed a decrease in ANN, which represents an increase in heart rate, and a decrease in SDNN and RMSSD, which reflect parasympathetic function, it may be appropriate to use HRV indices related to parasympathetic function to make prognoses at end of life in older patients.

Our results showed a change in HRV indices approximately 35 days before patients’ deaths. A previous study of signs of mortality and the timing of their appearance in end-of-life patients in Japan [41] was based on the subjective perceptions of nurses working at a special nursing home for older people; it reported that the signs of mortality were divided into 19 categories and classified them according to the time they appeared. The study found that some signs appeared approximately 1 month before death and others appeared 2 days before. Signs that appeared 1 month prior to death included lack of eyepath, paleness, lack of vitality, somnolence, and decreased food intake compared to previous stable daily activities. Notably, the changepoint of the HRV indices was observed approximately 1 month before death in our study, and there may be some relationship between the signs recognized by the nurses and the change in HRV indices, that is, they may run in parallel. Therefore, in the future, it may be possible to construct a more accurate model that can predict the survival time of patients by combining more objective changes in HRV with the subjective symptoms identified by nurses.

**Strength**

The strength of this study lies in the analysis of data collected continuously from patients for more than 2 months. For example, the Palliative Performance Scale (PPS) and Palliative Prognostic Index (PPI) scores at admission are commonly used as prognostic tools for terminal cancer patients [42]. However, many studies rely solely on values at admission to assess prognoses. In contrast, Kao et al [43] postulated that using only the PPI score on the first day may be limited because it does not consider subsequent changes in the patient’s condition. They showed that combining PPI scores from day 1 and 1 week later improved prognostic accuracy. In addition, Chan et al [44] examined changes in PPS scores at admission, week 1, and week 2 in terminally ill patients to predict patient survival. They found that all of these changes were independent predictors, with the greater the change, the higher the hazard ratio. These studies underscore the importance of analyzing changes over time. Although it is relatively convenient to measure the items needed to calculate PPS and PPI in a clinical setting, it is burdensome to observe these items daily. Therefore, if the sheet-type device used in this study can be used to measure HRV indices without inconvenience to the individual and facilitate making prognoses in end-of-life patients, it could be a very useful approach.

**Limitations**

There are several limitations in this study. First, it was retrospective and used existing data from a single institution; therefore, selection bias was unavoidable. Second, the study used a small amount of data from 15 patients, which could have affected the statistical validity. Third, the patients’ detailed background information was not available, and the study included patients with a variety of underlying diseases. Therefore, the results of this study may have been influenced by chance or by confounding factors, such as the patients’ medical histories and medical conditions while they still survived.

**Conclusions**

To our knowledge, this is the first study to assess HRV changepoints estimated from BCG signals in older patients at end of life. We found changepoints occurred approximately 1 month before a patient’s death, indicating that these changes could be used to predict patients’ deaths. This study also suggests the possibility of developing more objective and accurate predictive tools and offers valuable insights for future research. Such tools could be created by integrating BCG data with the subjective judgments of nurses, caregivers, and other health professionals, as well as established tools like the PPS, to make prognoses in cancer patients. However, since the findings were obtained in a retrospective study, future research is needed to determine how to detect these changes when observed prospectively.

Abstract

Background: Using a human-centered design (HCD) approach can provide clinical trial design teams with a better understanding of the needs, preferences, and attitudes of clinical trial stakeholders. It can also be used to understand the challenges and barriers physician stakeholders face in initiating and completing clinical trials, especially for using off-label drugs (OLDs) to treat unmet clinical needs in cancer treatment. However, the HCD approach is not commonly taught in the context of clinical trial design, and few step-by-step guides similar to this study are available to demonstrate its application.

Objective: This study aims to demonstrate the feasibility and process of applying an HCD approach to creating clinical trial support resources for physician stakeholders to overcome barriers to pursuing clinical trials for OLDs to treat cancer.

Methods: An HCD approach was used to develop OLD clinical trial support concepts. In total, 45 cancer care physicians were contacted, of which 15 participated in semistructured interviews to identify barriers to prescribing OLDs or participating in cancer OLD clinical trials. Design research is qualitative—it seeks to answer “why” and “how” questions; thus, a sample size of 15 was sufficient to provide insight saturation to address the design problem. The team used affinity mapping and thematic analysis of qualitative data gathered from the interviews to inform subsequent web-based co-design sessions, which included creative matrix exercises and voting to refine and prioritize the ideas used in the final 3 recommended concepts.

Results: The findings demonstrate the potential of HCD methods to uncover important insights into the barriers physicians face in participating in OLD clinical trials or prescribing OLDs, such as recruitment challenges, low willingness to prescribe without clinical data, and stigma. Notably, only palliative care participants self-identified as “frequent prescribers” of OLDs, despite high national OLD prescription rates among patients with cancer. Participants found the HCD approach engaging, with 60\% (9/15) completing this study; scheduling conflicts caused most of the dropouts. Over 150 ideas were generated in 3 co-design sessions, with the groups voting on 15 priority ideas that the design team then refined into 3 final recommendations, especially focused on increasing the participation of physicians in OLD clinical trials.

Conclusions: Using participatory HCD methods, we delivered 3 concepts for clinical trial support resources to help physician stakeholders overcome barriers to pursuing clinical trials for OLDs to treat cancer. Overall, integrating the HCD approach can aid in identifying important stakeholders, such as prescribing physicians; facilitating their engagement; and incorporating their
perspectives and needs into the solution design process. This paper highlights the process, methods, and potential of HCD to improve cancer clinical trial design. Future work is needed to train clinical trial designers in the HCD approach and encourage adoption in the field.

Introduction

Project Goals
Cancer clinical trials involve the coordination of many stakeholders but frequently fail to meet enrollment goals, prespecified end points, and timelines [1,2]. Effective stakeholder engagement can be essential to cancer clinical trial design, conduct, and reporting of clinical research [3]. However, traditional design approaches often lack consideration of stakeholders’ needs, preferences, and experiences, which can lead to recruitment and retention challenges or to study results that are less generalizable or applicable to real-world settings. Trial stakeholders include physicians who face unique barriers, especially when designing trials for off-label drugs (OLDs) to treat unmet clinical needs in cancer treatment [4]. Assumptions that stakeholders will be willing to participate in a trial may not adequately factor in the unique challenges and barriers that patients with cancer and stakeholders face. In addition, underrepresented and marginalized populations’ needs can also be missed because their perspective is rarely represented by clinical trial designers, which can lead to a lack of diversity in clinical trial participants and potential disparities in treatment outcomes [1].

To overcome these limitations, a human-centered design (HCD) approach offers both a process to learn about the needs of the trial stakeholders as well as flexible tools to test assumptions, uncover barriers, and work collaboratively with study stakeholders to optimize the clinical trial design. An emerging body of literature on HCD for health care innovation yields many HCD methods to choose from [5], making it difficult for novice innovators to know where to start and which methods to use. The purpose of this paper is to demonstrate HCD methods through a case study, where cancer care physicians were invited to share their perspectives and needs into the solution design process. This paper highlights the process, methods, and potential of HCD to improve cancer clinical trial design. Future work is needed to train clinical trial designers in the HCD approach and encourage adoption in the field.

Introduction

Project Goals
Cancer clinical trials involve the coordination of many stakeholders but frequently fail to meet enrollment goals, prespecified end points, and timelines [1,2]. Effective stakeholder engagement can be essential to cancer clinical trial design, conduct, and reporting of clinical research [3]. However, traditional design approaches often lack consideration of stakeholders’ needs, preferences, and experiences, which can lead to recruitment and retention challenges or to study results that are less generalizable or applicable to real-world settings. Trial stakeholders include physicians who face unique barriers, especially when designing trials for off-label drugs (OLDs) to treat unmet clinical needs in cancer treatment [4]. Assumptions that stakeholders will be willing to participate in a trial may not adequately factor in the unique challenges and barriers that patients with cancer and stakeholders face. In addition, underrepresented and marginalized populations’ needs can also be missed because their perspective is rarely represented by clinical trial designers, which can lead to a lack of diversity in clinical trial participants and potential disparities in treatment outcomes [1].

To overcome these limitations, a human-centered design (HCD) approach offers both a process to learn about the needs of the trial stakeholders as well as flexible tools to test assumptions, uncover barriers, and work collaboratively with study stakeholders to optimize the clinical trial design. An emerging body of literature on HCD for health care innovation yields many HCD methods to choose from [5], making it difficult for novice innovators to know where to start and which methods to use. The purpose of this paper is to demonstrate HCD methods through a case study, where cancer care physicians were invited to share their perspectives and needs into the solution design process. This paper highlights the process, methods, and potential of HCD to improve cancer clinical trial design. Future work is needed to train clinical trial designers in the HCD approach and encourage adoption in the field.

Background
HCD is a problem-solving methodology that focuses on discovering needs and developing solutions for individuals within a system; it is increasingly being used in cancer care settings [6-8]. HCD is particularly well-suited for uncovering and understanding the complex attitudes and barriers contributing to physician off-label prescribing behavior for a variety of Food and Drug Administration--approved drugs with strong safety profiles such as aspirin that may have anticancer properties [9]. These medications have shown early evidence when prescribed off-label, in reducing the risk of developing certain types of cancer such as colorectal cancer, or in improving patient outcomes. However, due to low financial incentives and resources, and the lack of further clinical testing to provide definitive prospective data, physician awareness is low, and prescription adoption has been minimal [10]. To help build incentives and engage physicians to consider repurposed OLD options, the Morningside Center for Innovative and Affordable Medicine (Morningside Center) [11] based at Emory University worked with staff trained in HCD methods from the Innovation Catalyst program within the Georgia Clinical and Translational Science Alliance (CTSA) [12]. The Georgia CTSA team set out to first learn more about the barriers to these types of prescriptions and then work together with physicians to propose support programs to increase the consideration of repurposed OLD treatment options for their patients. We explored the implications of these findings for physician receptiveness to conducting clinical trials with repurposed OLDs.

Methods

Study Design
HCD is an iterative and flexible process for generating solutions to problems that typically includes 3 phases: learning about the humans involved in the situation, coming up with and refining concepts, and implementation. Additional steps can be added to address the specific needs of the project, and the CTSA research team emphasized stakeholder analysis because many stakeholders influence prescription decisions, so understanding who had the greatest influence was important to forming the guiding questions for the ideation activity. Thus, the team followed four steps with each step matched with an appropriate HCD method: (1) collect, sort, and analyze insights using semistructured interviews and affinity mapping; (2) identify influences using a stakeholder power-interest grid; (3) generate and prioritize ideas using a co-design activity called a “creative matrix” [13]; and (4) produce concepts to prototype by refining and ranking ideas generated from the co-design activity (Figure 1). The team identified 45 physicians who met the cancer care inclusion criteria within the Emory academic medical center ecosystem or community practice setting. From this pool, 15 agreed to participate in semistructured interviews. Of the 15 physicians interviewed, 8 were oncologists, 3 were palliative care specialists, 2 were urologists, 1 was an anesthesiologist, and 1 was a family medicine physician (Multimedia Appendix 1). Although this sample size is small, it was adequate to achieve insight saturation, or the point where participants were providing similarly themed insights.
Collect Insights

Within the HCD approach, qualitative research methods such as interviews, focus groups, or ethnography are typically used to gain insights about the situation, influencing factors, as well as the needs and wants of the stakeholders involved. The Georgia CTSA research team conducted semistructured interviews, which involve asking open-ended questions that allow for more free-flowing conversation than in structured interviews. A set of predetermined questions or topics guided the conversation, but there was also flexibility to follow-up on interesting or unexpected responses and to explore topics in more detail. Some of the key questions the team sought to answer were:

- Have you prescribed OLDs? Why or why not?
- What level of information or data do you need to prescribe?
- Where do you find information on OLDs?
- Who influences your OLD prescription decisions?
- What influences your decision to participate in OLD clinical trials?

The interviews produced dozens of pages of transcribed data, which the team reduced to key points on Post-it notes in preparation for a thematic analysis process called affinity mapping. Concepts that are related to each other were grouped, and a theme was coded for each group (Figure 2). In addition, stakeholders who influenced prescription decisions were also noted.
Identify Influencers

To validate assumptions about who ultimately makes OLD prescribing decisions and to verify decision-making impact, the Georgia CTSA research team identified stakeholders based on the insights collected from the interviews and affinity mapping process (Multimedia Appendix 2). This list of stakeholders was then mapped to a power-interest grid, which involves plotting stakeholders on a 3D grid based on their level of power or influence over the situation and their level of interest in outcomes (Figure 3). Stakeholders with high levels of power and high levels of interest are considered key players and require the most engagement while high-interest and lower-power stakeholders should be kept updated.
Generate Ideas

Co-design activities include the end users of a solution in the ideation of that solution. Co-design is an effective way to increase stakeholder engagement, which is essential to project success, particularly in cancer care delivery research [3]. There are many methods to collaboratively come up with ideas, such as rapid ideation, brainwriting, mind mapping, thumbnail sketching, and many others. Which method to select depends on the goals of the session, the time allotted, and who is participating. The Georgia CTSA team selected the creative matrix method (Figure 4), which concentrates ideation on a particular topic using a visual grid with 2 questions and up to 4 categories. This method can generate a high volume of ideas in a short time and within a specific context. The research team selected salient topics that arose from the affinity mapping exercise to create the context for 2 creative matrix exercises used in three 1-hour co-design sessions with 9 physicians. Participants were allotted 6 minutes to generate ideas and 3 minutes to select 2 concepts that they believed had the most valuable to help support the consideration of repurposed OLDs for prescription. These “best ideas” were subsequently mapped on a grid for impact versus effort to identify which ideas would have the most impact and lowest effort.
**Vote and Produce Prototypes**
Involving co-design participants in the idea evaluation process is important for getting feedback on the feasibility, desirability, and viability of the ideas [14]. It can increase participants’ sense of ownership and investment in the final solution, potentially leading to greater adoption and success. While co-design sessions can generate a high volume of ideas quickly, further refinement to create workable prototypes for testing is sometimes necessary, and this study’s team distilled concepts that were well-received by physicians during the co-design sessions into 3 prototype-ready directions.

**Ethical Considerations**
This study was reviewed by an ethics committee to ensure the protection of research participants, and it was approved by Emory University Institutional Review Board (STUDY00004025). Each participant provided consent to be interviewed and that their responses could be used in our design study without additional consent. The privacy and confidentiality of participants and their responses were ensured by removing names and any other fact that might point to participants’ identity in this study; also, research records are kept private to the extent required by law. The compensation for participation in this study was a US $50 gift card.

Results

Thematic Analysis
Of the 45 physicians we contacted, 15 agreed to be interviewed and share their experiences and opinions on OLD prescribing for cancer care. Key themes that emerged from the interviews showed that, in contrast to documented high off-label prescription rates in cancer [15-17], the interviewed physicians were less likely to self-identify as “frequent prescribers,” citing a range of barriers. A lack of clinical trial evidence to support the prescription was most frequently expressed as a barrier to prescription, as well as cost and reimbursement concerns and the lack of knowledge of off-label options. A notable exception to off-label prescription hesitancy was seen in palliative care specialists who expressed few barriers to prescribing off-label but emphasized that their focus was on easing symptoms and not providing treatment. To learn about OLDS, physicians described a variety of sources but most often relied on professional social networks to discover and deepen knowledge; however, they struggled to find information on specific OLDS when they needed it.

On the power-influence grid, cancer care physicians were identified as the stakeholders having the highest power and interest in patient prescriptions, validating the assumption that they are the primary prescription decision makers who require the most engagement. Patients and their families were mapped to the high-interest but less power quadrant and were sometimes the source of OLD prescription requests that did not always lead to prescriptions.

Concept Generation
The Georgia CTSA research team synthesized insights from the interviews into 2 brainstorming themes used during 3 co-design sessions with 9 physician participants. The first context explored types of support needed for physicians to consider OLDS as concurrent treatment, which generated 70 concepts. The second context focused on what support was needed to make it easier to start and complete an OLD clinical trial, which produced 95 concepts. Of the 165 total concepts, participants voted for 14 of the ideas that they felt best supported their needs, which the physicians mapped to identify which were high impact or lower effort. The selected concepts included providing dedicated clinical research coordinators, protected research time for clinical trials, electronic medical record prompts or reminders, incentive programs, an OLD reference database or app, and endorsements for OLD trials at team meetings to support recruiting efforts (Multimedia Appendix 3).

The research team further synthesized these concepts into 3 prototype-ready directions listed inTextbox 1.

Textbox 1. Recommended concepts delivered to the Morningside Center after this study.

</tbody>
</table>

In a web-based survey, all 15 physician participants were asked to force rank the concepts that they felt was the most impactful to supporting repurposed OLD prescription decisions; we received 7 responses (Multimedia Appendix 4). The fellowship program concept surfaced as the leading idea with a mean of 2.0 (SD 0.93; Figure 5). Overall, concepts that resonated most either supported clinical trial development or bolstered social interfaces from which they could learn about OLDS from other physicians.
**Discussion**

**Principal Findings**

Using this case study, we have demonstrated the flexible nature of HCD as it relates to accommodating unique characteristics of the project, selecting from a wide range of ideation techniques, and adapting to participant ideas and preferences. The findings also demonstrate the potential of HCD methods to uncover important insights into physician decision-making processes that can lead to improving OLD prescription and clinical trial practices. Clinical trial designers can similarly use these methods to gain a deeper understanding of the target audience’s needs, preferences, and attitudes toward a potential trial. Insights can help overcome barriers to participation, such as language or cultural differences, and inform more effective trial protocols that lead to greater participant engagement and retention. Without using the grounded approach of first synthesizing stakeholder insights, ideation sessions may not be as productive.

A notable feature of HCD is high engagement among participants, also demonstrated in this study with 60% (9/15) of physicians participating from the initial interviews to the ideation and final voting exercises. Further, I participant said, “I really appreciate being listened to and would be willing to volunteer to test these ideas.” HCD can be used to increase patient engagement by incorporating the needs, preferences, and attitudes of potential trial participants [18]. Participants who did not participate in all activities of this study either did not respond to the invitations or declined because of scheduling conflicts.

HCD’s participatory nature contrasts with the traditional clinical trial design, which often does not engage the participants for which the trial is designed. This can lead to important perspectives or data being missed and result in low patient engagement and incomplete or biased research outcomes. The high failure rate of clinical trials has led to increasing interest in using stakeholder and patient engagement to support clinical trial design [3,19]. In the context of clinical trial design, a co-design activity could involve collaborating with patients, health care providers, and other stakeholders to co-design trial materials, such as patient education materials or data collection forms to ensure that they are acceptable and feasible.

While HCD offers a flexible process and many methods to choose from, it is very different from the linear thinking and hierarchical norms associated with traditional scientific approaches [20], which may thwart the adoption or effective implementation of the HCD process. Additional challenges can include the potential for interviewer bias and the time- and resource-intensive nature of conducting interviews and co-design workshops. While HCD is becoming an increasingly familiar term, access to training remains low as few institutions have internal design teams, usually found in innovation centers [21], to consult with or to run projects. Thus, acquiring and building HCD expertise can be expensive, and it remains to be seen how future clinical innovation funding or such services will be allocated.

**Conclusions**

Although a relatively new problem-solving approach in health care, HCD can provide tangible, flexible, and reproducible methods that include stakeholders in the ideation and problem-solving process [22]. HCD can help identify and engage
important stakeholders such as physicians and patients in the design process and then integrate their perspectives and needs into the subsequent solutions, which is increasingly seen as an important contributor to cancer clinical trial success. This case study provides a step-by-step guide on how to apply the HCD process and selected methods to generate stakeholder-centered solutions. HCD has the potential to be an important tool to increase success rates of clinical trials, but increased institutional support and researcher training will be needed for HCD to provide its fullest benefit.

Abstract

Background: The number of overdose deaths in the United States involving opioids continues to exceed 100,000 per year. This has precipitated ongoing declarations of a public health emergency. Harm reduction approaches, such as promoting awareness of, ensuring access to, and fostering willingness to use naloxone to reverse opioid overdose, are a key component of a larger national strategy to address the crisis. In addition, overdose reversal with naloxone directly and immediately saves lives. Because of pharmacies’ ubiquity and pharmacists’ extensive clinical training, community pharmacies are well-positioned, in principle, to facilitate naloxone access and education.

Objective: In 2022, a single-site pilot study of PharmNet, a community pharmacy intervention incorporating naloxone distribution, awareness building, and referral, showed promising outcomes for both naloxone and resource distribution in the community. As a next step, this study was intended to be a pilot randomized controlled trial of PharmNet in 7 pharmacies. However, due to circumstances outside of the study team’s control, data collection was unable to be fully completed as planned. In keeping with open research standards, we transparently report all available data from the study and discuss trial barriers and processes. We do so both to provide insights that may inform similar studies and to avoid the “file-drawer” (publication bias) problem, which can skew the aggregated scholarly literature through nonpublication of registered trial results or selective publication of findings affirming authors’ hypotheses.

Methods: This paper reports an in-depth implementation study assessment, provides the available observational data, and discusses implementation considerations for similar studies in independent (eg, nonchain) community pharmacies.

Results: Retrospective assessment of study outcomes and fidelity data provided for robust discussion around how resource differences in independent community pharmacies (vs well-resourced chain pharmacies), as well as high demands on staff, can affect intervention implementation, even when leadership is highly supportive.

Conclusions: Community pharmacies, particularly independent community pharmacies, may require more support than anticipated to be successful when implementing a new intervention into practice, even if it might affect estimates of real-world effectiveness. Further implementation science research is needed specific to independent community pharmacies. All study elements are outlined in the International Registered Report Identifier (IRRID) PRR1-10.2196/42373. Although this paper reports results associated with that registration, results and conclusions should not be given the weight assigned to findings from a preregistered study.

International Registered Report Identifier (IRRID): RR2-10.2196/42373

Introduction

Introduction

Background

In the last decade, hundreds of thousands of lives have been lost in the United States due to fatal opioid-involved overdoses [1], and annual overdose death rates (computed as 12-month year-over-year incidence) have remained over 100,000 in recent reports from the Centers for Disease Control and Prevention [2]. Additionally, overdose deaths represent one-third of all accidental deaths in the United States [3], with the majority involving illicitly manufactured fentanyl, a synthetic opioid [4]. In the state of Indiana, where this study was conducted, preliminary data indicate 2250 overdose deaths in 2022 [5], around 71% of which involved fentanyl or other synthetic opioids [5].

Naloxone, an opioid antagonist, works by blocking the effects of opioids and can allow persons who have overdosed to resume normal breathing [6]. It is a safe and effective way to rapidly reverse the effects of opioid overdose and can prevent death [6,7]. Research has shown that overdose deaths decline when overdose education and naloxone distribution (OEND) efforts are undertaken in communities [8], and that OEND programs are both an effective [9,10] and cost-effective [11] strategy to address overdose fatality.

In 2018, the US Surgeon General issued an official recommendation that all US citizens carry naloxone [12]. By 2021, most US states, including Indiana, had begun to address the overdose epidemic using combinations of policies that generally included “Good Samaritan” laws and standing orders for naloxone at pharmacies [13]. More recently, the declaration of an opioid public health emergency was renewed in September 2023 [14], approximately a year after the release of the US National Drug Control Strategy, which outlines goals that include the expansion of access to evidence-based harm reduction practices, including naloxone [15].

Beyond the impact in terms of lives saved, individuals who are revived with naloxone and who also have opioid use disorder (OUD) have an opportunity to engage with an “Opioid Cascade of Care” [16], such as through treatment initiation with medications for opioid use disorder (MOUD) in the emergency department [17]. For these benefits to accrue, however, naloxone must be easily accessible by those who can use it to reverse an opioid overdose. In the United States, naloxone was recently approved for over-the-counter sale [18], following a unanimous vote by Food and Drug Administration advisors [19]. While this change might in principle increase the number of people carrying naloxone, data from Australia suggest that it may be a helpful but not sufficient step to increase access [20].

Even as additional means of obtaining naloxone are developed (eg, naloxone vending machines [21]), community pharmacies will likely remain an important component of supporting naloxone access and education. In some populations, patients interact with their pharmacists more often than with their primary care physicians [22], and pharmacists have been identified as some of the most accessible health care providers in the United States [23,24]. Studies show that community pharmacists generally acknowledge their role in assisting in harm reduction [25-27], and an Arizona study found that community pharmacists were typically comfortable providing consultation around and dispensing naloxone, even when they were uncomfortable with other harm reduction approaches such as syringe dispensing without a prescription [28]. As such, community pharmacists are theoretically well-positioned to improve harm reduction education and accessibility of related supplies. At the same time, recent studies also continue to suggest that naloxone remains unavailable for purchase in some community pharmacies and may be less likely to be available in independent pharmacies compared to chain pharmacies [29].

The PharmNet Intervention

To better understand the dynamics and potential of community pharmacy harm reduction practice, we completed multiple preliminary studies [26,28,30-35]. Our work examined naloxone access, pharmacist comfort with harm reduction, pharmacy-based research approaches, and the “fit” of the pharmacy environment for harm reduction–related services. The studies were conducted from 2016 through 2022, and many of them engaged community and academic pharmacists as part of the research team.

By the end of the process, we had determined that our initial conceptualization of a “short” or “minimally demanding” intervention (eg, the first draft of PharmNet, a 10- to 15-minute screening and brief intervention-style intervention) would likely be perceived as useful but not necessarily feasible without a substantive added support system (eg, financial and personnel). Further, there was variability in the a priori intervention components that would be available at different pharmacy types. For example, a systematic review [36] in addition to our own earlier research in Indiana [33] and a recent study in North Carolina [29] identified independent pharmacies as being significantly less likely to stock or dispense naloxone compared to chain pharmacies (eg, ability to dispense naloxone, even at cost, could not be assumed). While independent pharmacies are, in theory, more likely to be able to participate in a small intervention implementation program (eg, they do not need to seek approval from a large bureaucracy associated with a national or international chain), they also lack the financial and systemic resources that are available to chain pharmacies, which can have implications for stocking and dispensing of products, as well as pharmacists’ availability to undertake additional work.

Thus, the PharmNet intervention was modified with the goal “to study procedures that have as minimal an impact as possible on pharmacy costs and operational functioning while maximally facilitating harm reduction from opioid overdose—in other words, to find an optimal intersection point of those concerns” [37]. The overall goals of the finalized PharmNet intervention are outlined in a previous paper, which reported the results of
our initial single-site pilot study [37]. For clarity, we excerpt them here verbatim:

1. Building awareness of naloxone availability at the site among patients (eg, the use of yard signs and scrolling messages on television screens).
2. Supporting awareness among pharmacists and pharmacy technicians about proactively offering naloxone (eg, customized post-it notes).
3. Facilitating service provision by conducting a priori negotiations and establishing written agreements with local nonprofits to facilitate a pipeline of no-cost naloxone for the pharmacy.
4. Emphasizing bidirectional naloxone provision (eg, pharmacist- and pharmacy technician–initiated offers in addition to patient-initiated requests), and
5. Facilitating referral by providing a physical, durable, and curated list of community resources that can be used by pharmacists, handed to patients, and placed into pharmaceutical bags.

Interestingly, these goals are generally aligned with the intervention approaches described in a scoping review of opioid counseling and naloxone services published after our study concluded [38]. The review found that “all studies incorporated naloxone recommendations into their pharmacy-based opioid counseling and naloxone services,” and that most programs focused mostly on OEND [38]. Further, most of our awareness and communication strategies were similar to those in the review, though only one study in the review used outdoor yard signs, and none appear to have established pathways for pharmacies to receive no-cost naloxone [38].

Our first implementation of PharmNet was in a single independent pharmacy in the Midwestern United States. In that 3-month single-site pilot study, naloxone dispensing by any means (paid or no cost) nearly doubled, increasing by 96.48% (+9.33 doses per month); this included both distribution of no-cost doses (+6 doses per month) and an increase in the monthly rate of naloxone sold (+3.33 doses per month) compared to the 3 months before the intervention [37]. An average of 2.85 referral and resource cards (1/4 page in size) customized to the local area were distributed to patients each day. The initial pilot study also allowed us to further adjust the procedures based on feedback from community pharmacists [37]. The most substantive change was a drop from 3 sets of different post-it reminders to one, because only one type was regularly used by the pharmacy staff members in practice.

To better understand the results, and to begin assessing the intervention’s scalability, we then developed and published a study protocol for a pilot randomized controlled trial (RCT) of PharmNet [39]. Our stated goal was “to facilitate an improved understanding of whether it is reasonable to believe that the PharmNet intervention causes increased dispensing of naloxone ...” and we proposed to test the hypothesis that, “Monthly naloxone dispensing (combined sales and no-cost distribution) will be significantly increased in the pharmacies implementing PharmNet compared to those in the control arm” [39].

This Report
This paper was originally planned to describe the results from a small RCT of PharmNet based on our protocol paper that also served as a registered report (International Registered Report Identifier: PRR1-10.2196/42373) [39]. However, several events and circumstances beyond the control of the study team (eg, a COVID-19 outbreak among pharmacists) resulted in substantial deviations from the proposed approach and outcome measures. The conceptual magnitude of these differences and the resultant effects on data and procedures mean that it would be inappropriate to attempt to assert that the information reported in this paper serves as answers to our original research questions.

At the same time, it is important for us to provide a complete description of the study and any resultant observations and lessons learned. In doing so, we avoid contributing to the “file drawer” (publication bias) problem, wherein studies that are perceived to be unsuccessful or that have nonsignificant results are never published to the detriment of the scientific enterprise and those affected by it [40-42]. Publication bias has been described as being conceptually similar to the practice of p-hacking [43]; it can skew the perception of a field of study in a particular direction through suppression (either deliberate or inadvertent) of results that do not align with the scientists’ goals. This can happen in at least 2 ways. First, results from registered trials may never be published at all (a recent study of RCTs in New Zealand found that 27% of results had not been published more than a decade after the study registration date) [44]. This can produce the mistaken impression that not much is known about a particular approach. Second, a “failed” study may be repeated with some minor modifications, and the resultant data reported as though it was the originally registered trial. This can lead to overestimation of the intervention’s likely outcomes as well as reducing the likelihood that procedural and implementation considerations—some of which may be important—are fully and transparently addressed.

Therefore, we share the results of this study in the form of an observational report that includes (1) the findings that we were able to collect, (2) the methods to collect that information, as well as (3) specific information related to deviations from planned data collection and analysis. Then, we provide a detailed written record of fidelity or process checks and the results of those checks. Finally, the implications of the external issues leading to these events, including discourse around the role that implementation fidelity checks may play in the conduct of intervention studies, and of the unique nature of independent pharmacies, are discussed.

Methods
Study Design
We planned to conduct a pilot cluster RCT with 7 independent community pharmacies consisting of 2 parallel groups. In total, 4 pharmacies were allocated to the intervention arm, and 3 pharmacies were allocated to the control arm. The original project flow diagram is provided as Figure 1 [39,45], along with colored marks added after the study to indicate the degree of completion for that step.
Detailed implementation notes were collected from the 4 pharmacies randomly assigned to the intervention arm. We also obtained data on naloxone sales and no-cost distribution for the 3 months prior to the study period as well as for a period of 3 or more months after the intervention began (more details on this timeframe are provided subsequently). Some preintervention staff data are provided and discussed.

No data were collected from control pharmacies, no posttest data were able to be collected from pharmacy staff members, and no counts of referral cards were able to be obtained from any pharmacy.

**Figure 1.** Original study protocol diagram for the PharmNet pilot trial, modified with indicators of completion status (adapted from Eldridge et al [39], which is published under the terms of the Creative Commons Attribution License 4.0 [45]).

**Sources of the Data**

There were 2 types of participants in this study, pharmacies and pharmacy staff members.

- The 7 participating pharmacies were part of a single independent pharmacy organization. They were allocated simultaneously to a study arm using a web-based random sequence generator with a 4:3 ratio.
- These pharmacies all operate in the Midwestern United States and have a shared leadership structure (eg, there are individuals who oversee operations at all 7 pharmacies). In addition, each pharmacy has a managing pharmacist (which we call “lead pharmacists” in this paper to avoid conflating their management role with those of pharmacists overseeing the whole organization).
- Lead pharmacists manage day-to-day pharmacy operations at single sites.
- Pharmacists and pharmacy staff members at each of the 7 sites (both the intervention and control arms) were asked to participate in the study by providing individual-level data at pretest. Posttest data collection was planned but not completed (as described in the Results section).

**Intervention Description**

The development of this intervention was described in detail in prior papers [37,39], and a structured table outlining the sequential steps of PharmNet was included in the published protocol paper [39]. The specific steps involved in the intervention are included in Tables 1 and 2, which describe each planned step (excerpted verbatim or paraphrased from the protocol paper, as appropriate, for clarity) as well as the actual outcome.

<tr>
<td><strong>Launch (on the start date)</strong></td>
<td>Launch verification calls were made by LAE to the intervention pharmacies on November 2, 2022 (the day after launch).</td>
</tr>
<tr>
<td>1. Verify the intervention has launched.</td>
<td>Pharmacy 1: The pharmacist who was working that day was a floating pharmacist and transferred LAE to the managing pharmacist. The managing pharmacist reported that the pharmacy &quot;has the supplies and is ready to go.&quot;</td>
</tr>
<tr>
<td>• Reminder post-its are placed in visible areas on the interior of the dispensing location (eg, staff side rather than patient side).</td>
<td>Pharmacy 2: The pharmacist who was working that day said they had just returned from leave and did not know where the PharmNet intervention materials were in the pharmacy. They reported they would contact the managing pharmacist to find out where the materials were. The pharmacist stated they had watched the training video and were aware of the PharmNet intervention.</td>
</tr>
<tr>
<td>• Harm reduction referral cards are placed at each checkout for easy access.</td>
<td>Pharmacy 3: The pharmacist who was working that day reported they were not aware of receiving the PharmNet materials. They put LAE on hold to check if the supplies were in the pharmacy. They reported to LAE that they could not locate any supplies.</td>
</tr>
<tr>
<td>• Yard signs are placed outside the building in visible locations where traffic (vehicle or foot) is common.</td>
<td>Pharmacy 4: The pharmacist who was working that day reported that they had watched the training video and were aware of the PharmNet intervention. They reported that the pharmacy had not received any PharmNet supplies.</td>
</tr>
<tr>
<td>• Scrolling television banner will be enabled to run continuously through the intervention, reading &quot;76.7% of overdoses happen at home. Bystanders who witness an overdose can be effective in reducing overdose mortality. Ask us about how you can save a life with naloxone today!&quot;</td>
<td></td>
</tr>
<tr>
<td>2. Obtain additional details about the launch.</td>
<td>On day 4 of the intervention, LAE called the organizational management team. The primary purpose of the call was to request that they contact intervention pharmacies 2-4 to inform the pharmacists where the PharmNet materials were. LAE asked the managing pharmacist to inform the lead pharmacists at the intervention pharmacies to begin PharmNet if they had not already done so.</td>
</tr>
<tr>
<td></td>
<td>The managing pharmacist informed the researcher that they would contact the pharmacists over the next few days. Unfortunately, soon after that call, we learned that the managing pharmacist had COVID-19 and was on sick leave. In addition, at least 1 additional lead pharmacist was also on sick leave for COVID-19, and pharmacists from other sites, and (when possible) the managing pharmacist, were often required to staff those roles when no additional staff members were available to do so.</td>
</tr>
</tbody>
</table>

Data
The primary data points that we report include preimplementation naloxone sale data from intervention pharmacies (August 1, 2022, through October 31, 2022), postimplementation naloxone sale data from the same pharmacies (November 1, 2022, through January 31, 2023), and doses of no-cost naloxone distributed between the receipt of the doses at the end of May 2023. These data were obtained through objective pharmacy record extraction and physical (manual) counts of remaining naloxone doses by the lead pharmacist at each intervention pharmacy.

Data from individual staff members were collected via a survey administered prior to the implementation start date for PharmNet. The questionnaire was built in Qualtrics (Qualtrics), a secure web-based survey and data collection tool. The organizational pharmacy manager was provided with a link to distribute to pharmacists and pharmacy technicians at all independent community pharmacies in the study (both the intervention and control pharmacies). Measures included sociodemographic information, questions about pharmacy practice, comfort with harm reduction practices, and belief-based measures about people who use drugs. The wording for each item is provided in Multimedia Appendix 1. Completion of the survey was specifically not required for any individual pharmacist or staff member, but they were encouraged to participate. A copy of the full survey instrument is available as an appendix to the published protocol [39].

Finally, we also originally intended to have a single in-person fidelity check for each intervention pharmacy around 1 month into the project’s launch. For the reasons we describe in the Results section, multiple additional checks were added, and the modality was switched to telephonic and email correspondence to facilitate the increased frequency.

Ethical Considerations
This study received ethics reviews prior to being initiated. Participation by pharmacies was designated as not human subjects research by the Indiana University institutional review board (document 12339). Participating pharmacy sites in the intervention arm were each offered an institutional incentive of US $1000 for their participation. Pharmacy employees completed a study information sheet prior to participating in the individual-level data collection and were compensated with a US $5 digital gift card for completing the pretest survey. Individual-level procedures were reviewed separately by the...
Indiana University institutional review board and received a designation of “exempt” (document 13956). Due to the small number of individual participants, data are reported only in aggregate and without cross-sectional tabulation.

**Results**

**Pharmacy-Level Outcomes**

On February 1, 2023, the intervention was concluded. From February through the first week of April 2023, we attempted to obtain pharmacy-level outcome data via phone calls, voicemails, in-person visits, and physical notes. However, these processes were unsuccessful. Our subjective observation is that a combination of illness and staffing complexity made it extremely difficult to collect the outcome data as originally planned in the protocol.

Although they were not originally involved in data collection, we were able to collaborate with the lead pharmacists at intervention pharmacies, who had participated in fidelity checking processes and were familiar with our team, to obtain the limited data set described in the Data section in May 2023. Importantly, we do not know the exact date when each pharmacy began offering no-cost naloxone doses, and the numbers of doses of no-cost naloxone dispensed were obtained several months after the intervention technically ended. As a result, we cannot compare naloxone distribution prior to and during the intervention period. However, we can still provide raw numbers (Table 3).

**Pharmacy Staff Preintervention Data**

A total of 8 staff members at least partly completed the study pretest during the period prior to the intervention, including 3 pharmacists and 5 pharmacy technicians. Pharmacy 4 was well-represented with 5 respondents, and there were 2 from pharmacy 3 and 1 from pharmacy 1. No staff members from pharmacy 2 or the control pharmacies participated.

All but 1 respondent who provided demographics (n=6) were female, and all were White, non-Hispanic, and heterosexual. Staff ages ranged from 32 to 52 years (n=5). Staff members who responded were comfortable with most harm reduction approaches, but fewer were comfortable with consulting with patients about pre-exposure prophylaxis for HIV prevention or dispensing syringes for nonprescription drug use. No participants indicated they were uncomfortable dispensing naloxone for overdose reversal or making referrals to community services. Further, staff member attitudes toward patients who use drugs or have OUD were not typically stigmatizing, though they expected that others (“most people”) might blame persons with OUD or believe that they are dangerous. A table of these data is provided in Multimedia Appendix 1.

**Fidelity Data**

We also collected a full written accounting of the 9 distinct fidelity checkpoints during the intervention period. This information helped to contextualize some of the implementation issues around which we provide interpretation and discussion in the next section. Although not all study processes were in place at the time of the final fidelity check at week 10 of the 12-week intervention, by the time we collected outcome data, the intervention was apparently functioning at all sites (even though the technical “intervention period” was over). All documentation is available in Tables 4 and 5.

<tr>
<th>Timeframe</th>
<th>Outcome</th>
</tr>
</thead>
</table>
| **Day 10—Calls to all intervention pharmacies** | • Pharmacy 1: The pharmacist who answered the phone reported that they were not the usual pharmacist and only work 1 day a week, but that the pharmacy did have the yard signs and the no-cost naloxone. However, they reported that the yard signs were not placed outside the store. They also indicated that the managing pharmacist was on leave and that they recommend calling when they returned the following week to follow-up about the yard signs.  
• Pharmacy 2: The pharmacist reported they were not the usual pharmacist and only work at the pharmacy 2 times a month, and that the regular pharmacist who works at that store would be back the following week. They did not know about PharmNet or about the no-cost naloxone, yard signs, or harm reduction referral sheets.  
• Pharmacy 3: LAE spoke with the same pharmacist as previously (the startup verification). The pharmacist reported that they did not think they had received PharmNet supplies, but that they were ready to start the intervention as soon as they received the supplies.  
• Pharmacy 4: We spoke with the same pharmacist as previously (the startup verification). The pharmacist reported that they did not think they had received PharmNet supplies. |
| **Day 14—Attempt to coordinate with the pharmacies** | • LAE attempted to reach the managing pharmacist at 2 separate pharmacies. A pharmacy technician called an additional 5 pharmacies but was unable to locate them. We left a voicemail at their office. We later learned that they were on leave during this period. |
| **Days 16, 17, and 21—Follow-up calls, after which we learned about illnesses or leaves among the pharmacists** | • We called the original pilot pharmacy attempting to contact the leadership team. LAE left a voicemail and sent them an email on each of the 3 days. |
| **Day 22—Calls to all intervention pharmacies** | • LAE learned that the managing pharmacist had returned to the office, but they were in a meeting when we called. A pharmacy technician took a message. Calls were also made to each of the pharmacies in the intervention arm.  
• Pharmacy 1: When LAE called and requested to speak to a pharmacist, the pharmacy technician transferred her to the original pilot pharmacy location (which was not part of the study). LAE spoke with a pharmacist at this location, and this pharmacist reported they were unaware of the status of PharmNet at pharmacy 1 as they never worked at that site. They transferred the researcher back to pharmacy 1, where the pharmacy technician forwarded the researcher to voicemail. LAE left a message.  
• Pharmacy 2: We spoke with a pharmacist who confirmed that the supplies had been received and that the intervention had begun.  
• Pharmacy 3: The pharmacist reported that they still were not aware of having received the PharmNet supplies.  
• Pharmacy 4: The pharmacist reported that they still had not received the PharmNet supplies. The pharmacist reported they had reached out to their leadership about the supplies and were informed that their supplies were located at pharmacy 1 and would be delivered after Thanksgiving. |

| Week 4—Additional verification calls to intervention pharmacies to determine status and if any additional supplies were needed | - LAE made calls to each of the pharmacies in the intervention arm (1) to determine if pharmacy 1 and 2 needed supplies and were following PharmNet protocols and (2) to assess if supplies were received and that PharmNet started at pharmacy 3 and 4.  
- Pharmacy 1: We spoke to an on-call pharmacist who confirmed that they were following PharmNet’s protocol and that they had enough supplies (eg, harm reduction referral cards and no-cost naloxone).  
- Pharmacy 2: The pharmacist confirmed that they were following PharmNet’s protocol and that they had enough supplies (eg, harm reduction referral cards and naloxone).  
- Pharmacy 3: The pharmacist reported that they still were not aware of having received the PharmNet supplies.  
- Pharmacy 4: The pharmacist reported that they still were not aware of having received the PharmNet supplies. |
| Week 6—Additional verification calls to intervention pharmacies to determine status and if any additional supplies were needed | - LAE made calls to each of the pharmacies in the intervention arm (1) to determine if pharmacy 1 and 2 needed supplies and were following PharmNet protocols and (2) to assess if supplies were received and that PharmNet started at pharmacy 3 and 4.  
- Pharmacy 1: The pharmacist confirmed that they were following PharmNet’s protocol and that they had enough supplies (eg, harm reduction referral cards and naloxone).  
- Pharmacy 2: The pharmacist confirmed that they were following PharmNet’s protocol and that they had enough supplies (eg, harm reduction referral cards and naloxone).  
- Pharmacy 3: The pharmacist reported that they still were not aware of having received the PharmNet supplies.  
- Pharmacy 4: The pharmacist reported that they had not received all of the PharmNet supplies, but they had received the referral cards in the mail. |
| Week 10—Additional verification calls to intervention pharmacies to determine status and if any additional supplies were needed | - LAE made calls to each of the pharmacies in the intervention arm (1) to determine if pharmacy 1 and 2 needed supplies and were following PharmNet protocols, (2) to assess if supplies were received and if PharmNet had started at pharmacy 3, and (3) to check if pharmacy 4 received the remaining supplies and started the intervention.  
- Pharmacy 1: The pharmacist confirmed that they were following PharmNet’s protocol and that they had enough supplies (eg, harm reduction referral cards and naloxone).  
- Pharmacy 2: The pharmacist confirmed that they were following PharmNet’s and that they had enough supplies (eg, harm reduction referral cards and naloxone).  
- Pharmacy 3: There was no pharmacist available. We left a message requesting a callback, but it was never received.  
- Pharmacy 4: The pharmacist reported that they had not received all of the PharmNet supplies, but that they were currently using the referral cards. |

### Discussion

#### Context of the Report

PharmNet was developed with independent community pharmacies in mind as a core implementation venue. This was partly because of trends around naloxone stocking and dispensing, as described in the Background section, which suggested that independent pharmacies might especially benefit from intervention support. In addition, there is a large segment of the US population, typically older, rural, and with lower income levels, for whom independent pharmacies are the primary point of pharmacy access (recent estimates place the number of individuals at over 15 million) [46]. Thus, it is particularly important to know whether interventions can operate effectively in independent pharmacy venues.

As we have previously indicated, our single-site pilot, which preceded this study, was successful [37], whereas this study encountered multiple barriers, even though they were conducted within the same small, independent pharmacy group. Our subjective qualitative assessment is that these were meta-structural barriers—perhaps common to independent pharmacies or related to the implementation decisions—and not a function of the individuals in the independent pharmacy group. Further, many of the barriers we encountered did not appear to be especially related to the program’s focal area (ie, naloxone distribution).

**Barriers Specific to Pharmacy Naloxone Distribution**

The research literature has identified several barriers that can occur when implementing pharmacy-based OEND programs, but interestingly, this study of the PharmNet intervention never encountered most of these barriers (though it encountered others). In some cases, this may have been due to the intervention’s design, as we spent considerable time in the development phase determining how we might obviate frequently discussed implementation issues. For example, multiple publications have identified that reimbursement for products and services can be an implementation barrier (eg, for the costs of naloxone, pharmacist time, or other program features) [38,47]. In certain program structures (eg, where free or reduced cost naloxone doses are unavailable), patients’ out-of-pocket costs to purchase naloxone can also be a concern [48]. However, PharmNet included a planning step where the research team negotiated with nonprofit organizations to procure sources of no-cost naloxone. This meant that pharmacies could continue selling naloxone where appropriate, but that they also had the ability to provide free doses when indicated (eg, to patients who could not afford it) without needing to find a source of reimbursement.
Similarly, while pharmacy-based counseling is sometimes included in pharmacy OEND interventions, we were concerned about its feasibility in low-resource pharmacies, especially after COVID-19. Thus, for PharmNet, we opted to provide referral and resource cards in prescription bags that were tailored to each unique geographic location. In doing so, we attempted to avoid common barriers reported by similar studies such as lack of time or space for counseling [48]. Another larger study in 2 pharmacy chains also reported adaptations resulting from COVID-19, such as “streamlined counseling and drive-thru provision adaptations ...” [49].

Further, while a study of opioid overdose prevention programs in pharmacies identified barriers related to pharmacy leadership support [48], our perception is that the leadership team and pharmacy management in place at this independent pharmacy group were incredibly motivated, competent, and willing to support this intervention to the best of their ability—and it appeared that they were primarily limited by factors of raw capacity. In addition, though our pharmacist and pharmacy technician data were not collected from all intervention pharmacies, the limited data set that we procured did not identify any substantive concerns around comfort with dispensing naloxone.

**Barriers Related to Independent Pharmacies as Scalable Intervention Sites**

We intentionally designed this pilot trial to be pragmatic, meaning that the implementation environment would mirror real-world practice [39]. Our primary concern was that the resources provided as part of an intensive trial support system would introduce a kind of heterogeneity of treatment effect [50], where pharmacies working to conduct the intervention outside of the context of the RCT would be systematically different by virtue of not having the same startup support. This would potentially inflate the effect size of the intervention within the study relative to its true effectiveness. Therefore, for individuals working in single pharmacies (eg, lead pharmacists, pharmacy technicians, and other staff members), we did not plan any direct face-to-face interaction with our team. Instead, the intervention materials themselves—introductory videos, instructions to the overall leadership of the organization, and materials, along with a planned fidelity check—were the primary means of dissemination.

However, the pharmacy practice environment is also experiencing a variety of substantive external pressures. For example, a 2022 survey from the National Community Pharmacists Association found nearly one-quarter of responding pharmacy owners or managers had difficulty filling pharmacist roles, and 88.8% had similar difficulty filling pharmacy technician positions [51]. A 2019 survey of full-time pharmacists found that even though independent pharmacists had higher job satisfaction, organizational commitment, and perceived control technician positions [51]. A 2019 survey of full-time pharmacists found that even though independent pharmacists had higher job satisfaction, organizational commitment, and perceived control.

We suspect that these or similar external stressors played a meaningful role in the outcomes of this trial. Lessons from remote decentralized clinical trials, for example, highlight how reducing the research burden on some elements of a team or partnership may inadvertently shift the burden onto others working in the field [54]. In other words, eventually, someone must do the work, and when staffing levels are low and exogenous stressors (eg, a COVID-19 outbreak) occur, an unreasonably large volume of responsibility may accrue to a small number of people. This is a particular concern due to the prevalence of pharmacist burnout, which a systematic review recently estimated to exceed 50% [55], though a slightly older review reported a lower mean percentage [56] (both reviews indicated heterogeneity among included studies). In this case, while we do not have (nor are intending to imply) any direct evidence of burnout, per se, we noted that there was not a “deep bench” of staff and that when illnesses or similar issues occurred in these independent pharmacies, the work was often covered by others who already had full-time (or greater) workloads.

In contrast, in one well-conducted, harm reduction–focused, pragmatic RCT of 175 community chain pharmacies, the researchers encountered both COVID-19 and wildfires [57]. Their study team conducted the majority of their fidelity checks face-to-face and had regular phone contact with the pharmacies. Their published protocol states the research team maintained a “close collaboration and regular meetings with the pharmacy corporate leadership.” Unexpected circumstances that arose were sometimes able to be mitigated by pharmacy corporate leadership (eg, the provision of additional pharmacists to relieve pharmacists from their regular work duties so that the onsite “academic detailing” could be conducted). These types of resources and supports may not be accessible to most independent pharmacies.

**Do Fidelity Checks Contribute to Intervention Effectiveness?**

The major differences between our single-site pilot study (which was completed successfully and which produced positive outcome data) [37] and this follow-up study remain of interest to our team. One of our working theories relates to the nature of implementation fidelity checking that occurred. Implementation fidelity checking has long been understood as an important component of implementation science [58], though community pharmacy intervention studies do not always report implementation fidelity tools or processes [59].

Our single-site pilot study incorporated face-to-face fidelity checks on a regular basis [37]. This involved a study investigator regularly visiting the pharmacy in person, speaking with staff members and pharmacists, obtaining interim information, and identifying necessary points of action. In designing this follow-up study, we did not consider the effects that regular in-person fidelity checking might have had on intervention effectiveness in our single-site pilot. In other words, we do not know how much of the implementation effectiveness in the original study was a direct or indirect result of the routine physical presence of a researcher in the pharmacy. It is not
necessarily the case that a single-site pilot is an insufficient first step to prepare for a larger-scale study, but rather, it seems that researchers might benefit from carefully examining the ways in which intensive fidelity procedures may actively contribute to successful implementation rather than merely documenting what happened.

**Limitations**
As noted throughout this paper, there were numerous limitations that resulted in our reporting of fidelity encounter data and limited outcome measures. Even though this study was preregistered, due to the differences in the data collected from what was planned, we could not test the planned hypotheses. This study should therefore be considered exploratory. In addition, while we carefully consider the context of the study in our Discussion section, the ideas presented therein are hypotheses only and should not be interpreted as definitive statements of fact.

**Conclusions**
Independent pharmacies, especially in rural areas, will likely continue to be key parts of US health care teams. For example, in April 2023, the Express Scripts business of Evernorth, a subsidiary of The Cigna Group, announced that they are extending their efforts to expand health care in rural communities via independent pharmacies [60]. As the prevalence of fatal opioid overdose remains high, multiple avenues to prevent fatality are warranted. Even though nasal formulations of naloxone are now available over the counter, pharmacies have a role in creating awareness and fostering accessibility for patients for whom the cost is prohibitive. As one peer reviewer aptly noted, “the optimal means of naloxone community distribution remains to be determined.”

In terms of broader program implementation considerations for pharmacies, it may be the case—especially for independent pharmacies—that the start of a new initiative needs to be accompanied by more substantive support in the current pharmacy practice environment. If a trial is conducted over a longer period, support could in theory be withdrawn, and effectiveness measured longitudinally. However, we could not, with the data obtained from this study, disentangle issues around fidelity checking and externalities from those related to the overall pharmacist workload and burden and the intervention mechanics.

The strength of this paper is its detailed process description and transparent disclosure of the issues that affected the intervention. Given the likely importance of independent pharmacies to the national overdose response effort, we encourage further implementation science research that is specific to independent community pharmacies, which are often collapsed with other types of pharmacies but that have unique facilitators and barriers to intervention uptake.

Abstract

Background: Twitter is a common platform for people to share opinions, discuss health-related topics, and engage in conversations with a wide audience. Twitter users frequently share health information related to chronic diseases, mental health, and general wellness topics. However, sharing health information on Twitter raises privacy concerns as it involves sharing personal and sensitive data on a web-based platform.

Objective: This study aims to adopt an interactive approach and develop a model consisting of privacy concerns related to web-based vendors and web-based peers. The research model integrates the 4 dimensions of concern for information privacy that express concerns related to the practices of companies and the 4 dimensions of peer privacy concern that reflect concerns related to web-based interactions with peers. This study examined how this interaction may affect individuals' information-sharing behavior on Twitter.

Methods: Data were collected from 329 Twitter users in the United States using a web-based survey.

Results: Results suggest that privacy concerns related to company practices might not significantly influence the sharing of general health information, such as details about hospitals and medications. However, privacy concerns related to companies and third parties can negatively shape the disclosure of specific health information, such as personal medical issues ($\beta=-.43; P<.001$). Findings show that peer-related privacy concerns significantly predict sharing patterns associated with general ($\beta=-.38; P<.001$) and specific health information ($\beta=-.72; P<.001$). In addition, results suggest that people may disclose more general health information than specific health information owing to peer-related privacy concerns ($t_{165}=4.72; P<.001$). The model explains 41% of the variance in general health information disclosure and 67% in specific health information sharing on Twitter.

Conclusions: The results can contribute to privacy research and propose some practical implications. The findings provide insights for developers, policy makers, and health communication professionals about mitigating privacy concerns in web-based health information sharing. It particularly underlines the importance of addressing peer-related privacy concerns. The study underscores the need to build a secure and trustworthy web-based environment, emphasizing the significance of peer interactions and highlighting the need for improved regulations, clear data handling policies, and users’ control over their own data.

**Introduction**

**Background**

Reports and analyses highlight that approximately 60% of health-related tweets contain links to health-related websites [1]. Twitter users frequently share health information related to chronic diseases, mental health, and general wellness topics [2]. Twitter is a popular platform for health-related conversations because it allows users to share their thoughts, experiences, and information in real time [3]. This platform can be particularly useful for sharing information about health events, such as disease outbreaks or public health campaigns. In addition, Twitter can be used to connect with others with similar health concerns or interests and to access information from health care professionals and organizations [4]. Twitter is a social media platform with a character limit, which makes sharing detailed information about health issues difficult. Moreover, the information shared on Twitter may not always be accurate or reliable, as it is not always fact-checked or verified. However, Twitter is a common platform for people to share opinions, discuss health-related topics, and converse with a wide audience. According to a survey conducted by the Pew Research Center, 21% of Twitter users have used the platform to share information about a health condition [5]. The survey also found that 20% of Twitter users have followed a health organization or medical professional on the platform, and 15% have searched for information about a health condition on Twitter. Users often express their views about health policies, medical breakthroughs, health care services, and public health issues [6]. Health professionals, researchers, advocacy groups, and patients actively participate in these discussions, contributing diverse perspectives and sharing evidence-based information. This open and rapid exchange of ideas allows health information dissemination and facilitates conversations that can influence public opinion and policy decisions [7].

Sharing health information on Twitter raises privacy concerns as it involves sharing personal and sensitive data on a public platform [8]. Information privacy refers to individuals’ control over collecting, using, and disclosing their personal information. Regarding sharing personal health information, web-based information privacy refers to protecting sensitive health data from unauthorized access, secondary use, or disclosure [9]. It involves ensuring that individuals can make informed decisions about how their health information is shared and used and that appropriate safeguards are in place to protect the confidentiality and security of this information. The potential privacy risks associated with sharing health information on Twitter can be grouped into 3 reasons. First, potential identification and disclosure of personal information—sharing health information on Twitter can inadvertently lead to disclosing personally identifiable information. A study found that anonymized data from health-related tweets could be reidentified to reveal the identity of users [10]. Researchers were able to reconstruct personal health stories and connect them to specific individuals, highlighting the potential privacy risks involved. Second, data mining and analytics— third parties can analyze and use health-related tweets for various purposes, including targeted advertising or creating consumer profiles. Researchers analyzed tweets related to mental health and found that the content could be used to predict users’ self-reported diagnoses, medication use, and other personal information [11]. This demonstrates the potential for extracting sensitive health-related data from Twitter. In addition, a study used deep neural networks to identify personal health experience tweets, highlighting the potential for using Twitter as a data source for health surveillance studies [12]. Third, public disclosure of sensitive health information—sharing health information on Twitter might inadvertently expose individuals to public scrutiny and judgment. A study examined tweets related to mental health and found that users often disclosed personal experiences, symptoms, and treatments [13]. Although this sharing can provide support, it can also expose individuals to potential stigma, discrimination, or unwanted attention.

Previous studies suggest that individuals may be comfortable with sharing general information that is not sensitive on social media [14]. However, people may not be likely to share personal information, especially health-related data, owing to privacy concerns [15]. According to previous studies, privacy concerns can arise from companies’ information collection and use policies in the age of medical big data [16] and web-based social interactions that may threaten information privacy [17]. Twitter is reported as an important data set for vendors, researchers, and medical companies to collect health-related information [18]. Many medical companies collect health information and patient experiences from Twitter for big data analysis to find patterns for public health management [19]. Although big data collection and data mining techniques could help generate intelligence for monitoring public health issues, they can cause privacy concerns. Reports highlight that many Twitter users have experienced invasion of privacy owing to companies’ collection, sharing, and analytics practices that use information from their tweets, including private health information [20].

Although there are various studies of vendor-related privacy concerns [21] and peer-related privacy concerns [22], little is known about whether these 2 aspects of privacy concerns may collectively influence information-sharing behaviors. As privacy violations can be related to peers (such as inappropriate comments and unauthorized retweeting) and companies (sharing personal information with third parties), more studies are required to examine whether information-sharing disclosure can be affected equally by vendor-related and peer-related privacy concerns. In this study, we aimed to determine whether both aspects of privacy concerns (ie, concern for information privacy [CFIP] and peer privacy concern [PrPC]) can mutually affect both aspects of privacy concerns (ie, concern for information privacy [CFIP] and peer privacy concern [PrPC]) can mutually affect
public and private health information on Twitter would be the main contribution that makes this study different from others.

This argument is built based on 4 reasons. First, although the main interactions on social media are mainly peer oriented, vendors can still collect a lot of personal data (such as health information) without authorization and use it for unconsented purposes [23]. There have been instances of social media platforms, including Twitter, being used by organizations for health-related data mining and analysis [24]. Twitter data can provide valuable insights into health-related trends for health care organizations through analytics [25]. Researchers and companies (such as pharmaceutical manufacturers) have used Twitter data to track and analyze health-related trends, including disease outbreaks, medication use, and public health concerns [26]. For example, a study found that Twitter data could be used to track the spread of influenza and predict outbreaks [27]. Another study uncovered that Twitter data could be used to monitor adverse drug reactions and identify potential safety concerns [28]. Pharmaceutical companies have also used Twitter data to monitor medication use and patient experiences. For example, a study reported that Twitter data could be used to monitor patient experiences with antidepressant medications [29]. Moreover, it is common for organizations and vendors, including those in the health care industry, to monitor social media platforms to gather insights about consumer opinions, preferences, and trends [30]. Twitter, as a popular social media platform, has been used for these purposes [31]. Health care organizations and vendors may collect health-related information, such as discussions about medical conditions, treatment experiences, and patient preferences, from public Twitter profiles [19]. These insights can be valuable for marketing and market research purposes.

Second, although the primary purpose of peer-to-peer (P2P) interactions on social media is to maintain social connections with peers and there are no explicit business-to-consumer interactions, companies can still use social media analytics to investigate published health information. Companies can leverage various analytics tools to gather and find meaning and patterns in data collected from social channels to support business decisions (such as predicting the risk factors to manage public health) [32]. Third, individuals share a variety of information (such as about lifestyle, health status, chronic issues, and medication) on social media, which can be more sensitive than conventional e-commerce information (such as transaction records). Disclosing a wide range of information across social media platforms could raise concerns about whether companies and peers misuse the shared data (eg, health information). Fourth, Web 2.0, a fundamental technology supporting social media, mainly focuses on bilateral relationships between peers. However, it does not remove traffic between companies and social media users. Thus, peers can comment on conversations about a user’s health condition and share others’ personal health information on their own channels. In contrast, companies can use big data analytical tools to collect, use, or share users’ personal health data with third parties.

Study Objectives
The main objective of this study was to investigate the concept of information privacy concerns in the context of social media based on both vendor-related and peer-related aspects. To do so, we used the survey research methodology and Twitter as the empirical context. We also relied on theories discussing 2 dimensions of information privacy (ie, CFIP and PrPC) as the theoretical foundation of our proposed model. In this study, CFIP, emphasizing both consumer perspectives and company responsibilities, represented privacy concerns related to web-based practices of companies and vendors (such as collection and sharing of self-shared information), and PrPC referred to privacy concerns about losing control over digital communications and web-based interactions with peers. Thus, we suggest that information privacy on social media can be multidimensional, focusing on privacy violations associated with companies’ (vendors’) practices and sharing behaviors of peers. The integration of CFIP and PrPC can comprehensively present the entirety of privacy concerns about web-based health information. This study contributes to both theory and practice. We shed more light on information privacy conceptualization in the context of social media. This study also provides an interactive outlook and practical recommendations for handling privacy issues by explaining how web-based vendors and peers may cause privacy violations when dealing with health information (general and specific) shared over the web.

Variable Conceptualization, Theoretical Foundation, and Research Hypotheses

General and Specific Health Information
Individuals can use web-based channels to share general health information, such as information about treatments, medications, side effects, hospitals, medical costs, and healthy behaviors [33]. For instance, people are likely to tweet about general obesity-related topics, such as the relationship between fast food and weight gain [34]. Another study identifies general tobacco-related tweets (such as information about smoking, cigarette risks, and quitting) as the primary conversational data sets for health-related topics on Twitter [35]. Moreover, people can use tools such as Twitter to share specific health-related information, including past medical history, allergies, personal medications, private health issues, and signs and symptoms. For example, a study indicates that people disseminate information about diagnoses, advice based on personal experience, use of specific medications, side effects, negative reactions, and treatments on Twitter [31]. Another study highlights that people use Twitter to share their COVID-19-related symptoms and personal health issues during the early stages of the pandemic [36]. Sharing public and private health information can be valuable for web-based peers and affect their health-related decisions. General information can enable web-based users to find some facts about hospitals, physicians, and diseases. Disseminating specific information can share important insights and advice based on personal health conditions, medical treatments, care planning, and medical experiences with chronic diseases. General health information can be publicly available regardless of personal experiences. However, specific health information...
can be unpleasant to share because it may contain more private information. As health information dissemination has 2 sides, questions still remain as to what dimensions of information privacy may strongly affect sharing behaviors on Twitter.

**CFIP Constructs**

There is evidence suggesting that companies use tweets to collect health information. For example, reports show that public health researchers use Twitter data to study the world’s health. A recent study indicates that the amount of textual health-related data, which could be personal, collected by various organizations is growing (especially during the COVID-19 pandemic) [37]. Another study argues that health care researchers and research companies have used social media data sources such as Twitter to study public health [19]. Owing to the importance of the Twitter database, the Centers for Disease Control and Prevention (CDC) designed a document to guide employees and contractors on using Twitter to disseminate health information and engage with individuals and partners [38]. A study indicates that companies increasingly use Twitter to share public health information and collect real-time health data using crowdsourcing methods [39]. Information privacy, which refers to people’s ability to control their information, is essential in e-commerce and social media [40]. Several studies explain the privacy concerns specific to the mobility data collection context [41]. Thanks to emerging technology (such as Web 2.0), protecting personal information has become a growing concern for web-based users. CFIP is a general concern about how organizations can use and protect consumers’ information [21]. CFIP explains concerns about organizations’ information collection practices, use policies, and access to consumers’ personal information [42]. Previous studies indicate that examining consumers’ concerns about how companies (vendors) may use their personal information significantly affects their willingness to engage in web-based transactions actively [43].

In this study, following most previous studies, CFIP is posited as a multidimensional construct with 4 dimensions to measure individuals’ concerns about organizations’ information privacy practices [44]. Collection pertains to individuals’ concerns about what web-based information is collected and whether such information is stored properly. Unauthorized secondary use explains individuals’ concerns about whether the information collected for a consented purpose may be unethically and illegally used for other purposes without obtaining authorization. Improper access implies individuals’ concerns about whether unauthorized people (entities) can access, view, and share their information. Finally, concerns about errors reflect whether individuals’ information is appropriately protected to minimize accidental or intentional errors [44]. Therefore, the multidimensional scale of CFIP reflects the complexity of individuals’ privacy concerns [21]. According to Stewart and Segars [40], CFIP is developed as a second-order construct with 4 reflective first-order factors. In this study, we also considered CFIP as a high-order construct with reflective factors. The logic behind conceptualizing this construct as reflective was that the privacy concerns related to companies are reflective of the 4 dimensions (i.e., collection, unauthorized access, errors, and secondary use) and the expected interactions among them. Therefore, these dimensions can reflect the same theme and may covary.

Although sharing information on Twitter is more oriented toward interactions with web-based peers, privacy concerns about the collection and misuse of digitized health information by vendors and companies still remain significant. Previous studies provide strong evidence suggesting that web-based users of Twitter are concerned about several aspects of their information privacy, from collection of a lot of data to misuse [45]. Our study focused on individuals’ perceptions about general CFIP owing to policies and practices of vendors and organizations that may collect, access, and use health information shared on Twitter rather than concerns about a particular vendor. According to the four dimensions of the CFIP construct, individuals who demonstrate high privacy concerns believe that (1) a lot of health information is collected by organizations from users’ Twitter accounts, (2) such health information is not appropriately protected against possible errors, (3) various organizations may use health-related information on Twitter for other purposes without authorization (such as data mining, surveillance, research, and business intelligence), and (4) there is lack of visibility into accurate security measures to control who can access and use health information from tweets.

Thus, the CFIP construct can be extended to privacy concerns about a wide range of vendors and companies accessing and using tweets containing health information. This concern is not the same as privacy issues owing to interactions with a specific vendor in the context of e-commerce (such as retail platforms). In these conventional interactions, privacy concerns may focus on personal, factual information shared in web-based transactions and services (such as demographic information). However, CFIP in the social media domain deals with concerns associated with the following uncertainty: which organizations collect personal posts, which unauthorized entities can view and share information, why and how the information is used (for instance, data mining), and how the information is protected from internal and external errors and misuse. Therefore, we argue that CFIP cannot be ignored in examining information privacy in social media because users may not have direct relationships with organizations on these digital platforms, but they are still concerned about how their posts can be collected and misused by various companies.

Sharing general health information could indicate a user’s rich medical information and wealth of medical knowledge. In contrast, sharing specific health information can show that the user may want to contribute or seek informational and emotional support by disseminating personal experiences and medical history. However, when privacy concerns about the collection and misuse of shared data by organizations are not addressed, users are not likely to disseminate general or specific health information on Twitter. Moreover, we can expect that because specific health information is more sensitive and private, web-based users may generally become more cautious about sharing it. Therefore, we hypothesized the following:

- **Hypothesis 1A (H1A):** CFIP negatively influences general health information dissemination on Twitter.
• Hypothesis 1B (H1B): CFIP negatively influences specific health information dissemination on Twitter.
• Hypothesis 1C (H1C): CFIP has a more negative effect on specific health information dissemination than on general health information sharing on Twitter.

**PrPC Constructs**

Owing to the nature of Web 2.0, users can communicate, create content, and share it via communities, social networks, and virtual worlds [46]. Web-based users can share a wide range of information and experiences on social media. The information can be objective (based on factual data) or subjective (based on personal interpretation, feelings, tastes, or opinions) [47]. The range can start with demographic information (eg, age, gender, and race); continue with political views, humanitarian opinions, and health information; and end with comments on others’ posts [48]. People can use different formats, such as text, pictures, and videos, to disseminate information. Peers are important components of social networks; however, they can threaten information privacy through inappropriate sharing behaviors and unintended consequences of web-based interactions [49].

Web-based transactions with peers on social media affect users’ decisions about whether they want to reveal their personal information (such as feelings and likes) and create an image consistent with their personal identity [50]. In this study, peers could be web-based friends who may have long-lasting and affect-laden connections with a user and any web-based users who interact through social media channels. Previous studies highlight the importance of PrPCs in the context of web-based interpersonal relationships where other peers can access and view a user’s web-based information [51]. Peer-related privacy refers to possible risks of privacy invasion because of direct and indirect web-based interactions with peers [17]. Social bots and fake and spam accounts can also raise privacy violation risks by potentially exposing several peers to a focal user’s posts using machine learning algorithms [52]. Previous studies indicate the threat of using social bots on social networks, increasing the likelihood of privacy breaches where even more private user data are exposed [53]. Understanding who can access web-based information (such as a post related to signs and symptoms of depression) and with whom such information is shared can significantly raise privacy concerns. For example, a study shows that sharing information with only selected friends in social networking services perceived higher control than sharing information with all friends [54].

Thus, information-sharing behaviors on social media may erode the ability of users to control their virtual space and personal boundaries. Leaving an inappropriate comment for a user who posted about seeking ways to lose weight, can increase privacy concerns about lack of control to maintain the privacy of their Twitter space. A study posits that managing the privacy of virtual territory refers to defining the level of access to and interaction others can have within a user’s territory (eg, allowing peers to see or comment on the post) [55]. Peers can also play a bilateral role in web-based social interactions. They can intentionally or unintentionally share a user’s personal health information with others and expose the user to others’ personal information that they might not like to view. The user may think that if others’ personal health information has been shared with me, my posts can also be revealed to others. Thus, communication privacy can significantly affect how individuals and relational parties share private information on social media [56].

A recent study defines PrPC as the sense of inability to control personal boundaries in web-based interactions owing to web-based peers’ behaviors [22]. They describe this term using 4 reflective dimensions: peer-related information privacy, psychological privacy, virtual territory privacy, and communication privacy. Peer-related information privacy denotes concerns about who can see what type of information and when and how such information is disclosed to other web-based peers. For posts shared by a user, the main concern is unauthorized access and secondary use of data by other peers. On Twitter, this can happen through retweeting and commenting. Peers can also initiate posts or conversation threads to disclose a user’s personal information without authorization. A privacy concern is about the accuracy of personal information shared by peers. Thus, peers’ sharing can be a source of private information leaks.

Psychological privacy explains the control over input information coming from others to shape feelings, opinions, and beliefs. Information sharing is 2-way traffic in social media (ie, from a user to peers and from peers to a user) [57]. As people are exposed to posts shared by celebrities, business magnates, politicians, and other web-based users, their behaviors and opinions are increasingly affected by input information from peers. Peers on social media can influence users’ behavior by applying social influence through public comments on posts [58]. Privacy concerns become more intense when users’ opinions and psychological independence are intentionally manipulated by social bots [59]. In this situation, users are not able to make a decision independent of other web-based peers’ ideas. Moreover, receiving a lot of unwanted information from peers may influence value systems, attitudes, identities, and choices.

Virtual territory privacy represents concerns about an individual’s inability to achieve control over other peers’ interactions with their virtual properties (such as Twitter accounts) and shared conversations (postings). Previous studies suggest that the sense of ownership and emotional attachment to personal territory can be generalized to the social media domain [60]. Similar to other personal belongings, virtual properties are seen as private. Thus, any unwanted addition to or revision of personal information can be considered as an intrusion, which may increase privacy violation risks [45]. Finally, communication privacy reflects an individual’s lack of control over how and when other peers can make direct web-based conversations. For example, peers may use various communication tools to engage individuals in a group conversation about potentially embarrassing or stigmatic health-related topics. Then, users may feel pressured by being involved in such undesirable conversations with unfamiliar people.

Individuals may become more likely to share general or specific health information on Twitter when they think it is useful for...
other web-based peers (eg, they can make better medical decisions). However, peer-related concerns may prevent them from disseminating such information. Peers are participants in social media and can freely collect and share information that is sometimes considered as unwanted interference. For instance, if peers retweet a post containing personal information about postsurgery recovery plans without authorization or tag a user who posted general educational content about HIV, these web-based interactions may violate privacy needs and raise privacy concerns. In return, users may change the pattern of health information dissemination and become more cautious in sharing medical facts or personal experiences. Thus, we formulated the following hypotheses:

- **Hypothesis 2A (H2A):** PrPC negatively influences general health information dissemination on Twitter.
- **Hypothesis 2B (H2B):** PrPC negatively influences specific health information dissemination on Twitter.
- **Hypothesis 2C (H2C):** PrPC has a more negative effect on specific health information dissemination than on general health information sharing on Twitter.

### CFIP and PrPC Are Privacy Concerns for Twitter Users

Although tweets are publicly accessible by default, users likely expect some degree of privacy and control over their personal health information shared on the platform. Previous literature has found that even when posting content publicly on social media, individuals still have privacy interests and concerns about how their data might be used or accessed [61]. General health information shared publicly on Twitter, such as mentions of hospitals, physicians, and common diseases, is not considered protected or private. However, more specific personal health details, such as past medical history, allergies, medications, and current symptoms, could reveal private information about an individual’s health status. Although these details may be shared publicly by default on Twitter, users likely still have privacy concerns about this content being widely disseminated or used without their consent.

The concepts of CFIP and PrPC capture these types of privacy concerns. Although users are voluntarily sharing health information publicly on Twitter, they may still desire control over how this data are accessed and used. CFIP reflects concerns about using or sharing personal health data by third parties such as researchers or companies without the user’s knowledge or permission. Even if users willingly post health information publicly, they may still desire control over how that data are collected, analyzed, or shared by entities such as researchers, pharmacies, insurance companies, and so on. PrPC represents concerns about controlling boundaries around health disclosures and limiting exposure to certain audiences, such as employers or insurers, who could misuse the information. Users must balance sharing personal details with managing social risks if the information reaches unintended viewers such as employers, family members, or friends. Thus, although Twitter data are technically public, users are likely to have nuanced privacy interests surrounding their health disclosures. Therefore, concepts such as CFIP and PrPC are useful for quantifying expectations regarding control, anonymity, and audience boundaries that persist even when posting health care–related content openly over the web.

### Difference Between the Conceptualization of CFIP and PrPC

#### Overview

We used an interactive approach to provide a holistic view of information privacy in the context of sharing health information on Twitter. Using this approach, this study actively engaged with the 2 aspects of privacy concerns (CFIP and PrPC) in a dynamic way, considering the interplay between them, as opposed to treating them as isolated, independent factors. Therefore, we examined how these 2 aspects of privacy concerns interact with each other and how this interaction affects individuals’ behavior on Twitter. It should be mentioned that the dimensions used for CFIP and PrPC may differ because of the different nature of the relationships and contexts involved. Although the underlying concept of privacy concerns remains the same, the specific dimensions or factors that contribute to CFIP and PrPC may vary owing to the distinct characteristics of vendors and peers as information trustees.

#### Role and Control

Vendors typically have a professional or business relationship with individuals, where they are entrusted with handling personal information for specific purposes (eg, health care providers and web-based retailers). In this context, individuals may be concerned about vendors’ control over their information; how it is collected, used, and shared; and the potential for data breaches or unauthorized access.

#### Trust and Reputation

CFIP dimensions often include factors related to trust and reputation, such as trustworthiness, perceived reliability, and credibility of vendors. As individuals rely on vendors to handle their personal information responsibly, dimensions related to trust and reputation become important for CFIP measurement.

#### Legal and Ethical Considerations

CFIP dimensions may also include factors related to legal and ethical considerations, such as compliance with privacy laws, informed consent, and transparency in data practices. Individuals may be concerned about whether vendors meet the legal requirements and ethical standards in protecting their health information.

In contrast, peers, who are individuals within an individual’s social network or community, may have different dimensions of privacy concerns. Social interactions, trust, reciprocity, and the potential for social consequences typically characterize peer relationship dynamics. Some factors that could influence PrPC dimensions include the following.

#### Social Norms and Expectations

PrPC dimensions may reflect concerns about social norms and expectations related to privacy within the peer group. Individuals may worry about how their health information might be perceived, shared, or used by their peers and the potential impact on their social relationships or reputation.
Social Influence and Peer Pressure
PrPC dimensions may capture the influence of peer pressure or the fear of negative social consequences. Individuals may be concerned about potential judgment, stigma, or discrimination based on their health information within their peer group.

Personal Boundaries and Intimacy
PrPC dimensions may include factors related to personal boundaries and the level of intimacy within peer relationships. Individuals may be concerned about the extent to which personal health information should be shared with peers and the potential impact on their privacy, autonomy, and self-disclosure.

Although the underlying concept of privacy concerns is present in both CFIP and PrPC, the dimensions may differ owing to the distinct characteristics and dynamics of the relationships involved. Thus, considering these differences when developing measurement instruments is important to accurately capture individuals’ concerns regarding privacy in different trust relationships.

Research Model
The model focuses on health information and Twitter (as the research context). There are a few critical differences in the privacy concerns around health information compared with other types of information. First, health information is considered to be very sensitive and private. It can reveal details about medical conditions, treatments, prescriptions, family history, and so on. Other types of information, such as social media posts or shopping habits, are generally not as sensitive. Second, health information has strict legal protections such as Health Insurance Portability and Accountability Act in the United States and General Data Protection Regulation in the European Union. These laws place restrictions on how health data can be collected, shared, and used. Other information does not have the same level of legal safeguards. Third, health information could potentially be used to discriminate against people in areas such as employment, insurance, and so on. This type of discrimination is legally prohibited, but the risk remains owing to the sensitive nature of the data. Other data, such as social media posts, have less potential for this type of discrimination. Finally, breach of health information is considered very serious, given the sensitivity of the data. Strong security protections are needed, and breaches can carry heavy penalties. Breaches of other types of data may not have the same level of severity.

Regarding privacy on social media, there are some key characteristics of the concerns around Twitter compared with other platforms. First, most Twitter content is public by default, whereas other platforms such as Facebook allow more privacy controls. This can raise concerns about a lack of control over dissemination. Second, tweets are often archived and searchable indefinitely; therefore, there are concerns about permanent availability even for “deleted” content. Other platforms may have more ephemeral sharing. Third, the open nature of Twitter makes it easy for tweets to spread rapidly and become viral compared with platforms such as Instagram, where sharing can be more controlled. This raises concerns about loss of context and lack of containment. Finally, the ability to create anonymous accounts on Twitter is greater than that on platforms such as Facebook that require real identities. This raises concerns about harmful speech, misinformation, and so on.

We proposed the following research framework for disclosing general and specific health information on Twitter by integrating 2 aspects of information privacy concerns (Figure 1). As several studies may have found empirical evidence for the hypotheses proposed in this study, we need to clarify what is new in our study. First, this study integrated both aspects of privacy concerns for the first time in a model. Previous studies examined either privacy concerns related to companies’ practices with web-based information (CFIP) [62] or concerns related to the web-based behaviors of peers (PrPC) [63]. However, as mentioned in the previous section, individuals may be concerned about disseminating their health information on Twitter because companies’ collection practices and web-based peers’ behaviors could violate their privacy. In this study, we wanted to examine whether both aspects of privacy concerns (ie, CFIP and PrPC) can collectively change health-related information-sharing decisions or whether one can dominate the other. For instance, whether the nature of the relationships and contexts with 2 different information trustees (ie, vendors and peers) can shape information dissemination behavior. Second, as Twitter is considered as a rich database for collecting individual health-related information to examine sentiments and manage public health [64] and reports highlight that individuals may be concerned about web-based interactions with peers [65], Twitter would be the best research context to meet the goals of this study. Third, this study distinguished between general and specific health information. Thus, we could offer more insights about privacy concern levels and disclosure behaviors related to the 2 types of health information on Twitter. These 3 reasons can make our study different from previous studies in the privacy literature.

In addition, we controlled for several variables such as age, gender, education, Twitter experience, privacy violation experience, and misrepresentation of identity on Twitter. According to previous studies in the privacy concern domain, some demographics, such as age [66], gender [67], and education level [68], can affect people’s intention to disclose information on social media. Moreover, the impacts of these variables have been examined in previous studies investigating individuals’ perceptions about sharing eHealth-related information [69,70]. The effects of these variables are often controlled in previous studies in the field of information privacy threats [71]. Thus, we assumed that individuals of different ages, genders, and educational levels engage in various disclosure behaviors because they have diverse backgrounds, individual characteristics, and personal differences. Therefore, we considered these demographics to be control variables in the proposed research model.

Moreover, the effects of misrepresentation of identity, experience with technology, and privacy violation experiences are controlled in previous studies examining relationships between privacy concerns and self-disclosure [22,42]. Thus, it is believed that individuals with different privacy violation experiences, previous identity misrepresentation, and experiences with Twitter are more likely to demonstrate various
disclosure behaviors. Therefore, we treated these experience-related variables as control variables in our model.

Methods

Research Approach and Survey Development

We administered a web-based survey questionnaire to achieve the defined objectives and test the proposed model and research hypotheses. The survey consists of 4 sections. In the first part, the purpose of the study is described clearly, and a qualifying question is used to select respondents. The question for filtering respondents attempts to screen individuals with a Twitter account. Thus, individuals without a Twitter account are excluded from data collection and analysis. In the second section, respondents are asked to express their perceptions about privacy concerns associated with companies and third parties, peer-related privacy concerns, and health information dissemination behaviors. In the third section, demographic questions (ie, age, gender, education, income, and race) are asked. Finally, the last section focuses on personal privacy experiences (ie, Twitter experience, privacy violation experience, and misrepresentation of identity).

Questions to measure each construct were adapted from validated instruments available in the existing literature. Slight changes in the wording were made to fit the context of this study. We adapted items to measure CFIP (as a second-order construct with 4 dimensions) from the study by Stewart and Segars [40]. Following Zhang et al [22], we also conceptualized and measured PrPC as a second-order reflective construct with 4 dimensions. Previously defined scales to measure general and specific health information disclosure were adapted from the study by Hsu et al [72]. Respondents rated all the measuring items included in the survey using a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Multimedia Appendix 1 shows the questions used in the web-based survey.

Data Collection and Data Analysis

Data were collected in April 2022 by uploading the questionnaire to Amazon’s Mechanical Turk (MTurk). MTurk is a crowdsourcing platform that enables researchers to access data from potential target samples to conduct a study. MTurk has been recognized as an acceptable web-based means for collecting individual-level data. Literature about health care analytics shows a growing number of studies using MTurk for health-related research [73]. Previous studies highlight that MTurk can measure individual perceptions in various domains, such as social media [74]. As the target population of this study was US citizens who use Twitter for web-based interactions, we limited the respondents’ location to the United States. Moreover, 2 attention-check questions were used to remove participants who chose answers without correctly replying to reverse-coded filler items [75]. The filtering questions were as
follows: (1) It does not bother me that my peers may try to influence me through comments on my health-related postings on Twitter and (2) I am not concerned that I have little control over who can start a health-related conversation with me on Twitter. We received 364 questionnaires and excluded 35 (9.6%) that were either incomplete or failed the response quality questions, resulting in 329 (90.4%) valid and usable responses. The average response time to complete the questionnaire was 12 minutes. The descriptive statistics for demographics were performed using SPSS (version 26; IBM). The research model was tested using AMOS (version 26; IBM) within the structural equation model framework.

Ethical Considerations
The institutional review board of Florida International University reviewed and approved the study (approval 112755). According to the institutional review board approval, written informed consent to participate in the study was obtained from all participants. Moreover, the data collected in this study were anonymous. We considered US $1 as an incentive for each respondent to participate in the study.

Results

Instrument Validation
We used confirmatory factor analysis to assess convergent and discriminant validity. Table 1 shows the results of the convergent validity test. The standardized factor loadings for all constructs exceeded 0.7, which is the acceptable range for factor loadings [76]. The composite reliability values and Cronbach α values were above the recommended value of .7, demonstrating the adequate reliability of the constructs [77]. All the values of average variance extracted (AVE) exceeded 0.5, which is the cutoff value [78]. These measures indicated the acceptability of the measurement model’s convergent validity.

Table 2 shows the discriminant validity of the constructs. All diagonal values (square roots of the AVEs) were >0.7 and greater than off-diagonal values (correlations) between any pair of constructs [79]. Thus, the discriminant validity requirements were satisfied for the research model.

Moreover, we checked the convergent and discriminant validity of the second-order constructs. The composite reliability, Cronbach α, and AVE values for CFIP were 0.91, .88, and 0.64, respectively, and these measures for PrPC were 0.94, .89, and 0.72, respectively. The correlation between the second-order variables (eg, CFIP and PrPC) was 0.58. Finally, the square roots of the AVEs for both constructs were >0.7 and higher than the correlations between the constructs. These results confirm an acceptable convergent and discriminant validity for both second-order constructs in the model.

Respondents’ Characteristics

Table 3 shows the participants’ characteristics. The descriptive statistics demonstrate that respondents were fairly distributed across gender, where 52.9% (174/329) were men and 47.1% (155/329) were women. The age range was positively skewed, indicating that most participants were young, with a range between 25 and 34 years (155/329, 47.1%) being high, followed by the range between 35 and 44 years (102/329, 31%). Approximately half (178/329, 54.1%) of the respondents had undergraduate or graduate education levels, which aligns with previous studies highlighting that people with high education levels tend to search more often for web-based health information [80]. The annual income was fairly distributed, with income between US $60,000 and US $79,999 showing a high range (135/329, 41%) among the provided categories. Most respondents were White (174/329, 52.9%), followed by Hispanic and African American individuals. Approximately half (174/329, 52.9%) of the respondents reported using Twitter for 4 to 6 years. Overall, 52% (171/329) of the respondents indicated that they had a privacy violation experience at least once (for instance, their account was hacked), and 38.9% (128/329) mentioned that they tried to use a fake account on Twitter (at least once).

Analysis of the Dimensions

When implementing second-order variables in a measurement model, there are 2 common approaches: the repeated items approach and the 2-step approach [81]. This study used a repeated items approach to measure reflective second-order constructs. In the repeated items approach, the indicators used to measure the second-order construct are included in the measurement model twice: once as indicators of the second-order construct and once as indicators of the corresponding first-order constructs [82]. This approach allows for a direct assessment of both the second-order and underlying first-order constructs in a single measurement model. The repeated items approach provides a holistic view of the measurement model by simultaneously assessing the second-order construct and its underlying dimensions [83]. Using the repeated items approach provides a more integrated perspective about how CFIP and PrPC are influenced by their respective first-order constructs. It allows for a direct examination of the relationships between the second-order construct and its underlying factors.

Both CFIP and PrPC are conceptualized as second-order reflective constructs, consistent with existing literature. A reflectively measured construct shares a common theme across subdimensions; the dimensions are expected to be highly correlated [84]. Table 2 shows that, consistent with reflective measurement, the 4 dimensions of CFIP (ie, collection, unauthorized secondary use, improper access, and errors) are highly correlated with each other. As expected, the 4 dimensions of PrPC (ie, psychological, communication, virtual territory, and peer-related information privacy concerns) are also highly correlated. Results show that the 4 dimensions of CFIP, as first-order factors, load significantly on the second-order construct. The loadings were 0.91 for collection, 0.80 for unauthorized secondary use, 0.95 for improper access, and 0.88 for errors. Therefore, the interaction among 4 dimensions reflects CFIP, which shares a common theme of losing control over information privacy owing to companies’ sharing behaviors. Furthermore, the 4 dimensions of PrPC also load significantly on the second-order construct. The loadings were 0.90 for psychological privacy concerns, 0.92 for communication privacy concerns, 0.86 for virtual territory privacy concerns, and 0.95 for peer-related information privacy concerns. Thus, interactions among these 4 dimensions represent PrPC, which exhibits a shared theme of privacy concerns about losing personal control owing to web-based peer behaviors.

Structural Model and Path Analysis

Consistent with privacy literature, we controlled variables such as age, gender, education, years of experience, privacy violation experience, and misrepresentation of identity in the structural model [42]. Findings demonstrate that when the control variables are present, the coefficients and $R^2$ change significantly. Specifically, when age ($\beta=-.12; \ p=.01$), education ($\beta=.19; \ p=.003$), and privacy violation experience ($\beta=-.58; \ p=.008$) are present in the model, they significantly influence health information disclosure. Thus, the findings confirm that young people with high education levels who have not experienced privacy violations are more likely to disclose health information on Twitter. However, no effects of gender, years of experience, and misrepresentation of identity were found on health information–sharing behaviors. We used the structural equation model technique to analyze the factors affecting health information disclosure on Twitter. The results of model fit indexes exhibit a good fit with the goodness-of-fit indexes ($\chi^2_{353}=2.2; \ \text{goodness-of-fit index}=0.84; \ \text{adjusted goodness-of-fit index}=0.81; \ \text{comparative fit index}=0.90; \ \text{normed fit index}=0.91; \ \text{incremental fit index}=0.90; \ \text{standardized root mean square residual}=0.03; \ \text{and root mean square error of approximation}=0.04$) where all indexes meet their recommended cutoff values [85]. Table 4 depicts the summary of path analysis for 4 hypotheses (ie, H1A, H1B, H2A, and H2B).

Figure 2 shows the standardized path coefficients of the structural model. Support is not found for H1A, which proposes that CFIP significantly influences general health information disclosure on Twitter ($\beta=-.07; \ p=0.16$). In contrast, the findings support H1B by confirming that CFIP significantly attenuates sharing behaviors when disclosing specific health information on Twitter ($\beta=-.43; \ p<.001$). H2A, which posits that PrPC would directly affect the disclosure of general health information on Twitter, is supported ($\beta=-.38; \ p<.001$). The analysis also exhibits that PrPC negatively shapes the sharing of specific health information on Twitter ($\beta=-.72; \ p<.001$), and this significant relationship supports H2B.

Regarding H1C and H2C, an alternative model was created for each hypothesis, and the 2 relationships in that hypothesis were constrained [86]. Next, a 2-tailed $t$ test was used to compare the difference between the alternative and the original model. H1C posits a significant difference between the impact of CFIP on general and specific information–sharing behaviors. As the $t$ value was significant ($t_{165}=3.45; \ p<.001$), we confirm that CFIP imposes a more negative effect on specific health information dissemination than on sharing general health information on Twitter. In addition, H2C posits that people may disclose more general health information than specific health information owing to peer-related privacy concerns. The $t$ value was significant ($t_{165}=4.72; \ p<.001$); thus, the effect of PrPC was more prominent in specific health information sharing than in disclosing general health information on Twitter.

Finally, the model explains 41% of the variance in general health information disclosure and 67% in specific health information sharing on Twitter. The $R^2$ scores suggest that the 2 aspects of information privacy concerns (ie, concerns about the web-based practices of companies and peers’ behaviors) can provide reliable explanatory power to predict the variance in sharing general and specific health information.

Discussion

Principal Findings

Information sharing is one of the most important objectives of social media. People use Twitter for conversation, and information sharing can initiate a web-based exchange of ideas about an issue. As health information is more sensitive than other types of personal information, disclosing such data can raise privacy concerns. Most previous studies have mainly focused on privacy concerns related to companies and vendors as they may collect and use individuals’ personal information for other purposes or may not properly protect the collected information [87]. Few studies have also explained privacy concerns related to the web-based behaviors of peers [22]. However, previous literature did not consider both sides of information privacy concerns in a model in the context of social media. Moreover, disclosure behaviors on social media can be contingent upon the type of health information owing to sensitivity levels. Few studies have examined the sharing
behaviors based on the unique characteristics of general and specific health information [86].

Although both antecedents (CFIP and PrPC) have been examined separately in previous studies, this study’s findings could propose scientific novelty. The study differs from previous research in this field because we integrated 2 aspects of privacy concerns (eg, related to companies and peers) to investigate the disclosure of general and specific health information on Twitter. In this study, we examined whether both aspects of information privacy concerns can jointly influence sharing decisions related to health-related information or whether the effect of one aspect can be overshadowed by the other; for instance, whether the nature of the relationships and contexts with 2 different information trustees (ie, vendors and peers) can influence people to share their health information on Twitter. The findings indicate that privacy concerns related to companies play a more significant role in predicting specific health information than in predicting general health information. Privacy concerns related to companies’ practices reflect the collection and misuse of health information by vendors, such as concerns about using health information for data mining and research purposes [88].

Our findings demonstrate that Twitter users are more concerned about vendors and companies using or sharing their personal health information than general health information. Thus, the dimensions of CFIP (ie, collection, unauthorized secondary use, improper access, and errors) become salient only when people want to disclose specific health information (such as information about their chronic diseases, signs, and symptoms or personal health status). Sharing public health information about hospitals, medical costs, and medications is not significantly affected by concerns about how companies may use such information. A plausible justification is that general health information cannot reflect any personal information associated with an individual, and even if it is used for data mining or big data analysis, it will not violate the user’s privacy needs. Consistent with previous studies [89], individuals may deliberately want to share general health information on social media to increase public awareness and knowledge about a medical situation, such as COVID-19 symptoms and vaccination. Regardless of information accuracy or misinformation, users may engage in sharing their general medical knowledge and public information about treatment options with almost no or minor privacy concerns related to companies and vendors’ collection and use practices.

Our results also show that peer-related privacy concerns can significantly shape both general and specific health information sharing on Twitter. Although Twitter is not the same as web-based health communities designed to share health information, many individuals use tweets to share personal and public health information [90]. Web-based interactions with peers may affect their sharing behaviors as they may feel unable to control who can see, comment on, or exchange the health information they share on Twitter. The dimensions of PrPC (ie, psychological, communication, virtual territory, and peer-related information privacy concerns) are important factors in predicting how users may disclose public and personal health information. However, peer-related privacy concerns are more intense for sharing personal than general health information. This finding indicates that when a user wants to share public information about a disease (for instance, cancer, COVID-19, or HIV), they are still concerned about how peers relate such general information to their profile. This concern becomes more salient when the user decides to reveal personal health information about that disease, such as what treatments or medications they are using daily or what medical procedures they will undergo in the future. Previous studies associate sharing personal health information related to physical health problems or mental disorders on web-based P2P networks with stigma [91]. The more sensitive the health information, the more stigma is attached to sharing such information with peers. Thus, being judged by peers (close friends and other web-based users) because of sharing personal health information may prevent them from disclosing that content on Twitter.

Although results show significant impacts of both aspects of privacy concerns on sharing specific health information on Twitter, peer-related privacy concerns are leading factors in shaping personal health information disclosure, more so than privacy concerns associated with companies and third parties. This result confirms the importance of web-based interactions with peers on social media and how to deal with their sharing behaviors, such as commenting or tagging [60]. This finding implies the critical effects of Twitter friends and the circle of people who can see and share tweets about private health information. Individuals may be first concerned about the Twitter circle and how peers would react to the shared personal information about health status and then become worried about how many companies may access such data and how they would use or share them. Thus, secondary dissemination of personal health information by web-based peers through liking, reposting, retweeting, or commenting on posts is more challenging to the maintenance of privacy controls than secondary use of data or unauthorized access to such private information by companies and vendors. Our finding that peer-related privacy concerns have a strong impact on health information sharing compared with privacy concerns associated with companies and third parties offers a counternarrative to prevalent assumptions in digital privacy research. This could be attributed to Twitter’s highly interactive and public nature, which might accentuate peer-related concerns. Previous studies, mainly those conducted in the context of web-based shopping or general social media use, might have overestimated the role of concerns associated with companies and third parties owing to the commercial and private nature of these web-based activities.

Theoretical Implications

This study may offer some theoretical contributions. First, our findings have implications for information privacy research in social media by integrating the existing privacy concern perspectives. This study can open up the discussions through which privacy needs related to companies, third parties, and peer-related aspects can be addressed. Then, this comprehensive mechanism may strongly affect users’ sharing behavior patterns. Second, this study distinguishes the differences between sharing private and public health information on Twitter. Although disclosing specific health information may help share personal experiences related to various medical situations that could be useful for peers, it is more challenging than disseminating general health information. The findings demonstrate how...
company-related and peer-related privacy concerns could shape the 2 types of information-sharing behaviors. Third, this study investigates the effects of information privacy mechanisms on health information sharing in the context of Twitter. The findings can promote discussions about health information disclosure in other P2P networks such as other social media platforms, virtual worlds, or Metaverse. Fourth, exploring the determinants of information sharing regarding different types of privacy concerns can expand our current understanding of knowledge acquisition. As sharing both general and specific health information on social media can contribute to people’s medical knowledge, addressing the barriers to specific health information sharing and removing the privacy challenges can significantly help the procedures of medical knowledge acquisition from web-based interactions with peers.

The study contributes significantly to the theoretical understanding of privacy concerns in web-based health information sharing. The evidence that peer-related privacy concerns influence more strongly than those related to companies and third parties highlights a potential oversight in theoretical perspectives. Current theories largely view companies as the predominant source of digital privacy concerns, and this may need re-evaluation. The results extend existing theories by emphasizing the role of peer interactions in privacy concerns, particularly in public and highly interactive web-based environments such as Twitter. This recognition of the social dimension of privacy concerns could be integrated into existing theoretical models to provide a more comprehensive framework for web-based privacy behavior. Furthermore, although our study is specific to Twitter and health information, the insights gained may have broad applicability. The potential role of peer-related privacy concerns could be a valuable area of exploration in other social media contexts and in sharing other types of sensitive information. Thus, our findings open up new avenues for theoretical exploration and suggest a need for further studies to fully understand the complexities of privacy behavior in the digital age.

Unlike other research approaches, such as experiments, observational data, or qualitative interviews to assess privacy concerns and information sharing, our study used a quantitative survey approach. This allowed us to capture data from a large and more diverse sample, providing a more robust and generalizable understanding of privacy concerns in web-based health information sharing. The strength of our quantitative approach lies in its ability to establish clear patterns and relationships among various factors influencing privacy concerns. This enabled us to derive a more comprehensive and systematic understanding of the factors that significantly influence privacy concerns and health information sharing on Twitter. In terms of comparison, our findings offer a novel perspective about the role of peer-related privacy concerns in shaping web-based health information–sharing behaviors. Previous studies have predominantly focused on company-related and third party–related privacy concerns. However, our study highlighted the paramount influence of peer-related privacy concerns, thus suggesting a reorientation of focus in subsequent research efforts in this area. Our study also provides quantifiable evidence about the relative influence of peer-related privacy concerns and such privacy concerns associated with companies and third parties on Twitter users’ health information–sharing behaviors. Such quantifiable insights could serve as valuable benchmarks for future studies seeking to measure and compare similar variables in different contexts or on different platforms. Our survey methodology, coupled with a comparative analysis of the findings, underscores the contribution of our study to the field, offering both nuanced insights and broad trends that enrich our understanding of privacy concerns and health information sharing on social media platforms.

**Practical Contributions**

This study also provides several practical and technical implications for promoting privacy protection on Twitter. To promote the sharing of specific health information, it is essential to address privacy concerns related to both companies and peers. However, addressing peer-related privacy concerns is vital to encourage the disclosure of general health information. This is because concerns related to companies and third parties do not significantly predict general health information sharing. Thus, a robust privacy policy cannot be developed regardless of information type. As the 2 types of health information require different ways of satisfying privacy needs, mechanisms and regulations facilitating general and specific health information sharing cannot be the same. Depending on the type of health information, it is essential to customize the ability of Twitter users to control their self-concept and meet different privacy protection requirements. General procedures and privacy policies to regulate the dissemination and use of personal posts are not sufficient to address the information privacy concerns. Twitter should allay users’ privacy concerns about sharing specific health information using advanced technology and management mechanisms. For example, Twitter can enable individuals to restrict access to their shared personal health information. Punitive regulations can be established for inappropriate behaviors (such as retweeting without consent) that may discourage sharing specific health information. All controlling mechanisms and privacy protection functionalities should be easy to understand and use and should not be an additional burden on the users.

As the 2 aspects (company-related and peer-related aspects) of privacy concerns manifest in several dimensions, different features can be developed to address the need for effective protection mechanisms. Twitter can add a new feature to tweets, enabling users to identify the sensitivity of posts related to health information. The content will be recognized as a private post if the sensitivity score (eg, calculated based on a scale ranging from 1 to 10) is more than average. Then, that post is automatically restricted from exposure to everyone, and users can share their thoughts and experiences only with a small crowd. Users can also define terms and conditions for peers or on different platforms. Our survey methodology, coupled with a comparative analysis of the findings, underscores the contribution of our study to the field, offering both nuanced insights and broad trends that enrich our understanding of privacy concerns and health information sharing on social media platforms.
applies high privacy settings for tweets marked as health related. In addition, given the significant role of knowledge in shaping privacy concerns, Twitter should consider educational campaigns or prompts to inform users about these features and the importance of privacy when sharing health information.

In May 2022, Elon Musk called for further investigation into the accuracy of spam and fake account estimates, which Twitter announced to be <5%. Fake and spam accounts could lead to undesirable social interactions with peers, unwanted peer-shared information, and an unpleasant web-based social environment. Twitter needs to use new procedures to detect spam and fake accounts and better control the functionality of Twitter bots to provide a more appropriate web-based social platform. This new mechanism could automatically limit the visibility of private posts containing highly sensitive health information to everyone, even to people who users follow. On the basis of the current Twitter privacy policy, people can mention who can reply to a specific tweet. However, it is hard to confirm who can actually see the posts because of bots and recommendation agents.

Social bots use computer algorithms to artificially create content and interact with people on social media [92]. Twitter bots can be manipulative and purposely change people’s attitudes and opinions about a topic [93]. For instance, bots can share posts with peers who are not following a user but usually read posts with health information content. The existence of bots may be useful for sharing general information but can be very harmful because it can increase exposure to private posts with sensitive health information. A plausible recommendation is to add new categories for sensitive content (such as specific health information) besides the photo, graphics interchange format (GIF), and poll categories. Then, users can create a new circle of people who are allowed to see, reply to, or share these sensitive posts. Users can also customize the configuration and limit the possible unwanted interactions by selecting who can see the posts but cannot share them. This small crowd can be saved for future use and can be easily modified later. The advantage of this new category is that people are notified to customize their Twitter circle depending on different content (eg, highly sensitive, semi-sensitive, and non-sensitive). For instance, a user can select everyone to see and comment on posts containing information about cryptocurrency, high-technology companies, or humanitarian issues. In contrast, the user can select a group of followers to see their thoughts about general health information and choose only a few close friends to see and comment on posts with sensitive health information.

Stringent privacy policies are required to enable Twitter users to limit who (ie, peers) can view, comment on, and share web-based content. People should be able to easily edit with whom they can share health information to exercise control over their personal digital information. Spambots on Twitter should also be controlled, modified, or filtered because they can involve potentially deceptive, harmful, or annoying activities. A more transparent policy is required to detect and deactivate invasive Twitter bots that can automatically like or retweet users’ postings without consent.

Finally, the insights from our study are not only limited to Twitter but also have implications for other social media platforms where users might share health information. Such platforms should recognize the significant role of peer-related privacy concerns and consider introducing similar audience control features. Health professionals and health-related organizations using social media for patient engagement should also be aware of these concerns and take steps to ensure that their communication respects patient privacy. Policy makers should consider our findings when developing regulations for health information sharing on social media to ensure that they address the most significant privacy concerns.

Limitations and Future Studies

Our study also has some limitations that can be considered as opportunities for future studies. First, a web-based survey through MTurk was used to collect data, which may be biased toward people familiar with crowdsourcing platforms. Future studies can use other data collection and sampling strategies, such as collecting data directly from Twitter. Second, we collected data from 329 Twitter users, which may not be a good representative of Twitter users. Next, studies can increase the sample size to reduce sampling bias and improve the generalizability of the findings. Third, we did not consider the effects of cultural dimensions (such as individualism, uncertainty avoidance, etc) on sharing health information on Twitter. It can be interesting for future studies to explore the effect of culture on disclosing different types of health information on social media. Fourth, our study tests a model to analyze health information sharing from the perspective of privacy concerns. However, there may be other essential variables. More studies are required to examine other factors inhibiting and promoting sharing behaviors on social media, such as reputation, incentives, trust, stigma, and social support. Fifth, this study did not examine the accuracy of the health information shared on Twitter or the risks of misinformation because it is not within the scope of this study. Future studies could expand upon our results to investigate the role of misinformation risks in information-sharing behaviors. Finally, our study focused on Twitter as a study context. We encourage future studies to extend the proposed model to other social media platforms (eg, Facebook, TikTok, and Instagram) where web-based interactions with peers are essential.

Conclusions

This study provides insights into health information sharing on Twitter from a privacy perspective. The findings suggest that including CFIP and PrPC constructs can help in better conceptualization of information privacy concerns in the context of social media. The integration of these 2 aspects of information privacy can expand the discussion about internet privacy by addressing the privacy needs associated with the practices of companies, such as collection, unauthorized secondary use, improper access, and errors. It also considers psychological privacy concerns, communication privacy concerns, peers’ sharing behaviors, and territory privacy concerns related to peers in such interpersonal interactions. This interactive approach can provide a more comprehensive analysis of information privacy (related to web-based vendors and web-based peers) and adds...
a more substantial explanation of privacy needs on social media channels (such as Twitter). Privacy concerns may not always prohibit disclosure behaviors on Twitter; it depends on the type of health information. The findings demonstrate that peer-related privacy concerns are more salient to predicting general and specific health information sharing on Twitter than privacy concerns related to companies and third parties. The results could propose practical contributions by shedding more light on the negative impacts of web-based peer behaviors on losing personal control over digital communications and information access. Privacy policies should focus on companies’ practices, such as sharing users’ information with third parties for big data analytics. We suggest mitigating privacy concerns and promoting health information sharing on Twitter by creating policies that tailor privacy needs to the type of health information shared (ie, general or specific).

Abstract

Background: In 2017, the Quebec government assigned the Association québécoise de prévention du suicide (AQPS) to develop a digital suicide prevention strategy (DSPS). The AQPS responded by creating a centralized website that provides information on suicide and mental health, identifies at-risk individuals on the internet, and offers direct crisis intervention support via chat and text.

Objective: This study aims to evaluate the effectiveness of suicide.ca, Quebec’s DSPS platform.

Methods: This study used a cross-sectional descriptive design. The study population comprised internet users from Quebec, Canada, who visited the suicide.ca platform between October 2020 and October 2021. Various data sources, such as Google Analytics, Firebase Console, and Customer Relation Management data, were analyzed to document the use of the platform. To understand the profile of suicide.ca users, frequency analyses were conducted using data from the self-assessment module questionnaires, the intervention service’s triage questionnaire, and the counselors’ intervention reports. The effectiveness of the platform’s promotional activities on social media was assessed by examining traffic peaks. Google Analytics was used to evaluate the effectiveness of AQPS’ strategy for identifying at-risk internet users. The impact of the intervention service was evaluated through an analysis of counselors’ intervention reports and postintervention survey results.

Results: The platform received traffic from a diverse range of sources, with promotional efforts on social media directly contributing to the increased traffic. The requirement of a user account posed a barrier to the use of the mobile app, and a triage question that involved personal information led to a substantial number of dropouts during the intervention service triage. AdWords campaigns and fact sheets addressing suicide risk factors played a crucial role in driving traffic to the platform. With regard to the profile of suicide.ca users, the findings revealed that the platform engaged individuals with diverse levels of suicidal risk. Notably, users of the chat service displayed a higher suicide risk than those who used the self-assessment module. Crisis chat counselors reported a positive impact on approximately half of the contacts, and overall, intervention service users expressed satisfaction with the support they received.

Conclusions: A centralized digital platform can be used to implement a DSPS, effectively reaching the general population, individuals with risk factors for suicide, and those facing suicidal issues.

Introduction

Overview

Information and communication technologies (ICTs) are increasingly used for suicide prevention. As demonstrated in a scoping study by Rassy et al [1], ICTs are used in a multitude of universal, selective, and indicated suicide prevention strategies.

As defined by the World Health Organization (WHO) [2], universal prevention strategies are designed to reach a whole population. They aim to optimize health for all and minimize the risk of suicide by removing barriers to care, expanding access to support services, and strengthening protective factors. Universal suicide prevention strategies using ICTs typically aim to promote mental health literacy, health behaviors, and help seeking [1]. They often take the form of psychoeducational websites and web-based awareness campaigns. Selective prevention strategies, in contrast, are aimed at specific groups or communities [2]. They can be developed based on sociodemographic or geographic characteristics or according to the prevalence of risk factors [3]. They may target individuals who do not exhibit suicidal behaviors but who are at risk for suicide [2]. Selective suicide prevention strategies using ICTs focus on identifying suicidal internet users, offering mental health self-management programs, and providing web-based training [1]. These strategies are, for the most part, included in broader programs involving direct contact between distressed individuals and health professionals. Finally, indicated prevention strategies focus on individuals who have suicidal ideation or who have previously attempted suicide [2]. Indicated suicide prevention strategies using ICTs include web-based suicide risk assessment and triage systems, web-based psychotherapy, chat- or text-based crisis interventions, and digital tools to support face-to-face interventions [1].

Despite the vast body of scientific literature discussing the application of ICT in suicide prevention, few studies have addressed how multiple ICT-based interventions can be combined and articulated together in the development of a digital suicide prevention platform [3] or, more broadly, as part of a digital suicide prevention strategy (DSPS). In a context where an increasing number of countries are developing digital health strategies [4], guidelines must be developed to guide organizations that wish to develop a DSPS. To deploy the 3 levels of prevention defined by the WHO (universal, selective, and indicated), it is crucial that these guidelines contain information on the best strategies for reaching the general population, identifying people with risk factors for suicide on the internet, and providing direct support to people struggling with suicidal issues.

Rassy et al [1] discussed ICT-based interventions aimed at a broad audience, including educational websites, web-based awareness campaigns, and social media platforms. They spotlighted the It Gets Better campaign launched in 2010, primarily directed at bullied teenagers, especially those identifying as gay, to prevent suicide. The campaign involved videos created by gay adults that conveyed the message that these teens’ lives would improve over time. These videos were hosted on an educational website and YouTube channel and extensively shared on social media, accumulating >50 million views [5]. Despite the limited evaluation of the effects of educational websites, web-based awareness campaigns, and social media initiatives, studies have demonstrated promising outcomes in terms of reducing suicidal ideation and behavior as well as enhancing knowledge, attitudes, and help-seeking behavior [1].

As highlighted by Rassy et al [1], further research is required to determine the specific characteristics of these interventions that are associated with positive outcomes. In addition, there is a need to develop effective methods for identifying beneficial websites and social media posts and to inform users about or guide them toward internet content that may be of help to them.

Using Google searches holds promise in identifying individuals at risk of suicide on the internet and guiding them toward beneficial web-based content, as individuals with suicidal ideations tend to search for suicide-related information on the internet [6-8]. Indeed, multiple studies have established a correlation between suicide-related Google searches and suicide rates across diverse populations [9-11]. The findings from these studies suggest that suicide-related Google searches can be used to identify individuals at risk of suicide on the internet, recognize intervention opportunities, and facilitate real-time monitoring of suicide risk at a population level. However, it is important to acknowledge that only a small number of real-world interventions based on Google searches have been developed to date.

An example of such an intervention is the study conducted by Sueki et al [12], in which they implemented a web-based gatekeeping intervention in Japan. This intervention involved targeted web-based advertisements directed at individuals searching for suicide-related terms on the web, redirecting them to an email-based consultation. The results of the study indicated a significant reduction in users’ suicidal ideation 4 weeks after being identified on the internet and redirected to the email-based intervention. Furthermore, Onie et al [13] conducted 2 studies to assess engagement levels with 2 advertisement campaigns on Google targeting individuals contemplating suicide. The researchers noted significant engagement with both campaigns, as evidenced by high click-through and conversion rates. Similarly, Google displays crisis helpline numbers at the top of the search results when a user performs a suicide-related search. To our knowledge, no empirical data on the actual impact of Google initiative on helplines use worldwide have been published to date. In addition, data on the characteristics of individuals who were identified by Google and directed to help services are also unavailable.

Regarding ICT-based interventions aimed at providing direct support to individuals facing suicidal issues, crisis lines that offer text- and chat-based services are likely to be the primary source of assistance for those seeking help on the internet. Research on the use and effectiveness of crisis text- and chat-based services is limited. Studies so far have shown that they seem effective in reducing users’ distress [14-18]. However, they reported quite different results regarding the suicidality of users. For example, evaluation of the Netherlands’ 1130Online chat service [16] and the US Lifeline Crisis Chat [16] suggested that >80% of their users were experiencing suicidal thoughts.
In contrast, evaluation of crisis text lines in the United States and Australia [17,18] indicated that the proportion of users experiencing suicidality was <30%.

In addition, studies suggest that conducting suicide risk assessments during chat- and text-based interactions poses challenges, resulting in fewer assessments completed by counselors [14,19]. These gaps in suicide risk assessments can impact the identification of callers at risk of suicide and potentially bias the reported statistics on suicidal callers by these services. Consequently, providing an accurate description of suicidality among users of these services becomes challenging. Therefore, it is imperative for crisis lines offering text- and chat-based interventions to establish strategies that enable a precise depiction of service users and an assessment of their level of suicidality, rather than solely relying on intervention reports completed by counselors.

In a similar vein, Zabelski et al [20] emphasized the need to investigate the accessibility of chat and text services for high-risk populations in their policy focus review of suicide prevention research on crisis lines. They suggested that if the effectiveness of these services is established, additional studies should be conducted to better understand the demographics and risk profiles of service users as well as to develop effective strategies to promote these services among high-risk populations.

This brief overview of ICT-based interventions highlights the potential of ICTs in the field of suicide prevention. However, it also underscores the existence of significant knowledge gaps that can have important implications for the development of DSPSs. Moreover, essential information required by mental health resources seeking to incorporate ICT-based interventions into their clinical practices is frequently absent from scholarly articles. For example, the technical aspects of developing, maintaining, and operating digital interventions have rarely been discussed [21,22]. Furthermore, there is a dearth of comprehensive research that adequately examines the implementation characteristics of ICT-based interventions in real-world settings, encompassing both the obstacles and factors that aid their implementation [23,24]. Ultimately, to support well-informed decision-making regarding the development of DSPSs, it is vital to establish whether ICT-based suicide prevention strategies are effectively reaching various target audiences or whether they are reaching the same individuals through different means. Therefore, research is necessary to explore digital platforms that incorporate a variety of ICT-based interventions, evaluate the presence of diverse user profiles on these platforms, and analyze the specific interventions they use.

Background
In 2017, the Quebec government asked the Association québécoise de prévention du suicide (AQPS) to set up a DSPS. This DSPS was intended to inform the population about suicide and mental health resources, identify people at risk for suicide on the internet, and offer web-based intervention to people who rarely use traditional help services.

The AQPS then launched a broad consultation process with Quebec suicide prevention stakeholders [7]. The objective of this consultation was to paint a picture of the current practices and needs regarding the use of digital technologies in suicide prevention in Quebec. In general, the consultation participants stressed the importance of developing new digital services by building on the programs, services, and intervention practices already in place in Quebec and of using a centralized website that would make it possible to meet several objectives (inform, identify, and intervene).

In this context, the AQPS, in partnership with its technology partner (the Montreal-based technology firm Nventive), developed the suicide.ca digital platform [25]. Suicide.ca is the official digital platform of the Quebec’s DSPS. Through this platform, a multitude of universal, selective, and indicated suicide prevention strategies are deployed.

Objectives
This study illustrates, through the example of suicide.ca, how a single digital platform can be used to reach the general population, identify people with risk factors for suicide on the internet, and provide direct support to people dealing with suicidal issues. Specifically, this study aims to document the use of the suicide.ca platform; describe the profile of users of the suicide.ca platform; and estimate the effectiveness of universal, selective, and indicated prevention strategies deployed via the suicide.ca platform.

Methods
Suicide.ca Platform
This section describes the universal, selective, and indicated suicide prevention strategies implemented through the suicide.ca platform.

Suicide.ca’s Universal Prevention Strategies
The components of the suicide.ca platform that enable the deployment of universal prevention strategies are its search engine optimization (SEO), the psychoeducation pages, the blog pages, and the promotion of the platform on social media.

SEO Strategy
To fulfill its mission, a digital suicide prevention platform must be known to the public and easily found on the internet. This is why positioning itself favorably in search engine results is at the heart of the suicide.ca platform’s promotional strategy. To do so, an SEO strategy was developed. SEO refers to all the strategies implemented to improve the natural referencing of a website on search engines. For example, all the content on the platform was carefully crafted with the explicit objective of prioritizing search engine ranking.

Psychoeducation Pages
When the user arrives at the platform’s home page, they are prompted to choose one of the following sections: I am thinking about suicide, I’m worried about someone with suicidal thoughts, or I’m grieving a loss by suicide. The section for suicidal people is presented as a guide to getting better. The content of the psychoeducation pages can be found on the platform [26].
Blog Pages
The suicide.ca platform includes a blog. The blog facilitates the regular generation of fresh content, thereby aiding the enhancement of the platform’s natural search engine rankings. It also provides a great deal of flexibility in terms of the topics covered. Content is sometimes developed based on frequent searches by suicide.ca users on search engines.

Promotion of the Platform on Social Media
The AQPS promotes the platform via posts on social media. These posts are generally aimed at promoting the intervention service and communicating information found on the platform. Content from the psychoeducation pages and blog pages is regularly used to create new posts.

Suicide.ca’s Selective Prevention Strategies
The components of the suicide.ca platform that enable the deployment of selective prevention strategies are the fact sheets on suicide risk factors, AdWords campaigns, the self-assessment module, the self-management tools, and the mobile app.

Fact Sheets on Risk Factors Associated With Suicide
The suicide.ca platform includes a section with numerous fact sheets on the risk factors associated with suicide. These fact sheets address mental health problems (eg, depression, anxiety, and schizophrenia) and difficult life situations (eg, relationship problems, money problems, and isolation). These fact sheets have a dual function: to help users cope with their situation and to identify the internet users who present risk factors for suicide on the web.

AdWords Campaigns
AdWords is a paid referencing system developed by Google. This allows organizations to promote their services using paid advertisements. These advertisements appear when internet users perform searches with keywords or expressions that are associated with the services offered. The AQPS frequently uses AdWords campaigns to identify internet users who are conducting research related to suicide, depression, or anxiety.

Self-Assessment Module
A self-assessment module consisting of French-validated questionnaires (refer to the details in the Data Collection Methods and Tools section) is available to users on the Taking Stock of Your Mental Health page.

The self-assessment is performed in 2 stages. During the first stage, users are invited to answer questionnaires allowing them to take stock of their suicidal thoughts, to identify the presence of signs of psychological distress, and to evaluate their positive mental health. If the result of this first evaluation reveals that the user is experiencing suicidal ideation, they are invited to contact the platform’s intervention service via a redirection button. If the user is not referred to the intervention service and the results indicate that they may have a mental health disorder (Kessler Psychological Distress Scale [K10] score [27]), additional questionnaires are offered to identify the presence of symptoms related to various mental health disorders.

Self-Management Tools and Mobile App
The platform contains a section called My Tools, which includes a safety plan and various mental health self-management tools. To make the various self-management tools accessible to people who do not have a smartphone, they have been developed in the web-mobile format. Therefore, users can access their information via the web or the platform’s mobile app (eg, like on Facebook or Twitter). Consequently, the user must open an account to access the tools. However, a user account is not required to access the intervention service and the self-assessment module.

Suicide.ca’s Indicated Prevention Strategies
The components of the suicide.ca platform that enable the deployment of indicated prevention strategies are the chat and text intervention service, the triage system, the suicide risk assessment tools, and the follow-up emails.

Intervention Service by Chat and Text Messaging
Suicide.ca is a digital intervention service that operates 24 hours a day, 7 days a week. It is operated by the AQPS and 3 suicide prevention centers. The service can be accessed via the web, the mobile app, or by SMS text messaging.

Triage
The intervention service triage system assigns a priority rating to contact requests. The first questions ask about age, gender, and reason for contact. Individuals at the risk of suicide are then asked, Are you planning to attempt suicide in the coming minutes or hours? If the user answers yes, the triage ends, and they are sent to the queue with a priority rating. If the user answers no or unsure, they are prompted to complete the Suicidal Ideation Attributes Scale—French version (SIDAS-FR [28]). Finally, the user may, if they wish, specify in a few words the reason for contacting the service.

Follow-Up Emails
At the end of the exchange, the counselors can ask users if they would like to receive a follow-up email. These follow-up emails are generally used when the user anticipates a difficult event that could lead to a suicidal crisis (eg, court appearance and meeting with an ex-spouse).

Suicide.ca Prevention Model
Using the classification proposed by Rassy et al [1], Textbox 1 illustrates how the different components of the platform are complementary and how they deploy universal, selective, and indicated prevention strategies.

Study Design

The evaluation of the suicide.ca platform used a cross-sectional design to document the use of the suicide.ca platform; to describe the profile of users; and to estimate the effectiveness of universal, selective, and indicated prevention strategies deployed through the platform.

Population

The population under study in the evaluation of the suicide.ca platform were the internet users who visited the suicide.ca platform.

Recruitment

This study was based on the analysis of secondary data collected by AQPS. Data were collected from internet users from Quebec, Canada, who visited the suicide.ca platform between October 2020 and October 2021.

Data Collection Methods and Tools

Overview

The evaluation of the suicide.ca platform was carefully considered during its development. The questionnaires integrated into the platform’s various components made it possible to measure the platform’s impact. The platform collects various types of data.

Google Analytics

Google Analytics is a statistical tool offered by Google. It allows website administrators to analyze the behavior of their users. The analytics used in this study are the number of times different pages of the platform were visited, the number of visitors (notwithstanding the number of visits), the sources of traffic acquisition on the platform (eg, search engines, social networks, and hyperlinks on other websites), and the landing pages (the first pages visited by users).

Firebase Console

The Firebase Console platform is a mobile app design tool supported by Google. It was used to count the number of times the My Tools app was downloaded and the number of user accounts created.

Self-Assessment Module Questionnaires

The self-assessment module consists of a series of validated questionnaires in French (Table 1). The results of the self-assessments are recorded in the platform’s Customer Relationship Management (CRM).

### Triage Questionnaire

The triage questionnaire includes inquiries about age, gender, reason for contact, whether the individual is planning to attempt suicide in the near future, and the SIDAS-FR. The results of the triage questionnaire are recorded in the platform’s CRM.

### Intervention Reports

In this study, the data used from the intervention reports were the reasons for contact, the needs and issues discussed with the users, and the users’ suicide risk ratings assigned by the counselors (suicide risk ratings: no foreseeable risk for a suicide attempt in the near future, low foreseeable risk for a suicide attempt in the near future, high foreseeable risk for a suicide attempt in the near future, and imminent danger of suicide attempt or attempt in progress). The categories of needs and issues discussed are not mutually exclusive. The intervention report also contains a section where the counselor is asked to indicate whether they think the user feels better and is more able to cope with their difficulties as a result of the intervention (response choice=yes, unsure, and no). These intervention reports are recorded in the platform’s CRM.

### Postintervention Questionnaire

This questionnaire includes 9 items in the form of 4-point Likert scales (1=strongly agree to 4=strongly disagree). The items focus on users’ perceptions of the quality of interventions and their impact on distress, feeling of being able to cope with the situation, and suicidal ideation. The items are illustrated in detail in the Results section.

### Analysis Methods

For each objective, several data sources were consulted, and different types of analyses were performed.
Objective 1: To Document the Use of the Suicide.ca Platform

To document platform use, Google Analytics data from the suicide.ca website [26] were analyzed to describe platform traffic and the number of visits to the psychoeducation pages. The Firebase Console data from the My Tools mobile app were analyzed to document the number of downloads of the mobile app and the number of user accounts created. CRM data were analyzed to describe the number of people who completed the self-assessment, the number of people who accessed the triage of the intervention service, and the number of interventions provided.

Objective 2: To Describe the Profile of Users of the Suicide.ca Platform

To describe the profile of platform users, frequency analyses were conducted using data from the self-assessment questionnaires, the triage questionnaire, and the reasons for contact recorded in the intervention reports.

Objective 3: To Describe the Impact of Universal, Selective, and Indicated Prevention Strategies Deployed Through the Suicide.ca Platform

The impact of the platform’s promotional activities on social media was investigated through an analysis of the platform’s traffic peaks. First, a visual inspection of the traffic curve was performed using Google Analytics. It was then decided to define the traffic peaks as days with >600 visits. This threshold corresponded to twice the average traffic and days when the increase in traffic was evident in the Google Analytics graph. AQPS internal documentation was then inspected to determine if these dates corresponded to dates when AQPS conducted promotional activities on social media or traditional media (eg, web-based publications, radio, or television interviews). The data analyzed to assess the impact of AQPS promotional activities cover the period from October 15, 2020, to October 17, 2021.

With respect to the AdWords campaigns and the suicide risk factor fact sheets, 2 analytical strategies were used to estimate their effectiveness. The first strategy was to use Google Analytics to describe the traffic acquisition sources of suicide.ca. In digital marketing, traffic acquisition sources identify how visitors to a website accessed a site (eg, via search engine queries, social media posts, AdWord advertisements [43]). Thus, traffic acquisition sources were used to describe the number and proportion of users who arrived at the site through an AdWords campaign. The second strategy was to use Google Analytics to identify the top landing pages on the platform. A landing page is the first page a user views when they arrive on the platform (eg, risk factor information page, psychoeducation page, and resource information page). In digital marketing, landing pages are used to better understand what users were looking for on the internet before they arrived at a site or what caught their attention [43]. For example, landing pages were used to describe the number and proportion of users who began their site visit by viewing a suicide risk factor fact sheet. The conversion rate for the AdWords campaigns was calculated based on the number of individuals who clicked on the advertisement and initiated the crisis chat triage. The analytical data on AdWords campaigns and fact sheets cover the period from December 31, 2020, to October 31, 2021.

The impact of the intervention service was assessed via an analysis of counselors’ Perceptions of the impact of their interventions (recorded in intervention reports) and the postintervention survey results. Approximately 3473 interventions were provided between the postintervention survey going live in late January 2021 and October 2021. Therefore, we estimated the response rate to the postintervention survey to be approximately 10%. As the SMS text messaging intervention service was in development at the time of data collection, only the data for the chat-based intervention are presented.

Ethical Considerations

This study is based on the secondary analysis of anonymous data collected by AQPS. Consent for primary data collection was obtained through a waiver form in suicide.ca’s self-assessment module and a consent form in the postintervention questionnaire of the intervention service. These forms specify that data collection is for the purpose of continuous service improvement and that any data shared with third parties will be anonymized and subjected to ethics approval by an institutional research ethics committee. The participants were not offered any compensation for their involvement in the study. Ethics approval for the secondary analysis of all data presented in this study was obtained from the institutional review board of the Centre intégré universitaire de santé et de services sociaux de l’Estrie—Centre hospitalier universitaire de Sherbrooke (project 2021-4016).

Results

In this section, the results concerning platform use; the profile of platform users; and the effectiveness of universal, selective, and indicated prevention strategies deployed through the suicide.ca platform are presented.

Use of the Suicide.ca Platform

Overview

A total of 127,495 visits were made to the suicide.ca platform from October 15, 2020, to October 17, 2021. The average number of visits per day was 346.45 (median 313.5, IQR 257-389). The least busy day had 123 visits, and the busiest day had 1774 visits.

Visits to Psychoeducation Pages

The number of visits to the psychoeducation pages of the 3 main sections of suicide.ca were much lower than the total number of visits to the site. Moreover, the number of page views dropped significantly after the title pages of all 3 sections were visited (Table 2).
Table 2. Suicide.ca’s psychoeducation pages.

Number of People Who Completed the Self-Assessment Module

With regard to self-assessment, 2488 users completed the SIDAS-FR. Moreover, 3100 users completed the K10 questionnaire, and 2644 users completed the Mental Health Continuum Short Form questionnaire. Overall, 1471 users completed phase 2 of the self-assessment module.

Number of Downloads of the Mobile App Versus Number of User Accounts Created

The analysis of downloads of the mobile app and the creation of user accounts was carried out for the period from November 23, 2020, to October 17, 2021. During this period, there were 5159 downloads of the mobile app, and 2178 user accounts were created.

Number of Crisis Interventions Provided and Triage Dropout Rate

From October 15, 2020, to October 17, 2021, suicide.ca’s intervention service received 6152 intervention requests. Of these 6152 requests, 1540 (25.02%) did not result in an intervention. The intervention reports provided reasons for not being able to intervene in 1321 of these cases. The most common explanation was the lack of response from the users at the beginning of the contact (840/1321, 63.59%).

Analysis of the intervention service triage data was conducted for the period October 15, 2020, through July 25, 2021 (Figure 1). As the gender question was optional, it was not included in the analysis. Of the 6300 users who responded to the first question, only 2711 (42.86%) completed the triage. The last question, which asked for the user’s first name or alias, resulted in a significant dropout rate. Specifically, only 46.54% (2711/5825) of the users who were presented with the question actually provided a response. As for the questions about suicidality, they resulted in few dropouts. Age, reason for contact, and plan to attempt suicide in the coming minutes or hours were not associated with the probability of abandonment during triage.
Profile of Users of the Suicide.ca Platform

To describe the profile of platform users, frequency analyses were conducted using data from the self-assessment questionnaires, the triage questionnaire, and the reasons for contact recorded in the intervention reports.

Characteristics of Individuals Using the Self-Assessment Module

Table 3 indicates the results of the users who undertaken a self-assessment. With regard to suicidality, the average score of the 2488 users who completed the SIDAS-FR questionnaire was 13.47 (SD 14.04; median 10). Among them, 868 (34.89%) reported no suicidal ideation in the last 30 days, whereas 825 (33.16%) reported severe suicidal ideation. In terms of psychological distress, of the 3100 users who completed the K10 questionnaire, 2721 (87.78%) obtained a score indicating the presence of a mental health disorder. With regard to positive mental health, of the 2644 users who completed the Mental Health Continuum Short Form questionnaire, 1024 (38.73%) exhibited languishing mental health.

In the 1471 users who completed phase 2 of the self-assessment, depressive and anxiety disorders were the most prevalent. Specifically, 62.2% (915/1471) of the users obtained a Patient Health Questionnaire-9 score indicating the presence of depression, 61.73% (908/1471) of the users obtained a Penn State Worry Questionnaire score indicating the presence of generalized anxiety disorder, and 53.2% (451/847) of the users obtained a Spin Phobia Inventory score indicating the presence of social phobia disorder.

**Characteristics of Individuals Using the Intervention Service**

Table 4 presents information on the age and gender of intervention service users. Information on user age was available for 4000 interventions. Most users were aged between 18 and 40 years (2829/4000, 70.73%). Information on the gender identity of users was available for 3569 interventions. Most users identified as woman (2555/3569, 71.59%). Users who identified as transgender, nonbinary, or listed other were generally young people aged ≤25 years (235/280, 83.9%). Information on the reason for contact was available for 4000 interventions (Table 5): 84.48% (3379/4000) of the users indicated I am thinking about suicide in the triage questionnaire and 10.1% (404/4000) of the users indicated I am worried about a loved one, and 5.43% (217/4000) indicated I am bereaved by suicide.

With regard to the suicidal risk of the users of the intervention service, 3490 answered the question (Table 6), Are you planning to attempt suicide in the coming minutes or hours? Of the 3490 users, 1800 (51.58%) answered no, 972 (27.79%) answered unsure, and 718 (20.57%) answered yes. A total of 2606 users completed the SIDAS-FR at triage. The mean score was 26.69 (SD 12.79; median 29). Overall, 75.56% (1969/2606) of the users had suicidal ideation of high severity.

Information on the needs expressed by the users was available for 3254 interventions (Table 6). Overall, 75.29% (2450/3254) of the users expressed a need to ventilate. The most frequently discussed issues were suicide (3033/3475, 87.28%), mental health problems (765/3475, 22.01%), emotional problems (657/3475, 18.91%), family problems (455/3475, 13.09%), self-harm (413/3475, 11.88%), loneliness (407/3475, 11.71%), and problems with peers or relatives (361/3475, 10.39%). Information on the counselors’ suicide risk assessments was available for 1783 interventions (Table 6). The most common assessments were “Low foreseeable risk for a suicide attempt in the near future” (955/1783, 53.56%) and “High foreseeable risk for a suicide attempt in the near future” (602/1783, 33.76%).

Effectiveness of Universal, Selective, and Indicated Prevention Strategies Deployed Through the Suicide.ca Platform

Impact of Promotional Activities on the Platform’s Traffic

Analysis of peak traffic (days with >600 visits) for the period from October 15, 2020, to October 17, 2021, indicated that they were primarily associated with promotion of the platform in traditional media and on social media (Figure 2; Table 7). Traffic tended to remain high for 1 or 2 days following these spikes and then returned to its average trend afterward.

Impact of AdWords Campaigns and Suicide Risk Factors Fact Sheets on the Platform’s Traffic

Table 8 shows the source of traffic and the top landing pages on the platform for the period from December 31, 2020, to October 31, 2021. The source of traffic to the platform was very diverse. AdWords campaigns on suicide risk factors were the second-largest source of traffic acquisition on the platform.

\(^a\)Pages designed to identify internet users at risk for suicide.

The AdWords campaign targeting anxiety and depression was displayed 72,713 times and received 9576 clicks, resulting in a click rate of 13.7%. This campaign also led to 36 crisis chat interventions, representing a conversion rate of 0.38%. Similarly, the AdWords campaign with suicide-specific keywords was displayed 27,961 times and received 2647 clicks, resulting in a click rate of 9.47%. This campaign resulted in 55 crisis chat interventions, with a conversion rate of 1.93%.

As for the first pages consulted by users (Table 8), 40% (4704/11,760) of the visits from search engine queries, excluding AdWords ads, began with a visit to a suicide risk factor fact sheet. Therefore, suicide risk factor fact sheets were an important source of traffic to the platform.

**Effectiveness of the Intervention Service**

Table 9 presents the counselors’ perception of the impact of their interventions. Counselors indicated that the users felt better after the intervention in 56.09% (2565/4573) of the interventions. They also reported that the users felt more able to overcome their difficulties in 51.08% (2336/4573) of the interventions.

Table 10 shows the results of the postintervention survey for 259 suicidal users and 91 users worried for a loved one or bereaved by suicide. Overall, 91.5% (237/259) of the suicidal users indicated that the counselor seemed warm and caring, and 89.5% (232/259) of the users indicated that they felt listened to, understood, and respected. In terms of the effectiveness of the interventions, 82.6% (214/259) of the suicidal users indicated that they felt better, calmer, or more relaxed following the intervention; 76.8% (199/259) of the users indicated that they felt more in control of their suicidal thoughts; and 72.5% (188/259) of the users indicated that they felt more able to overcome their difficulties.

**Discussion**

**Principal Findings**

The objectives of this study were to document the use of the suicide.ca platform; to describe the profile of its users; and to estimate the impact of the universal, selective, and indicated prevention strategies deployed via the platform.

The results for universal prevention strategies indicated that there was a wide range of sources for acquiring traffic to the platform, that actions to promote the platform on social media were directly associated with increased traffic, and that there was little traffic to psychoeducation pages.

The results for selective prevention strategies indicated that AdWords campaigns and fact sheets on suicide risk factors are important sources of traffic acquisition on the platform, that the platform reaches people with varying degrees of suicidal risk, and that the user account was a barrier to the use of mental health self-management tools.

The results for the indicated prevention strategies indicated that triage questions involving personal information result in a significant number of dropouts, that counselors feel that their interventions have a positive impact on the user in half of the contacts, and that intervention service users are generally satisfied with the service they received.

**Universal Prevention Strategies**

The sources of traffic acquisition on suicide.ca were very diversified, and only 40% (50,271/125,677) of the users started their visit on the home page. Moreover, the platform’s social media promotion was directly associated with traffic peaks. These results highlight the importance of being proactive in promoting the platform and using a wide variety of promotional strategies (eg, SEO strategy, social media posts, AdWords campaigns, and referral links on other websites). They also highlighted the importance of collaborating with digital experts to adapt traditional digital marketing strategies to suicide prevention.

The number of visits to the psychoeducation pages was far less than the total number of visits to the site. For example, the first page of the psychoeducation section for people with suicidal risk was visited only 5312 times in the first year. This number is far less than the 127,495 visits that were recorded on the site for this period. This result suggests that the vast majority of users do little exploration of the platform after viewing the content that brings them to the site. These results highlight the importance of looking beyond the total number of visits to a digital suicide prevention platform to describe its use and of dissecting its analytics data in detail to fully understand the content that is consulted.

**Selective Prevention Strategies**

AdWords campaigns and suicide risk factor fact sheets were important sources of traffic acquisition on the platform. For example, 40% (4704/11,760) of the visits from search engines, excluding AdWords advertisements, began with a suicide risk factor fact sheet. Although it is challenging to determine from the analytical data whether the individuals who accessed the fact sheets or clicked on the advertisements were at risk for suicide, it is evident that they conducted a Google search related to suicide or suicide risk factors and landed on the suicide.ca platform. Furthermore, the AdWords campaigns targeting anxiety and depression achieved click rates of 13.7% and 9.47%, respectively, which are significantly higher than the average Google Ads benchmarks of 3.17% observed in e-marketing [44] and the click rates of 4% and 5% reported in the study by Onie et al [13]. However, despite the high click rates, the conversion rates for crisis chat interventions were relatively low, with 0.38% for the anxiety and depression campaign and 1.93% for the suicide-specific campaign. It is challenging to interpret why these clicks did not result in more crisis interventions. Although the average conversion rate in e-marketing is 3.75% [44], there are currently no established benchmarks for conversion rates in suicide prevention. Although our findings should be interpreted with caution, they offer initial support for suicide.ca’s strategy of using AdWords campaigns and fact sheets as tools to identify internet users presenting suicide risk factors through search engine platforms.

Previous research has predominantly focused on how Google can enhance support for suicide prevention, paying limited attention to how suicide prevention actors can leverage Google to identify individuals at risk (eg, [12,13,45,46]). More research is required to discover optimal methods for using Google search.
to identify internet users at risk of suicide and to guide them toward support resources.

A major finding of this study is that the platform reaches users with different degrees of suicidal risk. The proportion of users with severe suicidal ideation on the SIDAS-FR was 33.16% (825/2488) for the self-assessment module and 75.56% (1969/2606) for the intervention service. Although the self-assessment module users presented less severe suicidal ideations than the intervention service users, 87.77% (2721/3100) of them obtained a K10 score, indicating the probable presence of a mental health problem. Furthermore, 62.2% (915/1471) of the self-assessment module users obtained a Patient Health Questionnaire-9 score indicating the presence of depression, 61.73% (908/1471) obtained a Penn State Worry Questionnaire score indicating the presence of generalized anxiety disorder, and 53.2% (451/847) obtained a Spin Phobia Inventory score indicating the presence of social phobia disorder.

Our best point of comparison is the 113Online chat service in the Netherlands, which also provides users with access to a self-assessment module and crisis interventions via chat. According to the evaluation of their first 3 years of operation [3], 78.36% (4741/6050) of the users who used the self-assessment module scored positively for depression and anxiety on the Depression and Anxiety Stress Scale. The module also included the Beck Scale for Suicidal Ideation, with results indicating that 7.22% (533/7381) of the users were not suicidal, 1.75% (129/7381) were mildly suicidal, 39.29% (2900/7381) were suicidal, and 51.74% (3819/7381) were severely suicidal. When comparing the results of this study with the observations on the 113Online platform, it appears that the suicide.ca self-assessment module is being used by individuals with lower levels of suicidality. These differences may, in part, be explained by the fact that the 2 platforms used different questionnaires to measure suicidality, depression, and anxiety. In addition, it may be explained in part by the identification strategy of the suicide.ca platform, which aims to reach individuals who have risk factors for suicide but may not be actively suicidal.

With regard to the self-management tools, between 22.99% (1186/5159) and 58% (2992/5159) of the users who downloaded the mobile app did not create a user account. It should be noted that a user can download the app to use the intervention service only and that doing so does not require the creation of an account. Technical problems experienced by users when creating their account could also contribute to this discrepancy [47]. Nevertheless, the discrepancy between the number of downloads and the number of accounts created is so large that it seems to indicate that setting up a user account is a practice that should be avoided as it seems to represent the first barrier to use. This finding highlights an important dilemma for digital suicide prevention interventions. Several studies indicate that users of digital interventions have concerns about the security and privacy of their data [48]. However, although the presence of a user account enhances data security and privacy, it is a barrier to use for some users [49]. These findings highlight the importance of identifying technologies that ensure the security of users' data while preserving their sense of anonymity.

**Indicated Prevention Strategies**

To our knowledge, this study is the first to report on the impacts of triage on the accessibility of a web-based intervention service. Our results indicate that the last question (What is your first name or alias?) was associated with a significant number of dropouts; only 46.54% (2711/5825) of the users who were asked the question answered it. Studies on crisis intervention through chat and text indicate that users prefer to use these services over phone helplines because of the sense of anonymity provided by these mediums [3,50,51]. It is possible that even asking for personal information or requesting an alias could discourage users, emphasizing the importance of maintaining their sense of anonymity.

With regard to the questions about suicidality, it is surprising to observe the low dropout rates they have caused. The requirement to complete the 5 questions of the SIDAS-FR during the triage resulted in a dropout rate of 4%. Web-based crisis service providers are sometimes concerned about implementing a triage. This study provides an estimate of the dropout rate that triage can lead to.

With regard to the profile of the intervention service users, most users (2019/3569, 56.57%) were women aged between 18 and 40 years. The most frequently discussed issues were mental health, emotional problems, relationship problems, self-harm, and isolation. These findings are consistent with those typically observed in digital intervention services [14-17].

It is also interesting to note that 7.85% (280/3569) of the users were from gender minority groups and 83.9% (235/280) of them were young people aged ≤25 years. This percentage is similar to that observed in the Canada Suicide Prevention Service (7.5%) and Lifeline Crisis Chat (7.5%) [14,15]. The age of these users likely reflects the high level of adversity experienced at this time for many gender minority youth [52]. These findings also highlight the relevance of digital intervention services for these youth.

This study provides valuable insights into the suicidality of users of chat intervention services, as multiple sources of information were used to evaluate the risk of suicide. These include data derived from a standardized suicide questionnaire (SIDAS-FR), risk assessments conducted by counselors, and a specific question regarding the risk of suicide attempts in the near future. Approximately half of the users (1690/3490, 48.42%) answered yes or uncertain to the question, Are you planning to attempt suicide in the coming minutes or hours? Moreover, 75.56% (1969/2606) of the users who answered no or uncertain to the question obtained a SIDAS-FR score indicating severe suicidal ideations. Therefore, the intervention service reaches its target population, that is, people at a high risk for suicide. These findings are consistent with those observed in the 113Online crisis chat evaluation [17], where a content analysis of intervention transcripts revealed that 61.1% (320/524) of the users expressed suicidal intentions, 21.2% (111/524) of the users reported both suicidal intentions and a suicide plan, and 3.8% (20/524) of the users were actively attempting suicide at the time of contact.
In terms of the impact of the intervention service, counselors reported that the user felt better after the intervention in 56.09% (2565/4573) of contacts and reported that the user did not feel better in only 9.81% (449/4573) of contacts. The response rate to the postintervention questionnaire was low. Nonetheless, the scores on the various satisfaction indicators were all very high, and 3 (199/259, 76.8%) out of 4 respondents felt that their suicidal ideation had decreased following the intervention. Again, these results are consistent with those typically observed in digital intervention services [15,16,18,53].

**Limitations of the Study**

This study had several limitations. First, the results on site traffic, traffic acquisition sources, page views, and app downloads were based on an analysis of the platform’s analytics data. However, analytical data do not allow us to understand the needs and motivations behind users’ browsing behavior on the platform. It is therefore important to complement this type of quantitative data in digital platform evaluations with other observational methods, such as qualitative interviews with users, or by directly observing their browsing and help-seeking behavior on the internet [22].

Similarly, analytical data are often inaccurate. For example, the traffic on the platform was analyzed according to the number of sessions. However, a session is the period during which a user was active on the site. If a user is inactive for ≥30 minutes, Google Analytics will attribute any subsequent activity to a new session. Therefore, the number of sessions is not exactly the same as the number of visits, but it is the closest indicator to it.

With respect to the analysis of app downloads, it was difficult to estimate the number of people who downloaded the app but did not create a user account. Therefore, it was impossible to provide an accurate estimate for this important issue. Moreover, it would be important to understand the needs and motivations that explain why so many people downloaded the app but did not open a user account. We explain this phenomenon by the users’ need for anonymity, but it would be important to validate this hypothesis with empirical evidence.

The results on the needs expressed by the intervention service users and the topics discussed during the contacts were based on the analysis of the intervention reports. The completeness of these reports may vary from one counselor to another, which may explain in part why the numbers on issues discussed were low. Furthermore, data on user-identified needs reflect the perceptions of counselors. Therefore, there is most likely a gap between these perceptions and the actual needs of the users. Therefore, it would be important to conduct qualitative interviews with users to understand their needs and motivations for using the intervention service.

An important limitation of this study was the absence of questions on gender and age in the self-assessment module. Therefore, we were unable to compare users of the self-assessment with users of the intervention service based on these characteristics. This information is crucial to understanding who is and is not being reached by suicide.ca and, consequently, by the Quebec DSPS. This highlights the importance of anticipating how the data collected by the various tools offered on a platform will compare with their users.

**Conclusions**

The results of this study indicate that it is possible to use the same platform to conduct universal, selective, and indicated suicide prevention. They also highlighted the importance of being strategic in the development of a digital platform to anticipate how different target populations will be identified, how different intervention modalities will be offered to them, and how the data collected by the platform will allow for the measurement of its impact.

Finally, the evaluation of suicide.ca produced several important results and was the source of a considerable amount of learning. We hope that sharing these learnings will help guide organizations interested in developing a digital suicide prevention platform and contribute to the development of guidance for the development of DSPSs (eg, the WHO [54]).

Abstract

The number of overdose-related fatalities continues to reach historic levels across Canada, despite ongoing efforts by authorities. To reduce mortality, a clinical trajectory ranging from preventative measures to crisis intervention, skill training to treatment, and risk assessment to risk management needs to be supported. The web-based Risk Assessment and Management Platform (RAMP) was developed to realize this concept and to empower people who use drugs through an integrated tool that allows them to better understand and manage their risk of overdose. This paper outlines the architecture and development of RAMP, which is built on the WordPress platform. WordPress components are mapped onto a 3-tier architecture that consists of presentation, application, and database layers. The architecture facilitates the development of a modular software that includes several features that are independent in functionality but interact with each other in an integrated platform. The relatively low coupling and high coherence of the features may reduce the cost of maintenance and increase flexibility of future developments. RAMP’s architecture comprises a user interface, conceptual framework, and backend layers. The RAMP front end effectively uses some of the WordPress’ features such as HTML5, CSS, and JavaScript to create a mobile, friendly, and scalable user interface. The RAMP backend uses several standard and custom WordPress plug-ins to support risk assessment and monitoring, with the goal of mitigating the impacts and eliminating risks together. A rule-based decision support system has been hard-coded to suggest relevant modules and goals to complement each user’s lifestyle and goals based on their risk assessment. Finally, the backend uses the MySQL database management system and communicates with the RAMP framework layer via the data access layer to facilitate a timely and secure handling of information. Overall, RAMP is a modular system developed to identify and manage the risk of opioid overdose in the population of people who use drugs. Its modular design uses the WordPress architecture to efficiently communicate between layers and provide a base for external plug-ins. There is potential for the current system to adopt and address other related fields such as suicide, anxiety, and trauma. Broader implementation will support this concept and lead to the next level of functionality.

Introduction

The Clinical Problem

In 2016, the British Columbia government declared a state of emergency in response to the increasing number of drug-related overdose fatalities [1]. Despite this measure, more than 14,000 British Columbians have since died due to high potent opioids, and the province has seen a >2-fold increase in the number of overdose deaths, from 20.5 per 100,000 individuals in 2016 to 46 per 100,000 individuals in 2023 [2]. High-risk substance use and overdose risk is often a reflection of complex concurrent mental and physical conditions, which are critical for understanding the risk constellation as well as overdose risk management [3,4]. Integration of informed approaches to address severe and early traumatic experiences, suicidality, and mental illness is necessary for a solution aimed at increasing the chance of survival and recovery among people who use drugs [5]. Web-based interventions have demonstrated effectiveness in improving health outcomes and reducing barriers for people who use drugs who are seeking support [6,7].

A Modular Architecture

Modular architecture is a model of designing web-based psychotherapy platforms and interventions [8,9]. A modular design implies that the content presented can be divided into multiple smaller pieces that can be completed independently or as a set [9]. The strengths of modular systems include the ability for users to focus on 1 area at a time and ease in replicating modules following a common structure. Therefore, this approach allows for the inclusion of new clinical trajectories beyond substance use and overdose for a significantly lower price. It will also reduce the cost of maintenance. This architecture lends itself well to web-based interventions for substance use because sections, topics, and features can work both independently and together to provide care to a unique population with diverse needs. Chronic conditions such as substance use disorder need to be seen as a long-term trajectory—a dynamic and often changing process, which requires a range of tools to adapt to the needs of users.

An ideal web-based platform addressing substance use would create an environment that provides tools to assess risks, gain deeper knowledge of risks, prevent deterioration and crises, and manage specific behavioral factors and symptoms. The tasks for the development team would be to add content and functionalities to make the system engaging and interactive. Our vision is a platform that can become a long-term tool providing an engaging learning environment where user choices and outcomes influence the trajectory and functionality of the platform. Tools such as machine learning and embedded trials would allow for a systematic internal evaluation of user choices as well as better referrals and decision support tools. Users can adapt the content and functionalities to their needs, add content and their own experiences, and provide feedback to become active drivers of the system.

Risk Assessment and Management Platform

The Risk Assessment and Management Platform (RAMP) was developed by the Addictions and Concurrent Disorders Research Group at the University of British Columbia, supported by funding from Health Canada. The goal of this web-based platform is to provide a low-barrier tool that educates and empowers users to make informed decisions for their own recovery journey. The platform consists of self-assessments, educational and therapeutic modules, and tools to help users plan and monitor their risk of overdose, for example, “Goal setting” and “Lifechart.” Interactions among RAMP features to identify and manage the risk of overdose are shown in Figure 1.
Users must create a free account in order to use the full functionalities of RAMP, including having their scores and data tracked over time. New users have the option to explore some selected features, such as modules and “Art with a Meaning” before they register. This allows users to better understand the system and feel comfortable with it enough to create an account. It also enables public access to modules, which, on its own, will have significant psychotherapeutic benefits for users.

Upon registration, the High-Risk Assessment (HRA) is proposed to the user. The HRA is a screening tool developed by the Addictions and Concurrent Disorders Research Group to identify the risk of overdose among people who use drugs through a rule-based algorithm. Development of the HRA will be explained in a separate publication.

Based on the results of each user’s HRA score, a clinical decision support system suggests the most relevant modules and goals to the user. The user may comply with the recommendations or choose to work on additional or substitute modules of their choice. The modules will help the user to gain knowledge about their risky behaviors and how to prevent or mitigate those risks. The Goals setting function will allow the user to make their risk mitigation plan and monitor their progress through the Lifechart feature. An email notification is sent to the user to inform them about their progress and to encourage them to continue interacting with the software by reminding them about their recent usage and how they can resume.

The core concepts and theoretical frameworks of RAMP will be presented in a series of publications. Topics will include the clinical concept underlying RAMP, development of the HRA, development of modules, and user interface evaluation. This paper is focused on the design and architecture of RAMP. The modular architecture of RAMP uses WordPress’ multilayer architecture, which lends itself well to the dynamic and customizable application design.

**Design of RAMP**

**Overview**

RAMP is a web application developed using the WordPress content management system (CMS). Therefore, description of the architecture of WordPress is essential to describe RAMP’s design and architecture.

WordPress is built on a PHP and MySQL architecture [10]. It uses a multilayer architecture to provide a flexible platform for building and customizing websites [11]. The purpose of a layered architecture is to organize the components of an application into horizontal logical layers and physical tiers. A layer is a logical unit that separates a specific role and responsibility within an application. Each layer manages its own software dependencies. A tier is a physical unit where the code runs, for example, a web server or a database. Scalability, maintainability, and resiliency are increased when tiers are physically separated; however, latency increases due to additional network communication.

Though WordPress does not strictly follow the traditional 3-tier architecture to separate the presentation, application, and database tiers, the WordPress components that are used to develop web applications can be mapped on a 3-tier design model [12,13].

---

**Figure 1.** Interaction among different features of the Risk Assessment and Management Platform to identify and manage the risk of overdose. HRA: High-Risk Assessment.
**Presentation Tier**
The presentation tier is responsible for showing the content and functionality to the user, using HTML, CSS, and JavaScript. HTML provides a way to create and structure the elements of a web page, such as headings, paragraphs, images, links, etc. CSS is a powerful tool for customizing the appearance and layout of WordPress websites. JavaScript is a scripting language that is used to add interactivity, dynamic behaviors, and effects such as animations, interactive forms, and user interface elements such as sliders and pop-up menus to web pages.

**WordPress Themes**
Themes control the appearance of a WordPress website. They include templates, CSS files, and other components that determine how the site is displayed.

**Application Tier**
**Overview**
The application tier in WordPress refers to the core PHP code that provides the underlying functionality and controls the flow of data between the presentation and database tiers. The application tier includes the WordPress core, plug-ins, and custom code that interacts with the database to store and retrieve data.

Plug-ins are add-ons that extend the functionality of WordPress. They can provide additional features such as contact forms, e-commerce functionality, etc.

The application tier is responsible for implementing the business logic as well as accessing the data stored in the database through the data access layer.

**Business Logic Layer**
The business layer in WordPress architecture refers to the layer that handles the business logic and processes in a WordPress website. This layer is responsible for performing tasks such as data validation, calculations, and decision-making.

In the context of WordPress, the business layer can be implemented in a number of ways, including custom plug-ins, custom code within the theme, or through the use of third-party plug-ins that provide specific functionality.

The business layer acts as the intermediary between the presentation and database tiers. It takes input from the presentation layer, performs the necessary business logic, and then communicates with the database tier to retrieve or store data. This architecture allows for greater flexibility and maintainability of WordPress products, as well as the ability to easily modify and extend the functionality of the website without affecting other tiers.

**Data Access Layer**
The data access layer in WordPress architecture refers to the layer responsible for accessing and manipulating data stored in the database. This layer is responsible for retrieving data from the database, performing operations on the data, and storing the results back in the database.

In WordPress, the data access layer is typically implemented using the WordPress database application programing interface (API), which provides a set of functions and methods for interacting with the database. These functions and methods allow developers to perform common database operations, such as inserting, updating, and retrieving data, in a consistent and efficient manner.

**Database Tier**
The database tier in WordPress is where all the data are stored, including posts, pages, users, and metadata. WordPress uses a Relational Database Management System, MySQL, to store this information, and it is accessed by the application tier to retrieve and manipulate data.

The database layer in WordPress works by creating tables and storing data in those tables. Each table contains rows and columns that represent the different data types stored in the database. For example, WordPress has separate tables for posts, users, comments, etc.

When a user interacts with a WordPress site, the database layer retrieves data from the appropriate table and returns it to the application tier. The data can then be displayed on the user interface of the site or being used to perform various operations in the backend.

In conclusion, the database layer in WordPress applications is a critical component that provides a structured way to store and retrieve data and plays an important role in the overall architecture of a WordPress site.

Overall, the architecture of WordPress promotes modularity. This modular design approach allows for easier customization, scalability, and maintainability of software products built on the WordPress platform. Developers can create independent modules that can be combined or modified without significant impact on other components, facilitating the creation of flexible and extensible software systems.

**RAMP** software design architecture follows the WordPress multilayer architecture.

**Ethical Considerations**
The RAMP HRA pilot project has undergone research ethics review and received ethics approval from the University of British Columbia Behavioural Research Ethics Board (H19-02231). Collection of data on RAMP is limited to only those necessary for the research objectives. Participant identities are kept confidential, and the research protocol is aligned with the Tri-Council Policy Statement on Ethical Conduct for Research Involving Humans (TCPS2). Informed consent forms include information about data storage, data security, data sharing, privacy protections, legal limits to confidentiality, and contact information of the University of British Columbia Behavioural Research Ethics Board. It clearly delineates how the data will be used and shared, and the process to report participant concerns.

Upon registration, the system stores their registered email IDs, names, last names, usernames, passwords (encrypted), login times, and IP addresses. Data are stored on secure cloud servers,
and security features such as reCAPTCHA and temporary login blocks are used to minimize the risk of brute force attacks. Upon login, their interactions with the system are stored and tracked. This includes assessments results, symptoms check, completed modules, goals, journal diaries, and achievements. Data are not shared with third parties unless for maintenance, software improvements, or legal obligations. The overall data governance plan of the project is modeled after the highest local, federal, and international standards of privacy, data management, and data sharing.

Figure 2. Mapping RAMP features on a 3-tier software architecture model that uses WordPress components. RAMP: Risk Assessment and Management Platform.

**System Description**

**Overview**

RAMP is designed as an engaging, learning, and open access web application that empowers users to manage their risk of overdose and concurrent mental health disorders. RAMP is a modular software that includes several features and functionalities.

The architecture and design of RAMP features is mapped on a 3-tier architecture model that uses WordPress components. Figure 2 demonstrates the mapping.
The Data Tier uses relational databases on the MYSQL 5.7.30 database management system. RAMP stores and retrieves various types of data including text, video, audio, and images, which can become bulky over time. The data layer is managed by the WordPress database tier, which provides secure and efficient methods to store, retrieve, and organize data. It uses indexing, caching, lazy loading, query optimization, and other techniques to improve its efficiency.

The Backend

The backend uses the WordPress 5.4 development framework. The system is a web application software compatible with most of the standard browsers such as Chrome, Safari, and Edge, and is responsive to mobile apps. The system’s administrative panel allows the administrator to add new reports, reorganize some user interface elements, and define new assessments (Figure 3). This panel also allows the administrator to monitor users’ activities and progresses and add new modules and other content. Certain key performance indicators can be found on the administrative panel.

Figure 3. RAMP’s administrative panel on WordPress (accessible to administrators only).

The RAMP backend also uses some standard and custom plug-ins. Some examples of the plug-ins that RAMP is using are listed below:

- Disable XML-RPC-API: a lightweight plug-in to disable XML-RPC API, Pingbacks, and Trackbacks for faster and more secure browsing of a website.
- Duplicate Page: a plug-in to duplicate posts, pages, and custom posts with a single click.
- LoginWP: a plug-in to redirect users to different URLs based on their role, capability, and more.
- Quform: a plug-in to create powerful and engaging quizzes, tests, and examinations within minutes, and to build an unlimited number of quizzes and questions.
- WP File Manager: a plug-in that manages WP files.
- WP SMTP: a plug-in that helps developers to send emails via SMTP instead of the PHP mail function. This plug-in...
is particularly useful to send email reminders to the user, which would less likely end up in junk mail; support superior authentication and encryption methods; and is more compatible with other WordPress plug-ins.

There are custom-built plug-ins created for different RAMP features such as Achievements, Assessments, Symptom Diary Forms, Journal, and Lifechart to enhance user experience.

The inference engine of a rule-based decision support system is custom-coded in the business layer. User responses to the HRA are used to determine relevant modules and goals, and to suggest them via the user interface.

**Figure 4.** Risk management process.

---

**The Front End**

RAMP front end uses WordPress presentation layer components such as themes, HTML5, CSS, and JavaScript to communicate with the user and provide a pleasant experience when showing content.

RAMP uses BuddyBoss as its core theme. However, a subtheme was derived and customized from BuddyBoss to enhance user experience and use consistent visual themes across RAMP’s branding.

Using HTML5 in RAMP has created more modern and effective web pages for the system with better accessibility, improved search engine optimization, higher performance, and mobile friendliness. Additionally, pages have been further fine-tuned by the developers for a better mobile experience. HTML5 has also allowed the developers to embed audio and video content directly into the web pages, eliminating the need to rely on third-party plug-ins such as Adobe Flash. RAMP is also using native lazy loading of images and script execution in parallel, which can improve the performance of web pages and reduce their load times.

RAMP uses CSS effectively to create websites that are visually appealing, flexible, responsive to mobile devices, and easy to use.

**Interaction With External Systems**

RAMP uses different WordPress plug-ins and features to interact with different external systems. YouTube videos in the modules are embedded into Elementor, a popular visual page builder plug-in for WordPress that allows users to create custom designs for their website and ensures the correct publication of the videos.

The mental health resource map is another example of an external system that is integrated into RAMP. The development team used Google My Maps to pin the location of mental health services, including clinics, youth services, and urgent care centers, onto a Google map. This software enables users to view services and facilities in their area, find their locations, hours of operation, contact information, and more on a Google map in a layered format. The system embeds this software using a simple script method by adding its link to RAMP.

The development team has also been working on a parallel project to create a machine learning model that would predict the risk of fatal overdose based on a comprehensive data set called the British Columbia Provincial Overdose Cohort curated by the British Columbia Centre for Disease Control. The model will subsequently be embedded into an API, which allows the predictive model to be used as a stand-alone tool. The aim is to use the developed predictive model in RAMP using a service-oriented architecture, where RAMP calls upon the predictive model’s API using WordPress REST API plug-in to send user-specific risk factors to the model. The model will then process the overall risk of fatal overdose based on user inputs, determine the likelihood of overdose, and send the results back to RAMP. The RAMP interface will display the results and provide tailored recommendations based on each individual’s risk factors.
Discussion

Background

The aim of RAMP is to empower people who use drugs to become more aware of their overdose risk and to provide a tool that promotes agency in helping them manage their risk factors. Although risk management is broad and may include several activities, the core concepts include key steps to identify, plan, and monitor risks, as well as tools to execute the plan to eliminate or mitigate the impact of these risks [14].

RAMP is a web application. In contrast to native apps, web applications have certain advantages that RAMP benefits from:

- Cross-platform compatibility and being installation-free: RAMP can run on any device with a web browser, which means that it is platform-independent and can be accessed from a wide range of devices, including desktops, laptops, tablets, and smartphones without the need to install the software on the device. In contrast, native apps are developed for a specific platform, such as iOS or Android, and need to be downloaded and installed on the user's device. This is helpful when considering the population of people who use drugs, who might not have consistent access to a smartphone but can access public or shared computers [15].
- Easier maintenance: RAMP maintenance and updating is easier and less costly than native apps, as changes can be made on the server side, and users are not required to download updates. This can save time and resources for developers and ensure that all users are using the most up-to-date version of RAMP.
- Lower development costs: developing a web application typically requires fewer resources than developing a native app, as there is no need to develop separate versions for different platforms such as iOS and Android. This can result in lower development costs and less time to deploy the application.

While web applications offer certain benefits, native apps offer advantages such as better performance, native features, push notifications, and access to device-specific capabilities. Web applications always need an active internet connection to the server, but native apps may not need constant access to the internet if there is no need to communicate with a centralized server on a continuous basis.

RAMP features effectively use the WordPress components and their multilayer architecture to support the user to make informed decisions. One example is the design of HRA, a 29-question screening tool that helps users identify several overdose risk factors across different domains.

The integration of a dynamic color-coded heat map on the user interface of the presentation tier, featuring a sliding score bar that slides as the questions are answered, assists the user in comprehending the relative significance of individual factors and whether they represent risks or protective factors. Upon responding to each question, the inference engine of a rule-based decision support system will use the responses that are stored in the RAMP database layer to determine and suggest the most relevant modules and goals that are critical to the management of the most pressing risks. The use of these features across layers empowers the user to accurately identify their risks, gain knowledge of such risks, establish relevant goals, and monitor progress—all through the use of RAMP.

RAMP’s modular design allows novice users to follow the decision support system recommendations and create relevant goals and educational plans, while providing more freedom to experienced users to focus on specific areas that are most related to their personal risk of overdose and lifestyle. This design is important for the risk planning phase. When the user executes the plan and performs the given tasks, the system provides rewards to further engage the user.

Strategies to Enhance User Engagement

Reward systems are one of the most common gamification strategies designed to encourage users. The system awards badges as the user makes progress. This provides reinforcement as an individual continues their recovery journey. There is broad interest in the use of digital badges to enhance learners’ motivation [16]. These web-enabled tokens of learning and accomplishment have the potential to induce excitement and elicit powerful forms of engagement and learning. Badges are one of the most powerful gaming elements that are widely used in digital health products to motivate users to keep interacting with the system [17]. This strategy is particularly important for the population of substance users where retention and long-term interaction might be difficult [18,19].

RAMP does not support on-screen or push notifications. Instead, the system uses reliable SMTP email notifications regularly to inform users about their progress and motivate them to continue their interaction with the system. Notifications are an important gamification tool to promote engagement with the platform [20]. The frequency and content of RAMP notifications is different for active and inactive users. Active users receive more frequent notifications with suggestions regarding next steps they might benefit from based on their current patterns of use, while inactive users may receive positive reinforcement notifications and encouragements to start interacting with the system or continue where they have stopped. Previous studies have shown that tailoring notifications to each user is an effective way of boosting the use of web-based health tools [21].

Application of RAMP to Other Disorders and Diseases

RAMP content is currently developed to support those struggling with substance use and who are at risk of overdose. However, the tool can also be used to empower patients in other related domains such as navigating trauma, managing anxiety, and preventing self-harm and suicide by adding relevant assessments, modules, and goals. Through the development of proper content, the same logic can be applied to other mental health domains without a need to customize or redevelop the features, which maximizes the reusability of the developed system. Furthermore, RAMP features are fairly independent but interact with each other based on the business logic and through interfaces. This is in line with the principles of software...
engineering in which subsystems of a modular software should have high internal cohesion and low coupling [22].

Limitations
The knowledge of the authors about the application of WordPress plug-ins and add-ons is limited to RAMP. RAMP is a web application; therefore, general limitations of web applications such as requiring continuous internet connection, etc., are also applicable to the present software.

RAMP is developed on the WordPress CMS. Security and performance of the software are limited to the WordPress development framework. Although many successful and secure applications are developed on the same CMS platform, there is news about possible security exploitations of the websites developed on WordPress such as being infected by malwares, backdoors, or being hacked [23,24]. The RAMP development team has attempted to use security best practices such as using a secure host and server, security protocols, reCAPTCHA, reducing log-in attempts, disabling XML RPC, and many more features to create a safe and secure environment for the users.

RAMP is developed with a limited number of users willing to share their ideas. Wider use of RAMP may reveal other limitations.

RAMP neither substitutes or replaces medical advice by professionals nor provides emergency services during times of crisis. RAMP is designed for adults and is not yet adapted for adolescents and young adults.

Conclusions
Web-based platforms such as RAMP can be powerful assets to address significant gaps in the mental health and substance use care systems and can address a major public health crisis. It can integrate different settings of care from prevention to crisis management, all on one accessible platform. In terms of its architecture, RAMP uses a modular design that allows for maximal personalization and integration of user engagement strategies. WordPress components that are used to develop RAMP are mapped onto a 3-tier architecture, where the presentation, application, and database layers communicate to ensure proper functionality for users.

Although web applications seem to be an appropriate development technology for the current and future developments of RAMP, users may also benefit from having certain features such as “Assessments” and “Goals” on a mobile app. This would allow users to access these features even without a reliable internet connection and to receive on-screen notifications as appropriate.

RAMP is currently focused on substance use disorders and specifically reducing overdose, but the tool is flexible enough to include many more domains such as suicide, anxiety, self-harm, and trauma. Broader implementation will support this concept and lead to the next level of functionality. RAMP’s modular design makes it a promising tool for addressing a breadth of mental health conditions among vulnerable populations, increasing the capacity of clinical settings and reducing barriers to care. Further research will need to investigate whether this architecture style is appropriate for eHealth tools addressing different populations and appropriate implementation strategies for eHealth tools addressing people who use drugs.

Acknowledgments
The authors appreciate and recognize Health Canada for funding the RAMP project and its publications (1819-HQ-000122). We also appreciate TelusHealth for their cooperation on providing detailed information on the design and development technologies of RAMP.

Abstract

Background: The global COVID-19 pandemic caused by SARS-CoV-2 created many unprecedented challenges for health care organizations worldwide, placing a great deal of strain on the health care systems, especially access to health care services. To address these challenges, Qatar established a centralized digital platform as a community call center, initially offering digital consultations via its hotline (number: 16000) and later expanding to include a COVID-19 vaccination hotline (number: 7077) for mass immunization.

Objective: This study aims to comprehensively examine the community call center’s operations and their significant role during the COVID-19 pandemic.

Methods: Retrospective data were collected from the Health Information and Technology Department of the Primary Healthcare Corporation, Qatar, from March 29, 2020, to January 27, 2022. Data analysis for the hotline (number: 16000) focused on telephone and video call volumes, call response rates, abandonment rates, and call classification. In addition, data from the COVID-19 vaccination hotline (number: 7077) were analyzed for call volumes, call response rates, abandonment rates, appointment booking rates, confirmations, rescheduling, and cancellations.

Results: The hotline (number: 16000) received a substantial total of 429,212 calls, with 284,849 (66.37%) calls effectively answered. The average number of calls received per day during the study period was 640.61 (SD 470.53), and the average number of calls answered per day was 425.14 (SD 206.64). Notably, of the total 128,468 consultations, video consultations were conducted for 3810 (2.96%). Among the diverse call categories, diabetes mellitus (6284/84,299, 7.45%), prescriptions and medications (4709/84,299, 5.59%), hypertension (3874/84,299, 4.6%), vitamin D-related issues (3770/84,299, 4.47%), upper respiratory tract infections (2690/84,299, 3.19%), and COVID-19–related inquiries (2590/84,299, 3.07%) were most frequently addressed. For the COVID-19 vaccination hotline (number: 7077), an impressive total of 1,512,354 calls were received, with a 58.27% (n=881,305) call response rate. The average number of calls per day during the study period was 3828.74 (SD 2931.94), and the average number of calls answered per day was 2231.15 (SD 1496.02). Appointment booking accounted for 26.37% (265,721/1,007,596), appointment confirmation accounted for 10.24% (103,136/1,007,596), rescheduling accounted for 7.95% (80,124/1,007,596), and cancellations accounted for 1.6% (16,128/1,007,596) of the calls.

Conclusions: The findings of this research highlight the crucial significance of the community call center hotline (number: 16000) and the COVID-19 vaccination hotline (number: 7077) in effectively addressing the multifaceted challenges posed by the global COVID-19 pandemic. In Qatar, the community call center emerged as an indispensable and accessible centralized resource, facilitating streamlined digital consultations and vaccination appointments. The impressive call response rate highlights its operational efficiency, adeptly managing a diverse range of health-related issues. This study emphasizes the critical role of community call centers in health care emergency response, signaling their potential as invaluable assets for future preparedness and effective mitigation strategies during similar public health crises.
Introduction

Background
SARS-CoV-2, an enveloped single-stranded RNA virus with an epicenter in the Hubei province of China, has caused the current COVID-19 pandemic [1]. It initially appeared as an outbreak of an unknown cause of pneumonia and marked the seventh coronavirus outbreak [2]. Following its emergence, it rapidly spread globally, resulting in significantly high morbidity and mortality rates. At the time of writing this paper, on August 18, 2022, there were 589,680,368 confirmed cases of COVID-19 globally, with 6,436,519 deaths and a fully vaccinated population of 4,857,273,828 [3]. In Qatar, 7,355,038 doses of COVID-19 vaccination were administered until the date of writing this paper.

The COVID-19 pandemic poses many challenges to health care systems worldwide and places considerable strain on them. One of the main challenges is to respond to the crisis and simultaneously maintain the provision of essential health care services, which is crucial for a high-quality and resilient health care system. During the COVID-19 pandemic, many essential health care services were disrupted, including cancer screening, tuberculosis screening, HIV testing, outpatient services, and maternal and child health services [4]. The lack of health care workers, diversion of health care staff to COVID-19 management, cancellation of planned treatments, and risk of viral transmission during on-site patient visits have disrupted health care services [5]. It is essential to take necessary steps to curtail the spread of COVID-19 using available resources and the best use of digital technologies [6]. Different countries have responded differently to the COVID-19 crisis. In the United Kingdom, the National Health Services established a COVID Response Service, accessible via 111 phone lines, with the recruitment of 5000 call handlers and 1500 retired clinicians [7]. The Gulf Cooperation Council (GCC) countries implemented various measures in response to the pandemic, including lockdowns of major cities, airline suspensions, school and university closures, restrictions on social gatherings and sporting events, free health care provision, and active screening for COVID-19 [8]. In Saudi Arabia, the Umrah pilgrimage was suspended, and travel restrictions were placed on GCC citizens who had visited COVID-19–affected countries [9]. To protect public health as a national health strategy in Qatar, the Ministry of Public Health has provided digital solutions by providing remote access channels to health care services at the Primary Health Care Corporation (PHCC) and Hamad Medical Corporation in collaboration with the TASMU Smart Program Qatar, Ministry of Transport and Communication, Hukoomi, and Qatar Post, along with notable digital solution providers [10]. A hotline (number: 16000) was set up to provide 24/7 service to patients’ inquiries regarding COVID-19. In addition, the PHCC established an inbound community call center on March 29, 2020, accessible via the hotline (number: 16000), to provide digital virtual primary care consultations as an alternative to face-to-face health center visits. Physicians and nurses working in health centers who were deemed to be at a high risk for COVID-19, such as those with chronic conditions (hypertension, diabetes, ischemic heart disease, chronic kidney disease, pregnancy, immunocompromised state, etc), were given the option of working in the community call center. On January 5, 2021, the community call center added a COVID-19 vaccination hotline (number: 7077) for booking, cancelling, and rescheduling COVID-19 vaccination appointments [11].

The community call center hotline (number: 16000) provides telephone and video consultation services to all registered patients from 28 health centers in Qatar. Individuals can access the call center through hotline (number: 16000) and book appointments for telephone or video consultation with physicians, dentists, and ophthalmologists from 7 AM to 11 PM. Initially, the calls were triaged by the nurses. For patients who are not registered with the health centers, such as visitors and single workers, the triage nurses direct them to the appropriate service. In cases of emergencies requiring immediate medical attention, patients are guided to dial 999 for ambulance services as appropriate. For nonemergency situations, visitors are directed to local health centers, whereas single male workers are referred to worker’s health centers (HC-21), which are operated by the Qatar Red Crescent Society (QRCS). A nurse-led telephone triage service is available from 11 PM to 7 AM, which signposts patients to appropriate services [12]. Although primarily established for the COVID-19 pandemic, it provided all types of consultations, whether urgent or nonurgent. There were 7 physicians and 9 nurse stations. There was 1 ophthalmology station, whereas for the COVID-19 vaccination hotline (number: 7077), there were 22 stations. The staffing level of the community call center varied according to its operational needs during the study period.

Digital consultations offer several advantages for patients, providers, and health care systems [13]. Patients benefit from avoiding waiting in queues, reducing travel burdens [14], convenience, cost efficiency [15], accessibility [16], and high levels of satisfaction in primary care settings [17]. Satisfaction levels are particularly high in digital consultations, which include communicating with physicians, addressing patients’ concerns and queries, developing treatment plans, improving illness comprehension, and offering usefulness and reliability [5]. During pandemics, digital consultations provide an excellent alternative to traditional face-to-face consultations for patients [18]. Providers also experience advantages, including flexible working hours, the ability to work from anywhere; a reduced risk of infection; increased job satisfaction [13,19,20]; and less psychological distress, burnout [13], and sickness, which can be a burden on the organization. From an organizational perspective, digital consultations provide centralized operations with weekly statistics and demand forecasting, eliminating unnecessary patient visits to health centers and resulting in...
smooth operations and reduced clinic congestion [13]. Moreover, they enable health care services in remote areas and offer an opportunity for service expansion whenever possible. In addition, they contribute to lower CO₂ emissions and cost savings [20].

Call centers can serve as central hubs to respond to public health emergencies by providing rapid information transfer to health care providers [21]. During the COVID-19 pandemic, telehealth call centers played a significant role in supporting rural community health workers in Uganda, facilitating prompt identification and referral of COVID-19 cases for appropriate care [22]. In South Korea, the telehealth system provided up-to-date information to callers, helping them protect themselves and others from COVID-19 effectively [23]. Similarly, China established psychological support hotlines to offer mental health assistance during the pandemic [24], and in Paris, France, health care workers benefited from psychological support services [25].

**Objective**

Despite the importance of call centers during the pandemic, there is limited information available on their operations and outcomes, especially in relation to the COVID-19 pandemic and the vaccination hotline. Existing literature does not include reports from GCC countries detailing the role and impact of community call centers during the pandemic. This study aims to fill this gap by examining call center operations; documenting their contributions; and analyzing call volumes, patterns, response rates, categories of calls, priorities, and problems or diagnoses. By investigating the effectiveness of community call centers in Qatar during the COVID-19 pandemic, this research seeks to provide valuable insights into their performance during public health emergencies.

**Methods**

**Study Design**

A cross-sectional study design was used to assess the community call center hotline operations and performance during the study period.

**Disease and Study Population**

This research mainly evaluated community call center services to handle the COVID-19 pandemic health care challenges, specifically focusing on their utilization and effectiveness. The study population consisted of patients seeking routine and urgent consultations and advice regarding COVID-19 and its vaccination.

**Location**

Data were retrospectively collected from the Health Information and Technology Department of the PHCC, Qatar headquarters, where the community call center is located.

**Time Frame**

Data for the community call center hotline (number: 16000) were collected from March 29, 2020, to January 27, 2022. Similarly, data for the community call center vaccination hotline (number: 7077) were collected from December 29, 2021, to January 27, 2022. This time frame encompassed critical phases of the COVID-19 pandemic and the subsequent mass vaccination campaign.

**Data Collection and Analysis**

This study involved meticulous analysis of 2 separate data sets: one pertaining to the hotline service (number: 16000) and the other concerning the COVID-19 vaccination hotline (number: 7077). The hotline service (number: 16000) data set was analyzed for various essential metrics, including call volume, percentage of calls answered or abandoned, call patterns, categories of calls, and specific health concerns addressed. Similarly, the COVID-19 vaccination hotline (number: 7077) data set was thoroughly scrutinized, considering call volume; call response rates; call patterns; and appointment-related information such as bookings, rescheduling, confirmations, and cancellations.

**Data Cleaning**

To ensure utmost data quality and reliability, a robust data cleaning process was meticulously executed. The 3-step approach encompassed vigilant screening of the databases to detect and address any suspicious features, precise diagnosis of faulty data to ensure accurate results, and appropriate treatment of identified discrepancies. Moreover, a separate copy of the original data was meticulously created in a new file to maintain data integrity during the cleaning process.

**Data Reporting**

Conforming to the highest standards of scientific reporting, this study adhered to the RECORD statement, an extension of the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement checklist. This ensured accurate and transparent reporting of the secondary data analysis, further enhancing the credibility of the study findings [26].

**Ethical Considerations**

This study obtained ethical approval from the PHCC Research Subcommittee, adhering to research ethics and ensuring participant protection (PHCC/DCR/2021/11/068). As the study used existing deidentified data, informed consent was waived in accordance with the approved protocol. Stringent privacy and confidentiality measures were implemented to safeguard the data. The study strictly complied with data protection regulations to maintain the confidentiality of sensitive information. No compensation was provided to human participants, as the study involved secondary analysis of deidentified data and did not involve direct interaction with participants. The research team took utmost care to handle the data responsibly and ethically throughout the study.

**Results**

**Community Call Center Hotline (Number: 16000)**

Table 1 shows the quarterly performance of the community call center hotline (number: 16000). During the study period, 66.37% (284,849/429,212) of the calls were handled, with the highest being handled in the third quarter (33,395/34,376, 97.15%), followed by the fourth quarter (34,543/35,885, 96.26%) of 2021.
The average number of calls per day during the study period was 640.61 (SD 470.53), and the average number of calls answered per day was 425.14 (SD 206.64).

**Figure 1** shows the hotline (number: 16000) call volume patterns during the study period. The peak of calls occurred on April 19, 2020; April 7, 2021; and January 5, 2022.

**Figure 2** shows the volume and pattern of the video consultations conducted during the study period. Video consultations accounted for 2.96% (3810/128,468) of the total consultations conducted. The number of video consultations conducted was highest in the beginning of the COVID-19 pandemic reaching its peak in the first week of July 2020 and then gradually declined.

**Figure 3** illustrates problem-based summary of consultations over hotline (number: 16000). The highest number of calls was related to diabetes mellitus (6284/84,299, 7.45%), prescriptions or medications (4709/84,299, 5.59%), hypertension (3874/84,299, 4.6%), vitamin D-related issues (3770/84,299, 4.47%), upper respiratory tract infection (2690/84,299, 3.19%), COVID-19 (2590/84,299, 3.07%), thyroid-related problems (2237/84,299, 2.65%), dermatological problems (1807/84,299, 2.14%), dyslipidemia (1358/84,299, 1.61%), pregnancy (1320/84,299, 1.57%), back pain (1216/84,299, 1.44%), fever (1089/84,299, 1.29%), cough (1060/84,299, 1.26%), dry eyes (1004/84,299, 1.19%), gastritis (984/84,299, 1.17%), and many other problems or diagnoses.

Community Call Center Vaccination Hotline (Number: 7077)

Table 2 shows the quarterly performance of the COVID-19 vaccination hotline (number: 7077). The COVID-19 hotline (number: 7077) handled approximately 58.27% (881,305/1,512,354) of the total calls, whereas 41.73% (631,049/1,512,354) were abandoned during the study period. The average number of calls per day during the study period was 3828.74 (SD 2931.94), whereas the average number of calls answered per day was 2231.15 (SD 1496.02). The highest percentage of calls answered was during the third quarter of 2021 (112,445/118,372, 94.99%), while the lowest number of calls answered was during the first quarter of 2021 (180,205/311,364, 42.12%).

Figure 4 shows the volumes of calls and the pattern received by the COVID-19 vaccination hotline (number: 7077) during the study period. The highest number of calls was received around mid-May and November and the last week of December 2021.

Table 3 displays the quarterly call categories for the COVID-19 vaccination hotline (number: 7077). The highest number of appointments booked occurred in the fourth quarter of 2021 (86,924/1,007,596, 8.63%), followed by that in the second quarter (81,331/1,007,596, 8.07%). Similarly, the highest number of confirmed appointments occurred during the second (51,122/1,007,596, 5.07%) and fourth quarter (16,735/1,007,596, 1.66%) of 2021. The highest number of appointment cancellations occurred in the second (7028/1,007,596, 0.7%) and third quarter (2072/1,007,596, 0.21%) of 2021. Notably, the highest call volume identified for the workers’ health centers (HC-21) operated by QRCS occurred during the second quarter of 2021 (62,208/1,007,596, 6.17%), followed by the fourth quarter of 2021 (43,735/1,007,596, 4.34%). Calls from patients who did not meet the age vaccination criteria, as announced by the Ministry of Public Health of Qatar, were the highest in the second quarter of 2021 (57,081/1,007,596, 5.67%), followed by the third quarter of 2021 (8337/1,007,596, 0.83%).

Table 4 illustrates the distribution of call categories for the COVID-19 vaccination hotline (number: 7077) during the study period. Among the incoming calls, approximately 26.37% (265,721/1,007,596) were associated with appointment bookings, 10.24% (103,136/1,007,596) were for confirming existing appointments, 7.95% (80,124/1,007,596) involved rescheduling appointments, and 1.6% (16,128/1,007,596) were calls to cancel previously scheduled appointments. In addition, 14.8% (149,117/1,007,596) of the calls were identified as related to the workers’ health centers (HC-21) operated by QRCS, while 7.11% (71,600/1,007,596) of the calls received did not meet the age criteria for vaccination.

Discussion

Principal Findings

According to the findings of this study, the community call center hotline (number: 16000) and the COVID-19 vaccination hotline (number: 7077) have played a pivotal role during the ongoing COVID-19 pandemic. These hotlines effectively answered 66.37% (284,849/429,212) of the calls for urgent consultation requests and 58.27% (881,305/1,512,354) of the calls for COVID-19 vaccination appointment inquiries. Notably, the community call center serves as a centralized and versatile resource for citizens and residents of Qatar, offering consultations for a wide range of cases, whether they are emergencies, urgent, or nonurgent, and enabling centralized operations for the mass vaccination program against COVID-19. It has provided a hub during challenging times when health care organizations have witnessed a rapid shift from face-to-face to virtual consultations.

The results of this study showed that after 4 weeks of the first COVID-19 case in Qatar, which was announced on February 29, 2020, the community call center was fully operating. The trajectory of the call volumes received is in line with the peaks of COVID-19 cases, with the first one occurring on May 30, 2020, the second occurring in the middle of April 2021, and the third occurring in the middle of January 2022. As a result, during the COVID-19 pandemic including the lockdown phases, the people of Qatar were able to receive the best medical care. This has also prevented the spread of COVID-19 while providing alternative solutions for patients to access primary health care services [27]. With the community call center, patients have been empowered in terms of flexibility and convenience to use virtual consultations as an alternative to traditional health care services.

The community call center’s diagnostic categories revealed its capacity to handle a diverse array of medical concerns, encompassing inquiries related to COVID-19; vaccination inquiries; acute problems; chronic diseases; medication and repeat prescription requests; requests for laboratory investigations; and various medical conditions related to ear, nose and throat, ophthalmology, dermatology, psychiatry, gynecology, gastrointestinal, neurology, cardiovascular, orthopedics, hematology, pediatrics, and endocrine and metabolic conditions. Interestingly, patients with diabetes mellitus accounted for the highest number of consultations, and virtual consultations have proved effective for managing type 2 diabetes with outcomes comparable with face-to-face consultations, as demonstrated in primary care settings in Australia [28]. Similarly, the management of hypertension via virtual consultations during the COVID-19 pandemic has offered a holistic approach to achieve hypertension control in the United States [29].

It is intriguing to note that video consultations experienced a significant surge in demand during the early phase of the COVID-19 pandemic, especially in the first week of July 2020, reaching a peak of 30 video consultations per day. However, following this peak, the use of video consultation gradually declined over time. Although there is some evidence indicating that video consultations were more sought-after during periods of higher COVID-19 cases, such as in early July 2020 and mid-April 2021, it is essential to highlight that this correlation is not consistently observed throughout the data set. Notably, there were instances of relatively low video consultation counts during times of higher COVID-19 cases, such as in mid-January 2022. The lower use of video consultations can be attributed to various factors, including patients’ preferences influenced by cultural and language barriers, their comfort or inclination toward telephone or face-to-face consultations, privacy and security concerns, and technical limitations. Cultural reasons play a role in shaping patient preferences; some individuals may feel more at ease and familiar with consultation methods such as telephone calls. The content, duration, and quality of video consultations might resemble those of telephone consultations, which could affect patient choices [30], aligning with the findings reported in existing literature. Interestingly, in the United Kingdom, video consultations constitute <1% of consultations in general practice [31]. This preference for other consultation methods, including telephone and face-to-face consultations, might be influenced by physicians’ perceptions that video consultations offer minimal advantages compared with the alternatives.

The COVID-19 vaccination hotline (number: 7077) played a crucial role in Qatar’s mass immunization program, facilitating services for booking, cancellations, and rescheduling initially based on professional group and age criteria. The program was launched on December 21, 2020, introducing the BNT162b2 (Pfizer-BioNTech) messenger RNA vaccine initially, followed by the mRNA-1273 (Moderna) vaccine 3 months later. Initially, priority was given to vaccinating frontline health care workers, individuals with severe or multiple chronic diseases, and those aged ≥70 years. Subsequently, the program was extended gradually by 1 age group at a time, along with selected professional groups, using age as the primary eligibility criterion throughout the rollout [32]. The data from the vaccination hotline revealed noteworthy call volume spikes during mid-May, mid-November, and the last week of December 2021, coinciding with new announcements related to the vaccination program’s expansion. However, the percentage of vaccination hotline’s answers was observed to be lower than that of digital consultation phones. This disparity in the response rates can be attributed to multiple factors. Periods of high demand, such as vaccination eligibility expansions or public announcements about vaccination campaigns, led to a surge in hotline calls, potentially affecting response times due to the increased call volume. Specific eligibility criteria for vaccination appointments also played a role, as some callers may not have met these criteria, resulting in redirection or absence of appointments. Technical issues, waiting times, and call congestion further influenced the hotline’s response rate. Notably, the third quarter of 2021 demonstrated a higher response rate for the vaccination hotline. This could be attributed to a relatively lower volume of calls received during this period, possibly influenced by factors such as expats traveling during summer vacations and the vaccination hotline’s capacity to meet the demand effectively. Understanding these dynamics is crucial for optimizing hotline performance and enhancing vaccination service accessibility. Both vaccines in Qatar have been found...
to elicit strong protection against COVID-19, prevent hospital admission, and reduce mortality [33]. Due to mass vaccination supported by the community call center and other measures taken by the Ministry of Public Health, Qatar’s mortality remained very low at 0.0016%, whereas globally, it was 1% at the time of writing this paper.

One of the most significant outcomes of the COVID-19 pandemic is that many outpatient appointments can now be managed efficiently via telemedicine without affecting patient care [34]. The COVID-19 pandemic has shown that health care workers can swiftly adjust to the new technologies required to use telemedicine [13]. In a study involving 23 primary care providers and 1692 patients, both providers and patients reported a desire to continue telemedicine visits after the pandemic in primary care settings in the United States [17]. Even before the COVID-19 pandemic, the telehealth business flourished, with a market value of >US $50 billion in 2019 and an anticipated growth rate of more than 9-fold over the next decade [35]. Virtual consultant jobs have also been advertised [36].

The significance of the community call center and vaccination hotline in providing consultations, vaccinations, and health care services during a challenging period demonstrates the potential and value of telehealth solutions in health care systems worldwide. By sharing the successful experiences and best practices of the community call center hotlines, this study can contribute to the enhancement of telehealth services and call centers globally. The lessons learned from operating the hotline can be invaluable for improving crisis response strategies and optimizing health care delivery during public health emergencies. By leveraging digital technologies, health care systems can enhance access to services, improve patient satisfaction, and manage public health emergencies effectively. Integrating call centers and telehealth into routine health care services and emergency response strategies can provide long-term benefits beyond the pandemic.

Limitations

This study has several limitations. The data presented in this study involved 3 peaks of COVID-19 that affected the overall percentage of calls answered by the hotline (number: 16000). The hotline answered 100% of all calls on several days of the week during the study period. Perhaps, the percentage of calls answered improved to 71.71% at the time of writing this paper. Similarily, for the COVID-19 vaccination hotline (number: 7077), a surge in the volume of calls due to a new announcement of rolling out of the vaccination program affected the overall percentage of the calls answered. COVID-19 vaccination hotline (number: 7077) also answered >97% of the calls on many days of the week during the study period. The percentage of calls handled by the COVID-19 vaccination hotline (number: 7077) improved to 62.17% by the date of writing this paper.

It is important to acknowledge that although this study provides valuable insights into the role of community call center during the COVID-19 pandemic in Qatar, the applicability of these findings to low- and middle-income countries (LMIC) may be subject to limitations. LMIC often face unique challenges, including resource constraints, technological disparities, and varied health care infrastructures. The digital divide prevalent in many LMIC could significantly exacerbate the access-to-technology gap, hindering the establishment and effectiveness of call centers. Moreover, the lack of access to robust health systems or timely responses in LMIC might impact the feasibility and sustainability of implementing similar call center solutions. The success of such initiatives in Qatar, being one of the richest countries globally, may not necessarily translate seamlessly to LMIC because of the nuanced economic, infrastructural, and health care disparities prevalent in those regions. Therefore, although call centers can be a valuable tool, particularly in health care emergencies, their feasibility and effectiveness must be carefully evaluated in the context of LMIC’s unique challenges and constraints.

Conclusions

This study highlights the significant role played by the community call center hotline (number: 16000) and the COVID-19 vaccination hotline (number: 7077) in effectively managing the challenges caused by the COVID-19 pandemic in Qatar. The community call center responded well to these challenges in Qatar by providing patients with an accessible, centralized resource as an alternative platform for telephone and video consultations and for managing a mass vaccination program. The findings demonstrate the call center’s operational efficiency to handle high call volumes and offer diverse consultations, effectively addressing a wide range of health concerns throughout different waves of the COVID-19 pandemic. Virtual consultations have emerged as a practical solution to empower patients with flexibility and convenience. Although video consultations experienced a temporary surge, their overall use gradually declined during the specified study period, reflecting patients’ preference for other consultation methods. Nevertheless, the community call center remained instrumental in managing various health care aspects, including chronic disease management and COVID-19–related queries. Moreover, the COVID-19 vaccination hotline played a major role in executing a successful mass immunization program. Prioritizing frontline health care workers and susceptible groups initially, the vaccination drive significantly contributed to reducing mortality rates in Qatar. This accomplishment can be attributed to the coordinated efforts of the community call center and other strategic measures implemented by the Ministry of Public Health of Qatar. As the COVID-19 pandemic recedes, it will be essential to adapt the community call center’s capacity and its services to address future health care challenges. Expanding community call center services to encompass specialized health services such as dermatology, counseling, health education, and psychological support could further enhance Qatar’s health care infrastructure. Our study emphasizes the critical significance of telemedicine and digital solutions in crisis response and health care delivery. The insights gained from the community call center in Qatar during the pandemic will provide valuable lessons for improving health care accessibility and emergency response strategies in the future. As health care systems transition to postpandemic norms, leveraging the knowledge and experience gained will foster resilience and efficacy in addressing upcoming challenges, ensuring the well-being of the population.

Abstract

Background: The COVID-19 pandemic stressed global health care systems’ acute capacity and caused a diversion of resources from elective care to the treatment of acute respiratory disease. In preparing for a second wave of COVID-19 infections, England’s National Health Service (NHS) in Leicester, Leicestershire, and Rutland sought to protect acute capacity in the winter of 2020-2021. Their plans included the introduction of a digital ward where patients were discharged home early and supported remotely by community-based respiratory specialists, who were informed about patient health status by a digital patient monitoring system.

Objective: The objective of the digital ward was to maintain acute capacity through safe, early discharge of patients with COVID-19 respiratory disease. The study objective was to establish what impact this digital ward had on overall NHS resource use.

Methods: There were no expected differences in patient outcomes. A cost minimization was performed to demonstrate the impact on the NHS resource use from discharging patients into a digital COVID-19 respiratory ward, compared to acute care length of stay (LOS). This evaluation included all 310 patients enrolled in the service from November 2020 (service commencement) to November 2021. Two primary methods, along with sensitivity analyses, were used to help overcome the uncertainty associated with the estimated comparators for the observational data on COVID-19 respiratory acute LOS, compared with the actual LOS of the 279 (90%) patients who were not discharged on oxygen nor were in critical care. Historic comparative LOS and an ordinary least squares model based on local monthly COVID-19 respiratory median LOS were used as comparators. Actual comparator data were sourced for the 31 (10%) patients who were discharged home and into the digital ward for oxygen weaning. Resource use associated with delivering care in the digital ward was sourced from the digital system and respiratory specialists.

Results: In the base case, the digital ward delivered estimated health care system savings of 846.5 bed-days and US $504,197 in net financial savings across the 2 key groups of patients—those on oxygen and those not on oxygen at acute discharge (both P<.001). The mean gross and net savings per patient were US $1850 and US $1626 in the base case, respectively, without including any savings associated with a potential reduction in readmissions. The 30-day readmission rate was 2.9%, which was below comparative data. The mean cost of the intervention was US $223.53 per patient, 12.1% of the estimated gross savings. It was not until the costs were increased and the effect reduced simultaneously by 78.4% in the sensitivity analysis that the intervention was no longer cost saving.

Conclusions: The digital ward delivered increased capacity and substantial financial savings and did so with a high degree of confidence, at a very low absolute and relative cost.
Introduction
Overview
The COVID-19 pandemic stressed global health care systems, diverting resources from elective care and prioritizing the care of people with acute respiratory disease [1].

The introduction of a digital ward that commenced enrolling patients in November 2020 in Leicester, Leicestershire, and Rutland (LLR) was a key part of National Health Service (NHS) preparations for an expected surge in COVID-19 infections in the winter of 2020-2021.

The background to this decision was the impact of the first wave on LLR acute bed availability and the use of digital technology to remotely monitor patients to support their chronic conditions, both at the start of the COVID-19 pandemic and previously [2,3]. There was evidence to support the care of people after discharge with a high risk of readmission [2-4], and digitally supported patients with infectious respiratory disease had a reduced length of stay (LOS) [5-7].

The primary objectives for the COVID-19 digital ward were to maintain acute bed capacity through safe, early acute discharge and step-down into a specialist respiratory–managed service in the patients’ homes. Patients with COVID-19 respiratory infections were discharged into the care of the Leicester Partnership Trust (LPT) specialist respiratory team who were supported by digital technology (Clinitouch, Spirit Health), which electronically conveyed clinical observations and health status information to clinicians in an algorithm-based, traffic light (red, amber, and green)–prioritized basis. The standard operating procedures (service description), inclusion and exclusion criteria, objectives, and outcome measures for the digital ward are displayed on the internet [8], and more detail related to the intervention can be found in a study that regarded the first 65 patients that accessed the digital ward [9].

Paper-based, phone-based, digitally-based, and wearable device–based digital wards were used during COVID-19 as vehicles for admission avoidance and for stepping down patients who had been acutely admitted. There were mixed results [10].

The findings could have implications for future pandemics and how health systems allocate resources to better recover from the pandemic.

Objective
The objective of this study was to demonstrate the impact of a digital COVID-19 ward on NHS resource use. Specifically, the study aimed to establish if the digital ward achieved its primary goal of freeing up beds and the extent to which it reduced or increased overall NHS resource use.

Methods
Participants
There were 310 patients admitted to the University Hospitals Leicester (UHL) NHS Trust with COVID-19 respiratory disease; they were either discharged home between November 2020 and November 2021 into a digital ward to support their oxygen weaning (31/310, 10%) or had not required oxygen at discharge and needed additional support to recover (279/310, 90%). The patients’ mean age was 55.0 (SD 13.7; median 56; range 22-86) years, 3.2% (n=10) of patients were 80 years or older, and 40.6% (n=143) of patients were female. No ethnicity, comorbidity, or socioeconomic status information was collected. Patients were given the option to go home early and be supported digitally when they met the inclusion criteria [8].

Resource Use, Perspective, and Time Horizon
This study was based on observational data and represents a cost minimization of a service evaluation. All patients discharged into the digital ward had confirmed COVID-19–related respiratory disease. The Consolidated Health Economic Evaluation Reporting Standards (CHEERS) 2022 guidelines for economic evaluations were followed [11] (see Multimedia Appendix 1). This cost minimization analysis only evaluated NHS resource use and the outcomes of interest were acute bed-days saved, their costs offset, and the costs of the digital ward. It was considered that the digital ward would not deliver any change in patients’ long-term, health-related quality of life or health outcomes.

The perspective taken was that of the English NHS. Any savings would have been in the acute sector and additional costs in the intermediate care sector. The resource use only considered the digital ward costs and the costs of its comparator, acute hospital care.

The time horizon was slightly more than over 12 months, and no discounting of costs was conducted. All costs were in 2020-2021 pounds sterling and converted to US dollars.

Resource Use Data Sources
Comparator data for patients not on oxygen with acute LOS were sourced from patients discharged immediately prior to the introduction of the digital ward in November 2020 and a published NHS data set [12]. The difference between the duration of the LOS for patients discharged into the digital ward for oxygen weaning and those discharged routinely were acquired from UHL by LPT and NHS X (now part of the NHS Transformation Directorate). Mean clinical consultation durations and staff seniority were sourced from LPT (both correspondence: JS). Individual acute LOS, readmissions data, and the cost of a day in a respiratory ward were sourced from
UHL (correspondence: SG). Staff unit costs were sourced from the Personal Social Services Research Unit (PSSRU) data set for 2020-2021 [13].

There were 2 principal costs associated with participants’ stay in the digital ward: the duration of patients’ digital ward LOS, which influenced the costs of the digital technology and was calculated on a per diem basis; and the number and duration of respiratory specialist–patient digital contacts. The duration of the digital ward stays and the number of contacts were sourced from the digital technology database. The method for estimating the mean duration of a clinical contact was described in the paragraph above.

Resource use data in both units and costs can be found in Multimedia Appendix 1.

Comparison of Acute Ward LOS Versus Actual and Imputed Comparators

There were 2 different populations discharged into the digital ward; those on oxygen at discharge and those who were not.

Those on oxygen were subjected to an analysis conducted by NHS X and LPT. They were discharged from the hospital, on average, 9.9 days earlier than similar patients who had not accessed the digital ward.

The first 65 patients not on oxygen discharged into the digital ward left acute care in 3.3 days, 2.2 days (40% relative reduction in LOS) earlier than controls who did not have the potential to access the digital ward [9]. The information on controls’ LOS (5.5 days) was sourced immediately prior to the digital ward’s introduction. This is an analysis of all patients admitted into the LLR COVID-19 digital ward prior to the end of November 2021 and prior to the availability of disease-modifying medicines that reduced acute COVID-19 illness severity. This study includes the first 65 patients.

Data Used to Estimate LOS, Patients Not on Oxygen—Comparators

The LOS in UHL was reported alongside the median and mean monthly LOS for COVID-19 discharges between March 20 and December 21 [12]. The linear relationship between UHL discharges and median acute LOS is illustrated in Figure 1. The red line displays the result of pulling the data on the median LOS (gray hashed line) 1 month back in time. In doing so, the $r^2$ improved from 0.31 to 0.75 in an ordinary least squares (OLS) model.

Mean LOS included a minority of patients with intensive resource use and very long LOS, skewing the LOS upward (see Figure 2 for differences between mean and median LOS for England and UHL). The estimated comparator LOS was calculated for patients who were discharged without requiring oxygen. The authors considered that the median LOS better reflected patients’ estimated LOS.

Figure 2 shows the mean and median LOS for England and for UHL [12]. The solid blue and orange lines show the mean and median English LOS. The hashed gray and yellow lines show the mean and median UHL LOS.

**Figure 1.** The relationship between median acute LOS and number of acute discharges in COVID-19 patients in UHL, March 2020-November 2021 ordinary least square model. LOS: length of stay; UHL: University Hospitals Leicester.
Patients Discharged Acutely Into the Digital Ward Not on Oxygen—Comparators

The 4 comparators below were then used to populate 2 simple simulations, creating 1000 random iterations for each of the 279 patients in both uniform and normal distributions, and the mean of both was taken as the base case.

1. An OLS regression was used to establish the quality of the relationship between monthly median LOS with the number of monthly acute discharges as the independent variable ($r^2=0.31$; see Figure 1).

2. A regression similar to method 1 was used, but it used the better-fitted median data (1 month in arrears, $r^2=0.75$). This improved relationship reflected that the data observed acute discharges instead of admissions in calendar months (see Figure 1).

3. The LOS in the comparator group in November 2020 was 5.5 days. This comparator assumed that LOS in November 2020 remained constant.

4. The comparator LOS data (5.5 days, prior to the introduction of the service) was 10% (5.0 days) longer than the median LOS for November 2020. This relative margin was continued in this median monthly LOS-based OLS comparator.

The data model used the 4 comparators and was conducted in Microsoft Excel. The RANDBETWEEN function was used to create a uniform model with 1000 iterations between the lowest and highest values of the 4 comparators for each patient’s LOS and the mean of the 1000 iterations was taken for all 279 patients. The same process was conducted to create a normal distribution of those data using the NORMINV and RAND functions, using the mean of the 4 comparators and their SD to develop 1000 iterations, from which the mean was taken. The final mean was taken from the 2 mean parameters and provided the base case.

Patients Treated With Oxygen—Comparator

The NHS X and LPT analysis was used as the basis of the comparator for all patients treated with oxygen discharged into the digital ward.

Sensitivity Analysis

A deterministic 1-way analysis was conducted to establish the extent to which varying the parameters influenced the savings. A 2-way analysis was developed to establish the extent to which the acute LOS and savings would have to be varied to reach the net savings threshold value of 0.

Statistical Methods

The data sets were not normally distributed for both study subgroups (patients on and not on oxygen) on acute discharge. To evaluate the data, 2-tailed Wilcoxon signed-ranks tests for paired samples were used. Individual patients’ LOS was compared with their comparators. Normal approximation and ties correction were used, and $\alpha$ was set to .05. These methods were used consistently to compare paired data.

Study Size

A total of 55 pairs were required for a 90% power to establish a difference between the 5.5-day LOS (the lowest comparator) for patients not on oxygen. The scale of the difference between the patients who were oxygen weaning meant that the number of pairs required was only 4. There were 310 patients in the study: 279 (90%) patients who were not discharged on oxygen and 31 (10%) patients who were discharged home and into the digital ward for oxygen weaning.

Resource Use in the Digital Ward

Patients in the digital ward were monitored against a range of clinical criteria and classified by an algorithm into red, amber, and green ratings, which were highlighted on the LPT specialist respiratory clinicians’ dashboards. Red alerts provoked clinical contact within 24 hours throughout the patients’ stay in the digital ward; amber alerted the same, but in the first week only; and green rated patients who had not been contacted previously but were contacted in their second week in the digital ward. Patients were monitored using digital technology, which was billed on a per diem basis.

Ethical Considerations

The study was evaluated by the Institutional Ethics Review body of DeMontfort University, with a decision reference of HLS FREC Ref: 2091/22. Approval was waived for the protocol.
as it was an economic analysis of a service that eligible patients routinely accessed as part of standard care. All analyzed data were deidentified. All patients accessed usual care. No payments were made to authors or patients. Patients or the public were not involved in the design, conduct, reporting, or dissemination plans of our research.

Software Used for Analyses
All analyses were conducted in Microsoft Office Excel, Excel Analysis Toolpak, and The R Foundation’s R Studio.

Results
Overview
The 2 different patient populations had differing acute LOS. For patients not on oxygen when discharged, the mean acute LOS was 4.2 (SD 2.1; median 4.2) days. For patients treated with oxygen, the mean acute LOS was 13.3 (SD 4.5; median 12.4) days. Overall, the mean acute LOS was 4.3 (SD 2.1; median 4.4) days.

The phasing of patients discharged into the digital ward reflected demand in UHL [14]. The number of discharges into the COVID-19 ward (bars in Figure 3) corresponded with key system stressors (lines in Figure 3) rising and falling. The 3 key stressors reported were the ratios of COVID-19–related absences divided by all absences, total COVID-19–related beds occupied divided by all beds occupied, and COVID-19–related mechanically ventilated beds divided by all mechanically ventilated beds occupied [14].

Patients Discharged Not on Oxygen—Acute LOS
Table 1 demonstrates the difference in acute LOS versus the imputed non–oxygen weaning LOS comparators.

The mean of the normal and uniform distributions from 1000 random iterations of the above data in each of the 279 non–oxygen weaning comparators were 6.31 and 5.95, respectively. The mean of both, 6.13, was used as the base case.

Table 1. Comparison of estimated comparators with acute University Hospitals Leicester length of stay prior to discharge into the COVID-19 digital ward in patients not weaning on oxygen between November 2020 and November 2021.

\textsuperscript{a}LOS: length of stay.\n\textsuperscript{b}W\text{\textsubscript{min}}: Wilcoxon signed rank test statistic.\n\textsuperscript{c}N/A: not applicable.
A UK study of patients with COVID-19 not admitted to an intensive care unit estimated the acute LOS as 8.0 to 9.1 days [15]. All acute LOS comparators in the non–oxygen weaning group fell below this range, with the base case being almost 2 days beneath the lower value [15], supporting the conservatism of the model. The mean digital ward LOS was 14.2 days (SD 4.9; median 15) for patients not on oxygen.

**Patients Discharged on Oxygen—Acute LOS**

The mean acute LOS for patients discharged into the digital ward on oxygen was 13.3 days, and the difference was 9.9 days (42.7%) between the actual LOS and the comparator LOS (P<.001). The mean digital ward LOS for patients on oxygen was 24.5 (SD 12.6; median 23) days.

**Digital Ward Resource Use**

Digital ward resource use was driven by 2 elements: the number of clinical contacts and the LOS; the details are shown in Table 2. Multimedia Appendix 2 contains a breakdown of unit costs. How they were calculated is outlined in the Methods section.

### Table 2. Total and per-patient costs of specialist respiratory consultations and digital technology in the COVID-19 digital ward between November 2020 and November 2021.

**Estimated Resource Use and Savings**

- The range of estimated bed-days saved in the 279 patients not on oxygen varied from 363.8 (constant 5.5 days) to 749.9 (median OLS+10%); the comparison of digital ward patients versus all imputed controls was significant (P<.001). The base case was estimated to have saved 490.3 bed-days in the patients not on oxygen (P<.001). The estimated bed-days saved in the 31 patients on oxygen was 306.9, with which there was greater certainty (P<.001). The total estimated bed-days saved were between 670.7 and 1056.8 (2.2-3.4 days per patient). The base case estimate was 846 bed-days saved.
- The cost of a bed day in a UHL acute respiratory ward in November 2020 was US $678.
- Estimated implications on costs are summarized below:
  - The total estimated gross savings related to bed-days were between US $454,404 and US $715,991 (US $1466-US $2310 per patient). The base case was US $573,490 (US $1850 per patient).
  - Health care professional interventions were made to address patient symptoms. There were 1355 digital specialist respiratory consultations costing US $51,294 (US $165.47 per patient).
  - The digital technology costs of the digital ward were US $17,999 (US $58.06 per patient).
  - The total costs of the digital ward were US $69,293 (US $223.53 per patient).
  - The total net savings were between US $385,411 and US $646,697 (US $1242-US $2086 per patient). The net savings in the base case were US $504,197 (US $1626 per patient).
  - The intervention was cost saving in all scenarios. The costs of US $54,420 were between 9.7% (US $715,991) and 15.2% (US $454,404) of the estimated gross savings.

**Readmissions**

There were 9 hospital readmissions (9/310, 2.9% of digital ward admissions) within 30 days. All readmissions were in the non–oxygen weaning cohort. In a systematic review, 10.3% (n=265,590) of those admitted with COVID-19 respiratory infections had a 30-day readmission [16]. Of the included English studies, 3 reported on 30-day readmission rates but included patients who had accessed critical care or had a high percentage of older adult patients [17-19] and reported readmission rates of 10.2% to 17.1%.

A total of 7.1% (n=154) of patients with mild or moderate COVID-19 disease, similar to the digital ward patients not on oxygen, discharged from a Turkish tertiary center were readmitted within 30 days [20]. Another systematic review [21] found that readmissions ranged from 4.2% [22] to 19.9% [23]. Evidence suggested that there was no difference between the rates of 30-day readmissions between the first and second COVID-19 waves [24]. If it was assumed the readmission rate for a comparator was 7.1% [20], the costs of readmissions would have been US $69,050 or 99.6% (US $69,293) of the total costs of running the digital ward. Using the lowest plausible comparator of 4.2% [22] would have offset 30.8% (US $21,342).
of the costs of the digital ward. Any potential savings associated with readmissions were excluded from the results of the analysis because of the uncertainty associated with any potential comparator and to aid in the overall conservatism of this study.

**Estimated Carbon Dioxide Emissions**

The carbon footprint associated with acutely hospitalized patients has been described as the most carbon-intensive care pathway and contributed 125 kg of carbon dioxide equivalent per day [25]. The gross reduction in 2019 carbon dioxide equivalent was 341 kg per patient in the base case and totaled 105.75 metric tonnes.

**Deterministic Sensitivity Analysis**

There were 8 variables in this analysis; the differences in acute LOS for those who were on the digital ward versus comparators, the cost of an acute bed-day, the number of clinical contacts, the clinical contact duration, the cost per hour of clinicians, the digital ward LOS, and the digital technology costs.

A 1-way sensitivity analysis demonstrated that the 2 variables that changed more than the relative input parameters were the LOS of patients who were and were not oxygen weaning. There was a linear 3.18% and 2.34% increase or decrease in the savings or costs for every 1% change in the value for the patients who did or did not access oxygen, respectively. All other resource-use variables increased or decreased at the same rate as the input variable. The parameter with the greatest uncertainty was the one that had the greatest impact on potential savings.

The cost of clinical consultations (respiratory specialists, LPT) and the cost of digital technology (Clinitouch, Spirit Health) were the 2 components of the digital ward costs. When the costs of both were simultaneously increased in a 2-way sensitivity analysis in the 279 patients not on oxygen by the same percentage as the LOS was reduced, it required a 75.4% change to reach the 0-threshold value. Performing the same for patients who accessed remote oxygen weaning, the threshold value was reached by simultaneously increasing costs and reducing the LOS cost offset by 87.5%. Overall, it took a reduction in effect and increase in costs of 78.4% (savings reduced from their estimated base case value of US $573,490 to 21.6% of that US $123,874 and costs to rise from US $69,293 to US $123,618) to reach a 0-threshold value.

**Discussion**

Resource use in the digital ward was lower than all of the potential comparators. The net savings were estimated to have been between US $385,111 and US $646,697, with an estimated saving of US $1850 per patient in the base case. The digital ward costs were relatively low compared with the estimated gross savings (9.7% to 15.2%). The risk to health care systems of the digital ward not being cost saving was low. The UHL mean and median acute LOS were tracked at or below the England overall mean and median LOS between November 2020 and November 2021 (see Figure 2) [12]. The gap was largest after times of peak acute COVID-19 bed demand, which is also when the digital ward was used most to reduce pressure on UHL beds (see Figure 3). Both lend face validity to the findings. The COVID-19 digital ward intervention achieved its primary goal of increasing acute capacity. It also reduced overall NHS resource use, had a very low rate of readmissions, and reduced carbon dioxide emissions. Patients were released from acute wards earlier but clinically monitored for longer in the digital ward, which may have accounted for a plausible reduction in 30-day readmissions.

The main limitations associated with this analysis were the observational nature of the data and the associated use of imputed indirect comparators for 90% (279/310) of patients. The findings were most influenced by the parameter around which there was the greatest uncertainty. This renders a degree of uncertainty around the savings. Leicester City has a greater population of South Asian ethnicity than those of White ethnicity [26]. It is documented that people of South Asian ethnicity were at a higher risk of hospitalization from COVID-19 than their White counterparts [27]. The lack of socioeconomic status, comorbidities, and ethnicity data made the representativeness of the results difficult to interpret for wider settings.

The United Kingdom has a crisis in demand for elective care driven by an aging population [28]. It also had a shortfall in elective health care supply during the COVID-19 pandemic [1]. The supply-side constraint has been exacerbated by the lowest number of hospital beds per capita of all G7 countries [29] and social care’s inability to accommodate patients medically fit for discharge [30].

Specialist community respiratory teams exist widely across the United Kingdom. In addition, 82% and 99% of people older and younger than 55 years, respectively, owned a smartphone in the United Kingdom in 2022 [31]. The low financial and safety risk to health systems, digital scalability, widespread digital literacy, and high access to smartphones has meant there is an opportunity to be better prepared for future pandemics and enable wider digital diffusion into health care to support patients with other diseases, especially when there is continued capacity constraint. The findings were broadly consistent with other evaluations of digital wards where reductions in LOS were observed [32,33], and cost savings were found [32].

**Acknowledgments**

The authors would like to thank Irene Valero-Sanchez, respiratory consultant from University Hospitals Leicester National Health Service (NHS) Trust, for help in developing and steering the project. The authors would also like to thank Zoe Harris from NHS England’s Transformation Directorate, who helped develop the project and shared resource use analysis while at the Leicester Partnership Trust and NHS X. NHS Leicester City Clinical Commissioning Group (CCG), NHS East Leicestershire and Rutland CCG, NHS West Leicestershire CCG and Ageing Well funded the intervention.

Abstract

Background: To safeguard the most vulnerable individuals during the COVID-19 pandemic, numerous governments enforced measures such as stay-at-home orders, social distancing, and self-isolation. These social restrictions had a particularly negative effect on older adults, as they are more vulnerable and experience increased loneliness, which has various adverse effects, including increasing the risk of mental health problems and mortality. Chatbots can potentially reduce loneliness and provide companionship during a pandemic. However, existing chatbots do not cater to the specific needs of older adult populations.

Objective: We aimed to develop a user-friendly chatbot tailored to the specific needs of older adults with anxiety or depressive disorders during the COVID-19 pandemic and to examine their perspectives on mental health chatbot use. The primary research objective was to investigate whether chatbots can mitigate the psychological stress of older adults during COVID-19.

Methods: Participants were older adults belonging to two age groups (≥65 years and <65 years) from a psychiatric outpatient department who had been diagnosed with depressive or anxiety disorders by certified psychiatrists according to the Diagnostic and Statistical Manual of Mental Disorders (Fifth Edition) (DSM-5) criteria. The participants were required to use mobile phones, have internet access, and possess literacy skills. The chatbot’s content includes monitoring and tracking health data and providing health information. Participants had access to the chatbot for at least 4 weeks. Self-report questionnaires for loneliness, depression, and anxiety were administered before and after chatbot use. The participants also rated their attitudes toward the chatbot.

Results: A total of 35 participants (mean age 65.21, SD 7.51 years) were enrolled in the trial, comprising 74% (n=26) female and 26% (n=9) male participants. The participants demonstrated a high utilization rate during the intervention, with over 82% engaging with the chatbot daily. Loneliness significantly improved in the older group ≥65 years. This group also responded positively to the chatbot, as evidenced by changes in University of California Los Angeles Loneliness Scale scores, suggesting that this demographic can derive benefits from chatbot interaction. Conversely, the younger group, <65 years, exhibited no significant changes in loneliness after the intervention. Both the older and younger age groups provided good scores in relation to chatbot design with respect to usability (mean scores of 6.33 and 6.05, respectively) and satisfaction (mean scores of 5.33 and 5.15, respectively), rated on a 7-point Likert scale.

Conclusions: The chatbot interface was found to be user-friendly and demonstrated promising results among participants 65 years and older who were receiving care at psychiatric outpatient clinics and experiencing relatively stable symptoms of depression and anxiety. The chatbot not only provided caring companionship but also showed the potential to alleviate loneliness during the challenging circumstances of a pandemic.
Introduction

As COVID-19 spread worldwide, many governments implemented stay-at-home, social distancing, and self-isolation measures to protect the most vulnerable people, including older adults, for whom deteriorating physical health could result in both physical and mental challenges [1,2]. As one of the most vulnerable groups to experience negative outcomes of COVID-19, older adults were instructed to self-quarantine and isolate themselves from others to mitigate the risk of infection. Consequently, they missed out on their standard interactions with others and spent substantial amounts of time in isolation. Limited contact with other people can lead to loss of social support, which is especially important for older adults [1,2]. Indeed, older adults who experienced social isolation during the pandemic have been negatively impacted by feelings of increased loneliness and reduced quality of life. Furthermore, the risks faced by individuals living alone, including older adults, are particularly pronounced with more challenging economic conditions [3,4]. Loneliness is defined as a subjective feeling manifesting as uneasiness and unhappiness linked to a lack of connection or inclusiveness with others, whereas social isolation describes the objective state of an individual’s social environment and interactional patterns [5]. Growing evidence shows that “loneliness” is closely related to physical and mental health in older adults; stronger feelings of loneliness can lead to the development of unhealthy lifestyle habits (eg, smoking and drinking) and a reduction in engagement with health-positive behaviors (eg, exercise and a nutritious diet) [6,7]. Loneliness is also associated with decreased sleep and sleep efficiency and poor subjective sleep quality in middle-aged and older adults, along with correlations to cognitive dysfunction, disability, cardiovascular disease, increased mortality, and even suicide [8-10]. Loneliness is also associated with negative emotion processing in the brain [11] and is a significant risk factor for anxiety and depression in older adults [12,13].

The prevalence of anxiety disorders and depression among older adults is high. Approximately 2% of adults older than 55 years are diagnosed with major depression, and 10%–15% of older adults have depressive symptoms [14]. Anxiety disorders are the most common psychiatric diseases, with a lifetime prevalence of up to 30%. Treatment of depressive and anxiety disorders in older adults is difficult and common challenges include poor drug efficacy, adverse drug reactions, and common drug interactions caused by polypharmacy. Coping with loneliness among older adults has potential benefits for depression and anxiety, as loneliness can affect older people’s physical and mental health, triggering psychological vulnerability, causing brain alterations beyond those associated with normal aging, and reducing intellectual or psychological flexibility caused by discrete and chronic stress [15]. Given the serious impact of social isolation and loneliness on older adults’ mental and physical health, researchers must investigate ways to mitigate these adverse health outcomes. As an assistive technology, chatbots and conversational agents may provide companionship and reduce the loneliness experienced because of the social restrictions imposed during a pandemic [7].

In recent years, there have been breakthroughs in the application of deep-learning techniques for natural language processing, allowing a variety of applications to be used in medical communication, disease detection, and treatment. For instance, chatbots have been developed to assist patients with autism and to provide social-skill training for specific fields such as mental health [16]. There is also a publicly listed application that provides cognitive behavioral therapy to improve anxiety and depression symptoms. Chatbots are also used for veterans as a screening tool for posttraumatic stress syndrome, and users of such applications have compared its use to interacting with real people, highlighting the chatbot’s ability to more freely and accurately reflect their own symptoms [17]. Additionally, chatbots used for mental illness discharge preparation can offer time-saving benefits for nurses and allow users to repeat questions without time pressure [18]. Upon reviewing previous research, it is evident that most chatbot users are relatively young, with limited availability of chatbots specifically developed for older adults in psychiatric clinics. While an overwhelming number of mental health apps are available to the public, these apps seldom focus on the needs of the older adult population. Furthermore, older adults can be apprehensive about using apps containing too many complex functions. This situation highlights the need to design and develop an older adult–user-friendly chatbot geared toward the specific interests of this population, while promoting their physical and mental health.

To address this gap, this study investigated the perspectives of geriatric psychiatric outpatient users of a mental health chatbot during the COVID-19 pandemic and sought to develop a chatbot for older adult users with anxiety and depressive disorders. This chatbot aims to offer companionship and promote self-awareness regarding emotions, sleep patterns, and physical activity to improve overall health. Therefore, our primary research objective was to examine whether chatbots can mitigate the psychological stress that older adults experienced during COVID-19.

Methods

Ethical Considerations

Ethical approval was granted by the Institutional Review Board of Chang Gung Memorial Hospital (202001915BO). The participants were recruited from the psychiatric outpatient...
department of the hospital between September 2021 and March 2022. Informed consent was obtained from each participant before study initiation. Data were deidentified by assigning a unique identifier code to each participant; only the study moderator has access to the file linking the code to the personal information, which is stored in a locked cabinet. Participants were provided with a travel compensation of ~US $15 for completing the postintervention questionnaires; no other compensation was provided for participation in the study.

Participants
Participants comprised two groups of individuals aged either 65 years and older or younger than 65 years who were diagnosed with depressive or anxiety disorders, including persistent depressive disorder, major depressive disorder, generalized anxiety disorder, panic disorder, or adjustment disorder with anxiety or depression. Certified psychiatrists made diagnoses according to Diagnostic and Statistical Manual of Mental Disorders (Fifth Edition) (DSM-5) criteria.

During the time of the study, none of the participants had experienced suicidal ideation or had an increase in medication 3 months prior to the beginning of the study. Participants included in the study were literate, active mobile phone users with internet access, who had used the chatbot regularly for at least 4 weeks. We excluded patients who were not literate, those with severe physical illness, and those diagnosed with a major neurocognitive illness (eg, schizophrenia, bipolar disorder, brain injury, substance abuse, stroke history, and dementia). During the case referral period, only one patient was excluded due to a diagnosis of bipolar disorder. All participants completed a questionnaire regarding their demographic characteristics.

Health Promotion Chatbot
Chatbot Design
The LINE Official Account Manager was used to build the “Health Promotion” chatbot. LINE was used as it is currently the most popular chatbot for older adults in Taiwan. Previous research found that some older adults have difficulty keeping pencil-and-paper sleep diaries [19]. This difficulty can be ameliorated using mobile technologies; thus, we designed a user-friendly interface for older adults using buttons in the chatbot app. The proposed chatbot is multifunctional and includes health diary data collection and hygiene education functions. Figures 1-4 provide screenshots of the Health Promotion chatbot functions translated into English.

Figure 1. Mood tracking function of the Health Promotion chatbot.
Figure 2. Sleep tracking function of the Health Promotion chatbot.

Figure 3. Daily activity tracking function of the Health Promotion chatbot.
Monitoring and Recording Health Data

The Health Promotion chatbot sent daily messages to all participants and collected their health diary responses. The diaries tracked three key response areas, including mood, sleep, and daily activity. Figure 1 depicts the participants’ rating of their mood using five status terms: great, not bad, indifferent, sad, and angry. Sleep quality was rated as good, not bad, or sleepless (Figure 2). In addition to keeping an activity diary, the chatbot sent messages such as “Did you go out today?” or “Did you do some exercise? What kind of exercise?” (Figure 3). These messages helped guide older adult users to complete their activity information in the formatted “Message buttons.”

Providing Health Information and Advice

The main health promotion education program consisted of three topics: sleep hygiene education, food education, and exercise videos. The educational videos were provided to help the older adults practice good sleep hygiene and exercise habits. The sleep hygiene education video helped users practice “abdominal breathing” for relaxation. The exercise videos were recorded by a professional rehabilitator to guide older adults in performing different types of body movements. Overall, the app proved to be an effective tool to help the users perform training courses at home. The health promotion education programs are shown in Figure 4.

Measures

Self-Assessments

Self-assessment scales for loneliness, depression, and anxiety were administered before and after chatbot use. Using a 7-point Likert scale, we also assessed individuals’ attitudes toward the chatbot post intervention.

Loneliness was measured using the University of California Los Angeles Loneliness Scale (UCLA-LS), which has demonstrated good reliability and validity for all ethnic groups as well as for older adults [20]. Participants rated themselves on a 1-4 scale for the 20 items, with a possible total score ranging from 20 to 80. As a one-dimensional measure, higher scores indicate greater loneliness.

Depression was measured using the Geriatric Depression Scale (GDS) 15-item short form; a cutoff score of 15 indicates clinical depression [21].

Anxiety was assessed using the Hospital Anxiety and Depression Scale anxiety subscale (HADS-A), which consists of 7 items. The depression subscale, also comprising 7 items, was not used in this study owing to the duplication of targets measured by the GDS [22].

Attitudes Toward the Chatbot

Based on the measure proposed by Bickmore et al [23], the questionnaire was modified to evaluate users’ attitudes toward the chatbot. The questionnaire covered four dimensions regarding satisfaction, usability, willingness to continue use, and adherence. All participants were asked to rate a series of
attitude statements using a 7-point Likert rating scale, ranging from 1 (strongly disagree) to 7 (strongly agree), to assess their attitudes toward the chatbot’s features, such as “I was satisfied with the chatbot,” “It was easy to use the chatbot,” “I would like to continue using the chatbot,” “I will follow the chatbot’s recommendations,” and others [23-26].

Utilization Rate
The participant utilization rate was determined according to the frequency of interactions with the chatbot, specifically measured as the ratio of the number of interaction days to the total test days for each participant. This score encompasses the percentage of responses to inquiries regarding emotions, sleep quality, sport participation, and daily outings. For example, if a participant responded to emotional inquiries 15 times (with only one interaction per day counted) during a 30-day testing period, their emotional inquiry response rate would be 50%.

Statistical Analysis
We compared the effectiveness of the chatbot between the age groups of ≥65 and <65 years. In Taiwan, individuals 65 years and older can enjoy old-age benefits (such as old-age pensions and bus discounts). Therefore, the division of participants into these two age groups allowed for a comparison of the effects of the chatbot on anxiety and depression in individuals who have already reached the age of eligibility for old-age benefits and those who have not. This distinction is important as it enables researchers to explore differences in psychological well-being between the two groups considering the impact of access to benefits and associated social support networks.

All statistical analyses were performed using SPSS for Windows 20.0 (IBM Corp). The Fisher exact test, Wilcoxon signed rank test, analysis of covariance, and Spearman rank correlations were applied as appropriate.

Results
Sample Characteristics
The age of the participants ranged from 55 to 82 years, with a mean age of 65.21 (SD 7.51) years; the study sample comprised 74% (n=26) female participants and 26% (n=9) male participants. There were no significant differences in the demographic variables between the groups, except that a greater percentage of participants in the older age group (≥65 years) were living alone (Table 1).

aN/A: not applicable.
bOne participant had comorbid major depressive and anxiety disorders.
cStatistical analysis was not applicable in this case since a single participant may have multiple psychiatric diagnoses.

### Attitude Toward the Chatbot

In the postintervention assessment, we collected the participants’ attitudes toward the chatbot using a 7-point Likert scale. The mean scores for satisfaction, usability, willingness to continue using, and adherence were 5.33, 6.33, 4.87, and 5.07, respectively, in the ≥65 years age group; the corresponding mean scores in the <65 years age group were 5.15, 6.05, 4.7, and 4.95, respectively. There were no group differences in satisfaction, usability, willingness to continue using, and adherence scores.

### Use and Response Rates

The use rate was determined by the frequency of a patient’s interaction with the chatbot, specifically measured as the ratio of interacting days to the total testing days for each participant. This included the rate of response to the inquiries for mood, sleep quality, and participation, as well as the “I went out today” inquiry.

There was no significant difference in the response rate between the two age groups. However, the response rate to the sport participation inquiry was less than 50%. Furthermore, during the 1-month intervention, the participants had a high use rate, with over 82% of the participants reporting being active daily (Table 2).

Discussion

Principal Findings

Usability and User Satisfaction of the Health Promotion Chatbot Among Older Adults During the COVID-19 Pandemic

This study took place during the COVID-19 pandemic, which greatly impacted people’s daily lives and led to notable reductions in interpersonal interactions and outdoor activities [27]. The pandemic also substantially affected the economy, impacting employment and raising anxiety for many who experienced both the disease itself and the protocols set in place to counter the spread of the virus [28,29].

The results of this study indicate that both age groups, ≥65 and <65 years, were equally satisfied with the chatbot. Its design was rated highly for usability and user satisfaction by both groups. The ≥65 age group provided a mean satisfaction rating of 5.33 and a mean usability rating of 6.33, whereas the corresponding scores for the <65 age group were slightly lower at 5.15 and 6.05, respectively. These high satisfaction ratings reflect the chatbot’s effectiveness in catering to a wide range of users and their positive reception of the user-friendly interface.

The use rate among the older adults was remarkably positive. Previous studies have suggested that systems that are not user-friendly for older adults are often met with resistance and ineffectiveness [30]. However, this system, which was specifically designed for older adults, features a simple and user-friendly interface to target the barriers that older adult users might face in terms of digital literacy and technical assistance [31,32]. Our Health Promotion chatbot was designed to have concise functions, aiming to provide companionship and support even to those who are less familiar with technological products. Additionally, the use and response rates showed that age did not affect the willingness to use the chatbot, further suggesting that the content and interface of the chatbot are well-received and accessible for older adult users.

Therefore, the findings of this investigation on chatbot applicability in geriatric psychiatric outpatient clinics indicate that the chatbot interface is user-friendly and meets the desired criteria.

Chatbots Mitigate Loneliness in Older Adults

Some studies have explored the potential of assistive technology in addressing social isolation and loneliness among older adults. For example, one prospective cohort study reported that humanoid robots improve patient outcomes by providing companionship and entertainment in acute hospital settings and may be an acceptable outlet for socialization among older adults [33,34]. In a systematic review, Chen and Schulz [7] found that information and communication technology interventions can effectively reduce social isolation among older adults and potentially improve their quality of life by enhancing social support, promoting social engagement, and reducing feelings of loneliness and depression. However, a cross-sectional study also showed that problematic social media use was positively
associated with perceived social isolation among older adults [35].

Four possible mechanisms by which information technology alleviates social isolation and loneliness have been proposed in the literature [7,36]: connection to the outside world, gaining social support, engaging in interesting activities, and boosting self-confidence. Boosting self-confidence was interpreted based on reports of older adults feeling younger and more equipped with new skills when taught how to use communication technologies. In our study, the chatbot greeted older adults daily and encouraged them to stay active. Some participants reported benefitting from the chatbot’s exercise videos; engaging with the chatbot and performing daily exercises made them feel rejuvenated and more purposeful.

Overall, our results suggest that the chatbot helped to reduce feelings of loneliness; the average UCLA-LS score of the total cohort at baseline was 40.4, which decreased to 38.1 post intervention. For the ≥65 age group, the average baseline score was 38.9, which decreased to 34.9 post intervention, representing a statistically significant difference (P=.006). However, the <65 age group had an average baseline score of 41.5, which remained stable post intervention with a nonsignificant difference (P=.98). Therefore, although the participants had decreased UCLA-LS scores post intervention on the whole, only the older participants (≥65 years) showed a significant improvement in loneliness.

Generally, the ≥65 age group responded well to the chatbot, as reflected in the UCLA-LS score changes, indicating that this age group can benefit from chatbots. Some potential reasons to explain the lack of an effect on loneliness for the <65 age group may be related to this group experiencing elevated stress in their daily lives [4,37] due to financial burdens and concerns about the future. Evidently, the effectiveness of chatbots in alleviating such stress is limited. Moreover, the <65 age group likely also had more opportunities for interpersonal interaction, even during the pandemic. Members of this group tend to not live alone and have more avenues (eg, different types of social media) to access information. Consequently, the influence of chatbot interventions on their lives was comparatively less pronounced.

Our study demonstrates the positive impact of chatbot interventions on older adults enrolled in psychiatric outpatient departments and with relatively stable symptoms during the pandemic. Previous studies have mentioned the importance of using technology to reduce the impact of loneliness on older adults, particularly in the context of pandemic-related restrictions [2,38,39]. Although this study was conducted during a period when the pandemic was more severe, it offers valuable insights into older adult care. To enhance the generalizability and applicability of future trials, we recommend expanding the participant pool to include older adults outside of clinical settings.

Limitations

This pilot study has some limitations. When assessing loneliness and depression, it is important to include in-depth interviews to understand users’ thoughts. However, due to the pandemic, interviews could not be conducted during the study period. We therefore aim to further enhance this aspect by including interviews in future research. In addition, given that the study was conducted during the COVID-19 pandemic, it was challenging to enroll participants, as many patients were unwilling to visit the hospital, resulting in a limited sample size. The improvement in loneliness may be due in part to the placebo effect. Additionally, the study sample was derived solely from the psychiatric outpatient department of a single medical center, potentially introducing bias in the referral process and limiting the generalizability of the findings to a broader population. Finally, the follow-up period was relatively short (within half a year); thus, determining the long-term effect of the intervention requires further research.

Conclusions

The chatbot interface developed in this study was simple and easy to use. The results demonstrated that older adults in psychiatric outpatient clinics with relatively stable depressive and anxiety symptoms could benefit from the chatbot’s care, companionship, and potential reduction in loneliness, particularly during a pandemic. Simultaneously, the accessibility and user satisfaction of chatbots, which are crucial for promoting the health of older adults through using such apps, enabled the participants to easily access health information and advice, thereby enhancing their health awareness and quality of life.

Future research can explore how more personalized mental health support can be provided by expanding on the functionality of chatbots to effectively manage depression and anxiety among older adults. Simultaneously, there should be in-depth exploration of how chatbots can be integrated with traditional health care services to establish a more comprehensive medical support system. Qualitative investigations through individual or group interviews could add further insights into their use and adaptation.

Acknowledgments

The authors would like to thank Tzu-Tao Huang, Chen-Ju Lu, and Tzu-Yun Tseng for their assistance in developing the chatbot. The authors are also grateful to Wei-Yang Chang and the Clinical Trial Center of Chang Gung Memorial Hospital for assistance with the statistical analysis. Abstract

Background: The COVID-19 pandemic exerted extraordinary pressure on health care workers (HCWs), imperiling their well-being and mental health. In response to the urgent demand to provide barrier-free support for the health care workforce, Pause-4-Providers implemented 30-minute live web-based drop-in mindfulness sessions for HCWs.

Objective: This study aims to evaluate the use, feasibility, satisfaction, and acceptability of a novel mindfulness program aimed at enhancing the well-being of HCWs during the COVID-19 pandemic.

Methods: Accrual for the study continued throughout the first 3 pandemic waves, and attendees of ≥1 session were invited to participate. The evaluation framework included descriptive characteristics, including participant demographics, resilience at work, and single-item burnout scores; feedback questionnaires on reasons attended, benefits, and satisfaction; qualitative interviews to further understand participant experience, satisfaction, benefits, enablers, and barriers; and the number of participants in each session summarized according to the pandemic wave.

Results: We collected descriptive statistics from 50 consenting HCWs. Approximately half of the participants (24/50, 48\%) attended >1 session. The study participants were predominantly female individuals (40/50, 80\%) and comprised physicians (17/50, 34\%), nurses (9/50, 18\%), and other HCWs (24/50, 48\%), who were largely from Ontario (41/50, 82\%). Of 50 attendees, 26 (52\%) endorsed feeling burned out. The highest attendance was in May 2020 and January 2021, corresponding to the first and second pandemic waves. The participants endorsed high levels of satisfaction (43/47, 92\%). The most cited reasons for attending the program were to relax (38/48, 79\%), manage stress or anxiety (36/48, 75\%), wish for loving kindness or self-compassion (30/48, 64\%), learn mindfulness (30/48, 64\%), and seek help with emotional reactivity (25/48, 53\%). Qualitative interviews with 15 out of 50 (30\%) participants identified positive personal and professional impacts. Personal impacts revealed that participation helped HCWs to relax, manage stress, care for themselves, sleep better, reduce isolation, and feel recognized. Professional impacts included having a toolbox of mindfulness techniques, using mindfulness moments, and being calmer at work. Some participants

https://formative.jmir.org/2024/1/e43875

JMI R Form Res 2024 | vol. 8 | e43875 | p.2200
(page number not for citation purposes)
noted that they shared techniques with their colleagues. The reported barriers included participants’ needing time to prioritize themselves, fatigue, forgetting to apply skills on the job, and finding a private place to participate.

**Conclusions:** The Pause-4-Providers participants reported that the web-based groups were accessible; appreciated the format, content, and faculty; and had high levels of satisfaction with the program. Both novel format (eg, drop-in, live, web-based, anonymous, brief, and shared activity with other HCWs) and content (eg, themed mindfulness practices including micropractices, with workplace applications) were enablers to participation. This study of HCW support sessions was limited by the low number of consenting participants and the rolling enrollment project design; however, the findings suggest that a drop-in web-based mindfulness program has the potential to support the well-being of HCWs.

**Introduction**

**Background**

The COVID-19 pandemic has jeopardized the mental health and well-being of health care workers (HCWs). Rapidly shifting public health guidelines have been implemented in response to the emergent scientific findings. The uncertain landscape of this pandemic has produced a sense of uncertainty, fear, and psychological distress in HCWs [1]. This was compounded by the realities HCWs faced, including inequitable access to rationed resources such as personal protective equipment and needed acute care beds [2]. Changes in procedural guidelines and service priorities, ramping down of nonessential services, and shifting standards of care have contributed to moral distress [3-5]. Risk factors for HCWs’ burnout included heavy workload, shifting roles, need for additional training, redeployment, and hybrid models of web-based care with feeling disconnected from their usual support and community of practice [6,7]. Greater COVID-19 exposure risks forced many HCWs into isolation owing to fears of infecting family members [1,8,9]. Early in the pandemic, significant levels of fatigue, insomnia, anxiety, depression, and psychological distress among HCWs were reported [8,10-15]. Informed by the literature on previous pandemics, it was anticipated that as the pandemic endured, moral distress, posttraumatic stress, and burnout would become problematic [16]. All combined, the COVID-19 pandemic amplified the challenges faced by HCWs within an already-strained workforce and was thus critically important to address [1,3,9,17-22].

Before the pandemic, evidence-based mindfulness interventions for HCWs were found to enhance stress management, awareness, emotion regulation, connection, self-compassion, empathy, and resilience [23-27]. Research demonstrates that mindfulness training for HCWs can improve well-being by promoting self-care and cultivating self-compassion [28]. The term “mindfulness” is defined as the “awareness that arises through paying attention, on purpose, in the present moment, and nonjudgmentally” and implies the cultivating of compassion [29]. Most interventions for HCWs evolved from manualized formats of mindfulness-based stress reduction, mindfulness-based cognitive therapy, and mindful self-compassion, which require a large time commitment [29-31].

“Pause-4-Providers” was created during the first wave of the COVID-19 pandemic to support HCWs and be accessible using a web-based drop-in platform. This extended the program’s reach to underserved areas and those in quarantine, with adherence to physical distancing requirements [17,21,32-34]. To establish a safe space for weary HCWs, no registration was required, and anonymity was allowed as we did not require participants to turn on their cameras or introduce or disclose information about themselves [35]. Unique to this program was the flexible curriculum, making it adaptable to the varied and changing needs of HCWs with time [36]. We implemented Pause-4-Providers drop-in sessions at the beginning of the COVID-19 pandemic to provide momentary refuge and respite from the intensity associated with working in health care during the pandemic.

**Objective**

The objective of this study was to evaluate the implementation of Pause-4-Providers, a 30-minute evening web-based drop-in mindfulness program for HCWs during the COVID-19 pandemic. We designed a descriptive and qualitative study to examine the feasibility, satisfaction, and experiences of the participants. The research questions for the descriptive study were as follows:

1. What is the feasibility and acceptability of the web-based drop-in mindfulness program?
2. What is the level of burnout and resilience among the consenting participants?

Research questions for the qualitative study included the following: What were the experiences, enablers, and barriers to participating in the Pause-4-Providers program?

**Methods**

**Program Development and Format**

Within the first weeks of the COVID-19 pandemic in Canada, our team of university-affiliated psychiatrists (ME, JH, DdCM, and OZ) with expertise in mindfulness met and collaboratively decided to offer free, 30-minute live web-based drop-in mindfulness sessions for HCWs with the objective of supporting their well-being. We defined HCWs as anyone working in a health care or social care setting, including those providing direct patient-facing services and those performing indirect...
roles. Along with health care providers and trainees, the sessions were open to those providing administrative facilities, those working in support services, and research staff. Our sessions used a secure, privacy-compliant Zoom (Zoom Video Communication, Inc) platform multiple times per week, starting on March 24, 2020. We e-blasted Pause-4-Providers program announcements to >400 health care institutions, hospitals, long-term care homes, shelters, university departments, and associations (eg, Ontario Medical Association, Royal College of Physicians and Surgeons of Canada, Canadian Mental Health Association, and Registered Practical Nurses Association of Ontario) for distribution of session links to their HCWs.

Our group of faculty facilitators had extensive mindfulness training and clinical experience in leading manualized mindfulness group interventions in health care settings for HCWs and patients in an oncology health setting (ME) [21,35,37], patients with pain disorders (OZ), women with mental health concerns (DdCM and JH), and hospital-based health leaders and policy makers (DdCM). As mental health professionals working in hospital settings, we were also attuned to the psychological impacts the unfolding public health crisis had on HCWs. Notably, because we used the term “facilitators” when referring to the faculty who led the web-based drop-in sessions, we chose to use the term “enablers” when referring to factors in the qualitative analysis that facilitated or promoted participation. The themed agenda for each drop-in session was based on mindfulness, compassion, or resiliency skills to fit the emerging needs of HCWs, distressing local and global events and the time of the year or holidays. An evolving curriculum allowed for flexibility and responsiveness to the changing needs of HCWs [36]. We canvassed attendees using a situational needs assessment with routine quick check-ins at the start of each session to tailor the agenda accordingly. Given the time pressures and competing demands placed on HCWs, the sessions were intentionally designed to be of short duration. Each 30-minute session followed a semistructured agenda as presented in Figure 1 and Multimedia Appendix 1 [27,28,38,39]. The session themes evolved to reflect the immediate needs of HCWs, with a curricular structure of the sessions that was maintained. This structure included 2 short practices, including a micropractice and a closing. Maintaining a consistent format, the sessions introduced different practices and themes that were aligned with the objectives and principles of mindfulness and self-compassion. In small doses, with time, during the prolonged pandemic, faculty facilitators introduced a wide variety of mindfulness practices based on HCW attendees’ needs and levels of emotions (eg, hyperarousal vs emotional numbing). Drawing from positive psychology and resilience factors [40-45], the faculty facilitators used mindfulness techniques to promote positive emotions, compassion, and coping in the midst of challenges. Sessions included at least 1 guided micropractice (ie, a practice that was distilled into ≤1 minute meant for integration by participants throughout their workday) to emphasize how participants could apply aspects of the practices for self-care moments in the workplace [35,44,46,47]. Many sessions concluded with poems, followed by invited reflections and feedback. To support the program, we also created a website for Pause-4-Providers, where HCWs could find the schedule and session links, and access 4 prerecorded mindfulness practices for use at any time and participate in the research study.

Ethical Considerations

This study was approved by the Sinai Health Research Ethics Board (20-0158-E). On the project website, participants were given a complete description of the study, and informed consent was obtained. The research assistant emailed the respondents who consented to be contacted for participation in a semistructured interview and obtained consent before the start of the interview. Participation in the study was voluntary and anonymous. The interviews were transcribed and deidentified to protect the identity of the study participants. The participants did not receive any compensation.

Research Methods

This study aimed to evaluate the feasibility and acceptability of a web-based drop-in mindfulness program. We assessed feasibility quantitatively with attendance and qualitatively by exploring participants’ experiences of barriers and facilitators or enablers of attending such a program. We assessed acceptability using a brief satisfaction questionnaire and
semistructured interviews with a subset of participants to explore their experiences of the program sessions. The burnout and resilience measures characterized the sample to learn about the potential suitability or appropriateness of the Pause-4-Providers program [48].

The study was open to all HCWs who attended ≥ 1 Pause-4-Providers session. Faculty facilitators informed HCW attendees in the sessions that they could visit the project website if they wished to participate or learn more about the research study. On the website, a banner informed HCWs of the research study with a link to a consent form and the confidential questionnaire package. Study participants could choose to participate in the descriptive portion of the study or both the descriptive and qualitative studies. The descriptive measures were collected once at study enrollment and included a questionnaire package consisting of demographics (eg, profession, age, sex, province or country of origin, and primary care setting), burnout and resilience measures, and a self-report feedback questionnaire focused on the participants’ reasons for attending, satisfaction, and utility of the sessions. At the end of the questionnaire, respondents could consent to be contacted for participation in a semistructured interview about their experiences of the program. There were no exclusion criteria for this study.

Descriptive Measures

The Single-Item Burnout Measure [49] instructed respondents to define burnout for themselves with the following question: “Overall, based on your definition of burnout, how would you rate your level of burnout?” Participants scored their responses on a 5-category ordinal scale. The self-defined burnout measure has been useful as an abbreviated burnout assessment tool in medical professionals [50, 51]. The self-defined burnout item correlates with the emotional exhaustion subscale of the Maslach Burnout Inventory (r=0.64; P<.001), defining burnout as a score of ≥ 23, with a correlation of 0.79, sensitivity of 83.2%, specificity of 87.4%, and an area under the curve of 0.93 (SE 0.004) [49].

The Resilience at Work Scale consists of 25 items measuring 7 aspects of workplace resilience, focusing on everyday behaviors. Participants rated their responses on a Likert scale, ranging from 0 (strongly disagree) to 6 (strongly agree) [52]. The scale is a validated tool for measuring and developing resilience among HCWs, with 67% of variance and an acceptable confirmatory factor analysis model fit (goodness of fit 0.97, Tucker-Lewis Index 0.98).

The Participant Self-Report Feedback Questionnaire was developed by us and asked about the number of sessions attended, reasons and motivation to attend (eg, to relax, improve sleep, be in a community, and learn mindfulness), benefits of attending (eg, increased awareness of emotional states, enhanced coping skills, and improved capacity to work with your team on a day-to-day basis), and overall satisfaction with the web-based mindfulness sessions. There were several open-text questions where respondents could describe how Pause-4-Providers influenced their coping (eg, positive or negative), describe the impact the pandemic had on their role and job, and provide feedback on the Pause-4-Providers program as presented in Multimedia Appendix 2.

Qualitative Methodology

Overview

To explore the participants’ experiences and views of the Pause-4-Providers program, we used a qualitative research design, which does not test or generate theory but instead gathers explicit insight into clinical or behavioral interventions [53, 54]. Qualitative methods are able to gather detailed insights into what does and does not work well to reveal the impacts, enablers, and barriers of program participation [55]. This is widely used in health service research to evaluate the determinants and impacts of interventions. The study complied with the standards for reporting qualitative research in accordance with COREQ (Consolidated Criteria for Reporting Qualitative Research) [54]. All participants consented before the interviews. There was no prior relationship between the qualitative researcher (Anna R Gagliardi) and the participants.

Sampling and Recruitment

At the end of the web-based questionnaire, respondents were asked if they were willing to be contacted for subsequent participation in an interview. Using a convenience sampling technique, all interested participants were emailed and invited to be interviewed by the research assistant (CK). The study and recruitment continued until June 2021, coinciding with the first 3 waves of the COVID-19 pandemic as defined by Public Health Ontario and presented in Multimedia Appendix 3. We sampled across 3 time frames corresponding to waves 1, 2, and 3 of the COVID-19 pandemic in Canada, with equal numbers of participants in each wave. We sampled concurrently with data collection and qualitative analysis and ceased when thematic saturation was achieved.

Data Collection

The audio-recorded (17-38 min), telephone-based, transcribed interviews conducted by the research assistant (CK) included questions about expectations, impacts, enablers, barriers, and recommendations to improve the program (Multimedia Appendix 4). Participants were asked about their motivation to attend the program, their experience of the program sessions, associated benefits or challenges, and feedback or suggestions for the future. Interview transcripts were independently analyzed by Anna R Gagliardi (a PhD-trained consultant with expertise in qualitative research), following which the findings were reviewed by all members of the research team.

Data Analysis

Descriptive Analysis

The total weekly attendees at drop-in sessions were tallied from April 20, 2020, to June 21, 2021, as shown in Multimedia Appendix 3; a single participant would count multiple times in these tallies if multiple sessions were attended. These totals were plotted against time, with the ends of the first 3 pandemic waves on August 14, 2020; April 1, 2021; and July 6, 2021, respectively. The remaining analyses pertained only to survey respondents. Counts and percentages were used to summarize their demographic characteristics. Responses to questions on burnout, motivation, and experience were summarized, and the motivation and experience scales were collapsed into 3 levels.
The 7 Resilience at Work subscale scores and the total score were each calculated according to the scoring guide, a 2-tailed $t$ test was used to compare the mean overall score to that from a study on the psychological impact of COVID-19 on >500 hospital workers by Maunder et al [56] (email, August 13, 2021), and a 95% CI for the mean difference in overall scores was calculated. The relationship between the number of sessions attended (1 vs $\geq 2$) and respondents’ feedback on the benefits of attending was assessed by cross-tabulating the 2 variables and calculating the $P$ value using a Fisher exact test. Participants with a missing value for a variable were omitted from the analyses of that variable.

**Qualitative Analysis**

We used content analysis to identify themes for inductive coding in the qualitative interviews. This was done through constant comparison to develop a preliminary codebook of themes and exemplar quotes (first-level coding) [53]. We shared themes for discussion with all members of the research team to verify them. For subsequent interview transcripts, the qualitative expert researcher (Anna R Gagliardi) performed coding to expand or merge themes (second-level coding), tabulated participant characteristics and data (eg, themes and quotes), and examined similarities or differences by participant sampling characteristics. The research team reviewed and discussed the findings and further grouped them into categories related to motivation and facilitators, which we refer to as enablers, barriers, and impacts associated with participation. The qualitative findings were triangulated using descriptive findings.

**Results**

**Descriptive Results**

Between April 20, 2020, and June 27, 2021, there were 1333 attendance entries at the drop-in sessions. Consent was obtained from 88 respondents, most of whom (66/88, 75%) were enrolled during the second wave of the pandemic. Of 88 respondents, we excluded 38 (43%) from the analysis because they did not submit the questionnaire, were not HCWs, or completed the questionnaire a second time to arrive at a total sample of 50 (57%) participants, as presented in Figure 2. At the time of survey completion, 50% (25/50) had attended 1 session, 24% (12/50) 2 to 5 sessions, 8% (4/50) 6 to 10 sessions, and 16% (8/50) $\geq 11$ sessions. If the participants indicated at the start of the questionnaire that they were completing it a second time, they were automatically taken to the end of the survey and only their first set of responses was included in the analysis.

Of 88 participants, the demographics were similar between the 50 (57%) included and 38 (43%) excluded participants. There were 5 sections in the survey on motivation, experience, satisfaction, burnout, and resilience. Overall, 90% (45/50) of the participants filled out all 5 sections, 10% (5/50) did not report on their prior experiences with mindfulness, and 6% (3/50) did not report on satisfaction. Of the 50 participants who submitted the survey, not all items or sections of the survey were completed. We included participants in the analysis if they provided data on $\geq 1$ section of the questions we examined. Of the 50 HCWs, 24 (48%) had participated in $\geq 1$ session; 17 (34%) were physicians, 9 (18%) were nurses, and the remaining 24 (48%) were other HCWs (eg, administrative or education assistant, occupational therapist, pharmacist, physiotherapist, psychotherapist, social worker, and others). Most respondents (40/50, 80%) were female individuals, 43% (21/50) were aged 20 to 39 years, 45% (22/50) 40 to 59 years, and 12% (6/50) $>60$ years, with participation primarily from the province of Ontario (41/50, 82%) and other Canadian provinces (eg, Alberta, British Columbia, New Brunswick, Quebec, and Saskatchewan).

Half of the HCWs (26/50, 52%) endorsed feeling burned out (score $\geq 3$). Regarding Resilience at Work scores, participants scored highly (mean score $>70$) on the subscales of “finding your calling” (mean score 78, SD 17), “building networks” (mean score 78, SD 17), “living authentically” (mean score 76, SD 12), and “interacting cooperatively” (mean score 75, SD 15). Participants also scored moderately (mean score 50-69) on the workplace resilience subscale items of “staying healthy” (mean score 73, SD 22) and “managing stress” (mean score 65,
SD 19) and reported difficulty with the subscale item “maintaining perspective” (mean score 48, SD 17). The overall mean resilience score was 69.4 (SD 12.6) [56].

In the self-report feedback questionnaire, participants’ most frequently reported motivations to attend the program included relaxing, managing stress or anxiety, wishing for loving kindness or self-compassion, and learning mindfulness, as presented in Table 1.

The most frequently endorsed benefits of attending included increased self-awareness of emotional states and reduced stress, as presented in Table 2. Participants who attended ≥2 sessions reported more positive benefits with coping skills (Fisher exact test \( P<.001 \)) and managing stress (Fisher exact test \( P=.008 \)) than participants who only attended 1 session. Of the 47 participants who reported their overall program satisfaction, 92% (43/47) rated it with a score of ≥4 on a 5-point Likert scale, with a mean score of 4.6 (SD 0.7).

### Qualitative Results

#### Participants

A total of 21 participants agreed to be contacted for participation in an interview and received a standardized invitation letter via email. Qualitative interviews were conducted with 15 consenting participants who answered the email and agreed to be interviewed, including 5 physicians, 2 administrative assistants, 2 physiotherapists, 2 psychotherapists, and 1 each of nurse practitioner, social worker, executive manager, and a speech pathologist. By age, this included 9 (60%) persons aged between 40 and 59 years and 6 (40%) 20 and 39 years. A considerable number of qualitative study respondents were women (13/15, 87%) than men, reflecting the fact that, out of 15 participants, 40 (80%) women and 7 (14%) men completed the descriptive questionnaire. Participants were evenly divided in terms of when they were interviewed during the COVID-19 pandemic: 5 (33%) in the first wave, 5 (33%) in the second wave, and 5 (33%) in the third wave. Interview participants completed a mean of 7 sessions (median 10, range 1 to 11) at the time of completing the questionnaire. Most participants had some prior exposure to mindfulness (11/15, 73%).

#### Themes

##### Overview

Themes, experiences, enablers, and barriers to participation were related to respondents’ motivation, satisfaction, impact, and program design. Qualitative findings are described with select quotes and summarized below. Where participants’ quotes are used, we have specified their study number, role, age, number of sessions attended, whether they had applied the mindfulness skills taught, and the pandemic wave during which they were interviewed. A summary of findings is presented in Figure 3 and all data are included in Multimedia Appendix 5.
Motivation to Attend and Expectations

A variety of reasons motivated the participants to take part in the program. Most were looking for ways to relax and manage their stress:

*Trying to help deal with the COVID and all the stress behind it. Dealing with the patients and their anxiety with it. I was kind of trying to be more relaxed.* [#02, administrative assistant, aged 40-59 years, ≤5 sessions, applied learning, techniques, or tools in daily life, wave 1]

Some participants wanted to decrease their sense of isolation created by the pandemic and have a way to connect with other HCWs:

*I had been looking all over the place just for some kind of event or experience or connection of some kind for healthcare staff, healthcare teams because I felt really isolated.* [#46, psychotherapist, aged 20-39 years, ≤5 sessions, applied learning, techniques, or tools in daily life, wave 2]

Others said that they were curious about mindfulness, had been exposed to it in the past, saw this as an opportunity to pick it up again, and desired to gather with others and be a role model to encourage other staff to participate:

*I am in a leadership position at the hospital and it was passed on to me as something that we could share with our staff. I wanted to encourage them to take it so I thought I should take it myself.* [#14, manager, aged 40-59 years, ≤5 sessions, not applied learning, techniques, or tools in daily life, wave 1]

When asked about expectations, participants largely said that they had none and came with an open mind. Several participants anticipated that it was likely to be beneficial but did not specify how:

*I didn’t honestly think about it that much other than I know, at least on some level, that mindfulness practice would be good for me, that just by showing up it would be a positive thing.* [#10, physiotherapist, aged 20-39 years, 6-10 sessions, applied learning, techniques, or tools in daily life, wave 1]

*Feeling quite unmotivated, just finding things at work difficult for the winter and the early part of spring, so it wasn’t necessarily fatigue, it was more feeling a bit overwhelmed with work.* [#75, physician, aged 40-59 years, 6-10 sessions, applied learning, techniques, or tools in daily life, wave 3]

Satisfaction

All participants said that the sessions were helpful, and some said that they surpassed their expectations and felt it was essential for getting through the pandemic:

*It was more than what I expected. I thought I would try, to help out with the burnout and with the pandemic. But it was a lot more relaxing than I thought it would be. I was able to get into a really deeply relaxed state.* [#22, psychotherapist, aged 20-39 years, ≤5 sessions, applied learning, techniques, or tools in daily life, wave 2]
In order to keep working and go on in my life, it’s been one of the very important things for me. [#35, physician, aged 40-59 years, applied learning, techniques, or tools in daily life, wave 3, did not indicate the number of sessions they attended]

When asked to rate the importance of the program to them on a scale from 1 to 10, in which 10 was very important, most participants articulated a moderately high score (mean 7.7, SD 1.48; median 8.0, range 5.0-10.0). Some participants commented on how this program was one of the several resources or supports, such as family, and that they were new to the program and could not yet fully appreciate how important the sessions may be:

I needed multiple things to help me through this time and so it was very important to me to have that regular time twice a week, where I would check-in and do these techniques to make sense of what’s going on, being able to deal with the difficult situation. In order to keep working and go on in my life, it’s been one of the very important things for me. [#35, physician, aged 40-59 years, applied learning, techniques, or tools in daily life, wave 3, did not indicate the number of sessions they attended; level of importance in life: score=10]

I’ve barely scratched the surface... it’s the beginning of a learning. I’m hoping that if and when it ends, I will be able to continue this. A 10 out of 10 would be a sort of life-changing, I don’t think it’s life-changing. I would call it life-enhancing. [#78, physician, aged 40-59 years, >11 sessions, applied learning, techniques, or tools in daily life, wave 3; level of importance in life: score=8]

I can’t say yet. I think I’m still pretty new. I’ve only done two sessions. Yes and no. In the sense that I think it’s nice to have that put in to your schedule a little bit but I can’t say that it’s translated into anything else in my life yet. [#44, physician, aged 40-59 years, ≤5 sessions, not applied learning, techniques, or tools in daily life, wave 2; level of importance in life: score=5]

Impact

The participants articulated the numerous positive benefits of the mindfulness program. Most participants said that it prompted them to disconnect from work responsibilities and take time for self-care. As a result, they were able to unwind and relax at the end of the day and sleep better:

It helps me to realize it’s not all about going, going, going and bringing home your work and thinking about it 24/7. I think it’s a good way to almost detach a little bit from that stuff. [#44, physician, aged 40-59 years, ≤5 sessions, not applied learning, techniques, or tools in daily life, wave 2]

It’s definitely easier to get into that relaxed state to go to sleep... I definitely feel more relaxed those nights when we have the session. [#22, psychotherapist, aged 20-39 years, ≤5 sessions, applied learning, techniques, or tools in daily life, wave 2]

Most participants said that participation in the program helped them to be more present and calm and to better manage stress or anxiety. Many participants applied mindfulness techniques in their daily lives, including at work:

Being present, being consistent and calm when you are working in very high stress environments...I did try that out when I was at work, and especially when you’re feeling overwhelmed or just tired. And so, I think just being able to use those skills can help you think more clearly, tackle things in a calmer manner. [#01, physician, aged 20-39 years, >11 sessions, applied learning, techniques, or tools in daily life, wave 1]

I’m much more productive with my time...and when you start to get more things done you don’t stress as much about it. It’s still pretty intense and it’s been a year and half... it just made me more level and able to work. [#78, physician, aged 40-59 years, >11 sessions, applied learning, techniques, or tools in daily life, wave 3]

I found it a very useful tool to use, in my personal toolbox, to help me be more grounded, to be more productive and actually slow down and listen to others. [#78, physician, aged 40-59 years, >11 sessions, applied learning, techniques, or tools in daily life, wave 3]

Engaging in a shared activity with other HCWs reduced feelings of isolation and loneliness, with gratitude for acknowledging HCWs as those who needed help to combat the undue stress of the pandemic:

I didn’t know any of the other people but you still kind of felt, even if you don’t know them everyone is facing similar challenges and probably having similar worries. That was nice to sit together. [#01, physician, aged 20-39 years, ≤5 sessions, applied learning, techniques, or tools in daily life, wave 2]

It’s really comforting to see the same people coming, even if I don’t see them, sometimes I see their comments... I always like the idea of a community so feeling included or part of the group, where I’m not lost in a big system, so that helps. [#35, physician, aged 40-59 years, applied learning, techniques, or tools in daily life, wave 3]

A few participants mentioned additional positive impacts, such as sharing mindfulness techniques with patients whom they thought might benefit.

Design

When asked about the program design and format, participants appreciated the web-based, drop-in nature requiring no advance registration, the flow and variety of activities during each session, and the interactive components. Participants also appreciated the soothing voices, reassurances and reminders...
offered by faculty facilitators, the timing of the evening sessions, and the short 30-minute session length:

*I love that it’s drop-in, you don’t have to register or sign up or make a plan.* [#04, nurse practitioner, aged 20-39 years, 6-10 sessions, applied learning, techniques, or tools in daily life, wave 1]

*I joined a couple sessions where it seemed to flow really nicely. I thought that there was kind of an initial activity and then a little interlude moment and then a second activity.* [#04, nurse practitioner, aged 20-39 years, 6-10 sessions, applied learning, techniques, or tools in daily life, wave 1]

*I really also enjoyed that there was a little bit of dialogue at the end, and I thought that was so nice for other people to share their comments, to be able to share mine.* [#14, manager, aged 40-59 years, ≤5 sessions, not applied learning, techniques, or tools in daily life, wave 1]

Furthermore, the participants noted specific aspects of the content they found helpful. In most cases, this referred to mindfulness exercises or techniques, for example, breathing exercises or body scans. In other cases, this referred to a concept, such as the need for self-care:

>Self-compassion practices are probably the ones that stick out most. [#10, physiotherapist, aged 20-39 years, 6-10 sessions, applied learning, techniques, or tools in daily life, wave 1]

> The whole practice was around being kind to yourself and kind to others even though we may differ in our opinions or views etcetera. [...] And that was really impactful given the social-political state the world is in right now, so much divide and social injustice and political divide. It was really refreshing to talk about community and generosity and focus on that, when we’re bombarded everyday with the news and tv about what’s different about us right now. [#22, psychotherapist, aged 20-39 years, ≤5 sessions, applied learning, techniques, or tools in daily life, wave 2]

> My personality is that I always helped other people, family. That’s me. That’s my job and that’s also my personality. I always put everybody in front of me instead of taking care of myself. Which I think I do have to change a little bit as I am getting older [...] if I am forced to get into a place where I am the center and not everybody else but just me only, I think that would help me tremendously. [#48, physiotherapist, aged 20-39 years, ≤5 sessions, not applied learning, techniques, or tools in daily life, wave 2]

Enablers

Participants noted multiple factors that enabled or challenged participation in Pause-4-Providers and the application of mindfulness outside the scheduled sessions.

These included a well-designed website and facilitated, web-based drop-in sessions. Although most participants appreciated the group nature of the sessions, they also valued their anonymity:

*It’s convenient because it’s online, you don’t have to go somewhere, you can just Zoom in. It’s hard to get myself going somewhere to an actual place, but it is good to be with people. You kind of feel like you are with them, even if you don’t see them, so for me, the virtual format was perfect.* [#35, physician, aged 40-59 years, applied learning, techniques, or tools in daily life, wave 3, did not indicate the number of sessions they attended]

*I think that’s a really powerful aspect of the program that invites more people to attend because you can change your screen name and be anonymous, so I thought that was cool. I think that anonymity aspect is really important so that everybody can just feel safe to access support and not have to reveal their identity from fear of judgement from coworkers.* [#76, administrative assistant, aged 20-39 years, ≤5 sessions, applied learning, techniques, or tools in daily life, wave 3]

Enablers to adopt or use mindfulness included faculty facilitators giving advice and examples on how to integrate practice into daily life, demonstrating techniques that were easy to adopt, and offering self-directed resources on the website to enable practice outside the sessions:

>The way the facilitators are able to link the practices to real, realistic, day-to-day moments where the skills might come in handy [...] the suggestions, gentle reminders of where these skills can be useful in daily life. [#10, physiotherapist, aged 20-39 years, 6-10 sessions, applied learning, techniques, or tools in daily life, wave 1]

>Even throughout the day I think of some of the exercises. I’m seeing that start to change in a positive way. I’m taking a break from work at my desk, I stand up and I’ll take a moment with the practices in mind. [#46, psychotherapist, aged 20-39 years, ≤5 sessions, applied learning, techniques, or tools in daily life, wave 2]

Barriers

Barriers to participation included competing demands that made it difficult to be a priority, being tired and feeling easily distracted, difficulty finding a quiet and private space at home, internet connection issues, and being seen by others in a susceptible state:

*I guess the time of day. Although it is very convenient for me to attend, I do have to make a choice to do. Either I fit in time with my husband, or I prep for tomorrow or clean up. It’s a choice. You have to make a choice to go cause there’s always something else that you could be doing.* [#04, nurse practitioner, aged <40 years, 6-10 sessions, applied learning, techniques, or tools in daily life, wave 1]

*Finding a quiet space in the house. I have to be really intentional about that part of things. I really need to...*
The Pause-4-Providers program was intentionally planned for implementation for HCWs with competing demands, time pressures, and exhaustion during the COVID-19 pandemic. Participants corroborated that they valued the program content and format that did not require registration, took place on the internet in the evening, was a drop-in session, and was of short duration (30 min) with the option of anonymity (eg, cameras could be switched off). The nonprescriptive nature of drop-in sessions allowed participants the choice to attend any number of sessions, unlike other structured mindfulness programs. Consistent with mindfulness literature, we observed a potential dose effect [31]. Participants who attended ≥2 sessions reported more positive benefits in coping skills (P < .001) and reduced perceived stress (P = .008).

Half of the participants attending Pause-4-Providers had moderate to high levels of burnout, as measured by the Single-Item Burnout Measure (26/50, 52%), similar to what others had during the COVID-19 pandemic [56]. This highlights the fact that some participants were in need of well-being interventions. In other words, some may have been motivated to alleviate burnout symptoms, while others sought to cultivate their well-being. We observed that resilience and burnout coexisted in this sample of HCWs during the COVID-19 pandemic.

The Pause-4-Providers study participants scored moderately high overall on the Resilience at Work Scale, with high subscale scores of “building networks, interacting cooperatively, finding your calling, and living authentically.” This may reflect HCWs’ need to pull together teams, with a shared purpose and a “calling”—resiliency factors that are essential during a pandemic. There is no ceiling on resilience, which can continue to grow. However, participants endorsed difficulty with the “maintaining perspective” subscale, scoring 48.1 (difficulty ≤ 50). This subscale represents an ability for flexible thinking and optimism. The pandemic has challenged HCWs to be adaptable and maintain positivity. The use of mindfulness training can help stressed individuals maintain perspective and shift from primitive survival stress responses (eg, fight, flight, freeze, or fold) to adaptive coping with mindful and reflective problem-solving skills. The participants scored moderately on the subscale of “managing stress” aligned with their endorsed reasons for taking the course to relax and manage stress or problem solving. The participants scored moderately high on the subscale of “building networks, interacting cooperatively, finding your calling, and living authentically.”

Discussion

Principal Findings

The strain placed on HCWs was evident from the start of the COVID-19 pandemic and persisted as the pandemic endured. This newly conceived well-being support program, Pause-4-Providers, consisted of synchronous, web-based, brief, drop-in mindfulness sessions for HCWs. It was feasible to implement as evidenced by its rapid deployment early in the first phase of the pandemic, with good use and continued session attendance during the first 3 waves of the pandemic (total attendance=1333). This program reached a wide range of HCWs, including physicians, a group typically more reluctant to attend well-being sessions, and more so during the pandemic [57]. It was acceptable to participants, with a large majority endorsing overall satisfaction of 5 out of 5 (32/47, 68%) and 4 out of 5 (11/47, 23%).

The Pause-4-Providers program was intentionally planned for implementation for HCWs with competing demands, time pressures, and exhaustion during the COVID-19 pandemic. Participants corroborated that they valued the program content and format that did not require registration, took place on the internet in the evening, was a drop-in session, and was of short duration (30 min) with the option of anonymity (eg, cameras could be switched off). The nonprescriptive nature of drop-in sessions allowed participants the choice to attend any number of sessions, unlike other structured mindfulness programs. Consistent with mindfulness literature, we observed a potential dose effect [31]. Participants who attended ≥2 sessions reported more positive benefits in coping skills (P < .001) and reduced perceived stress (P = .008).

Half of the participants attending Pause-4-Providers had moderate to high levels of burnout, as measured by the Single-Item Burnout Measure (26/50, 52%), similar to what others had during the COVID-19 pandemic [56]. This highlights the fact that some participants were in need of well-being interventions. In other words, some may have been motivated to alleviate burnout symptoms, while others sought to cultivate their well-being. We observed that resilience and burnout coexisted in this sample of HCWs during the COVID-19 pandemic.

The Pause-4-Providers study participants scored moderately high overall on the Resilience at Work Scale, with high subscale scores of “building networks, interacting cooperatively, finding your calling, and living authentically.” This may reflect HCWs’ need to pull together teams, with a shared purpose and a “calling”—resiliency factors that are essential during a pandemic. There is no ceiling on resilience, which can continue to grow. However, participants endorsed difficulty with the “maintaining perspective” subscale, scoring 48.1 (difficulty ≤ 50). This subscale represents an ability for flexible thinking and optimism. The pandemic has challenged HCWs to be adaptable and maintain positivity. The use of mindfulness training can help stressed individuals maintain perspective and shift from primitive survival stress responses (eg, fight, flight, freeze, or fold) to adaptive coping with mindful and reflective problem-solving skills. The participants scored moderately high on the subscale of “managing stress” aligned with their endorsed reasons for taking the course to relax and manage stress or anxiety. This is consistent with areas that mindfulness sessions can address by helping individuals to keep calm and reduce anxiety. This is consistent with areas that mindfulness sessions can address by helping individuals to keep calm and reduce anxiety.
The reported benefits of the program in the qualitative study included being better able to disconnect and decompress after work, seeing a need to prioritize self-care, and an improved ability to manage stress at work. This aligned with the survey findings of increased self-awareness of emotional states (25/45, 56%) and reduced stress (24/45, 53%). By providing a toolbox of mindfulness strategies and skills, participants were empowered to be calmer and more present. Brief mindfulness micropractices provided a potential mechanism for HCWs to navigate stressful and demanding workplace environments, as demonstrated in previous work done by one of the authors (ME) [13,35,36]. The themed agendas of each session focused on workplace applications of mindfulness practices. Respondents described how the particular use of micropractices allowed them to be more present, calmer, and more balanced at work. Some participants shared these mindfulness tools with their coworkers and patients. Participants also valued the faculty facilitators’ encouragement, tips, and examples of ways to use practices in the workplace, on the go.

Many participants did not turn on their cameras, although many did offer their thoughts and feedback (often gratitude) in the chat at the end of each session. Without their cameras turned on and in their homes in the evenings, the participants reported feeling less susceptible and more relaxed. Despite the anonymity of participation, the attendees endorsed a decreased sense of isolation in the context of the pandemic and felt connected to the group. We speculate that the combination of the live format, the commonality of being with HCWs during the pandemic, and the shared experience of practicing self-care in a group setting was sufficient to promote a sense of connection. This is similar to other mindfulness skills–based groups in which participants do not talk about their life experiences and yet endorse an increased sense of connectedness [37].

The use of an evolving curriculum allowed the team of faculty facilitators to perform practical ongoing needs assessment by checking in with attendees at the start of each session and flexibly adapting the session in response to the relevant needs of the attendees [36]. This was important as HCWs’ needs changed with the course of the pandemic. In the first wave, HCWs were frightened and needed to find ways to cope with uncertainty and change, whereas, with time, participants shared experiences of moral distress, exhaustion, and elements of posttraumatic stress [6,22]. The faculty facilitators could garner an iterative understanding of challenges and burnout factors with time as mental health experts, mindfulness specialists, and HCWs.

Limitations

We largely relied on a top-down approach to invite HCWs to Pause-4-Providers sessions, contacting leadership in a wide array of institutions and health care settings. This dissemination strategy included outreach to interprofessional stakeholder organizations at the provincial, university, and hospital health care system levels. We did not track how or if they disseminated the information, and we did not have a consistent strategy to follow up with these organizations. Although this session recruitment strategy supported an expedient deployment strategy, it may have affected attendee recruitment. Prioritizing anonymity and open access to drop-in web-based sessions with no required registration meant that we were not able to provide attendance reminders and relied on participant engagement and institutions to notify and remind potential attendees. This likely limited session attendance, retention, and study recruitment. Nonetheless, the study design was pragmatic for the drop-in nature of the program, with rolling recruitment during the first 3 waves of the pandemic. Approximately half (24/50, 48%) of the participants attended >2 sessions at the time of survey completion. Participants’ reports on resilience and burnout could have been affected by how many sessions they had attended before study enrollment and how far into the pandemic they started to attend sessions. We do not know if the consenting study participants were representative of the entire Pause-4-Providers attendee population or the HCWs’ population at large, limiting generalizability.

When the program was developed, we did not expect the pandemic to endure and have multiple waves. Attendance in the program was well distributed across the first 3 waves of the pandemic, and survey responses were concentrated between the end of wave 1 and the end of wave 2. It is possible that HCWs became more accustomed to the COVID-19 pandemic, with reduced stress and improved coping with time. Alternatively, the cumulative effect of the pandemic may have adversely affected the well-being of HCWs (eg, with increased levels of moral distress). The sample size was too small to determine how the motivations, benefits, satisfaction, and experiences of the participants may have differed across time points. Consistent with qualitative research standards, saturation of the findings was identified, and our sample size was consistent with the qualitative methodology [55,58].

It is unknown how representative the 50 study HCW participants were in relation to the larger sample of all attendees. The demographics did not include data on race, ethnicity, or intersectional identity, nor did they distinguish between work practice settings (eg, intensive care unit vs outpatient clinics) or whether HCWs were in COVID-19 patient-facing practice settings. Any of these factors could have affected or moderated the findings on burnout, workplace resilience, and pandemic-related stresses. The faculty facilitators in this project were White women psychiatrists. Future iterations of this program would benefit from a more culturally diverse and larger group of interprofessional faculty facilitators and participants. With respect to generalizability, qualitative findings were obtained from participants in the province of Ontario, Canada, and thus may not represent other health settings in other locations. Nurses represent approximately half of the health care workforce in Canada, and yet only 18% of the study participants were nurses. This low level of nurse participation may have been because of long, 12-hour shifts and competing priorities, such as family or childcare during the pandemic. This may also be related to free alternative support provided through their professional organizations (eg, individual psychotherapy) [6].

The format of live web-based mindfulness sessions is resource intensive as it relies on faculty facilitators; therefore, it may not be sustainable without funding or a dedicated team. Early in the COVID-19 pandemic, with heightened uncertainty and major
changes in health care, faculty facilitated 8 evening sessions per week. As the pandemic continued, to reduce the burden on the faculty facilitators, the frequency of sessions was decreased to once a week.

Conclusions
This descriptive, qualitative study and program evaluation demonstrated that the Pause-4-Providers program was feasible, acceptable, and appropriate, with high levels of satisfaction. Half of the participants endorsed moderate to high burnout, which may have motivated their attendance. Most participants endorsed positive benefits enabled by the curriculum, the faculty facilitators and the drop-in, low-dose, open-access format of the program. Importantly, participants reported feeling more relaxed after the sessions and using mindfulness tools at work and in their daily lives.

As Dana Faulds, an American poet, writes, “It only takes a reminder to breathe, a moment to be still, and just like that, something in me settles, softens, makes space for imperfection...I can make the choice to stop, to breathe, and be, and walk slowly into the mystery” [38]. The Pause-4-Providers program reminded HCWs to breathe, create space to be still, reflect on mindful self-compassion, and use microskills in the workplace and at home. To address the unprecedented negative psychological effects and burnout during the COVID-19 pandemic and support the well-being of HCWs beyond the pandemic, this program of brief web-based drop-in mindfulness merits further study.

Acknowledgments
The Pause-4-Providers program was supported by the Innovation Fund of the Alternative Funding Plan for the Academic Health Sciences Centres of Ontario. The authors gratefully acknowledge the Sinai Health System, University Health Network, Women’s College Hospital and University of Toronto, Department of Psychiatry, the Lunenfeld-Tanenbaum Research Institute, and Drs Jon Hunter and Robert Maunder for their mentorship; the Ontario Medical Association; and the contributions of Anna Gagliardi for the qualitative analysis, George Tomlinson and Fuzo Yosh for descriptive analyses in this study, and Natalie Heeney for the design of study figures.

Data Availability
The data sets generated and analyzed during this study are not publicly available because participants’ approval for public data sharing was not explicitly requested in the consent form approved by the research ethics board.

Abstract

Background: Misinformation in Spanish on social media platforms has contributed to COVID-19 vaccine hesitancy among Latino parents. Brigada Digital de Salud was established to disseminate credible, science-based information about COVID-19 in Spanish on social media.

Objective: This study aims to assess participants’ reactions to and engagement with Brigada Digital content that sought to increase COVID-19 vaccine uptake among US Latino parents and their children.

Methods: We conducted a 5-week intervention in a private, moderator-led Facebook (Meta Platforms, Inc) group with Spanish-speaking Latino parents of children aged ≤18 years (N=55). The intervention participants received 3 to 4 daily Brigada Digital posts and were encouraged to discuss the covered topics through comments and polls. To assess participants’ exposure, reactions, and engagement, we used participants’ responses to a web-based survey administered at 2 time points (baseline and after 5 weeks) and Facebook analytics to calculate the average number of participant views, reactions, and comments. Descriptive statistics were assessed for quantitative survey items, qualitative responses were thematically analyzed, and quotes were selected to illustrate the themes.

Results: Overall, 101 posts were published. Most participants reported visiting the group 1 to 3 times (22/55, 40%) or 4 to 6 (18/55, 33%) times per week and viewing 1 to 2 (23/55, 42%) or 3 to 4 (16/55, 29%) posts per day. Facebook analytics validated this exposure, with 36 views per participant on average. The participants reacted positively to the intervention. Most participants found the content informative and trustworthy (49/55, 89%), easy to understand, and presented in an interesting manner. The participants thought that the moderators were well informed (51/55, 93%) and helpful (50/55, 91%) and praised them for being empathic and responsive. The participants viewed the group environment as welcoming and group members as friendly (45/55, 82%) and supportive (19/55, 35%). The 3 most useful topics for participants were the safety and efficacy of adult COVID-19 vaccines (29/55, 53%), understanding child risk levels (29/55, 53%), and the science behind COVID-19 (24/55, 44%). The preferred formats were educational posts that could be read (38/55, 69%) and videos, including expert (28/55, 51%) and instructional (26/55, 47%) interviews. Regarding engagement, most participants self-reported reacting to posts 1 to 2 (16/55, 29%) or 3 to 4 (15/55, 27%) times per week and commenting on posts 1 to 2 (16/55, 29%) or <1 (20/55, 36%) time per week. This engagement level was validated by analytics, with 10.6 reactions and 3 comments per participant, on average, during the 5 weeks. Participants recommended more opportunities for engagement, such as interacting with the moderators in real time.

Conclusions: With adequate intervention exposure and engagement and overall positive participant reactions, the findings highlight the promise of this digital approach for COVID-19 vaccine–related health promotion.

(JMIR Form Res 2024;8:e51331) doi:10.2196/51331
Introduction

Background

US Latino individuals have experienced distressing COVID-19 disparities related to morbidity and mortality. Recent studies have demonstrated this heightened risk in Latino adults, who have a 1.5 times greater risk of infection, 2.3 times greater risk of hospitalization, and 1.8 times greater risk of death [1-5]. These increased risks are likely related, in part, to slower vaccine uptake during the pandemic [6,7]. Although adult COVID-19 vaccination rates have increased, with 57.1% of US Latino adults having completed a primary vaccine series as of March 2023, only 8.5% of Latino adults have received a bivalent booster dose, the lowest coverage across racial and ethnic subgroups [8].

What is also alarming is the underrepresentation of Latino children in some age groups among the population vaccinated against COVID-19. The vaccination rates of Latino children continue to lag, with only 5.1% of Latino children aged 6 months to 4 years having completed a 2-dose vaccine series as of December 2022 and 28.8% of Latino children aged 5 to 11 years, 57.8% of Latino adolescents aged 12 to 15 years, and 70.4% of Latino adolescents aged 16 to 17 years having completed the primary series as of August 2022 [9,10]. Booster dose coverage among Latino children is also worrisome, with only 4.6% of Latino children aged 5 to 11 years, 20.7% of Latino adolescents aged 12 to 15 years, and 32.3% of Latino adolescents aged 16 to 17 years having received a booster dose as of August 2022 [9,10]. These low rates are particularly concerning, given that research has demonstrated an increased risk among Latino children and adolescents aged <18 years for COVID-19 infection, hospitalization, multisystem inflammatory syndrome, and related health complications [11-16]. These findings emphasize the need for targeted interventions to mitigate these disproportionate risks and increase immunization rates.

Research has revealed that COVID-19 vaccine hesitancy has been a significant obstacle to reducing these risks for US Latino communities [4,17-19], especially among Latino parents, who have exhibited considerable reluctance toward vaccinating their children against COVID-19 [20-23]. This hesitancy has been partly fueled by exposure to misinformation regarding COVID-19 vaccines, primarily through social media networks [20,24-27]. This exposure has created more mistrust and concerns among Latino parents regarding the safety and efficacy of COVID-19 vaccines for children [28-32], and studies have shown an association between exposure to misinformation on social media and increased hesitancy and decreased intention to vaccinate [33-39].

Although there have been efforts to address vaccine hesitancy among Latino individuals, including communication campaigns and community-based outreach initiatives [25,40-42], few social media–based intervention studies have focused on Latino parents. Ramirez and colleagues [43] implemented a Facebook (Meta Platforms, Inc)–based pilot intervention to promote COVID-19 vaccine uptake among rural community residents in South Texas, whereby intentions to vaccinate were assessed following exposure to video testimonials that acknowledged misinformation and promoted vaccination using peer modeling. Although not explicitly focused on parents, this study demonstrated significantly higher vaccine intentions following exposure to such video testimonials compared with exposure to standard Centers for Disease Control and Prevention advertisements. In addition, a study by Panameno and colleagues [44] assessed Latino parents’ experiences with MiVacunaLA, a mobile phone–delivered digital intervention for improving Latino parents’ vaccination intentions and Latino children’s vaccination rates. The study found that digital technology was beneficial for delivering language-tailored and culturally tailored pediatric COVID-19 vaccine information to Latino parents, which addressed their specific informational needs and increased their confidence in COVID-19 vaccines. This study highlighted the importance of concise, accessible information delivered by trusted sources, such as videos portraying physicians or community health workers, to overcome barriers to health literacy or other barriers to COVID-19 vaccination. Furthermore, this study revealed a persistent need for culturally tailored information about COVID-19 vaccines and boosters, specifically information delivered in Spanish and through trusted sources.

Objectives

In response to information gaps among US-based Spanish-speaking audiences, we established Brigada Digital de Salud in 2021 to disseminate accurate, credible, and science-based COVID-19 information and prevention messages in Spanish based on the latest research and public health guidelines. Brigada Digital aims to serve as a social media resource for Spanish-speaking individuals who want to make sound decisions about their health and the health of their families in the face of web-based misinformation [45]. This paper details the findings from a 5-week study among Latino parents in a private Facebook group to assess their reactions to and engagement with Brigada Digital social media content and to elicit their recommendations for future iterations of the intervention.

Methods

Participant Recruitment

Eligible study participants included Latino adults aged ≥18 years who were parents of at least 1 child aged <18 years, spoke fluent Spanish, and reported using Facebook at least once daily. We recruited participants through 8 targeted Facebook advertisements between August 12 and August 22, 2022. All interested individuals completed an 8-item screener to determine eligibility, and eligible participants were automatically directed to an informed consent form and a baseline survey administered using Qualtrics (Qualtrics International Inc). The participants who completed the baseline survey were assigned to either the intervention Facebook group (N=55) that received Brigada
Digital content or the control Facebook group (n=65) that received only a link to the Centers for Disease Control and Prevention web-based COVID-19 information in Spanish (standard of care) but did not receive the intervention content. This paper discusses the reactions and engagement of only the participants in the intervention group.

**Intervention Overview**

A 5-week intervention delivered through Facebook groups was created to educate participants on the risks of COVID-19, COVID-19 prevention methods, and the importance of adult and child vaccination. The intervention aimed to address common misinformation often spread through social media. Intervention content development was informed by the Theory of Planned Behavior, according to which beliefs about vaccination, social norms, perceived control over vaccination, and attitudes about vaccination influenced COVID-19 vaccination intentions [46]. The intervention content was developed before the study and was carefully crafted to be accessible to a broad Latino audience, regardless of education or health literacy levels. For example, scientific concepts were explained in simple terms, prevention recommendations were accompanied by visual aids, and the text was audio narrated in Spanish (Figure 1).

Once participants were accepted into the Facebook group, they received prerecorded welcome videos from moderators, 3 posts, and an overview of group expectations and guidelines and were invited to introduce themselves to the group. This point onward, posts were scheduled to be shared with the group on a daily basis. In total, 101 posts were shared during the 5-week period, with at least 2 posts per day being educational and the remainder alternating between posts intended to counter COVID-19 misinformation and posts intended to engage group members.

The content was delivered using various formats, such as a narrated slide carousel, animated images with text and music, and videos featuring health professionals and subject matter experts (Figure 2).

Furthermore, the post content was ordered to progress through various themes related to COVID-19, beginning with fundamental scientific concepts behind disease transmission and then covering topics with increasing complexity. For example, we incorporated content explaining the connection between carbon dioxide levels in indoor environments and COVID-19 transmission risk, which educated participants regarding the risks associated with gathering indoors in crowded spaces and encouraged them to improve ventilation indoors to reduce their risk (Figure 3).

When promoting the use of web-based resources, posts included tools for assisting participants with navigating these resources, such as tutorials and step-by-step instructions (Figure 4).

![Figure 1. Brigada Digital social media post using Spanish audio narration to emphasize the importance of wearing a mask to reduce respiratory viral transmission.](https://formative.jmir.org/2024/1/e51331/fig1.png)

Rates of monthly hospitalizations associated with COVID-19 by vaccination status among children and adolescents aged 5 to 17 years old, COVID-NET June 2021-March 2022

Figure 3. Brigada Digital educational post using animated images with text and Spanish audio narration to educate about the link between carbon dioxide levels and COVID-19 risk and provide guidelines for indoor mask use. NIH: National Institutes of Health.

WHAT DOES (CO2) TELL US?

- The air that people exhale (CO2) has small particles. If someone has a COVID infection, those particles can also contain the virus.

- With poor ventilation (airflow), CO2 - and infectious particles - accumulate in the air.

- We can measure CO2 levels in closed spaces. A high CO2 level indicates that it is a riskier place for COVID-19 transmission.
The post content covered a wide range of topics related to COVID-19, including the science of COVID-19 and its transmission, risks, and prevention (36/101, 35.6%); COVID-19 testing (5/101, 4.9%); COVID-19 vaccine information, such as the safety and efficacy of adult and pediatric vaccines and boosters (28/101, 27.7%); risks associated with pregnancy or breastfeeding and COVID-19 (4/101, 4%); COVID-19 treatment and post–COVID-19 condition (6/101, 5.9%); and understanding COVID-19 misinformation (15/101, 14.8%). Furthermore, (7/101, 6.9%) posts were included on related topics for the purpose of participant engagement (refer to Multimedia Appendix 1 for the complete 5-week schedule of intervention post topics). The posts were scheduled to be delivered every morning, afternoon, and evening. Furthermore, the members of the group had unrestricted access to the Facebook group content, allowing them to view the posts and engage with all the content at any time.

The Facebook intervention was facilitated by 2 Spanish-speaking moderators. The moderators engaged group members in discussions about the posts by posing questions, eliciting opinions, and encouraging the sharing of relevant experiences. Group activity was monitored daily to promptly respond to comments and acknowledge group member participation in a timely manner to encourage continued engagement. Furthermore, the moderators aimed to be helpful in responding to questions by providing detailed responses and links to additional information and resources. In addition, 5 weekly polls were administered to inquire about the group members’ risk perceptions, attitudes, and vaccine intentions. Given the timing of the intervention leading up to the start of the school year for children, the poll questions inquired about parents’
concerns about sending their children back to school with COVID-19 still circulating as well as barriers and intentions to vaccinating their children. During their interactions with participants, the moderators prioritized adherence to culturally appropriate expectations of respect, attentiveness, and kindness [47-49].

Data Collection

Survey

A brief, web-based survey was self-administered in Spanish using the Qualtrics software. Following approval by the George Washington University Institutional Review Board committee and participants’ informed consent, the survey was administered at 2 time points, namely at baseline and after 5 weeks. The participants were incentivized for survey completion. This paper reports intervention group participants’ survey responses at the 5-week follow-up and participants’ sociodemographics reported at baseline, including age, sex, education, income, employment status, household composition, and whether they were born in the United States.

The survey instrument included an item for self-reported adult COVID-19 vaccination, with the response options of “I received 1 dose of a 2-dose series,” “I received both doses of a 2-dose series,” “I received a one-dose vaccine (for adults only),” and “I have not been vaccinated against COVID-19.” Furthermore, a survey item for child COVID-19 vaccination was included for parents with children in the age groups of <5 years, 5 to 11 years, and 12 to 17 years, with response options similar to those provided for the item for adult COVID-19 vaccination. In addition, participants were asked whether they had been required to vaccinate.

To assess participants’ intervention exposure, 2 categorical survey items focusing on self-reported exposure asked how frequently participants visited the Brigada Digital Facebook group and saw the group posts in an average week during the intervention. The survey included standardized and open-ended items related to participants’ reactions to the intervention content, moderators, and group environment. A total of 4 categorical survey items assessed participants’ opinions regarding the information received in the group (ie, how informative or trustworthy the information was, the most useful topics, and their preferences regarding post formats); 2 categorical survey items assessed participants’ opinions about the group moderators; and 2 categorical survey items assessed participants’ opinions of the Facebook group environment and members. These items asked the participants to select their level of agreement with a series of statements, using a 5-point Likert scale ranging from disagree to strongly agree. For participant engagement, we used 3 categorical survey items focusing on self-reported engagement, asking whether they introduced themselves to the group and how frequently they reacted to and commented on posts. Furthermore, 3 open-ended items were included to inquire about participants’ reasons for not engaging in each of these actions. Finally, to elicit participants’ feedback about the intervention, we included 3 open-ended survey items that asked what they liked or did not like about the Facebook group and what suggestions they had for improving the intervention.

Facebook Analytics

Facebook analytics facilitated the tracking of views, reactions, and comments for each post and each participant. We assessed participants’ exposure to the intervention using the metrics of total post views and total views for each participant. We assessed participants’ engagement using the metrics of total post reactions and comments and total reactions and comments for each participant.

Ethical Considerations

All study protocols were reviewed and approved by the George Washington University Institutional Review Board (study #NCR213586). All study participants provided informed consent before enrollment, including their acknowledgment that their survey responses were confidential and that data would be deidentified for analysis and reported in aggregate. The participants were compensated with US $65 in retail gift cards for enrolling in the group and completing the surveys.

Data Analysis

We performed a mixed methods analysis. The survey items were assessed cross-sectionally among intervention participants (N=55) only at follow-up. The survey results for participants’ intervention exposure and reactions as well as participants’ self-reported engagement and opinions about the intervention content, moderator, and group environment were assessed using response frequencies for 13 categorical survey items. The participants’ qualitative responses to 6 open-ended survey items were thematically analyzed to identify the predominant reasons for not engaging with the intervention and areas of concordance for what was liked or disliked about the intervention and to summarize suggestions for improving the intervention. The participants’ quotes were selected and translated into English to illustrate these themes and topics.

Facebook metrics were cumulatively assessed for the duration of the intervention. The Facebook metrics of total post views, reactions, and comments were summed to further assess participants’ intervention exposure and engagement. Views, reactions, and comments were also summed for each participant, and participant averages were tabulated for each of the 3 metrics. The Stata (version 17; StataCorp) software was used for quantitative analysis, and the NVivo (version 14; QSR International) software was used for qualitative analysis.

Results

Overview

The 55 intervention group participants had an average age of 38 (SD 7) years, 91% (n=50) were female, 67% (n=37) had less than a college education, and 91% (n=50) were foreign born. Among the intervention group participants, 64% (n=35) reported having children aged 0 to 4 years living in their household, 64% (n=35) had children aged 5 to 11 years, and 49% (n=27) had adolescents aged 12 to 17 years. Regarding employment status and income, 44% (n=24) of the participants were employed, 49% (n=27) reported being unemployed or staying at home, and 58% (n=32) reported earning an annual household income of ≤US $35,000. At baseline, 85% (n=47) of the parent
participants had received an initial 1-dose COVID-19 vaccine or completed a 2-dose vaccine series, with 29% (n=16) of the participants saying that they had been required to vaccinate. Among the intervention participants, 3% (1/35) of the parents with children aged 0 to 4 years said that their children had completed the 2-dose vaccine series, with 31% (11/35) of the parents with children aged 5 to 11 years and 70% (19/27) of the parents with adolescents aged 12 to 17 years also saying that their children had completed the 2-dose vaccine series (Table 1).

Participants’ Intervention Exposure
When asked how many times they visited the private Facebook group per week during the study, 40% (22/55) of the participants reported visiting the group 1 to 3 times per week, a substantial proportion (18/55, 33%) of the participants reported visiting the group 4 to 6 times per week, a smaller proportion (8/55, 15%) of the participants reported visiting <1 time per week, and an even smaller proportion (7/55, 13%) of the participants reported visiting the group ≥7 times per week (Table 2).

In addition, when asked how many posts, on average, they viewed per day, 42% (23/55) of the participants reported viewing 1 to 2 posts per day, approximately one-third (16/55, 29%) of the participants reported viewing 3 to 4 posts per day, approximately one-fifth (12/55, 22%) of the participants reported viewing <1 post per day, and a small proportion (4/55, 7%) of the participants reported viewing ≥5 posts per day. Facebook group analytics from the 5-week period validated this level of participant exposure, with a total of 2004 post views or an average of 36.4 post views per participant.

Reactions to the Intervention Content
The participants generally had positive reactions to the content of the intervention. Most participants (49/55, 89%) indicated that they agreed or strongly agreed that the intervention content was informative, whereas only 7% (4/55) disagreed or strongly disagreed. When asked what they liked about the intervention, 78% (43/55) of the participants responded that they liked the information provided and found it to be important and beneficial to them:
They give a lot of very important information, and more for parents, it’s super important to keep us informed.  
Very good information for our benefit.  
Everything, I like it because they inform us well about the vaccine.

Specifically, 13% (7/55) of the participants responded that they liked how the group content kept them informed of the latest, up-to-date information about COVID-19:

It is a very helpful group informing and trying to keep people up to date on COVID.

Furthermore, 13% (7/55) of the participants expressed that they liked that the topics were covered in detail yet in a way that was easy to comprehend, concise, and interesting. One of the participants commented on how the information provided in the group helped her make COVID-19 vaccination decisions:

All the information was explained well and the posts were understood. I had no problems understanding the topics.  
I like the way the topics are fully explained.  
All the information that was given to me in the group seemed very interesting to me.  
This helped me be confident in decisions about the COVID vaccine.

In addition, most participants (49/55, 89%) agreed or strongly agreed that they trusted the information presented in the posts, whereas very few (2/55, 4%) disagreed or strongly disagreed. When asked what they liked about the intervention, 3 (5%) of the 55 participants echoed this viewpoint, indicating that they liked receiving “official” information about COVID-19 vaccines that was from a trusted source or supported by data:

That it addresses issues about vaccines and gives official information that many times one does not know.  
That I can get information and opinions from a safe place.

I liked that they talked about the importance of vaccines with data since there are a lot of incredulous people that give out different kinds of information.

When asked for feedback on the quantity of posts received, 89% (49/55) of the participants thought that they had received the correct quantity of posts, and 11% (6/55) thought that they had not received enough posts. Furthermore, the intervention participants were asked which post topics they deemed to be the most useful. According to the participants, the 2 most useful topics were the safety and efficacy of adult COVID-19 vaccines and understanding the levels of COVID-19 risks for children, with over half (29/55, 53%) of the participants selecting each of these 2 topics (Table 3).

Furthermore, 44% (24/55) of the participants found the information about the science behind COVID-19 and its variants to be the most useful, and 38% (21/55) thought that the adult and child COVID-19 booster information was the most useful. Approximately one-fifth to one-quarter of the participants thought that the topics of COVID-19 testing (14/55, 25%), pregnancy and COVID-19 (12/55, 22%), and understanding COVID-19 misinformation (13/55, 24%) were the most useful.

When asked for feedback on how to improve the Facebook group experience, 5 (9%) of the 55 participants suggested having more content in general and continuing to provide information on COVID-19, COVID-19 vaccine side effects, COVID-19 vaccines for children, and other health topics.

Regarding preferred post types or formats, the participants indicated that they liked video content, with 51% (28/55) of the participants liking video interviews with experts, 47% (26/55) of the participants liking instructional videos, and 29% (16/55) of the participants liking audio-narrated educational posts (Table 4).

Most participants (38/55, 69%) indicated favoring educational content that could be read, and a substantial proportion also liked formats that were meant to be engaging, including group polls (25/55, 45%) and funny posts (16/55, 29%).

**Reactions to the Moderators and Group Environment**

When asked what they liked about the group, 7 (13%) of the 55 participants said that they liked everything about the group. Furthermore, the results revealed that most participants *agreed* or *strongly agreed* that the moderators were well informed (51/55, 93%) and helpful (50/55, 91%), whereas 2% (1/55) and 5% (3/55) *disagreed* or *strongly disagreed* with these statements, respectively. When asked what they liked about the intervention, 6 (11%) of the 55 participants specifically praised the moderators for being empathetic and responsive:

*I really liked the moderator of the group.*

The information that they provided and the empathy that was shown.

The information and the attentiveness to answer comments.

Regarding the group environment, a large proportion (51/55, 93%) of the participants *agreed or strongly agreed* that joining the group was helpful and had positive opinions about the group members. Most participants said that their perceptions of other group members were that they were friendly (45/55, 82%) and supportive (19/55, 35%) during their interactions with the group (Table 5).
A little more than one-third (18/55, 33%) of the participants thought that other group members were similar to them; one-fifth (11/55, 20%) of the participants thought that other group members were tolerant; and few participants thought that other group members were critical (3/55, 5%), bothersome (1/55, 2%), or different than me (3/55, 5%).

When asked what they liked about the intervention, 2 (4%) of the 55 participants said that they liked how the group supported the Latino community with an opportunity to connect with people from many locations and with diverse ways of thinking:

I like the interest that exists to inform and support the Latino community.

It is very entertaining and friendly. You meet people from all over with different ways of thinking.

When asked whether they had recommendations for the intervention, 3 (5%) of the 55 participants indicated that they thought that the posts were not always reaching participants and suggested disseminating more posts or repeating posts:

Be more insistent in repeating the posts so that they go out to all the participants.

More posts, so if I miss one, I can look at others.

Participants’ Engagement

The participants were asked about their average weekly engagement with the post content. The levels of engagement were relatively evenly distributed in terms of self-reported reactions to posts, with 13% (7/55) of the participants reacting to ≥5 posts in an average week, 29% (16/55) reacting to 1 to 2 posts per week, 27% (15/55) reacting to 3 to 4 posts per week, and 27% (15/55) reacting to ≤1 post per week. A small proportion (2/55, 4%) of the participants did not react to any posts. This level of participant engagement through post reactions was validated by Facebook analytics; the group had a cumulative total of 584 reactions or an average of 10.6 post reactions per participant. When asked about the reasons for having never commented on posts, the most common reasons were that the participants preferred only receiving information from the posts, disliked commenting, or were shy.

When asked about recommendations for improving the intervention, 3 (5%) of the 55 participants suggested adding more opportunities for engagement, 1 (2%) requested adding more polls, and 2 (4%) suggested having opportunities to interact in real time with the moderators and group members:

Maybe they could do something to get to know each other a little more and resolve certain doubts.

Discussion

Principal Findings

This intervention entailed the delivery of health promotion messaging and engagement with Spanish-speaking Latino parents in a Facebook group to increase the uptake of adult and child COVID-19 vaccination. The study results suggest that this is a promising approach that should be further tested. The digital setting was particularly appealing because of the flexible opportunities it offered parents to interact both with the educational content at their own pace and with the group members and moderators to resolve concerns, ask for advice, and seek social support. This group-based approach also...
facilitated the use of multimedia educational formats, which included accessibility features, such as audio narration or video-based delivery, that are preferred by parents and address barriers related to literacy or health literacy.

A substantial quantity of daily posts was shared in the group over the 5-week period, with content tailored to a Latino parent audience and covering a wide range of topics related to COVID-19 risk, prevention, and vaccination. Intervention content was intended to provide updated, accurate information to influence parents’ attitudes and beliefs about adult and child COVID-19 vaccination and, ultimately, increase intentions to vaccinate. It is important to note that all content was developed before the intervention, with great attention paid to the selection and sequencing of topics, accessibility to diverse educational levels, and cultural aspects of messaging and delivery. This enabled the scheduling and delivery of many posts within a short time frame. However, given that the intervention was implemented during an ongoing pandemic, which was a rapidly evolving context, it was necessary to review and update all content immediately before scheduled delivery to ensure that the messaging was still consistent with current public health guidelines, overall risk levels, and vaccine recommendations.

With the abundance of misinformation and mixed messaging on social media, this is highly important for establishing and maintaining trust and credibility in participants’ eyes [50-53]. Future interventions seeking to replicate this approach, especially in rapidly changing contexts, should also prioritize the review of scheduled content before delivery to ensure the accuracy and consistency of messaging and alignment with the latest guidelines. In addition, given that the group members resided in different areas of the United States, messaging was developed to be relevant to national COVID-19 community transmission trends and risk levels; geographically focused interventions should tailor content to reflect local circumstances more closely.

**Participants’ Intervention Exposure**

The participants reported viewing posts and visiting the group a fair number of times during the intervention, with 78% (43/55) of the participants saying that they viewed at least 1 post on an average day and 85% (47/55) of the participants saying that they visited the group at least once during an average week. However, 22% (12/55) of the participants reported viewing <1 post on an average day and 15% (8/55) reported visiting the group <1 time in an average week. Although there was considerable variability in participants’ self-reported exposure to post content, posts received an average number of 36.4 views per participant during the 5 weeks.

In addition to creating content that was varied in format and tailored to the Latino parent audience, posts were scheduled to be delivered at different times of the day (10 AM, 3 PM, 5 PM, and 7 PM) to increase the likelihood that participants would receive the intervention posts in their Facebook feed, regardless of when they were using the platform. However, some participants had still not been exposed to all intervention content. This was also reflected in the participant responses, and 3 (5%) of the 55 participants stated that they thought that the posts were not always reaching group members. This could be because of a number of barriers experienced by the participants, such as competing demands for their time, or platform-specific factors, such as the Facebook algorithm for user feed content curation. Given that the Facebook algorithm is personalized and operates based on the user’s history and patterns of content interaction, more exposure will be attained based on past contents, post formats (eg, videos and photos), and posts from sources with which an individual frequently interacts [54]. For example, if intervention participants do not engage with or view posts delivered earlier in the intervention, they are less likely to be exposed to similar content in the later weeks of the intervention. Similarly, if users predominantly engage with video content, they are less likely to be exposed to content containing only images. This algorithm that dictates content in users’ feeds has implications for group-based public health interventions that rely on content exposure to improve knowledge, shift attitudes and beliefs, and increase access to resources and tools for health behavior changes. Because exposing participants to content is imperative for public health impact, future interventions could take actions to increase the likelihood that this algorithm works in their favor, such as placing content or formats that have demonstrated (or are theorized to have) higher levels of engagement at the beginning of the intervention to boost early views and engagement; sending content that varies in terms of format each day or week; and prioritizing early, active engagement strategies as well as continued engagement opportunities each week. Furthermore, as suggested by the study participants, the moderators could post content multiple times to maximize reach or use targeted engagement strategies to prompt the viewing of posts, including tagging or direct messaging specific users. In addition, the Facebook platform, in particular, has added features that allow users to customize their feed to a certain extent, including the option to select up to 30 people and pages to add to “Favorites.” Future interventions should include protocols as part of participant recruitment that request users to select the intervention group as one of their Favorites during the intervention period to increase content exposure. Furthermore, interventions can include information and prompts that explain different ways in which the group members can access content, including through their feed or direct access to the group.

**Participants’ Reactions**

Overall, the Latino parent participants had positive reactions to the intervention. The participants liked various aspects of the group environment, including the opportunity to come together with other parents like them, support the Latino community, stay informed about COVID-19, and learn the perspectives and experiences of others. The participants’ perception of other group members was very positive in that they viewed others as friendly, supportive, tolerant, and “similar to them.” For future interventions that aim to recruit participants with distinctly opposing views about vaccination or any health issue with polarized viewpoints, group moderators should be trained and prepared to navigate interactions that could become less friendly and tolerant, thus potentially stifling group members’ willingness to interact. This intervention did establish group guidelines at the outset, which did not need to be reinforced at any point during the 5 weeks; however, future interventions...
should consider explicitly stating in the guidelines the grounds for removal from the group to prevent guideline violations.

Another aspect that appeared to contribute to participants’ positive reactions was their perceptions of the group moderators. In addition to being deemed well informed and helpful, the participants provided feedback that the moderators were attentive to the group members’ needs and questions and showed empathy. We prioritized the selection of group moderators to include individuals who were familiar with and adhered to social norms and expectations of positive interpersonal dynamics common to Latin culture, including respect for others, kindness, and attentiveness [47-49]. The moderators were also parents of children aged <18 years, enabling them to relate to the participants’ concerns about their children’s health and safety.

Future interventions should seek to replicate a similar group environment with Latino parent audiences, including by having culturally competent moderators who adhere to these expectations for interactions with participants and who are highly responsive to group members’ inquiries.

Overall, participants’ feedback indicated that the intervention content was perceived to be informative and useful. There were 3 topics in particular that the participants thought were especially useful, namely the safety and efficacy of adult COVID-19 vaccines, understanding the levels of COVID-19 risks for children, and the science behind COVID-19 and its variants. Future interventions should explore these topics in depth and, as recommended by others, such as de Vere Hunt and Linos [55], should directly address COVID-19 misinformation in these areas through audience-tailored, culturally representative messaging. In addition, Latino parent participants appreciated the importance of staying up to date with COVID-19 information by regularly receiving concise content, which has also been reported elsewhere, including by Panameno and colleagues [44].

Interventions seeking to replicate this approach, especially in the context of a rapidly evolving public health emergency, should capitalize on how the interventions can address this need for parents by delivering accurate and convenient messaging at regular intervals. Furthermore, when asked what they liked about the intervention, many participants highlighted that they liked that the information was presented in detail yet in an interesting manner that was easy to comprehend. The main goal of Brigada Digital content was to address the gaps in Spanish-language COVID-19 information that was appealing to and appropriate for the audience and fully explained health and scientific concepts to build vaccine confidence. The combination of supportive, empathetic moderators with topic expertise and the delivery of content that was updated, had consistent messaging, and was accessible to audiences with diverse educational backgrounds likely contributed to 89% (49/55) of the participants saying that they trusted the information provided in the group. Source credibility and trust are paramount to effective health promotion interventions, particularly when promoting COVID-19–related behavior change [56-59]. Future interventions should work to establish this credibility and level of trust among participants by carefully considering the characteristics and selection of group moderators, fostering a welcoming group environment, and tailoring content to the specific audience.

### Participants’ Engagement

Intervention participants demonstrated an early willingness to engage with the group following recruitment, with 89% (49/55) of the participants introducing themselves to the Facebook group when prompted by the moderators. In addition, with averages of 10.6 post reactions and 3 post comments per participant, engagement was similar to or higher than that with other parent-focused Facebook interventions [56,60], although comparable interventions reaching Latino parents specifically are very limited. Combined with positive feedback regarding the group dynamics, these are promising signs of Latino parents’ willingness to engage with Brigada Digital content and learn about and discuss health-related topics in this digital group format. Similar willingness has been observed in other Latino parent–focused digital health promotion interventions [61].

The moderators of future interventions should aim to similarly establish rapport and expectations for group interactions that can promote participants’ willingness to engage with the group. This rapport might be further fostered by offering additional opportunities for engagement throughout the intervention, for example, through live discussions and events, as suggested by the participants, or through polls, which almost half of the participants said that they preferred. The kind of engagement observed among the intervention participants through platform analytics as well as from participant self-report is consistent with typical patterns of engagement among social media platform users, including Latino individuals, who are most likely to simply view content and less likely to comment on posts than react [62,63]. Future efforts might explore ways to boost more active engagement, including using polls as catalysts for discussion or addressing individuals directly with targeted engagement tactics. Moreover, based on feedback from the participants, future interventions should explore ways to offer more opportunities to interact with and get to know group moderators and members, which would further develop rapport, establish trust in the information provided, address parental concerns, and increase engagement by making experts available to answer questions that are of the most interest to participants.

In addition, delivering content in a wide variety of formats and then inquiring about preferences helped us hone in on formats that participants gravitated toward the most. Similar to the study by Panameno and colleagues [44], which demonstrated Latino parents’ preferences for COVID-19 educational information in video formats from trusted sources, approximately half (28/55, 51%) of the study participants indicated that video interviews with experts were preferred, as were instructional videos, which often portrayed a Spanish-speaking health professional giving a demonstration. Formats intended to bridge potential literacy barriers, such as videos with audio-narration features, were also well received. One surprising finding, given social media audiences’ increasing affinity for multimedia content, was that most parents liked educational posts they could read; it is possible that the inclusion of an audio-narration feature helped increase parents’ preferences for these types of posts. This may also indicate that parent audiences interested in a particular health topic, especially for their children’s well-being, may be willing to invest time and effort in reading social media content if they perceive the content to be beneficial, trustworthy, and
valuable to them. Implementers of future social media group–based interventions should also aim to offer a diversity of content delivery formats, with an emphasis on video and other multimedia formats “in consonance with “content delivery formats”) accessible to audiences with diverse levels of literacy and health literacy.

Limitations
This study has some limitations that should be considered when interpreting the results. This study included a relatively small sample (N=55) of Spanish-speaking Latino parents, with an overrepresentation of female participants. Therefore, the results may not be generalizable to a broader population of Latino parents, particularly fathers. In addition, the study was only 5 weeks in duration, potentially limiting insights into the sustainability of participant engagement and the long-term impact on vaccine uptake. Furthermore, given that the participants were recruited through their response to Facebook advertisements, there is a potential for selection bias that could have resulted in a sample that was more interested in health-related topics and COVID-19 in particular, was more supportive of vaccination in general, and had the time and ability to participate in the group. In addition, it was not possible for this pilot study to fully track all participants’ engagement, and we did not track Facebook log-ins, the length of time using the platform, or the number of times accessing the group. Besides platform metrics of active participant exposure and engagement, such as views, reactions, and comments, data were limited to participant self-reports of group visits and post views.

Conclusions
The findings of this study highlight the promise of a Facebook group–based intervention approach to engage Spanish-speaking Latino parents in health promotions related to COVID-19 and vaccination. The intervention participants experienced adequate exposure to the intervention content and engagement and reported overall positive reactions to the intervention. Future efforts should consider using this digital health promotion approach while integrating strategies to augment participants’ exposure to health promotion content; cultivating regular participant engagement, including using concise, audience-tailored messaging; and moderating the group with culturally aligned facilitators to foster trust, address misinformation, and promote child vaccine acceptance among parents.

Abstract

Background: In 2019, the World Health Organization declared the reluctance to vaccinate despite the availability of vaccination services as one of the top 10 threats to global health. In early 2021, self-reported reluctance to vaccinate among military personnel might have been considered a significant threat to national security. Having a choice architecture that made COVID-19 vaccination optional rather than required for military personnel could have inadvertently undermined military readiness if vaccination uptake did not reach an acceptable threshold.

Objective: The purpose of this observational study was to examine Marines’ self-reported reasons for planning to decline the COVID-19 vaccine to understand their barriers to vaccination.

Methods: As the vaccination became available to 1 company of Fleet Antiterrorism Security Team (FAST) Marines in early 2021, company command required those planning to decline vaccination to write an essay with up to 5 reasons for their choice. These essays provided the data for this study. Qualitative descriptive analysis with elements from grounded theory was used to thematically categorize FAST Marines’ written reasons for planning to decline the COVID-19 vaccine into a codebook describing 8 key behavioral determinants. Interrater agreement among 2 qualitatively trained researchers was very good (κ=0.81).

Results: A troop of 47 Marines provided 235 reasons why they planned to decline the COVID-19 vaccine. The most frequent reasons were difficulty understanding health information (105/235, 45%), low estimates of risk (33/235, 14%), and fear of physical discomfort (29/235, 12%). Resulting interventions directly targeted Marines’ self-reported reasons by reducing barriers (eg, normalized getting the vaccine), increasing vaccine benefits (eg, improved access to base gyms and recreational facilities), and increasing nonvaccine friction (eg, required in writing 5 reasons for declining the vaccine).

Conclusions: Understanding the barriers military personnel experience toward COVID-19 vaccination remains critical as vaccine acquisition and availability continue to protect military personnel. Insights from subpopulations like FAST Marines can enhance our ability to identify barriers and appropriate intervention techniques to influence COVID-19 vaccination behaviors.

(Keywords: behavioral barriers; benefits; COVID-19; Marine Corps; military; vaccine reluctance)

Introduction

In 2019, the World Health Organization declared the reluctance to vaccinate despite the availability of vaccination services as one of the top 10 threats to global health [1]. Since COVID-19 emerged in late 2019, COVID-19 vaccination specifically has been deemed a critical public health priority [2]. Vaccination is associated with reduced hospitalization and death rates following COVID-19 infection [3-5], as well as reductions in transmission and severity of infection [5,6]. Yet, it has proven challenging to achieve the desired rates of vaccination in the United States generally [7] and within specific subpopulations such as rural dwellers [8], political conservatives [9], and people with previous diagnoses of COVID-19 [10].
Combating uneven and inadequate uptake of COVID-19 vaccines requires an understanding of the behavioral determinants (ie, barriers and facilitators of the behavior) leading people to vaccinate or not [11]. Behavioral design frameworks, such as the COM-B (capability, opportunity, motivation, behavior) model of behavior change which suggests that capability, opportunity, and motivation are essential for behavior change, provide a categorization scheme for behavioral determinants that then allows interventionists to select techniques that target the specific barriers preventing people from completing a desired behavior [12-16]. While there are some behavioral determinants that may be addressable through directives from credible sources, as traditional public health campaigns may be described, these campaigns are unlikely to be broadly successful or sufficient in isolation to promote widespread behavior change. This is because they do not adequately account for the breadth of people’s barriers to performing the behavior or adequately enhance the benefits of the behavior [17,18]. Counteracting a crisis like the COVID-19 pandemic necessitates understanding how people make decisions, what gets in the way, and what gets people to take action [19]. Qualitative research approaches that yield richer insights might contribute to a better understanding of these nuances [20-23].

Barriers to COVID-19 vaccination in the general population include, among others, beliefs of low susceptibility to infection, perceived low severity of COVID-19, beliefs of low vaccine effectiveness, concerns about side effects, desires for more information, and not having explicit endorsement from a health care provider [24,25]. Not having received a vaccine in the past year is also associated with lower vaccination rates [26]. Barriers differ for population subgroups based on characteristics such as geographical location, work responsibilities, income level, educational attainment, and insurance status [25], several of which are social determinants of health. To effectively influence vaccination behavior within a population subgroup, researchers should seek to understand the specific barriers prevalent in that group.

One such group is military personnel and veterans. A specific study of the behavioral determinants of COVID-19 vaccination in military personnel is critical, as vaccination against infectious diseases supports operational readiness [27]. Moreover, given military veterans’ high rates of mental health issues and suicide, there has been some effort to consider veteran status as a social determinant of health [28]. A better understanding of the health decisions of military personnel therefore has the added potential of supporting improved health equity.

In early 2021, medical experts and government leaders considered the lack of COVID-19 vaccination among military personnel a potential threat to national security [29,30]. Unlike influenza, tetanus, diphtheria, pertussis, smallpox, and other vaccines, which are required aspects of force readiness, the COVID-19 vaccine was initially optional for military personnel before becoming mandatory [31] and finally becoming optional again on January 10, 2023 [32]. Having a choice architecture that makes COVID-19 vaccination optional for military personnel [33] could inadvertently undermine military readiness if vaccination uptake does not reach an acceptable threshold. Therefore, it is important to understand the reasons why military personnel might not vaccinate to appropriately intervene on those barriers.

In the United States, military personnel are socialized to a specific set of values, including honor, bravery, and personal sacrifice [34]. Each branch of the US military then has characteristics that may influence the specific behavioral determinants of its troops toward vaccination. For example, within the United States Marine Corps, values such as the need for control and independence are reinforced, sometimes to the detriment of health-promoting behaviors [35,36]. Marines report a lower likelihood of vaccine receipt than other branches of service [37,38]. These differences may reflect true differences between the branches or, more likely, may reflect underlying differences in the characteristics of individuals choosing to serve in different branches.

Junior Marines (E1-E4) experiencing a high degree of external control and loss of agency due to service [39] might feel an enhanced need to establish autonomy when given the chance, such as by declining an optional vaccine. Research has found that military personnel ranked E1-E4 were the most likely to reject an avian influenza vaccine [37]. While the Marine Corps has embraced an approach of informed health care choice for its members, there is a rocky history of medical paternalism (eg, anthrax vaccination in the 1991 Gulf War, but see [40]) that may negatively influence modern Marines’ perceptions of vaccination campaigns.

Given their overall health and fitness and the risks that come with their jobs, Marines may also have a low perceived personal risk from the COVID-19 infection and a tolerance for risk that others may find uncomfortably high. Although data were limited at the time, it was projected in early 2021 that those who contracted COVID-19 had a 0.5%-5% chance of developing a critical illness requiring intensive care or resulting in death [41]. Those odds might have seemed acceptable to Fleet Antiterrorism Security Team (FAST) Marines, who are trained to provide security forces to guard high-value naval installations, most notably those containing nuclear vessels and weapons. FAST Marines find themselves in high-risk situations as part of their regular training, for example with live fire, extreme exposure to the elements, and sleep and nutrition deprivation. FAST Marines’ daily work likely undermines their perceived severity of contracting COVID-19. In contrast, the perceived severity of contracting anthrax among 22 Department of Defense (DOD) personnel in 2015 resulted in near 100% adherence to a complex emergency postexposure prophylaxis following accidental exposure to live Bacillus anthracis spores [42]. Americans’ willingness to get the COVID-19 vaccine declined from 72% in May 2020 to 51% in September 2020 [43] and rebounded to 60% in November 2020 [44]. Surveys from early 2021 found that fewer than half of military troops and military spouses planned to receive the vaccine [45]. At the time of the study, FAST Marines in Yorktown, Virginia, were in a privileged position: they were 1 of 12 bases nationwide to be offered the COVID-19 vaccine before widespread availability [46]. Yet an informal poll of Marines in 1 FAST company showed that only 10% planned to get the COVID-19 vaccine,
much lower than other estimates at the time [43,44]. The FAST Marines’ company command introduced key friction to those FAST Marines who planned to decline the COVID-19 vaccine: they had to write formal papers outlining up to 5 reasons why. This observational study makes use of these written data to understand FAST Marines’ barriers to COVID-19 vaccination.

**Methods**

**Ethical Considerations**

We followed the Standards for Reporting Qualitative Research [47]. This research was approved by an Exception Determination Official with the Naval Medical Center Portsmouth Research Subjects Protection Division. The study does not meet the Naval Medical Center Portsmouth Research Subjects Protection Division’s definition of research in accordance with 32 CFR 219.102 and DoDI 3216.02. Therefore, no written consent was obtained for the qualitative analyses. Study data were deidentified.

**Sample**

The FAST platoon is the core operational unit of the Marine Corps Security Force Battalion. There are 18 FAST platoons divided into 3 FAST companies that are based in Norfolk and Yorktown, Virginia. The battalion commander of 1 of the 3 FAST companies asked his Marines to either obtain the COVID-19 vaccine or to provide, in writing, at their own leisure but with a deadline, up to 5 reasons why they did not want the COVID-19 vaccine. One platoon of 47 male junior FAST Marines (ie, E1-E4) exclusively chose to provide written reasons for declining the COVID-19 vaccine. Their responses were collected by the battalion commander, entered into Microsoft Excel (Microsoft Corp) without demographic information, and shared with the researchers. Demographic data were not collected, and Marines did not receive compensation because the writing task was originally intended as a troop exercise and an intervention to promote COVID-19 vaccination, not a research project. Data were collected in February 2021. There were no efforts to retroactively identify which FAST Marine submitted which reasons or determine their demographics or ranks.

**Qualitative Descriptive Analysis**

The purpose of our study, to examine FAST Marines’ self-reported reasons for planning to decline the COVID-19 vaccine to understand their barriers to vaccination, guided our choice of qualitative descriptive analysis. Qualitative description is an appropriate approach to gathering insights on novel or poorly understood phenomena [20]. We conducted a rapid review to develop a codebook of empirically supported barriers to obtaining a COVID-19 vaccine that we coded the FAST Marines’ responses against. We used thematic analysis [48,49] with elements from grounded theory [50,51]. The 2 qualitatively trained researchers independently coded the responses in Excel. We calculated interrater agreement with Cohen’s κ [52], which accounts for change agreements. The interrater agreement was very good (κ=0.81). See Table 1 for the final codebook consisting of 8 codes.
Table 1. The codebook used for qualitative descriptive analyses of 47 Yorktown, Virginia, Fleet Antiterrorism Security Team Marines’ 235 written reasons for why, in February 2021, they planned to decline the COVID-19 vaccine.

A total of 45% (105/235) of all responses (each FAST Marine gave up to 5), and 3 times as many as the second largest barrier, had to do with difficulty understanding medical information. In fact, 96% (45/47) of FAST Marines—all except 2 FAST Marines—indicated difficulty understanding medical information, ranging from the inability to understand basic medical information to the inability to grasp nuances in the medical literature.

Discussion

Overview

A qualitative descriptive analysis of 235 reasons for planning to decline the COVID-19 vaccine provided a contemporaneous understanding of the barriers to vaccination experienced by an infrequently studied population subgroup: junior FAST Marines. FAST Marines’ barriers to COVID-19 vaccination included low health literacy, perceived low susceptibility to COVID-19 and its severity, concern over vaccine safety and potential side effects, and other less frequently reported barriers. These findings are consistent with work on Air Force personnel who self-identified as vaccine-hesitant and indicated concerns about efficacy, side effects, and vaccine-induced illness as top barriers to vaccination [61], while adding the insight that low health literacy may be associated with such concerns.

Our findings extend previous work on barriers to COVID-19 vaccination in part because we captured in-the-moment attitudes, beliefs, and cognitions about the COVID-19 vaccine in a less frequently studied population subgroup: junior FAST Marines. The barriers described in the written responses were not subject to the same demand characteristics as barriers elicited through formal research. That is, FAST Marines were not restricted to a preselected list of barriers to COVID-19 vaccination as might have been the case in survey research, nor were they aware of a research framing that might have prompted more socially acceptable responses.

Impact on Future Interventions Suggested by Findings

Fear is a common, if not primary, motivator used by Marine Corps leadership. Instead of fear-based messaging, which might induce reactance [62,63], and based on our results from the qualitative descriptive analysis, we recommended to the company command placing emphasis on the fact that FAST Marines are young and healthy, they must get the COVID-19 vaccine. This kind of messaging emphasizes resilience and self-efficacy [55,63] and builds on FAST Marines’...
esprit de corps. Future research should evaluate building upon the positive and strong military identity [34] to promote health behaviors in military personnel.

What makes Marines great at their jobs might get in the way of success elsewhere. That is, feeling invincible could positively support junior Marines in performing their job but could become a barrier when they decide whether or not to get the COVID-19 vaccine. Our results do not suggest or endorse changing traits or skills that make Marines great at their jobs. Instead, the results suggest using that information to better speak the Marines’ language and motivate them to get vaccinated. In this case, intervention design should not treat some of these qualities as barriers to overcome so much as consider them to be facilitators to be leveraged.

The study results provided insights for behavioral intervention at the troop and company levels. Company command developed interventions that directly targeted FAST Marines’ self-reported reasons for increasing nonvaccine friction (eg, required in writing 5 reasons for declining the vaccine), reducing barriers (eg, normalized getting the vaccine by encouraging senior personnel to get vaccinated), and increasing vaccine benefits (eg, provided fringe benefits to vaccinated FAST Marines such as the higher likelihood of approval for out-of-area leave).

**Limitations and Directions for Future Research**

The primary limitation stems from the nature of the data. The 235 written reasons to decline the COVID-19 vaccine were intended as a troop exercise and not a scientific study. We were unable to explore demographics known to be determinants of COVID-19 vaccination because of the deidentified data.

The second limitation involves our inability to determine our results’ direct impact on COVID-19 vaccination in the troop of FAST Marines. Company command introduced a number of behavioral interventions following this study but implemented them inconsistently across the troops within the company. The goal of managing COVID-19 transmission surpassed scientific rigor. It is therefore difficult to determine why only 10% (11/114) of FAST Marines in the company expressed intentions to accept the COVID-19 vaccine in January of 2021 but, 8 weeks later, 84% (105/114) of the company had chosen to receive the vaccine. Some FAST Marines likely chose to vaccinate due to the interventions implemented by their leadership to address their barriers, but it is also likely that the intention-behavior gap accounts for some of the discrepancy [23]. Future research on vaccine campaigns in the military should explore the impact of behavioral interventions like the ones implemented here and should also capture how vaccines are administered: with informed choice, under time pressure, etc (see Murphy et al [40]).

**Conclusion**

Understanding the barriers military personnel experience toward COVID-19 vaccination remains critical despite the success of COVID-19 vaccination to date, with 96% of US military personnel fully vaccinated as of January 2023 [32], compared to roughly 70% for all Americans [64]. It is hard to overstate the impact of even small wins when it comes to the health of military personnel. Vaccine acquisition and availability continue protecting military personnel, and the DOD currently offers 17 different vaccines for the prevention of infectious diseases among military personnel, where appropriate [65]. The historical and cultural context of the Marine Corps, and specifically the Marine Corps’ FAST, likely gave rise to a particular constellation of barriers to the COVID-19 vaccine. Identifying these barriers early and as the COVID-19 vaccine was made available helped shape how a FAST company command successfully ensured vaccine participation. With the return to a choice architecture that makes ongoing COVID-19 vaccination voluntary, coupled with the knowledge that ongoing boosters will be necessary to maintain resistance to infection, military leadership has ample opportunity to continue to offer behavioral interventions tailored to their troops’ needs.

Correction of: https://formative.jmir.org/2021/10/e31862

doi:10.2196/56570

In “Evaluating the Clinical Feasibility of an Artificial Intelligence–Powered, Web-Based Clinical Decision Support System for the Treatment of Depression in Adults: Longitudinal Feasibility Study” (JMIR Form Res 2021;5(10):e31862), the authors noted one error.

In the section “Assessing Physician and Patient Trust in the CDSS and Its Effect on the Clinician-Patient Relationship”, the STAR-P and STAR-C total scores were listed as:

The mean STAR-P and STAR-C scores were 33.62 (SD 2.90) and 31.14 (SD 2.63) comparable with 38.4 (SD 12.0) and 31.5 (SD 6.9) in the original Scale to Assess Therapeutic Relationships in Community Mental Health Care study.

They have been changed to read in the following manner:

The mean STAR-P and STAR-C scores were 42.69 (SD 5.57) and 40.29 (SD 5.65), comparable with 38.4 (SD 12.0) and 31.5 (SD 6.9) in the original Scale to Assess Therapeutic Relationships in Community Mental Health Care study.
The correction will appear in the online version of the paper on the JMIR Publications website on January 24, 2024 together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 19.01.24; this is a non–peer-reviewed article; accepted 19.01.24; published 24.01.24.

Abstract

Background: Research has found a COVID-19 pandemic–related impact on HIV medical services, including clinic visits, testing, and antiviral therapy initiation in countries including Japan. However, the change in trend for HIV/AIDS testing during the COVID-19 pandemic has not been explored extensively in the Japanese population.

Objective: This infodemiology study examines the web-based search interest for two types of HIV tests, self-test kits and facility-based tests, before and during the COVID-19 pandemic in Japan.

Methods: The monthly search volume of queried search terms was obtained from Yahoo! JAPAN. Search volumes for the following terms were collected from November 2017 to October 2018: “HIV test,” “HIV test kit,” and “HIV test health center.” The search term “Corona PCR” and the number of new COVID-19 cases by month were used as a control for the search trends. The number of new HIV cases in the corresponding study period was obtained from the AIDS Trend Committee Quarterly Report from the AIDS Prevention Foundation.

Results: Compared to the search volume of “corona-PCR,” which roughly fluctuated corresponding to the number of new COVID-19 cases in Japan, the search volume of “HIV test” was relatively stable from 2019 to 2022. When we further stratified by the type of HIV test, the respective web-based search interest in HIV self-testing and facility-based testing showed distinct patterns from 2018 to 2022. While the search volume of “HIV test kit” remained stable, that of “HIV test health center” displayed a decreasing trend starting in 2018 and has remained low since the beginning of the COVID-19 pandemic. Around 66%-71% of the search volume of “HIV test kits” was attributable to searches made by male internet users from 2018 to 2022, and the top three contributing age groups were those aged 30-39 (27%-32%), 20-29 (19%-32%), and 40-49 (19%-25%) years. On the other hand, the search volume of “HIV test health centers” by male users decreased from more than 500 from 2018 to 2019 to fewer than 300 from 2020 to 2022.

Conclusions: Our study found a notable decrease in the search volume of “HIV test health center” during the pandemic, while the search volume for HIV self-testing kits remained stable before and during the COVID-19 crisis in Japan. This suggests that the previously reported COVID-19–related decrease in the number of HIV tests mostly likely referred to facility-based testing. This sheds light on the change in HIV-testing preferences in Japan, calling for a more comprehensive application and regulatory acceptance of HIV self-instructed tests.
Introduction

HIV prevalence in Japan is <0.1% among adults aged 15-49 years, and the cumulative total of people diagnosed and living with HIV at the end of 2018 was approximately 30,000 [1]. A recent study using a national database found that 81.5% of people living with HIV who were on antiretroviral therapy (ART) had at least one chronic comorbidity [2]. According to recent national statistics, the proportion of people diagnosed and living with HIV on ART was 86% and 80% as of 2018 [3], lower than the first two 90-90-90 Joint United Nations Programme on HIV and AIDS (UNAIDS) goals, while the proportion of people living with HIV on ART who are virally suppressed was as high as 99% as of 2020 [4], reaching the UNAIDS goal. Evidence has suggested that earlier HIV diagnosis and linkage to treatment should be the core strategy in controlling the HIV epidemic [5]; however, the sudden and ongoing COVID-19 pandemic has overwhelmed the health care system globally and caused severe disruptions in medical service provision, ranging from elective procedures to routine surveillance for manageable diseases such as HIV infections [6-11]. Additionally, social distancing measures implemented early in the pandemic affected people’s access or willingness to visit health care facilities.

There are concerns that disruptions caused by the COVID-19 pandemic may lead to increased HIV incidence and mortality and pose challenges to the international community’s goal to eliminate the HIV or AIDS epidemic by 2030 [1]. Reports from Africa, Asia, Europe, Japan, and the United States have found a pandemic-related impact on HIV medical services, including clinic visits, testing, and antiviral therapy initiation [1-6]. In particular, the number of HIV tests conducted in health centers in Japan reduced from 142,000 in 2019 to 69,000 in 2020, with the difference amounting to a 50% decline in the first year of the COVID-19 pandemic [3]. The number of HIV consultations performed in public health centers also significantly declined in the second quarter of 2020 (32,565 tests) compared to the same period the year before (11,689 tests) [2].

In Japan, voluntary HIV testing is free of charge and anonymous, and offered as a package service bundled with pre- and posttest counseling at appointed public health facilities by law. Although the number of health center–conducted HIV tests increased steadily and peaked in 2008, a 30% decline was observed before the COVID-19 pandemic [8,12]. This is possibly due to the commercial availability of HIV self-tests in Japan, with the number of dry blood spot HIV self-tests increasing from 26,000 tests in 2005 to 91,000 tests in 2016 [7,12]. However, the HIV self-testing technique is not yet approved by the health authorities in Japan.

The internet is a common source of disease- and health-related information, and internet use influences care initiation and the treatment decisions of people living with HIV [13]. During the COVID-19 pandemic, infodemiology studies found that web-based search trends for symptoms associated with COVID-19 coincided with the disease outbreak [14]. Conversely, the global web-based interest in information on HIV/AIDS care services decreased [15]. However, the search engine trend for HIV/AIDS testing during the COVID-19 pandemic has not been explored extensively in the Japanese population. This study aims to characterize and compare the trend for web-based search interest in HIV testing before and during the pandemic to investigate whether there is a change in HIV/AIDS health-seeking behavior in Japan.

Data from the search engine provided by the Yahoo Japan Corporation will be used for this study because Yahoo! JAPAN is the most visited website in the country, and compared to most other countries, Japan uses Google less frequently.

Methods

Data Source

To examine the pattern of web-based search interests in HIV testing before and during the COVID-19 pandemic, the monthly search volume of selected search terms was determined based on the number of searches over a specified period extracted from Yahoo! JAPAN, which is one of the most used digital services in Japan, and compared to the rest of the world, Google is used less. According to the data, 68.9% of the population (aged >2 years) used Yahoo! JAPAN at least once a month between January and November 2021, while 65.1% used Google in the same period [16]. Search volume data were retrieved with authorized access from the Yahoo Japan Corporation server via the DS.INSIGHT People portal. It has been used in studies focusing on transition or trends in search behavior over time among different demographics (eg, gender, age, or prefecture) [17]. The user manual is available on the web [18].

The internet user population is the number of internet users throughout Japan, calculated based on the “Telecommunications Usage Trends Survey” published by the Ministry of Internal Affairs and Communications.

The quarterly number of new COVID-19 cases between January 2019 and December 2022 was obtained from an excerpt from the Japan Ministry of Health, Labour and Welfare [19].

The number of newly infected people with HIV between December 31, 2018, and June 26, 2022, was obtained from the AIDS Trend Committee Quarterly Report from the AIDS Prevention Foundation, API-Net AIDS Prevention Information Net [20].

Search Queries Used in the Analysis

The search term “HIV検査” (ie, “HIV test” in Japanese) was used to assess the web-based interest in general HIV testing from January 2020 to October 2021. The result is presented together with the search volume of “コロナPCR” (ie,
“corona-PCR” in Japanese) and the number of new COVID-19 cases by month. The search volumes of “HIV検査キット” (ie, “HIV test kit” in Japanese) and “HIV検査保健所” (ie, “HIV test health center” in Japanese) were compared to analyze the difference in web-based interest in self-instructed/postal and facility-based HIV testing from November 2018 to October 2022.

Data Standardization

The monthly number of searches per prefecture for each search query was obtained, adjusted by sex, and converted to standardized z scores according to the following formula:

“Query A” refers to the queried search term.

Statistical Analysis

Internet users were stratified according to age on the day of the search, sex, and year. Demographics were summarized as the number and percentage of patients for categorical variables. Descriptive statistics were summarized using Excel (Microsoft Corporation).

Ethical Considerations

This infodemiology study adhered to chapter 1, section 3, part 1, subsection (C), item 3 of the ethical guidelines for Medical and Health Research Involving Human Subjects of the Ministry of Health, Labour and Welfare of Japan [21]. In accordance with this guideline, since this study used previously anonymized and deidentified data, an ethical review was waived, and patient informed consent was not required.

Results

Between 2018 and 2022, 50% to 51% of overall adult internet users were male, and the user population was evenly distributed across different age groups by decade (11%-18% across different age groups in 2018, 12%-17% in 2019, 12%-18% in 2020, 13%-17% in 2021, and 13%-17% in 2022; Tables 1-3). The first nationwide state of emergency concerning COVID-19 was from April 7 to May 25, 2020, in Japan; since then, the increase in web-based interest in COVID-19 polymerase chain reaction testing (represented by the search volume of “corona-PCR”) roughly corresponded to the peaks and troughs of new COVID-19 infection cases in recent waves of the COVID-19 pandemic in Japan during mid 2021, early 2022, and late 2022. In contrast, the web-based interest in general HIV testing represented by the search term “HIV test” appeared to be relatively stable (Figure 1). Although the sex distribution of the “corona-PCR” search volume varied between 2020 and 2022, people aged 40-49 years consistently showed the highest web-based interest (26%-27%) for COVID-19 polymerase chain reaction testing, followed by those aged 50-59 years (21%-23%) and 30-39 years (15%-18%). In line with the characteristics of people with an increased risk of HIV infection, 57%-60% of the “HIV test” search volume between 2020 and 2022 were from male internet users, and people aged between 20 and 29 years (30%-31%) showed the most interest in general HIV testing within this period, followed by those aged between 30 and 39 years (24%-27%) and 40 and 49 years (17%-20%; Table 1).

\(^a\)The internet user population is the number of internet users throughout Japan, calculated based on the “Telecommunications Usage Trends Survey” published by the Ministry of Internal Affairs and Communications [22].

\(^b\)hiv検査キット: HIV test kit (in Japanese).

\(^c\)hiv検査保健所: HIV test health center (in Japanese).

\(^d\)The internet user population in 2022 uses the figures for 2021.

Figure 1. Monthly web-based search interest in HIV testing and COVID-19 genetic testing and the number of new COVID-19 cases from 2020 to 2022. The monthly search volumes of search terms “HIV検査” (HIV test in Japanese, blue line) and “コロナPCR” (corona-PCR in Japanese, red line) from January 2020 to October 2022 according to the search engine Yahoo! JAPAN are shown. The number of new COVID-19 cases in the corresponding months, according to the Ministry of Health, Labour and Welfare in Japan, is also shown in green bars in this figure.
Web-based interest in HIV testing was further refined as either facility-based HIV tests or self-instructed HIV-testing kits. The search volume for HIV facility-based testing was high in late 2018 and decreased in several instances over the next 3 years, especially in 2020 and 2022 (Figure 2). The search volume of “HIV test kit” (used as a representative search term for HIV self-testing) was lower than that for HIV facility-based testing at the end of 2018. However, the interest remained high over the next 4 years relative to facility-based testing, particularly during the COVID-19 pandemic (Figure 2). Around 66%-71% of the search volume of “HIV test kit” was attributable to searches made by male internet users between 2018 and 2022, and the top three contributing age groups were those 30-39 years (27%-32%), 20-29 years (19%-32%), and 40-49 years (19%-25%). The overall search volume of HIV test health centers decreased from 950 in 2018/2019 to 580 in 2020. The actual search volume for “HIV test kit” versus “HIV test health center” was 560 versus 280 among male internet users in 2020 and 590 versus 290 in 2021; while among female internet users the actual search volume for “HIV test kit” versus “HIV test health center” were similar: 230 versus 300 in 2020 and 310 versus 350 in 2021. Hence, the main population searching for “HIV test health center” shifted from male to female users (n=300, 52%) in 2020 and the following years (n=350, 55% in 2021 and n=180, 64% in 2022). Internet users aged 20-29 years (27%-35%), 30-39 years (24%-32%), and 40-49 years (14%-20%) were the top three representative age groups for the search volume of “HIV test health center” (Tables 2 and 3).

The quarterly number of newly infected HIV cases remained relatively stable since the declaration of a nationwide state of emergency concerning COVID-19, and the search interest remained high for self-testing relative to facility-based testing (Figure 3).

Figure 2. Monthly web-based search interest in HIV self-instructed and facility-based tests and the number of new COVID-19 cases from 2018 to 2022. The monthly search volumes of search terms “HIV検査キット” (HIV test kit in Japanese, orange line) and “HIV検査 保健所” (HIV test health center in Japanese, purple line) from November 2018 to October 2022 according to the search engine Yahoo! JAPAN are shown. The number of new COVID-19 cases in the corresponding months, according to the Ministry of Health, Labour and Welfare in Japan, is shown with green bars.
Figure 3. Monthly web-based search interest in HIV self-instructed and facility-based tests and quarterly number of new infected HIV cases from 2019 to 2022. The monthly search volumes of search terms “HIV検査キット” (HIV test kit in Japanese, orange line) and “HIV検査保健所” (HIV test health center in Japanese, purple line) from January 2019 to December 2022 according to the search engine provided by Yahoo! JAPAN are shown. The number of new HIV cases in the corresponding quarter, according to the AIDS Trend Committee Quarterly Report from the AIDS Prevention Foundation, API-Net AIDS Prevention Information Net, is shown with blue bars.

Discussion

The analysis in our study illustrated that the web-based search interest in general HIV testing remained stable in Japan during the ongoing pandemic. Furthermore, compared to a decrease in HIV facility-based testing, the web-based interest in HIV self-testing has not changed in Japan. The findings suggest that a proportion of the population interested in getting an HIV test or obtaining relevant information may have a lower preference for HIV facility-based testing. This could imply that individuals might have opted for HIV self-testing during the COVID-19 pandemic.

A prolonged decreasing trend in the search volume of “HIV test health center” from late 2018 was observed in this study. This change in search volume was related to the real-world situation reported by recent publications that underscored the situation of facility-based HIV testing during the pandemic [7,8,23]. A trend analysis study exploring data from 2015 to the second quarter of 2020 (during the nationwide state of emergency in Japan) reported a significant decline in the number of HIV tests performed by public health centers in the second quarter of 2020 (n=9584 vs n=35,908 in Q2 2019) [7] and that this decrease coincided with the increase in the number of new HIV cases with an AIDS diagnosis in Japan [7]. Similar situations were reported in other countries, where an approximately 31% to 50% reduction in the number of HIV tests performed by public health centers was observed between 2019 and 2020 due to difficulty accessing testing facilities, shortage of medical staff for HIV-testing services, or closure of HIV-testing facilities [23,24].

Our search trend showed that the web-based search volume for HIV self-tests was relatively unaffected in Japan. Furthermore, we noted the trend for HIV-testing preference was more evident among male internet users. In Japan, men who have sex with men (MSM) constitute more than 70% of newly diagnosed people living with HIV [3,25]; therefore, the difference in search volume for different HIV-testing services most likely reflects the changing preferences among male internet users. This is consistent with the real-world situation reported by other countries. Investigators focusing on the high-risk population’s (MSM) HIV-testing behavior in China during the COVID-19 pandemic found the use of HIV self-testing increased compared to facility-based HIV testing, which decreased by more than 50% overall [26,27]. Earlier investigations in Sweden and Japan showed the interest and demand for HIV self-testing in high-risk populations such as MSM even before the COVID-19 pandemic [12,28]. A study in France also reported that the number of HIV self-testing kits sold in 2021 increased by 3% compared to 2020 [29]. Together, these publications further emphasized the

In this study, interest in HIV self-testing has remained relatively high during the COVID-19 pandemic. Even though web-based search interest only indicates clinical information-seeking behavior, recent infodemiology studies, including that by Ornos et al [15], showed that search volume indices correlated positively with HIV prevalence and negatively with financial and health care service status. Another recent study in Japan by Ishimaru et al [30] also observed a positive correlation between internet search frequency for HIV/AIDS–related terms and the number of voluntary tests.

The change in search volume on HIV-testing preferences in Japan, which highlights the availability, accessibility, and regulatory approval status of HIV self-tests, may be imperative to reduce new HIV infection [7,8]. The pros and cons of alternative HIV-testing approaches such as the use of dried blood spot (DBS) test cards delivered by postal service have been investigated in Japan [8]. So far, DBS-based tests have not been approved as clinical samples for HIV testing in Japan; however, their use has steadily increased in the last two decades, most likely due to convenient and easy self-preparation of blood spots without the need to visit medical facilities [8]. Although the use of DBS is less sensitive than with a plasma sample, the feasibility and reliability of postal DBS have been preliminarily demonstrated in an outreach study in Japan [12]. Other HIV testing to be considered should include the introduction of HIV self-testing, DBS, or oral swabs as an alternative to plasma or serum specimens. However, since HIV self-testing is not yet approved by health authorities, individuals with positive test results may not have been referred to medical facilities for consultations after the test or received appropriate HIV care and treatment. This concern was illustrated in the study by Ejima et al [7], which reported that both the number of HIV tests and consultations performed by public health centers declined during the COVID-19 pandemic in Japan. We believe relevant supporting services, for instance, the provision of web-based counseling services and referral services after HIV self-testing, would be necessary to mitigate the potential concerns and negative impact of using HIV self-test kits without counseling and medical follow-up. Soon, the development of artificial intelligence chatbots may be used to provide real-time instruction and counseling for HIV self-testing users, which may offer potential solutions to this problem [31].

Several factors may limit the generalizability of the preliminary findings presented in this report. First, the data source was solely from Yahoo! JAPAN, and the internet searches conducted using other search engines were not included. Second, the data obtained from a web-based search engine may be subject to the nonrepresentative sampling or methodology bias inherent to the search platform. Third, there could be considerable differences in clinical information-seeking behavior between the internet user population and actual men and women who are affected by HIV; direct and causal relationships cannot be inferred from this study. Nonetheless, most previous studies using search engines have used Google Trends data, but in Japan, Yahoo! JAPAN is the most visited digital service in the country. In addition, sex and prefecture adjustment is possible with Yahoo! JAPAN data, making it appropriate to research topics likely affected by sex differences. Therefore, our preliminary infodemiology using the search engine provided by Yahoo! Japan Corporation is likely representative of the general trend in Japan.

Our infodemiology study indicated that there was a notable decrease in search volume for HIV facility-based testing during the COVID-19 pandemic. Further, a change in HIV-testing preference and interest in HIV self-testing was noted in Japan. To fully delineate and comprehend the changes in HIV-testing behavior, the situation should be continuously monitored and validated by clinical studies.

Acknowledgments

The authors would like to thank 4DIN Ltd, Japan, for the data analysis and for assisting with preparing the manuscript and other materials for journal submission. This work was supported by the Ministry of Health, Labour and Welfare Research on HIV/AIDS (program grant JPMH21HB1005).

Data Availability

The data sets generated or analyzed during this study are not publicly available, complying with the Yahoo! Japan Corporation regulation, but they are available from the corresponding author upon reasonable request.

Authors’ Contributions

FU and TN conceptualized this study. RK and KU are responsible for the methodology. NF and MY collected the data. RK, FU, KU, TM, SV, MS, and HM analyzed the data. RK, NF, MY, and TN prepared the initial draft. RK, FU, KU, TM, SV, MS, HM, and TN critically revised the manuscript. HM and TN obtained the funding. MS was responsible for project administration. All authors approved this version of the manuscript to be submitted.

Abstract

Background: The COVID-19 pandemic has highlighted gaps in the current handling of medical resource demand surges and the need for prioritizing scarce medical resources to mitigate the risk of health care facilities becoming overwhelmed.

Objective: During a health care emergency, such as the COVID-19 pandemic, the public often uses social media to express negative sentiment (e.g., urgency, fear, and frustration) as a real-time response to the evolving crisis. The sentiment expressed in COVID-19 posts may provide valuable real-time information about the relative severity of medical resource demand in different regions of a country. In this study, Twitter (subsequently rebranded as X) sentiment analysis was used to investigate whether an increase in negative sentiment COVID-19 tweets corresponded to a greater demand for hospital intensive care unit (ICU) beds in specific regions of the United States, Brazil, and India.

Methods: Tweets were collected from a publicly available data set containing COVID-19 tweets with sentiment labels and geolocation information posted between February 1, 2020, and March 31, 2021. Regional medical resource shortage data were gathered from publicly available data sets reporting a time series of ICU bed demand across each country. Negative sentiment tweets were analyzed using the Granger causality test and convergent cross-mapping (CCM) analysis to assess the utility of the time series of negative sentiment tweets in forecasting ICU bed shortages.

Results: For the United States (30,742,934 negative sentiment tweets), the results of the Granger causality test (for whether negative sentiment COVID-19 tweets forecast ICU bed shortage, assuming a stochastic system) were significant ($P<.05$) for 14 (28%) of the 50 states that passed the augmented Dickey-Fuller test at lag 2, and the results of the CCM analysis (for whether negative sentiment COVID-19 tweets forecast ICU bed shortage, assuming a dynamic system) were significant ($P<.05$) for 46 (92%) of the 50 states. For Brazil (3,004,039 negative sentiment tweets), the results of the Granger causality test were significant ($P<.05$) for 6 (22%) of the 27 federative units, and the results of the CCM analysis were significant ($P<.05$) for 26 (96%) of the 27 federative units. For India (4,199,151 negative sentiment tweets), the results of the Granger causality test were significant ($P<.05$) for 6 (23%) of the 26 included regions (25 states and the national capital region of Delhi), and the results of the CCM analysis were significant ($P<.05$) for 26 (100%) of the 26 included regions.

Conclusions: This study provides a novel approach for identifying the regions of high hospital bed demand during a health care emergency scenario by analyzing Twitter sentiment data. Leveraging analyses that take advantage of natural language processing techniques for sentiment analysis and time series forecasting, this study demonstrates the potential of infodemiology to inform the allocation of critical medical resources in real-time.
processing–driven tweet extraction systems has the potential to be an effective method for the early detection of medical resource demand surges.

**Introduction**

**Background**

The World Health Organization declared COVID-19 a pandemic on March 11, 2020 [1]. The emergence of this pandemic, caused by SARS-CoV-2, led to an unprecedented disruption in the global health care system that exposed and exacerbated existing vulnerabilities in health infrastructure around the world. In particular, the COVID-19 pandemic has had a profound impact on the global medical supply chain, leading to people struggling desperately to access crucial medical resources in the face of case surges and high resource demand [2].

The unprecedented nature of the pandemic and the limited availability of resources, no matter the country, will inevitably lead to the need for prioritizing scarce medical resources to different extents [3,4]. Wealthy countries, such as the United States, experienced shortages of personal protective equipment (PPE) and ventilators [5,6]. This led to the Centers for Disease Control and Prevention developing guidelines for the optimal sourcing of COVID-19 mitigation equipment such as face masks [7]. The pandemic also resulted in an increased strain on hospital capacity around the world. This was especially true for low- and middle-income countries, where health care systems are likely to already be underresourced and stretched thin, making them particularly vulnerable to becoming overwhelmed [8,9].

Considering the potential for future pandemic scenarios and for the recurrence of existing disease outbreaks as new virus variants emerge, the development of accurate real-time methodologies for detecting and forecasting disease impacts is critical for an effective global health response [10,11]. For hospitals that experience volatile demand surges in the face of a finite medical resource supply, timely solutions are required that can allow for rapid and precise decisions to be made regarding resource allocation.

Given that social media are an emerging source for real-time and easily accessible information, there is potential to leverage data from social media for forecasting real-world outcomes [12-15]. Social media platforms and web search data host a wealth of real-time data that broadly reflect the current state of affairs in a particular region [16]. Although the standards of validation for these new data streams are still being validated because they do not have a track record of use, these unconventional data sources have the potential to aid in short- and long-term surveillance, although the surveillance goals must be clearly defined. Studies have found that leveraging social media to identify shortages has the potential to be a cost-effective solution that can be used in real time [17,18]; for instance, Get Us PPE is a grassroots organization that leveraged Twitter (subsequently rebranded as X) to address medical supply shortages in US health care facilities during the first year of the COVID-19 pandemic [19]. Its success in garnering both public and governmental attention to the PPE shortage crisis has demonstrated that Twitter can be a useful tool for mobilizing efforts to address gaps, identifying regional PPE shortages, and informing decision-making in the health care supply chain. In other countries too, such as India, people used Twitter during the pandemic to amplify demands for medical oxygen and intensive care unit (ICU) beds during periods when health care facilities were overwhelmed by case surges [20].

Studies examining the role of social media to glean information about the characteristics of the pandemic note that data derived from social media and search engine data were used to predict new cases in countries such as South Korea [21], the United States [22-24], China [25-27], and Iran [28]. Twitter data have been analyzed to understand the population-level spread of disease [29-31]. Furthermore, forecasting models have been created to track demand for ICU capacity planning in countries such as Chile [32,33], Brazil [34], Colombia [35], the United States [36], India [37], and China [38]. Previous studies have applied convergent cross-mapping (CCM) analysis to explore possible relationships involving antiepidemic measure–related tweets [39], the dynamics of misleading news on Twitter [40], and the identification of the global drivers of influenza [41]. However, to our knowledge, there are limited studies examining the potential of social media, particularly Twitter, to better understand hospital bed demand.

**Objectives**

This study aimed to investigate the potential for social media, a relatively novel data stream, to be leveraged as an early warning and detection system for forecasting medical resource shortages. Specifically, this study sought to determine whether the COVID-19 discourse on Twitter could be linked to real-world ICU bed demand. We applied the Granger causality test and CCM analysis to explore whether a causal relationship exists between the volume of negative sentiment COVID-19 tweets and the proportion of ICU bed occupancy in real time in the United States, Brazil, and India. If social media can be successfully leveraged to develop an effective early warning system for forecasting medical resource demand, health care workers and governments may receive real-time insights into pandemic scenarios to inform urgent resource allocation decisions and gain a head start in preparing for demand surges.

**Methods**

**Overview**

For our analyses, the volume of negative sentiment COVID-19 tweets was compared with ICU bed demand data for each
subregion in the United States, Brazil, and India. These 3 countries were selected for this study because they have high cumulative COVID-19 death tolls [42], and they are among the top 4 nations in terms of Twitter users [43]; in addition, publicly accessible validation data on ICU bed demand are available for each country. Three main restrictions in terms of how many patients can be treated at a hospital during the pandemic are available PPE, available ICU beds, and available health care professionals per shift [44]. The number of available ICU beds was selected as the validation parameter for our model.

**Data Sets**

For tweets, we used the publicly available Twitter data set Two Billion Multilingual COVID-19 Tweets with Sentiment, Entity, Geo, and Gender Labels (TBCOV), which contains >2 billion COVID-19 multilingual tweets, including geographic location and positive, negative, and neutral sentiment labels [45]. From this data set, negative sentiment tweets were selected to capture the volume of negative Twitter discourse surrounding COVID-19 for the United States, Brazil, and India. From this TBCOV data set, for the period from February 1, 2020, to March 31, 2021, a total of 59,832,393 tweets were extracted for the United States, of which 30,742,934 (51.38%) contained negative sentiment. For Brazil, there were 5,343,723 tweets, of which 3,004,039 (56.22%) contained negative sentiment. For India, there were 9,509,766 tweets, of which 4,199,151 (44.16%) contained negative sentiment.

Real-world hospital bed demand was defined as *inpatient_beds_used_covid_coverage* from the US Health Data COVID-19 Reported Patient Impact and Hospital Capacity by State Timeseries (RAW) data set [46] for the United States and as ICU beds needed from the Institute for Health Metrics and Evaluation COVID-19 Projections data set for Brazil and India [47]. The COVID-19 Projections data set contains daily information about each region’s need and capacity for hospital beds overall, including ICU beds. In India, similar to Brazil, the greatest medical supply demand during the pandemic was for oxygen cylinders and ICU beds [48]. Amid the pandemic, the insufficient oxygen-manufacturing capacity and the fragmented nature of the Indian health care system made it extremely difficult for people to obtain the supplies they needed in time [49]. Hashtags and sample tweets posted by the Indian public during the pandemic to secure oxygen cylinders and express the urgent need for ICU beds in specific regions have been documented [50,51].

Data collection and analysis were conducted using Python (Python Software Foundation).

**Granger Causality Test Analysis**

A time series of each region was generated using the number of negative sentiment tweets per week. This time series was standardized with mean and SD calculated from historical tweet data. Another time series, the ground truth frequency of ICU bed demand, was generated from our preprocessed medical data. In general, all time-series data were binned in intervals of 1 week.

The Granger causality test was used to determine whether past negative tweet frequency contains information that can help forecast ICU bed demand, in addition to the information contained in the past values of ICU bed demand alone [52]. In theory, this test can be applied to a stationary time series. For a nonstationary time series, first or higher difference can be used instead [53,54]. To see whether the time series could satisfy the requirement for the Granger causality test, the augmented Dickey-Fuller (ADF) test, which determines whether a time series is stationary or nonstationary, was used. In our implementation, the functions `grangercausalitytests` and `adfuller` from the `statsmodels` package for Python were used.

**CCM Analysis**

The CCM analysis workflow consisted of embedding, cross-mapping, and convergence analysis as well as validation and performance testing. In embedding, the negative sentiment tweets and ICU bed demand for each region were embedded into higher dimensional spaces to capture their underlying dynamics. In cross-mapping, the embedded time series were compared to identify their relationship. In convergence analysis, the results were assessed using statistical measures to determine whether there is a robust relationship between negative sentiment tweets and ICU bed demand.

Put another way, given 2 time series X and Y, their data point entries can be considered to exist in a vector space with x and y axes, and the points over time form a trajectory in the space. Likewise, one can include the time-delayed values of X as new axes, where the vectors can be *<X(t), X(t−3), X(t−6)…,**, *<X(t−1), X(t−4), X(t−7),…>* , etc.

If the values of X over time do indeed influence or are linked to the values of Y, then a distance-weighted k-nearest neighbor model in the *X, X with delay 1, X with delay 2,* etc vector space applied to the same Y (and delay axes) space can have its output converge to the actual observed values of Y, that is, predict the value of Y. If the convergence between *modeled Y from X with delays* and the actual observed values of Y is close, we can say that the model constructed represents the causality relation between X and Y.

In our implementation, the `causal_ccm` package for Python was used.

**Ethical Considerations**

Ethics approval was not required for our study because all data and information are publicly available. In addition, all user-identifiable information was excluded from the study results.

**Results**

**Overview**

From the TBCOV data set, for the period from February 1, 2020, to March 31, 2021, a total of 30,742,934 tweets containing negative sentiment were extracted for the United States: 3,004,039 tweets containing negative sentiment were extracted for Brazil; and 4,199,151 tweets containing negative sentiment were extracted for India. Our results can be categorized into (1) Granger causality test analysis and (2) CCM analysis.
Granger Causality Test Analysis

United States

Figure 1 shows time series graphs comparing negative sentiment COVID-19 tweets with real-world ICU bed demand data for each of the 50 US states.

Before performing the Granger causality test, the 2 time series were checked to determine whether they were stationary or nonstationary using ADF tests. After taking the second difference of the 2 time series, the $P$ values of the ADF tests for negative sentiment COVID-19 tweets and ICU bed demand were found to be <.05 for all US states, meaning that we were able to reject the null hypothesis ($H_0$) that a unit root was present in the time series samples; in other words, the 2 time series were stationary. The results are summarized in Multimedia Appendix 1.

The results for the Granger causality test with $H_0$, that is, negative sentiment COVID-19 tweets do not Granger-cause ICU bed demand in US states, are presented in Table 1. At lag 2, $H_0$ was rejected for 14 (28%) of the 50 US states ($P<.05$).

Brazil

Figure 2 shows time series graphs comparing negative sentiment COVID-19 tweets with real-world ICU bed demand data for each of the 27 Brazilian federative units. Before performing the Granger causality test, the 2 time series were checked to determine whether they were stationary or nonstationary using ADF tests, and $H_0$ was rejected for all Brazilian federative units ($P<.05$), qualifying all of them for the Granger causality test. The results are summarized in Multimedia Appendix 2.

The results for the Granger causality test with $H_0$, that is, negative sentiment COVID-19 tweets do not Granger-cause ICU bed demand in Brazilian federative units, are presented in Table 2. At lag 2, $H_0$ was rejected for 6 (22%) of the 27 Brazilian federative units ($P<.05$).

CCM Analysis

United States

Figure 4 illustrates the results of the CCM analysis for the United States, where a significant causal relationship was found between ICU bed demand and negative sentiment COVID-19 tweets for 46 (92%) of the 50 states (P<.05). The full list of correlation coefficients (r) and P values for the CCM analysis across US states is presented in Table 4.
Figure 4. Graphs showing the convergence of the correlation coefficient (r) in convergent cross-mapping analysis as the time series length (L) approaches the maximum possible value for each US state. Series X=negative sentiment COVID-19 tweet proportion and series Y=intensive care unit bed demand. The blue graph represents the correlation coefficient when modeling X causing Y (X→Y). The orange graph represents the correlation coefficient when modeling Y causing X (Y→X). The correlation coefficients ranged from 0.0405 (Vermont) to 0.7670 (New York). The $P$ values ranged from .44 (Vermont) to <.001 (New York). Of the 50 US states, 46 (92%) had $P$ values <.05.
Table 4. Results of the convergent cross-mapping analysis for each US state. The correlation coefficients ($r$) ranged from 0.0405 (Vermont) to 0.7670 (New York). Series $X$=negative sentiment COVID-19 tweet proportion and series $Y$=intensive care unit bed demand. $X \rightarrow Y$ refers to the correlation coefficient when modeling $X$ causing $Y$; $Y \rightarrow X$ refers to the correlation coefficient when modeling $Y$ causing $X$.

**Brazil**

Figure 5 illustrates the results of the CCM analysis for Brazil, where a significant causal relationship was found between ICU bed demand and negative sentiment COVID-19 tweets for 26 (96%) of the 27 Brazilian federative units ($P<.05$). The full list of correlation coefficients ($r$) and $P$ values for the CCM analysis across Brazil is presented in Table 5.
Figure 5. Graphs showing the convergence of the correlation coefficient (r) in convergent cross-mapping analysis as the time series length (L) approaches the maximum possible value for each Brazil subregion. Series X=negative sentiment COVID-19 tweet proportion and series Y=intensive care unit bed demand. The blue graph represents the correlation coefficient when modeling X causing Y (X → Y). The orange graph represents the correlation coefficient when modeling Y causing X (Y → X). The correlation coefficients ranged from 0.0751 (Amapá) to 0.8010 (Amazonas). The P values ranged from .14 (Amapá) to <.001 (Amazonas). Of the 27 Brazilian federative units, 26 (96%) had P values <.05.

Discussion

Principal Findings

Given the need to prioritize the use of limited medical resources during a health care emergency scenario such as the COVID-19 pandemic, social media hold promise in identifying shortages and can be a cost-effective tool for the proper allocation of medical resources, particularly ICU beds, because when governments and organizations are well informed with real-time shortage data, they have the capacity to adequately address the immediate funding and supply needs of health care facilities. This strategy may help mitigate immediate risk to the public until a more systematic solution is possible.

This study sought to determine which patterns existed between negative sentiment COVID-19 tweets and real-world ICU bed shortages during the pandemic, with the aim of leveraging social media to pinpoint regional surges in ICU bed demand in the United States, Brazil, and India. Two statistical tests were conducted to investigate this: the Granger causality test and CCM analysis.

The Granger causality test aims to identify causalities where, in a stochastic system, 1 separable variable is useful for forecasting another. The results of the Granger causality test for this analysis (Figures 1-3 and Tables 1-3) indicate that negative sentiment COVID-19 tweets Granger-caused ICU bed shortage ($P<.05$) for 14 (28%) of the 50 US states, 6 (22%) of the 27 Brazilian federative unit, and 6 (23%) of the 26 Indian regions included in the analysis (25 states and the national capital region). By contrast, the CCM analysis aims to identify causalities for nonseparable variables that are linked in a dynamic system and can identify and quantify weak to moderate causalities that may be missed by the Granger causality test. For the 3 countries, nearly all subregions—46 (92%) of the 50 US states, 26 (96%) of the 27 Brazilian federative units, and 26
(100%) of the 26 Indian regions included in the analysis—had a significant \((P<0.05)\) result in the CCM analysis (Figures 4-6 and Tables 4-6), indicating a relationship between negative sentiment COVID-19 tweets and ICU bed demand.

For the United States (Tables 1 and 4), of the 50 states, 13 (26%) had a significant result for both the Granger causality test and the CCM analysis (Alabama, Arizona, Florida, Illinois, Massachusetts, Michigan, North Carolina, North Dakota, New Hampshire, Nevada, New York, Rhode Island, and Virginia), 33 (66%) passed the CCM test but not the Granger causality test (Alaska, Arkansas, California, Colorado, Connecticut, Delaware, Georgia, Hawaii, Iowa, Idaho, Indiana, Kansas, Kentucky, Louisiana, Maryland, Minnesota, Missouri, Mississippi, Montana, Nebraska, New Jersey, New Mexico, Ohio, Oregon, Pennsylvania, South Carolina, South Dakota, Tennessee, Texas, Utah, Washington, Wisconsin, Wyoming), 1 (2%) passed the Granger causality test only (Oklahoma), and 3 (6%) passed neither the Granger causality test nor the CCM test (Maine, Vermont, and West Virginia). Considering that the majority of the US states (33/50, 66%) passed the CCM test but not the Granger causality test, it can be inferred that the causal relationship between negative sentiment COVID-19 tweets and ICU bed shortage is weak to moderate for US states because CCM analysis is better at detecting weak to moderate causalities than the Granger test. This also implies that the relationship between the 2 variables (social media sentiment and ICU bed shortage) is dynamic and influenced by a number of complex interacting factors such that CCM analysis may be the more appropriate method for detecting and modeling this relationship.

For Brazil (Tables 2 and 5), a similar pattern occurred such that nearly all federative units (26/27, 96%) passed the CCM test, but only a few (6/27, 22%) passed the Granger causality test. Of the 27 federative units, 6 (22%) passed both the Granger causality test and the CCM test (Ceará, Maranhão, Pará, Paraíba, Pernambuco, and Roraima), 20 (74%) passed the CCM test but not the Granger causality test (Acre, Alagoas, Amazonas, Bahia, Federal District, Espírito Santo, Goias, Minas Gerais, Mato Grosso do Sul, Mato Grosso, Pará, Piauí, Rio de Janeiro, Rio Grande do Norte, Rondônia, Rio Grande do Sul, Santa Catarina, Sergipe, São Paulo, and Tocantins), none passed the Granger causality test only, and 1 (4%) state passed neither test (Amapá). This result again supports the idea of a dynamic and complex causal relationship being detected between negative sentiment COVID-19 tweets and ICU bed shortage.

For India (Tables 3 and 6), a similar pattern emerged. Of the 26 regions included in the analysis (25 states and the national capital region), 3 (12%) passed both the Granger causality test and the CCM test (Manipur, Kerala, and Maharashtra), whereas the remaining 23 (88%) passed the CCM test only (Haryana, Madhya Pradesh, Andhra Pradesh, Uttar Pradesh, Punjab, Karnataka, Jharkhand, Bihar, Arunachal Pradesh, Sikkim, Mizoram, Goa, West Bengal, Tripura, Delhi, Uttar Pradesh, Rajasthan, Nagaland, Odisha, Telangana, and Chandigarh), meaning that all 25 states and the national capital region of Delhi passed at least the CCM test. This further demonstrates that CCM analysis is capable of successfully detecting a causal pattern between negative sentiment pandemic tweets and real-world medical resource shortage and that this can potentially be used to pinpoint specific regions that are expected to face surges in medical resource demand at a given time.

Overall, these results suggest that a significant relationship exists between negative sentiment COVID-19 tweets and real-world ICU bed demand at subnational scales and that this relationship can be effectively detected and modeled using CCM analysis. These findings also indicate that the data contained within social media discourse regarding the COVID-19 pandemic can indeed be leveraged to identify and forecast the real-world impacts of the pandemic in the form of ICU bed demand surges. Further optimization of methods for identifying patterns between X sentiment and real-world medical emergencies can support the development of an early warning system for the robust real-time prediction of health care demand surges. Such a system may give health care workers and government decision makers a critical head start when deciding how to most effectively allocate medical resources in a crisis.

**Future Directions**

These results open up the possibility to develop tools that can forecast hospital bed demand in certain regions, although further research is required. This modeling approach can have a significant impact in the context of the health care supply chain. Forecasting ability is a potential factor affecting supply chain performance [27-29]. One study found that tweets related to food insecurity were strongly correlated with real food insufficiencies [16]; the authors noted that there is potential for tweet sentiment analysis to be used as a cost-effective early warning system that can help direct food-related interventions. Similarly, our results suggest that there is potential for negative sentiment COVID-19 posts to relate to actual medical resource shortage in regions where people use public discourse platforms such as Twitter (since rebranded as X). Although the current iteration of the methods described in this paper is only relevant to the time before a peak infection in the region, such methods have the potential to advance preparedness measures for future pandemics as they become more robust [31,32].

Digital data sources can aid in the identification of changes in disease activity, and it is worth exploring whether they show better performance in this regard than traditional COVID-19 metrics such as confirmed cases [33]. In low- and middle-income countries, there is potential for social media to act as a cost-effective early warning system to identify priority regions for medical resource allocation in real time. User behavior data can be extracted, given the unique social network parameters of a region, including the language spoken and the preference for 1 social media platform over another [34]. Similar to how a multilingual data set was used in the analyses in this study, Lopreite et al [55] analyzed a data set of tweets posted in various European languages and found that there were early warning signals of COVID-19 outbreaks before public announcements about an outbreak were made. Social networks that are particular to a region can provide user behavior data that can inform early warning detection systems specific to that region; for example, using Baidu search data, Qin et al [56] were able to predict the number of new COVID-19 cases such
as fever, coronavirus, and pneumonia. Their study, along with similar social media–based early warning detection efforts [37-40], shows potential for the creation of a more effective yet affordable model to forecast new cases.

As noted in the previous subsection, there are complex interacting factors that may explain the results observed. Thus, further investigation is needed to unveil the dynamics underpinning the relationship between X negative sentiment pandemic tweets and medical resource demand; for instance, sociopolitical and economic challenges may have had varying influences on the X discourse by affecting public perceptions of COVID-19 management measures across countries. For Brazil (Figure 2), it can be seen that an increased proportion of negative sentiment preceded the ICU bed demand surge. Concern about preventing the proliferation of COVID-19 was among the major emergent X topics in Brazil, and politics also influenced the X landscape [57]. Brazil has a decentralized health system where the federal government finances the states and municipalities that provide health care services. Different levels of government must be able to coordinate effectively, and a failure to do so can lead to a disjunction in the care provided. A study by Neves et al [58] found that key government stakeholders underestimated the magnitude of the pandemic in the early weeks; for example, the Minas Gerais State Health Department posted messages on social media about not suspending the carnival, which is Brazil’s largest festival. When questionable COVID-19 management decisions are made that increase public health risk, such as decisions not to suspend major public events (e.g., Brazil’s annual carnival), it is possible for the X discourse to reflect negative public perceptions of these government decisions before their negative impacts on case count and ICU bed demand. Further research is required to better understand the reliability of social media discourse in reflecting current pandemic management landscapes so that web-based public sentiment can accurately forecast pandemic impacts.

Incongruencies among different levels of government may have also contributed to the results observed. The then President of Brazil, Jair Messias Bolsonaro, issued messages that conflicted with those issued by states and municipalities, such as defending hydroxychloroquine as a COVID-19 treatment and countering mask use and physical distancing [59]. At a state-specific level, the governor of Rio de Janeiro state faced charges regarding irregularities in contracts for building emergency field hospitals, which prevented efforts to relieve strain on hospitals [60]. In addition, the state government of São Paulo was being investigated for ventilator fraud, which led to a shortage of ventilators that prevented citizens from accessing life-saving equipment [61]. Overall, the lack of coordinated effort and strategy for dealing with the pandemic contributed to the inconsistent implementation of preventive measures across the states and resulted in confusion for the public. State-specific challenges may have also contributed to the rise in negative sentiment and increased medical resource demand, which can help explain the results observed.

A similar exploration of potential factors for India can shed light on how they contributed to the nuanced and complex relationship observed between negative sentiment COVID-19 tweets and medical resource demand. India emerged as an interesting case study during the pandemic because of the novel use of X by citizens as a way of sourcing ICU beds and ventilators for their loved ones. As citizens found out that there was a shortage of equipment in the hospitals, they took to X in an effort to source medical supplies that were desperately needed. Adherence to government policy is another factor to consider in the Indian X discourse; for example, both COVID-19 waves were associated with nationwide shutdowns, but as the months wore on, people started to adhere less to measures such as masking and physical distancing. This may have contributed to an increase in cases, overwhelming hospitals [62].

Further exploration into region-specific factors as well as social and political contexts will be important for refining our forecasting models and gaining a better understanding of the complex relationship between X negative sentiment pandemic tweets and medical resource demand.

Limitations

One process in our methodology involved using tweets that already had sentiment labels and analyzing them. However, we are aware that there may not be data sets containing pandemic-related tweets in future contexts. Therefore, I recommendation would be to first extract relevant keyword–related tweets and increase accuracy with the help of supervised natural language processing models. A similar study with the aim of predicting medical resource shortages based on tweets was conducted for the state of New York [63]. The method consisted of using supervised learning to find related tweets, which is a more robust method.

One other limitation is that the ICU bed data sets for Brazil and India that were used to validate the model have decreased reliability because they only provide an estimate of the actual data [18], and they may not have accounted for fluctuations in ICU bed supply. However, because there were no other publicly available data sets, it was reasonable to use these data sets.

The use of X data has some important ethical considerations that lie at the intersection of privacy and data collection; for example, social media data collection can be considered a double-edged sword. On the one hand, it provides very valuable data that can increase the possibility of creating important solutions such as a more cost-effective and faster method of gauging PPE shortages and medical resource demand. On the other hand, current artificial intelligence and data collection practices have raised concerns about privacy and the selling of personal data.

Conclusions

The COVID-19 pandemic has made it clear that adequate demand-based allocation of medical resources and adequate preparedness for surges in hospital admissions are paramount to reduce cases and deaths at the onset of a pandemic. Between the time that a pandemic hits and the time that a vaccine is developed and distributed, it is vital that the medical supply is carefully managed to ensure that all health care facilities have adequate capacity and proper plans for meeting unprecedented medical resource demand surges. This study analyzed negative sentiment COVID-19 tweets that were compared with real-world
ICU bed use data. Our results show promise that leveraging social media, particularly X, has the potential to provide a cost-effective relatively rapid method that can inform resource allocation to facilities that need it most. Further investigation into the potential of X data in the modeling of medical supply shortages may lead to the development of powerful tools that can inform health care decision-making in pandemic scenarios. X causal analysis in shortage forecasting has the potential to be applied broadly in a global context for identifying medical resource demand and informing health care supply chain decisions.

Abstract

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune inflammatory disease affecting various organs with a wide range of clinical manifestations. Cutaneous lupus erythematosus (CLE) can manifest as a feature of SLE or an independent skin ailment. Health-related quality of life (HRQoL) is frequently compromised in individuals living with lupus. Understanding patients’ perspectives when living with a disease is crucial for effectively meeting their unmet needs. Social listening is a promising new method that can provide insights into the experiences of patients living with their disease (lupus) and leverage these insights to inform drug development strategies for addressing their unmet needs.

Objective: The objective of this study is to explore the experience of patients living with SLE and CLE, including their disease and treatment experiences, HRQoL, and unmet needs, as discussed in web-based social media platforms such as blogs and forums.

Methods: A retrospective exploratory social listening study was conducted across 13 publicly available English-language social media platforms from October 2019 to January 2022. Data were processed using natural language processing and knowledge graph tagging technology to clean, format, anonymize, and annotate them algorithmically before feeding them to Pharos, a Semalytix proprietary data visualization and analysis platform, for further analysis. Pharos was used to generate descriptive data statistics, providing insights into the magnitude of individual patient experience variables, their differences in the magnitude of variables, and the associations between algorithmically tagged variables.

Results: A total of 45,554 posts from 3834 individuals who were algorithmically identified as patients with lupus were included in this study. Among them, 1925 (authoring 5636 posts) and 106 (authoring 243 posts) patients were identified as having SLE and CLE, respectively. Patients frequently mentioned various symptoms in relation to SLE and CLE including pain, fatigue, and rashes; pain and fatigue were identified as the main drivers of HRQoL impairment. The most affected aspects of HRQoL included “mobility,” “cognitive capabilities,” “recreation and leisure,” and “sleep and rest.” Existing pharmacological interventions poorly managed the most burdensome symptoms of lupus. Conversely, nonpharmacological treatments, such as exercise and meditation, were frequently associated with HRQoL improvement.

Conclusions: Patients with lupus reported a complex interplay of symptoms and HRQoL aspects that negatively influenced one another. This study demonstrates that social listening is an effective method to gather insights into patients’ experiences, preferences, and unmet needs, which can be considered during the drug development process to develop effective therapies and improve disease management.

Introduction

Systemic lupus erythematosus (SLE) is an autoimmune inflammatory disease affecting multiple systems in the body; it is characterized by fluctuating symptoms and periods of exacerbation and remission [1-3]. The most common symptoms of SLE include fatigue, skin rashes, fever, and joint pain or swelling [3]. SLE has several phenotypes and clinical manifestations involving various organs, including the joints, skin, kidneys, and organs of the neurological or hematological systems [1,2]. Cutaneous lupus erythematosus (CLE) can manifest as either a feature of SLE or an independent skin ailment [4,5]. The most prevalent symptoms of CLE include rashes, hair loss, blood vessel inflammation, ulcers, and increased sensitivity to light [6,7]. Living with these symptoms can be physically debilitating for patients and can disrupt their family, social, and professional life, thereby negatively impacting their health-related quality of life (HRQoL) [8,9].

Globally, SLE and CLE are estimated to have incidence rates of 5.1 and 4.3 per 100,000 person-years, respectively [10,11]. These rates vary widely according to demographic factors such as ethnicity, sex, and socioeconomic status, with a higher incidence in women, African Americans and other non-White populations [10,11]. The current treatment options for SLE include immunosuppressive agents, new biological therapies, and combination therapies of biologicals with immunosuppressive and immunomodulating agents [12]. Despite recent advances in therapeutic strategies, most of the current medications available for the treatment of lupus provide only symptomatic relief and are frequently associated with undesirable side effects [13,14].

Considering the high clinical variability, inadequate treatment options, and poor HRQoL of patients, understanding the perspectives and experiences of patients with SLE and CLE may be critical for developing effective therapies and improving disease management [13-15]. In the context of drug development, regulatory bodies and health care decision makers are emphasizing patient-focused drug development, which involves actively seeking and incorporating patients’ perspectives when designing interventions that can meet their needs, improve outcomes, and enhance the overall patient experience [16]. The increased presence and active engagement of patients on digital platforms, specifically social media, can serve as a source for understanding their needs, treatment experiences, and the factors affecting treatment decisions in real-world scenarios [15]. Additionally, data regarding the experiences of patients living with the disease can potentially influence key decisions and activities during drug development [16].

Data regarding the experiences of individuals living with diseases can be obtained through various sources, such as observational studies, interviews, focus groups, and patient advisory boards. Social listening is a promising newer approach that complements traditional methods of data collection by providing additional insights into patients’ perspectives beyond clinical settings [17]. Furthermore, this method captures the voices of vulnerable and difficult-to-reach populations who may otherwise not participate in clinical or epidemiological studies, thereby providing an opportunity for data triangulation [17,18]. In this social listening study, we explored the experience of patients living with lupus (SLE and CLE), as discussed in web-based social media platforms, such as blogs and forums, by searching for posts regarding disease burden, HRQoL impacts, treatment experience, and unmet needs.

Methods

Study Design

Overview

This retrospective exploratory social listening study was conducted between October 2019 and January 2022 across 13 publicly available English-language social media platforms (Multimedia Appendix 1). The processes of data identification, collection, and analysis involved have been previously presented [19-22]. The process involved algorithmic processing steps (1-3) and research steps (4 and 5) performed by human analysts (Figure 1). A glossary of terms are provided in Multimedia Appendix 2.
Figure 1. Overview of the study methodology.

**Data Source Identification and Data Collection (Step 1)**
Identifying data sources was the first step, followed by data collection. Lupus-related keywords, defined and revised by human domain experts, were searched in SocialGist, a third-party search engine providing access to social media sites through an application programming interface search engine, to detect websites hosting relevant lupus-specific content. The following keywords were used for the search: “lupus,” “lupus” AND “systemic” AND “cutaneous” AND “subacute” AND “erythematous” AND “autoimmune” AND “disease,” “SLE,” and “CLE.” All posts from relevant websites found through the searches were retrieved and collected in Pharos, a proprietary data visualization and analysis platform from Semalytix GmbH.

**Filtering and Aggregating Content (Step 2)**
Filtering and aggregating the content based on algorithmically determined inclusion criteria was the second step. Posts collected in step 1 were aggregated by unique authors, and all posts by the same author were collapsed into 1 author-specific record. Based on algorithmically determined inclusion criteria, only records classified as having been authored by a patient with lupus were retained. Posts authored by nonpatients, such as caregivers and health care providers, and those involving other types of documents, such as journal papers and press releases, were excluded. Throughout this process, human language engineers and data labeling specialists carefully monitored the patient classifications to ensure accuracy and reliability.

**Algorithmic Coding of Patient Experience Concepts (Step 3)**
Patient experience themes were algorithmically coded in the study’s third step. All lupus-specific patient records from step 2 were algorithmically annotated with patient experience tags using natural language processing. Patient experience themes mentioned in texts related to disease burden, HRQoL, and treatment experiences were added to patient records as semantic tags. Individual aspects (facets) of HRQoL were investigated based on the taxonomy provided by the World Health Organization Quality of Life instrument [23], which served as a guide for developing the inventory of patient experience tags used in this study. Human language engineers and data labeling specialists monitored, cross-validated, and adapted the algorithms as needed. A subject matter expert reviewed the study’s overall approach and medical content.

**Quantitative Analysis (Step 4)**
Quantitative data analysis was involved in the fourth step, wherein analysts used the Pharos Patient Experience Platform to generate descriptive statistics regarding patient experience tags. The statistics provided insight into the magnitude of individual patient experience variables, the differences between them, and the associations among the algorithmically tagged variables.

**Qualitative Analysis (Step 5)**
Qualitative data analysis was involved in the fifth step. Human analysts used Pharos to investigate the relationships between tags, such as symptoms and outcomes or symptoms and impacts, as well as the language patients used to describe their experiences on social media to identify any emerging themes. The results of the qualitative analysis were used to identify themes in patient language, connections to tagged variables, potential connections between themes, emerging themes, and reorganized themes.
Study Population
Authors of posts who self-identified as patients living with lupus or any of its subtypes (SLE and CLE; algorithmically identified) were included in this study. All posts by the same user were aggregated into a unique patient record for further data analysis. A machine learning algorithm classified authors as patients based on the language used in their self-reported posts. The algorithm was specifically designed to differentiate expressions that indicated that a patient had lupus (“I have lupus” or “I was diagnosed with SLE in 2020”) from those that were ambiguous.

Study Outcomes
Posts from social media platforms were analyzed to investigate symptom burden, impact of lupus on HRQoL, treatment experience, and unmet needs. The related outcomes are described in Table 1. These outcomes were investigated in the SLE as well as CLE-related posts, depending on the robustness of the data.

aOwing to low sample size or insufficient data, these outcomes were not analyzed in the cutaneous lupus erythematosus population.
bHRQoL: health-related quality of life.

Ethical Considerations
Research using data from social media can present ethical challenges owing to the limited guidance on the participants’ consent and anonymity [24]. The data analyzed in this study were obtained from publicly available sources. Identities of the patient posts were appropriately anonymized while ensuring that the data answered specific research questions. To ensure personal data protection, a strict General Data Protection Regulation–compliant process was adopted. Please refer to Multimedia Appendix 3 for further details on the appropriate measures implemented to ensure personal data protection. This study was exempt from ethical review because it examined retrospective publicly available data from a sizeable number of patients.

Results

Patients
During the initial data collection (step 1), a total of 76,538 lupus-related posts were collected, of which 45,554 posts from 3834 patients were included in the lupus-specific data set based on the algorithmically determined inclusion criteria. Among these patients, 1925 (with 5636 posts) and 106 (with 243 posts) patients were identified as having SLE and CLE, respectively. In the population with SLE, sex information was available for 583 patients, and the female-to-male ratio was 9:1. Age data were available for 402 patients, with 76.7% (n=308) aged <60 years.

In the following sections, we report the findings regarding the population with SLE followed by the population with CLE. The study results are structured under 3 primary sections: disease burden as reported by patients, overall HRQoL, and treatment experiences reported for both patient populations separately.

Disease Burden in Patients With SLE

Overview
Disease burden was evident among patients with SLE as indicated by a total of 2029 patient mentions across different social media platforms. Disease burden was quantified in terms of the symptoms that were patient-reported, most burdensome, their severity, areas of involvement (body parts), and comorbidities.

Patient-Reported Symptoms
The most frequently reported symptoms (n=2029 patients) were pain, fatigue, and rashes. Some patients were more specific regarding the type of pain they experienced, including arthralgia, cephalgia, and arthritis. Other less frequently (<10% [203 patients]) reported symptoms included anxiety, clinical depression, alopecia, and pyrexia (Table 2). In total, 20 patients (in approximately 30 posts) reported experiencing...
photosensitivity, with excessive sun exposure leading to flare-ups and worsening of symptoms such as joint pain, weakness, and fatigue.

Table 2. Symptoms most frequently reported by patients with SLE\textsuperscript{a} (n=2029\textsuperscript{b} patient mentions from 5636 posts) and CLE\textsuperscript{c} (n=118\textsuperscript{b} patient mentions from 244 posts).

\textsuperscript{c}CLE: cutaneous lupus erythematosus.

\textsuperscript{d}Not available.

Although sleep disturbances were not among the top 10 patient-reported symptoms, it was found to significantly impact the HRQoL of patients with SLE. Among the 114 patients discussing “sleep and rest” topics, over half of the patients (n=70) reported experiencing recurrent insomnia since many years. Nighttime sleep disturbances and daytime napping were common, with some patients stating that insomnia or a hyperactive mood was an early sign of disease flare-ups. Patients reported that insomnia was also linked to the side effects of certain medications taken for their lupus, such as hydroxychloroquine, methotrexate, and prednisone, whereas medications such as cannabidiol and nonpharmacological interventions including exercise, meditation, and acupuncture had a positive impact on sleep maintenance disorders. Quotations of patients with SLE describing their symptoms are provided in Multimedia Appendix 4.

Most Burdensome Symptoms

The most burdensome symptoms were identified by analyzing the degree of severity with which a patient with SLE was affected based on linguistic cues provided by them. The most burdensome symptoms included pain (general pain: 289/870, 33.2%; arthralgia: 59/228, 25.9%; and cephalgia: 65/154, 42.2%); fatigue (192/474, 40.5%), and anxiety (51/193, 26.4%). Other symptoms that were perceived burdensome included clinical depression (30/128, 23.4%), photosensitivity (5/33, 15%), arthritis (12/99, 12.1%), hypothyroidism (2/36, 5.6%), and antiphospholipid syndrome (4/79, 5.1%). Of note, it is possible that the same patient may have reported more than one symptom or sign.

Areas of Involvement

The most frequently reported areas of involvement (n=1778 patients) were the skin (n=224, 12.6%), face (n=224, 12.6%), and eyes (n=197, 11.1%; Multimedia Appendix 5).

Comorbidities

In addition to the symptoms from the main indication, patients with SLE reported experiencing multiple comorbidities (n=488 patients). The most frequently (>5% [24 patients]) reported comorbidities were major depressive disorder (n=98, 20.1%), fibromyalgia (n=66, 13.5%), infection (n=62, 12.7%), dry eye syndrome (n=50, 10.2%), rheumatoid arthritis (n=40, 8.2%), and hypothyroidism (n=34, 7%).

Overall HRQoL in Patients With SLE

Overview

To investigate the HRQoL of patients, the frequency of mentions and the perceived importance of issues related to HRQoL facets were analyzed. Social networking communities discussed several aspects of HRQoL, as evidenced by 2199 patient mentions and 2138 posts accounting to 37.9% (2138/5636) of all posts analyzed in this study. These posts on HRQoL by patients with SLE contained descriptions of how they perceived the most burdensome symptoms and the impact on their daily lives. The most commonly discussed HRQoL aspects based on the total
number of patients mentioning any HRQoL facet (n=2199 patient mentions) were “negative feelings” (n=521, 23.7%) and “recreation and leisure” (n=314, 14.3%). Other commonly discussed HRQoL aspects included “health care availability,” “positive feelings,” “mobility,” “energy and motivation,” “cognitive capabilities,” “sleep and rest,” “work capacity,” and others (Table 3).

Table 3. Distribution of HRQoL aspects among patients with SLE (n=2199 patient mentions from 5636 posts) and CLE (n=78 posts from n=47 patients).

HRQoL: health-related quality of life.
SLE: systemic lupus erythematosus.
CLE: cutaneous lupus erythematosus.
Indicates that patients were counted more than once if they discussed more than one HRQoL aspect in a post.
Not available.

Patients frequently reported impairments in areas such as “mobility,” “cognitive capabilities,” and “recreation and leisure,” for which pain and fatigue were the leading causes. While pain primarily affected “mobility,” “recreation and leisure,” and “sleep and rest,” fatigue affected multiple HRQoL facets. Overall, the impact of pain on “mobility” and fatigue on “cognitive capabilities” was the most substantial factor impairing HRQoL (Multimedia Appendix 6).

Psychological Well-Being

Negative Feelings

Posts from 1371 patients revealed “negative feelings” (339/521, 65.1%) as the highest-ranked HRQoL facet in terms of high importance to the patient. Further examination of these posts from 521 patients revealed that severe symptoms or side effects such as pain, fatigue, rashes, and depression affected the HRQoL of these patients, thereby leading to frequent mentions of “negative feelings.”

Positive Feelings

“Positive feelings” were expressed by the patients who experienced feelings of satisfaction or wellness and emotions, such as excitement, interest, pride, love, and optimism. “Positive feelings” were mentioned less frequently than “negative feelings” (183/2199, 8.3% vs 521/2199, 23.7%); nevertheless, they were still considered as highly important HRQoL by 63.2% (116/183) of patients, which is comparable to the high importance of “negative feelings” (339/521, 65.1%), suggesting that patients viewed both dimensions as equally important. Among the positive emotions mentioned, “feeling better,” “thankfulness,” and “hopefulness” were the most commonly reported. Notable patient quotations on “negative feelings” and “positive feelings” are presented in Multimedia Appendix 7.

Physical Well-Being

Mobility

Patients reported that the severity of their symptoms limited physical activity and mobility. “Mobility” was mentioned in 176 patient posts corresponding to 8% of all HRQoL patient mentions (n=2199). Within this facet, approximately 58% (103/176) of patients considered this HRQoL aspect as of high importance. Primary factors impeding “mobility” (Multimedia Appendix 6) were attributed to the pain and fatigue they experienced. Moreover, patients noted that reduced mobility negatively impacted their overall health, social life, and mental well-being. One patient described “immobility” as analogous to “poor-performing robot” (Multimedia Appendix 7).
Activities of Daily Living
This HRQoL facet explored a person’s ability to perform usual daily living activities. This facet was identified as highly important by 50.4% (53/106) of patients. Most patients described problems performing (routine) household activities, personal hygiene, going (outside) for a walk, or even getting out of bed due to pain or lack of energy. Patients’ quotations on their struggles with “activities of daily living” are provided in Multimedia Appendix 7.

Recreation and Leisure
For most patients (129/314, 41.3%), the HRQoL facet “recreation and leisure” was described as being highly important. Owing to the severity of the symptoms, this aspect was frequently described as being hindered, limited, or achievable only with appropriate treatments. Patients reported that joint pain, bleeding, or exhaustion frequently limited their physical activity. Additionally, patients with photosensitivity found it challenging to perform leisure activities such as outdoor sports, watching television, or just relaxation. Patients’ quotations on “recreation and leisure” are provided in Multimedia Appendix 7.

Role Participation
Symptoms, especially when combined with flare-ups, limited the everyday functions of patients with SLE and impacted their role participation in multiple ways. Patients reported a decrease in self-esteem and restricted social relationships. Several patients felt that they could not fulfill their parenting duties and were a burden to their partners. Moreover, patients reported that symptoms of SLE compromised their ability and capacity to work.

Treatment Experience of Patients With SLE
Overview
To evaluate the treatment experiences and unmet needs of patients with SLE, the most frequently used current treatment options (nonpharmacological and pharmacological interventions) mentioned by patients were quantitatively analyzed. The level of satisfaction among patients with SLE with existing treatment options and coping mechanisms is described below.

Current Treatment Options
Exercise, sun protection measures, meditation, and massage were the most commonly reported nonpharmacological interventions (Table 4). Patients found that nonpharmacological interventions, particularly exercise activities such as walking, e-biking, swimming, yoga, or Pilates, and other activities such as meditation and massages to be effective coping mechanisms for dealing with the disease and its symptoms. Additionally, based on 1566 posts, hydroxychloroquine, prednisone, and methotrexate were the most frequently reported pharmacological interventions (Table 5). Negative feedback for pharmacological interventions was mostly related to the drug’s side effects (Multimedia Appendix 8).

Table 4. Nondrug treatments most frequently reported by patients with SLEa (n=482b patient mentions and n=267 patients) and CLEc (n=24b patient mentions from n=16 patients).

*Treatment Options and HRQoL Aspects*

Many relevant aspects of HRQoL, such as “recreation and leisure,” “energy and motivation,” “activities of daily living,” and “mobility,” were improved by nonpharmacological interventions, particularly exercise or meditation. Despite the undesirable side effects, patients frequently used medications, such as hydroxychloroquine, azathioprine, prednisolone, or mycophenolate mofetil, which improved SLE symptoms, although to a lesser extent than that achieved using nonpharmacological interventions. Regarding treatment effects on different aspects of HRQoL (n=5336 posts), 473 (8.9%) reported worsening, while 286 (5.4%) reported improvement of an HRQoL aspect. The most burdensome symptoms, such as pain, fatigue, and rashes, were poorly managed by available drug treatment options for patients with SLE.

*Level of Satisfaction With Current Treatment Options*

Both positive (65/286 posts) and negative (56/473 posts) feedback were documented when analyzing the level of satisfaction. The reasons for a low level of satisfaction included the lack of treatment options, failure of previously successful treatments due to side effects, or no treatment at all. A high level of satisfaction was primarily attributed to the management of symptoms, initiation of treatments following a successful diagnosis, knowledge level of the doctors treating the patients, and availability of options in case of treatment failure. The most effective pharmacological interventions included prednisone and hydroxychloroquine. However, side effects, such as allergic reactions, insomnia, and increased appetite, caused some patients to discontinue treatment. Discontinuation of treatment and patient satisfaction with drug treatments were frequently attributed to insurance coverage (such as expensive medications). Patient quotations on the levels of satisfaction with current treatment options are presented in Multimedia Appendix 8.

*Diagnosis and Access to Care*

Health care availability was frequently mentioned in 285 posts authored by 205 patients with SLE. Health care availability was considered as the most important aspect of HRQoL by 45.8% (n=94) of patients with SLE. Some patients with SLE (n=10) reported having received a misdiagnosis or a correct diagnosis only after several years of experiencing symptoms. Several patients with SLE experienced delays in diagnosis and did not receive proper treatment until they found a doctor with enough expertise to diagnose or investigate their symptoms or until they were referred to a specialist. Patients with SLE often managed and advocated for themselves by switching doctors and actively seeking specialists.

*Coping Mechanisms*

Despite their symptom-related restrictions, patients with SLE reported attempting to stay active and perform daily tasks, even if they could manage only a few of them. Reducing the number of their daily activities helped patients prevent negative side effects and flare-ups. Patients shared coping strategies such as taking medications for side effects and establishing healthy routines involving adequate sleep, proper nutrition, exercise, and hydration. A total of 28 patients (n=40 posts) reported that physical activities or exercise positively affected their physical and psychological well-being. Exercise, meditation, Tai Chi, and yoga were all reported to reduce the burden of symptoms. Some patients found that following an anti-inflammatory diet.
helped reduce skin and joint pain, thereby allowing them to engage in more physical activities. Patient quotations on coping mechanisms are presented in Multimedia Appendix 8.

**Disease Burden in Patients With CLE**

**Overview**

The investigation of disease burden in patients with CLE was limited owing to the small sample size (106 patients with CLE and 243 patient posts). Disease burden could be quantified only for the most prevalent symptoms, areas of involvement (body parts), and sleep disturbances.

**Patient-Reported Symptoms**

Based on an analysis of 244 posts from 118 patients, the most frequently (>5% [6 patients]) reported symptoms were rash (n=27, 23%), pain (n=25, 21%), and fatigue (n=19, 16%) alopecia (n=11, 9%), arthralgia (n=10, 8%), and anxiety and scar (each n=7, 6%; Table 2). Sleep disorders were reported by a total of 8 patients in 10 posts, with insomnia (n=2, 25%) being the most common side effect of lupus medications. Notable quotations from patients describing their symptoms are presented in Multimedia Appendix 4.

**Areas of Involvement**

Based on an analysis of 169 posts from 148 patients, the skin (n=38, 26%), face (n=20, 14%), legs (n=15, 10%), and hairs (n=15, 10%) were the most frequently reported areas of involvement affected by symptoms (Multimedia Appendix 5).

**Overall HRQoL of Patients With CLE**

HRQoL facets were discussed by 47 patients with CLE in 78 of 243 (32.1%) posts. The distribution of HRQoL facets of this population (n=78 posts) was similar to that of patients with SLE, with “negative feelings” (n=20, 26%) and “recreation and leisure” (n=14, 18%) being the most frequently reported dimensions of HRQoL based on the total number of posts (Table 3). Few patients mentioned that their condition negatively affected their ability to work. Although “positive feelings,” “health care access,” and “mobility” were frequently mentioned, differences in ranking could not be identified because of the small sample size (n<10) of individual HRQoL facets. Quotations of patients with CLE regarding their HRQoL are available in Multimedia Appendix 7.

**Treatment Experience of Patients With CLE**

**Overview**

The treatment experiences and unmet needs of patients with CLE were quantitatively analyzed by assessing the most frequently used treatment options (pharmacological and nonpharmacological interventions) as mentioned by the patients and exploring patient experiences related to diagnostic delay, health care availability, and coping mechanisms.

**Nonpharmacological Interventions**

From 24 posts, sun protection (n=12, 50%) and exercise (n=7, 29%; Table 4) were the most frequently reported nondrug treatments. Patients found dietary changes, massages, and exercise to be helpful in managing their symptoms and flare-ups.

**Drug Agents**

The most frequently reported medications (n=119 posts) were hydroxychloroquine (n=42, 35%), methotrexate (n=29, 24%), and prednisolone (n=17, 14%; Table 5). Negative statements regarding treatment experiences were mostly related to side effects of the medications (Multimedia Appendix 8). Methotrexate was associated with side effects, such as fatigue, brain fog, and lack of sleep, which led to patients having to take time off work. Positive statements regarding pharmacological interventions were infrequent (Multimedia Appendix 8).

**Diagnosis and Access to Care**

Patients with CLE reported difficulties in receiving the correct diagnosis because health care providers did not give sufficient consideration to their skin lesion complaints. They reported being confused or misled by the recommendations of dermatologists and rheumatologists, and they received little support with an understanding of their diagnosis and the symptoms to expect from their health care professionals (HCPs). Patients reported feeling frustrated because dermatologists referred them to rheumatologists who prescribed different medications which only made their symptoms worse (Multimedia Appendix 8). Despite showing clear symptoms and positive diagnostic markers, HCPs often advised patients that they “do not have lupus” or had gone “dormant,” highlighting a concerning trend of misdiagnosis and lack of belief by HCPs when it comes to lupus and related conditions.

**Discussion**

**Principal Findings**

This retrospective study investigated the experiences of patients living with SLE or CLE, who publicly discussed their experiences in web-based social media platforms. Patients who were active on these platforms frequently shared and discussed their HRQoL, their perceptions of the disease burden, and treatment experiences affecting their daily lives. Pain and fatigue were identified as symptoms that most impaired HRQoL, negatively impacting physical and psychological well-being. The most frequently used pharmacological interventions included hydroxychloroquine, prednisone, and methotrexate, while nonpharmacological interventions included exercise, meditation, and proper nutrition (diet). Nonpharmacological interventions were more frequently associated with improved HRQoL.

Several studies have explored the disease burden and treatment experiences among patients diagnosed with SLE and CLE [25-31]. Qualitative studies focusing on outcomes reported by patients with SLE suggest that HRQoL is significantly impaired in these patients [26-29]. A qualitative literature analysis of 58 studies relating to the burden of SLE found that in all of these studies, the factors that appeared most frequently affecting the HRQoL in patients with SLE (based on the number of citations) were advanced age, fatigue, the coexistence of neurological or psychiatric conditions (especially depression or anxiety), limited educational achievement, and financial challenges such as poverty or low household income [26]. This is mostly consistent with the findings of this study, wherein pain and fatigue were
identified as key factors negatively impacting HRQoL in patients with SLE. The severity of these symptoms affected patients’ mobility, cognitive abilities, recreation and leisure activities, and sleep and rest. Patients with SLE often found it challenging to engage in work or recreational activities such as sports, biking, or running. Moreover, these impairments had a negative impact on psychological aspects such as low self-esteem, social relationships (such as feeling like a burden to others), and role functions (such as parental responsibilities and the capacity to work).

Lupus symptoms often result in sleep disturbances, which may in turn aggravate fatigue and exhaustion. Sleep disorders in patients with SLE are often linked to disease activity, pain, and fatigue and are influenced by psychosocial and psychological factors [30]. This is consistent with the findings of this study, wherein patients with SLE or CLE reported symptoms such as pain, fatigue, and anxiety, which primarily impacted the “sleep and rest” HRQoL facet. In this study, the correlation between sleep and lupus symptoms was found to be bidirectional, that is, disrupted sleep was associated with increased fatigue and may also worsen symptoms such as pain and discomfort leading to poor sleep quality, thereby, negatively impacting the overall HRQoL. Additionally, some patients regularly experienced insomnia-related difficulties, which even lasted for years in some cases.

In this study, patients with SLE discussed worsening of HRQoL twice as much in the context of pharmacological interventions, suggesting that the most burdensome symptoms, such as pain, fatigue, and rash, were still inadequately controlled under the current treatment options. Notably, patients receiving pharmacological interventions reported positive experiences with HCPs, who considered their symptoms seriously and had adequate knowledge of lupus for providing effective treatments. They appreciated receiving treatments that helped manage their symptoms or the availability of other options if treatments failed, particularly following a successful diagnosis. In contrast, a low satisfaction level with current treatment was attributed to the lack of treatment options available, previously successful treatments that later failed, or not receiving any treatment at all. This finding highlights that effective patient-physician communication and improving patients’ knowledge about disease and treatment through patient education strategies are important for improving patients’ adherence to therapy in SLE [31].

Medications that are effective in treating lupus are frequently associated with undesirable side effects, thereby leading to patient dissatisfaction [31]. This can also be emotionally challenging for patients as it can negatively impact their HRQoL. To overcome such difficulties, patients may seek alternative nonpharmacological treatment options and associated coping strategies [32-34]. Notwithstanding the symptom-related limitations, the patients with SLE and CLE included in this study reported that they attempted to remain active and complete daily tasks despite being able to manage only a few tasks.

As observed in patients with SLE, patients with CLE experienced the same impacts on their HRQoL: “negative feelings,” “recreation and leisure,” and “health care availability.” The HRQoL of these patients with CLE was also impacted by the visibility of lesions regardless of the levels of disease activity. Skin lesions or scars that were constantly visible, alopecia, photosensitivity, and the chronic nature of the disease significantly impaired HRQoL. Patients with CLE felt that they were neglected and did not receive the necessary attention in health care settings. They highlighted that they experienced more difficulties than patients with SLE owing to misdiagnosis, delayed diagnosis, and contradictory treatment approaches between dermatologists and rheumatologists.

This study demonstrated that social listening could be useful for the generation and analysis of large amounts of data from web-based platforms, such as social media, and patient forums. The approach offers an opportunity to obtain insights from a large patient population by capturing their real-time conversations and contextual understanding of their perspectives [17]. Thus, social listening complemented with traditional methods, such as interviews, surveys, focus groups, and advisory boards or panels, can facilitate a deeper understanding of patients’ perspectives and their unmet needs. Additionally, social listening is fast, eliminates the need for patient recruitment, reduces recall bias through instant platforms, does not burden patients, and offers anonymity in reporting socially embarrassing symptoms, thereby reducing reporting bias [17,18].

We departed from traditional methods and used natural language processing and artificial intelligence in this study to apply and enhance both qualitative and quantitative methods. This facilitated more rigorous analyses of large amounts of unsolicited patient-reported narratives from multiple web-based patient forums to better understand patients’ perspectives and disease burden and identify unmet medical needs.

In the context of drug development, identifying and integrating unmet patient needs and experiences in the decision-making process and evidence-generation strategies are important to ensure that patients’ perspectives and needs are considered and truly represented across the entire continuum of the process [16]. Social media offers access to difficult-to-reach populations or help to concentrate on groups with specific conditions or disorders [35,36]. By actively listening to patients’ descriptions of their challenges on social media platforms, pharmaceutical organizations could gain insight into their daily struggles and identify the most relevant and impactful factors [17]. The increasing presence of patients on social media represents an opportunity for pharmaceutical organizations to identify relevant knowledge for different stages of drug development, with a focus on patients’ HRQoL and beyond.

Limitations

This study had several limitations. First, this study relied on publicly available social media data, raising concerns regarding the accuracy of self-diagnosis or self-reported patient experience. Patients who opted not to publicly share their profiles (and were therefore excluded from the study) may have different opinions, thereby resulting in potential bias. Second, the data set may contain duplicate author profiles, wherein similar authors could have been active on multiple social media platforms. Third, this study only included English-speaking countries and younger populations, which could be a source of
bias. Fourth, this study did not examine differences across subgroups (patient populations with SLE and CLE) owing to the inability to identify race or ethnicity or other sociodemographic variables. Fifth, the analysis of patients with CLE was limited by a small sample size, which is why several outcomes reported for SLE could not be reported for CLE; therefore, the results regarding CLE should be interpreted cautiously. The authors’ opinion is that similar type of analyses should be conducted in the future for other novel pharmacological agents to gather valuable insights into the experiences of patients while living with the disease.

Conclusions
This social listening study sheds light on the experiences of patients living with SLE and CLE active on social media, providing valuable insight into their experiences, which have not been extensively investigated. SLE and CLE affect all aspects of patients’ lives owing to their wide-ranging manifestations. This study showed varying severity and frequency of symptoms that were reported as burdensome by patients. Moreover, several aspects of HRQoL and factors contributing to HRQoL improvement or worsening were discussed by patients. The results of this study suggest that current treatment options provide insufficient relief, thereby warranting the development of more effective treatments with good tolerability and safety to address the heavy disease burden and unmet needs of patients with SLE and CLE. Our findings can serve as a valuable resource to inform and shape activities and decisions in drug development to meet patients’ needs and improve their HRQoL.

Abstract

**Background:** Ocular pain has multifactorial etiologies that affect activities of daily life, psychological well-being, and health-related quality of life (QoL). Chronic ocular surface pain (COSP) is a persistent eye pain symptom lasting for a period longer than 3 months.

**Objective:** The objective of this social media listening study was to better understand COSP and related symptoms and identify its perceived causes, comorbidities, and impact on QoL from social media posts.

**Methods:** A search from February 2020 to February 2021 was performed on social media platforms (Twitter, Facebook, blogs, and forums) for English-language content posted on the web. Social media platforms that did not provide public access to information or posts were excluded. Social media posts from Australia, Canada, the United Kingdom, and the United States were retrieved using the Social Studio platform—a web-based aggregator tool.

**Results:** Of the 25,590 posts identified initially, 464 posts about COSP were considered relevant; the majority of conversations (98.3%, n=456) were posted by adults (aged >18 years). Work status was mentioned in 52 conversations. Patients’ or caregivers’ discussions across social media platforms were centered around the symptoms (61.9%, n=287) and causes (58%, n=269) of ocular pain. Patients mentioned having symptoms associated with COSP, including headache or head pressure, dry or gritty eyes, light sensitivity, etc. Patients posted that their COSP impacts day-to-day activities such as reading, driving, sleeping, and their social, mental, and functional well-being.

**Conclusions:** Insights from this study reported patients’ experiences, concerns, and the adverse impact on overall QoL. COSP imposes a significant burden on patients, which spans multiple aspects of daily life.

**KEYWORDS**
chronic ocular surface pain, patients’ experiences; quality of life; social media; Twitter; unmet needs; ocular pain; ophthalmology; ocular; listening; experience; experiences; tweet; eye pain; eye condition; social media platforms; social media use; patient experience; chronic pain; pain; internet; eye; retina; online health; digital health; web; vision; optical
Introduction

Chronic ocular surface pain (COSP) is defined as moderate to severe corneal-induced chronic pain lasting more than 3 months. COSP distracting from, or interferes with, regular daily activities, which may result in poor quality of life (QoL) and health-related QoL, thus impacting the individuals’ ability to carry out daily activities and their psychological well-being [1]. Common pain-related symptoms include ocular irritation, burning, dryness, and other pain descriptors such as corneal sensitivity, shooting, stabbing, grittiness, sharp pain, a hot burning sensation, light sensitivity, and the sensation of a foreign body on the ocular surface. The intensity of ocular pain ranges from simple discomfort to intense unbearable pain; however, evidence elaborating a classification system for COSP is limited [2,3]. COSP can be considered an umbrella term due to the wide spectrum of clinical manifestations, which can result from multiple factors [4].

Patient-reported outcomes (PROs) and patients’ experiences are most often analyzed via conventional methods by using cross-sectional surveys (digital, face-to-face interviews, questionnaires, etc) in different research settings (at hospital sites, home, on the web, through patient-supported organizations, etc). In countries with high internet penetration, access to electronic devices and social media platforms has significantly influenced the health care landscape [5,6]. Social media platforms enable patients to share their perceptions about diseases, treatment patterns, satisfaction with outcomes, and other factors affecting their lives. Therefore, these platforms act as a source to obtain disease-related information, identify and access health care resources, network with fellow patients, and communicate problems and experiences on the web [5-7].

Social media listening (SML) is a new approach to gather information from social media platforms and can be useful in generating insights from users’ experiences. SML has been used to monitor and analyze discussions on health-related topics in diverse diseases [8-13]. Social media facilitates efficient capture of patients’ understanding of a disease and their coping strategies. In addition, SML provides a clear understanding of the patients’ perspectives of a disease, their barriers to health behavior change, and disease-related symptoms [14]. To date, there is no published literature on the use of SML to investigate the needs and experiences of patients with COSP. This study explores SML as a research tool to provide insights on disease burden, diagnosis, treatment patterns, and QoL in patients with COSP.

The objectives of this study are to (1) understand the burden of COSP, its symptoms; its impact on daily life, activities, and QoL, including social well-being and mental health; its management; and the hurdles, gaps, and needs from a patient’s perspective; and (2) capture information directly from patients or caregivers by using their own words and in their familiar environment regarding when and how they feel at that moment, attempting to understand related emotions as well.

The results of this study could help define COSP-related gaps and needs from patients’ perspectives and set priorities for drug development to address them. Our results would also help to develop adequate tools (PRO questionnaires) to quantify the impact of COSP on patients and to develop new PRO end points in clinical studies assessing the potential improvement of new treatments.

Methods

Study Design and Data Source

A comprehensive search from February 2020 to February 2021 was performed on social media platforms (Twitter, Facebook, blogs, and forums) for English-language content posted on the web. Social media platforms that did not provide public access to information or posts were excluded. The following predefined search terms were used to retrieve the relevant web content: “chronic ocular pain” OR “chronic eye pain” OR “ocular surface pain” OR “ocular pain” OR “eye pain” OR “eye aching” OR “eye ache” OR “eye surface pain” OR “keratoconus pain” OR “conjunctivitis pain” OR “keratitis pain” OR “blepharitis pain” OR “Iritis pain" OR “corneal neuropathy pain.” Social media posts from Australia, Canada, the United Kingdom, and the United States were retrieved using the Social Studio platform [15]—a web-based aggregator tool. In the first step (wave 1), the study was limited to English-speaking countries; non–English-speaking countries were assessed later (in wave 2) and will be the subject of a separate publication.

Selection of Posts and Text Data Cleaning

We used the Social Studio tool to download the links of posts with the date stamp and geographic location of users from web-based social media platforms on the basis of the abovementioned keywords. The tool assigned a unique article ID for each downloadable link. These links were used to retrieve the content and remove duplicates (based on unique article IDs and content snippets), irrelevant comments, and out-of-scope content. Irrelevant posts including job postings, aggregator, or junk websites (ie, websites leading to unsolicited advertisements or unrelated misleading links), nonfunctional links, promotional content, and pharmaceutical or e-retailer market reports were removed. Spelling correction was applied while evaluating the content of the post. Additional secondary research including hand searching for posts was performed for patients’ or caregivers’ conversations on forums to increase the robustness of insights and volume of data. The term “mention” indicates the number of times a symptom, treatment, diagnostic test, or another parameter is mentioned in each post. The number of mentions were independent of the number of posts, and due to data anonymization, these users could not be tracked across different platforms. The terms “conversation,” “post,” and “discussion” were synonymously used.

Categorization and Indexing of Social Media Posts

The downloaded links were further indexed using the WordNet Lemmatizer natural language processing (NLP) model to arrive at a sample of possible patient posts using patient lexicons and disease-related keywords. A relevancy check was carried out through a two-step process: (1) NLP was used to identify the relevancy and (2) a manual evaluation of relevant posts identified using NLP was carried out. Gender, age, work status, and other demographic information about the users was recorded.
when available or categorized as unknown if the information was not available at the time. Final analysis was conducted manually to generate patient or caregiver insights. A 4-level hierarchy of the decision-making process was followed to ensure the creation of a robust model of consensus-based analysis and tagging of posts. A self-review, followed by a peer review by analysts, a review by senior analysts, and finally a team review were performed during the study (Figure 1).

**Figure 1.** Decision-making process for including and tagging of posts.

The key themes identified were patient demographics, perceived causes of COSP, symptoms, disease management (medical consultations, diagnosis, and treatments), and QoL aspects (impact on physical, functional, emotional and social well-being, and work productivity). Posts were further analyzed for the “number of mentions” of a particular theme in the posts. Posts with a mention of COSP-related symptoms (itching, pain, irritation, etc) were used to provide a qualitative description of the patients’ self-reported experience with the disease. The impact of COSP on patients’ QoL was analyzed using posts describing work productivity loss or inefficiency and problems in performing activities of daily living. One post can have multiple mentions (themes) across the patient journey.

**Ethical Considerations**

This paper does not contain any studies with identifiable participants. All web-based content was anonymized and was in accordance with the HIPAA (Health Insurance Portability and Accountability Act) search strategy and data collection. Approval was obtained from the Novartis safety registry 1P1R—the governing body that holds oversight on the use of social media by Novartis (1P1R ID DE005899). All relevant local and global laws affecting and relating to the use of social media were aligned with and, as reflected in Novartis processes, followed in the conduct of this study. The authors of this manuscript consent to the publication of the submitted manuscript and declare that no individual patient data requiring consent has been presented.

**Data Analysis**

All data were analyzed using descriptive statistics and are presented as the number of posts, number of mentions, or percentages. All posts were analyzed by (1) social media channel (Twitter, Facebook, forums, and blogs), (2) country (Australia, Canada, the United Kingdom, and the United States), (3) tone (positive, neutral, or negative), and (4) key themes of discussion.

**Results**

**Characteristics of Analyzed Posts**

A total of 25,590 outputs were initially extracted from social media platforms using COSP-related keywords during the study period. In all, 5100 patient posts were identified by NLP, which facilitated an automated process of generating unique patient posts. A total of 464 posts determined to be written by patients or caregivers were thus identified and included for further analysis. Figure 2 summarizes the filtering of posts.
Forums and Twitter were the key channels for discussions across all geographies, contributing to ~59% and ~39% of the total conversations, respectively. A detailed list of domains from where the posts were obtained and demographic information are provided in Multimedia Appendix 1. Most of the social media posts were from the United Kingdom (n=208), followed by the United States (n=175), Canada (n=65), and Australia (n=16; Figure 2). Of the 130 conversations mentioning the duration of their ocular pain, the majority of patients had experienced ocular pain for several years (53.1%, n=69), followed by 7 to 12 months (18.5%, n=24), 4 to 6 months (14.6%, n=19), and 3 months (13.8%, n=18).

The majority of conversations were from patients (95%, n=441) as compared to 3.9% (n=18) from caregivers. The gender of the patient was mentioned in 118 posts, of which 57.6% (n=68) of posts were from women and 42.4% (n=50) of them were from men. Only 42 posts specified the patients’ ages; 40.5% (n=17) of patients were 21-30 years of age and 26.2% (n=11) of them were >60 years of age. Approximately 214 posts mentioned whether the patients were adults (99.1%, n=212) or children or teenagers (<18 years of age; 0.9%, n=2). Regarding the work status of the patients determined from among 52 posts, the majority of patients were working (51.9%, n=27), 19.2% (n=10) of them were students, and 19.2% (n=10) of them were retired.

Key Themes of Discussion
Of the 464 conversations, symptoms (61.9%, n=287) and the causes of COSP (58%, n=269) were the most common themes that emerged, along with the impact on QoL (20%, n=93). Patients or caregivers also discussed their experiences with health care professionals (HCPs; 25%, n=116), diagnosis (8%, n=37), triggers of their COSP (19%, n=88), treatments (18.1%, n=84), and coping strategies and lifestyle modifications (15.9%, n=74).

Symptoms described by patients varied widely and could be categorized as eye pain–related, such as burning and irritation; vision-related, such as blurred vision and light sensitivity; and physical, such as insomnia and headache (Figure 3). The severity of the symptoms was ranked (high and moderate to low) on the basis of key words and phrases used in the posts. Of the 261 conversations, 85.8% (n=224) of posts were rated as high severity and 14.2% (n=37) as moderate to low severity. Some phrases for high severity mentioned by patients included “eyes burn like hell,” “excruciating (eye) pain,” “eye pain is the
absolute worse,” “unbearable pain,” etc. Moderate to low–severity phrases included “mild redness in my eye occasionally,” “discomfort to mild pain,” and “the pain is pretty manageable.” In 154 conversations, patients also cited emotions that were related to their symptoms, including being upset (35.1%, n=54), worried (26%, n=40), angry (23.4%, n=36), and confused (5.8%, n=9; Figure 3).

Figure 3. Patient-reported symptoms on social media by the number of mentions in the posts.

Figure 3: Severity of Symptoms

There were 282 mentions of the causes of COSP, of which 46.1% (n=130) mentioned underlying ocular medical conditions such as dry eye disease and ocular surgery, and 53.9% (n=152) of them mentioned nonocular conditions contributing to COSP, such as migraine and COVID-19 (Multimedia Appendix 2). Commonly reported environmental triggers of eye pain, such as exposure to bright light or sun and long screen time use (Multimedia Appendix 3), reflect the burden on daily activities.

Overall, 158 patients mentioned the type of HCP they consulted. Of them, 27 consulted an ophthalmologist; 25 consulted an eye, retina, or cornea specialist; 21 consulted a doctor (unspecified specialty); 15 consulted an optometrist; and 14 consulted an optician. Others consulted a neurologist, neuro-ophtalmologist, eye clinic or eye surgeon, otorhinolaryngologists, etc. When the HCP consulted was mentioned (158 patients), the majority of the related comments (n=123) were negative. Many patients expressed that they were not able to get a proper diagnosis and hence expressed negative sentiments in various conversations, citing emotions such as confusion and worry. Pharmaceutical drugs (140/247, 56.7% treatment-related mentions) were cited as the major treatment option for managing COSP symptoms such as topical or oral drugs, followed by alternative remedies (83/247, 33.6%) such as hot compresses, lenses, etc, and lifestyle modifications (24/247, 9.7%) such as sleep, diet changes etc (Multimedia Appendix 4).

Impact of COSP on Patients’ QoL

A total of 159 posts by patients, ascertained to describe their QoL, were grouped in 4 domains: physical, emotional, functional, and social impact (Figure 4). COSP symptoms significantly impacted all aspects of patients’ QoL. Of the 159 posts, various aspects reported were difficulty watching TV or using a phone or computer (8.8%, n=14), executive dysfunction (cognitive, behavioral, and emotional difficulties; 5%, n=8), difficulty performing day-to-day activities such as reading (5%, n=8), and difficulty driving (4.4%, n=7). Emotional well-being, including feelings of depression or hopelessness (10.1%, n=16), frustration or anger (6.9%, n=11), fear (6.3%, n=10), and even suicidal thoughts (1.9%, n=3), were also mentioned. Conversations also mentioned the impact of COSP on functional well-being such as difficulty at the work place or at the place of study (6.9%, n=11), reduced productivity or having to quit their job (5.7%, n=9), as well as social impacts such as being irritated around people (1.9%, n=3) and having a less active social life (2.5%, n=4). Overall, COSP greatly affected the patients’ functional and psychological well-being, as illustrated through patients’ example quotes in Figure 5.
Patients’ Perspectives on Unmet Needs

Patients’ perceptions of unmet needs were grouped under 4 broad categories: diagnosis, HCP-related, treatment, and price- or access-related. A summary of patients’ perceptions of unmet need is presented in Figure 6. Failure to obtain a diagnosis of the underlying cause of COSP, even after undergoing multiple tests, emerged as the primary concern; this also led to a loss of confidence in HCP consultations in most cases.
Figure 6. Key unmet needs across different themes. HCP: health care professional.

Although not assessed in detail, no major differences were observed among the 4 English-speaking countries. Of note, however, the eye pain and related symptoms described by patients most often referred to the eye in general without specification of the ocular surface, so the study assessed chronic ocular pain rather than COSP.

**Discussion**

**Principal Findings**

This SML study attempts to use relevant data from social media platforms to understand patients’ problems and concerns related to COSP. This is the first study to use an SML approach to analyze the COSP disease burden and patients’ perspectives on COSP-related symptoms, causes and triggers, treatment options, and QoL aspects. The study provides a useful insight of the significant burden of COSP on patients’ daily activities, such as reading and driving and the negative impact on their emotional and social well-being and their work productivity. The strong wording that patients are using in describing their pain and its impact on their daily life illustrates patients’ suffering as well as their frustration in desperately seeking effective relief for their chronic ocular pain. This highlights the importance and difficulty of interpreting patients’ own wording expressed in spontaneous SML quotes to understand their real suffering. The results also illustrate how the lack of disease awareness to confirm a diagnosis, a dearth of effective treatment options, and the need to increase awareness of COSP among patients and HCPs are the key unmet needs.

The available treatment options for chronic eye pain are very limited, ranging from the use of artificial tear drops, anti-inflammatory agents or local immunomodulators, and analgesic drugs [16]. In this study, symptoms, multifactor etiological causes, diagnosis, and especially treatments of COSP are most frequently discussed in the context of their impact on patients’ lives. This is suggestive of the need for current COSP treatment paradigms to include qualitative aspects of patient experience to develop a patient-centric model of COSP management.

Two broad aspects of patient experience that this study identify are negative impact on QoL and patient perception of unmet needs. Almost 1 in 5 COSP patients described the negative impacts of COSP on work performance. Treatment strategies could be improved by understanding the issues related to patients’ QoL from social media posts. A common theme among patients’ conversations was the delay in the diagnosis of COSP, which resulted in multiple clinic visits and suboptimal management of COSP symptoms. In this study, patients reported that delayed diagnosis and a lack of proper treatments are associated with a negative perception of COSP. Additionally, even after being diagnosed with COSP, patients cited a lack of pain relief despite using multiple pain management options.

Social media interactions on the web present an inherent opportunity to identify and analyze unfiltered experiences of COSP directly from the own words of patients and caregivers. SML has been shown to be a valuable approach to gain an understanding of the patients’ experience of diseases and treatments with a particular advantage that it can allow data to be gathered from a very large, representative sample that is geographically dispersed (ie, from a wide range of countries or locations) [17]. SML has been used as a tool to investigate patients’ perceptions for different indications, including cancer screening [9], dry eye disease [18], HIV [11], inflammatory bowel disease [10], multiple sclerosis [8], presbyopia [19], total joint arthroplasty [13], and Zika virus [12]. Insights and summaries derived from such conversations can be a vital resource in enriching treatment outcomes associated with chronic diseases. It is, however, critical to carefully detect and assess different aspects included in the sometimes lengthy web-based conversations, ensuring the correct interpretation of patients’ posts, including the underlying emotional aspects. In our study, the high severity of COSP symptoms and its lasting effect resulted in negative sentiments in most patients. The variety in terms and the often strong wording used to describe their pain symptoms, their feelings, and the impact on their daily lives reflects the importance of SML in collecting first-line patient information that has been spontaneously expressed. Careful attention must be paid to capture the different aspects addressed in multiple conversations and interpret them correctly.
to adequately understand individuals’ actual suffering. Correct categorization and indexing of the SML posts was critical. Multiple analysts, senior analysts, and experts reviewed the posts during the whole process in order to obtain robust data. This highlights the importance and difficulty of interpreting patients’ own wording expressed in spontaneous SML conversations.

NLP has been widely used in SML studies, and the resulting data have been reported for a variety of diseases [10,12]. In this SML review, NLP has been used for its high-throughput capability, which was then paired with manual assessment to provide the necessary focus and specificity of the outputs. Inherent biases that may affect the accuracy (representativeness of the collected sample and linguistic selection in posts), reliability (consistency of reports from individual patients across time points or descriptors), and quality of information (self-selection bias) obtained from any social media platform may be present in this study as well [20]. One of the limitations of this study was that only publicly available information on digital platforms has been accessed and used; all the personal identifiers were anonymized in the report. Further, owing to the unstructured nature of social media data, it was not possible to obtain information on every research question; therefore, we objectively determined whether the available information supported the research question and, accordingly, our findings, which may be considered a limitation of this study.

Conclusions

Insights from this study reported the experiences and concerns and the adverse impact on overall QoL among patients with COSP. Assessment of patients’ own wording demonstrated that COSP imposes a significant burden of impaired QoL on patients, which spans multiple aspects of daily life, including physical and functional impacts, as well as impacts on emotional and social well-being. The lack of disease awareness among HCPs with long diagnostic delays and the inefficacy of prescribed treatments were cited as concerns. The variety in terms patients used on the web to describe their suffering, issues, and needs as well as the different aspects addressed herein contribute to a better understanding of the patients’ perspectives and highlight the value of SML studies. It is indeed most critical to obtain patients’ insights and address their unmet needs when considering disease management including drug development.

Abstract

Background: Health misinformation and myths about treatment for opioid use disorder (OUD) are present on social media and contribute to challenges in preventing drug overdose deaths. However, no systematic, quantitative methodology exists to identify what types of misinformation are being shared and discussed.

Objective: We developed a multistage analytic pipeline to assess social media posts from Twitter (subsequently rebranded as X), YouTube, Reddit, and Drugs-Forum for the presence of health misinformation about treatment for OUD.

Methods: Our approach first used document embeddings to identify potential new statements of misinformation from known myths. These statements were grouped into themes using hierarchical agglomerative clustering, and public health experts then reviewed the results for misinformation.

Results: We collected a total of 19,953,599 posts discussing opioid-related content across the aforementioned platforms. Our multistage analytic pipeline identified 7 main clusters or discussion themes. Among a high-yield data set of posts (n=303) for further public health expert review, these included discussion about potential treatments for OUD (90/303, 29.8%), the nature of addiction (68/303, 22.5%), pharmacologic properties of substances (52/303, 16.9%), injection drug use (36/303, 11.9%), pain and opioids (28/303, 9.3%), physical dependence of medications (22/303, 7.2%), and tramadol use (7/303, 2.3%). A public health expert review of the content within each cluster identified the presence of misinformation and myths beyond those used as seed myths to initialize the algorithm.

Conclusions: Identifying and addressing misinformation through appropriate communication strategies could be an increasingly important component of preventing overdose deaths. To further this goal, we developed and tested an approach to aid in the identification of myths and misinformation about OUD from large-scale social media content.

addiction treatment; machine learning; misinformation; natural language processing; opioid use disorder; social media; substance use

Introduction

In the United States, more than 100,000 drug overdose deaths occurred in 2021 [1]. Beyond lives lost, the economic costs of both fatal opioid overdose and opioid use disorder (OUD) are estimated to be greater than 1 trillion US dollars per year [2,3]. Furthermore, the extent of OUD is significant; in 2020, about 2.7 million people in the United States aged 12 years or older met the diagnostic criteria for an OUD in the past year [4].

https://formative.jmir.org/2024/1/e44726

JMIR Form Res 2024 | vol. 8 | e44726 | p.2303
(page number not for citation purposes)
The American Psychiatric Association’s Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) defines OUD as a “problematic pattern of opioid use leading to clinically significant impairment or distress” [5]. OUD is characterized by 11 defining criteria, including taking opioids in larger amounts or over a longer period of time than intended [5]. Medications for opioid use disorder (MOUD), including methadone, buprenorphine, and extended-release naltrexone, are effective treatments for OUD [6]. MOUD increase treatment retention and reduce opioid use and overdose mortality, among other public health benefits [7]. Yet in 2020, it is estimated that only 11.2% of people with OUD received treatment with MOUD in the past year, based on data from the National Survey on Drug Use and Health [8]. Despite its effectiveness, MOUD are underused, in part due to stigma, financial constraints, treatment availability, and a lack of perceived treatment need [4].

When individuals do seek information on MOUD—often on the internet or through social media—they may access inaccurate and potentially harmful health misinformation [9]. A recent review pointed to several areas of misinformation regarding MOUD, including that MOUD may be detrimental to health and can be perceived as simply substituting one addiction with another [10]. Although social media provides a venue for individuals to seek help, advice, and support surrounding their OUD experiences, journeys, and recovery goals [11-13], these platforms also provide a mechanism for misinformation about MOUD to spread [14]. However, most studies to date have focused on general opinions and attitudes regarding MOUD, and less is known about specific misinformation that is shared. For example, Tofighi et al [15] conducted a qualitative analysis of 1010 Twitter (subsequently rebranded as X) posts related to MOUD, assessing general experiences and perceptions. A subsequent study by Chenworth et al [16] assessed tweets that mentioned methadone or suboxone and found that a large percentage expressed negative sentiment about MOUD. Pertaining specifically to misinformation, a study [14] quantified the prevalence of a single myth about MOUD across multiple social media and web-based communication platforms. This myth was drawn from clinical literature; however, it is likely that other myths or misinformation related to MOUD are emerging or being discussed that have not been previously described. Indeed, health care professionals’ understanding of what misinformation and myths may be circulating related to substance use disorder treatment is currently limited to expert opinion, and there is no systematic or large-scale quantitative approach to identify new opioid-related myths from web-based communications and social media platforms. Thus, in this study, we developed and evaluated an approach for identifying potentially novel myths that may exist regarding MOUD. This approach can help identify harmful content to inform strategies to educate clinicians and the public about MOUD and counter myths and misinformation related to MOUD.

Methods

Overview

To accomplish our goal of identifying potentially new myths about MOUD from social media, we used a multistep analytic pipeline (Figure 1), described in detail below. The steps included curating a data set of social media posts across multiple platforms; extracting posts with a high probability of including a myth; using a clustering algorithm to group these posts into themes; and lastly, examining the resulting content for language indicative of misinformation and myths.

Figure 1. Pipeline for the identification of new myths pertaining to treatment for opioid use disorder. We start by transforming each post and myth into a mathematical representation. Next, we identify the posts closest to myths in meaning and have public health experts annotate them for accuracy. We then computationally cluster similar themes together and have public health experts assign a clinical theme. KNN: k-nearest neighbor.

Data Set Curation

We first developed a lexicon of opioid-related keywords; for this, we adopted a 2-pronged approach that combined insights from the substance use literature and feedback from the substance use expert coauthors of this study. Our lexicon encompassed different types of opioids, such as natural opiates, semisynthetic opioids, and synthetic opioids, and included opioids that were prescription or illicit. For each generic drug name, we also included brand and combination product names. In addition, we also included street names of substances, where useful, from the Drug Enforcement Administration. Our final lexicon of 152 keywords was then used in the ensuing data collection.

Using this lexicon, we constructed a diverse data set from Twitter, YouTube, and online health communities (OHCs) such as Reddit and Drugs-Forum. For all the platforms we
investigated, we focused on public posts and messages created between January 1, 2018, and December 31, 2019. Our data set collection methodology for Twitter included querying for all public posts that contained 1 of the words in our lexicon using the then-available Twitter Academic application programming interface (API). This process yielded 6,365,245 posts. For YouTube, due to rate limitations imposed in the data collection process by the platform’s API, we restricted the keywords to 11 MOUD treatment keywords such as buprenorphine and naltrexone. We used the YouTube API to identify 552 public YouTube videos that contain 1 of the 11 keywords in the title and then collected all of the associated comments (99,386 comments). We relied on expert domain knowledge to identify subforums pertinent to OUD for Reddit and Drugs-Forum. We used data from 22 opioid-specific subreddits (carfentanil, opioids, fentanyl, opiatesmemorial, modiquittingkratom, methadone, suboxone, kratom, heroin, quittingkratom, Tianeptine, loperamide, naltrexone, oxycodeone, OpiatesRecovery, opiatewithdrawal, lean, heroinaddiction, HeroinHeroines, OpiateChurch, suboxone, OurOverUsedVeins), resulting in 1,189,590 posts and 12,293,829 comments. Additionally, we collected 5549 messages posted under the various “Opiates and Opioids” subforums on Drugs-Forum. Throughout this paper, we combine Reddit and Drugs-Forum content under the category of OHCs because of their similar affordances.

**Mixed Methods Approach to Identify Social Media Posts Relevant to MOUD Myths**

We began our analytic and data processing efforts by investigating three “seed” myths drawn from the substance use literature [17-20]: (1) agonist therapy or medication-assisted treatment for OUD replaces one drug with another, (2) only patients treated with opioids who have certain characteristics are at higher risk for opioid addiction, and (3) tramadol is a nonaddictive nonopioid alternative. These seed myths were used, in concert with machine learning approaches, to filter the large volume of semantically rich social media content that would be subsequently investigated for the presence or absence of a new MOUD myth.

Specifically, we used InferSent, a sentence embedding method that provides semantic sentence representations [21], to construct document embeddings for the 3 myth statements noted above. Document embeddings are long sequences of numbers that mathematically represent the semantic meaning of each document (ie, a social media post). InferSent embeddings have been shown to outperform unsupervised methods such as SkipThought vectors on a range of natural language processing (NLP) tasks [21]. In our experiments, we evaluated the embedding values of the social media posts most similar to the seed myths and observed that, indeed, the most similar posts express a similar meaning but are expressed differently (eg, the following blockquote from a sample post in our data set was found to be similar to the seed myth “agonist therapy or medication-assisted treatment for OUD replaces one drug with another”).

```
...So I have decided to discontinue treatment. My family doesn’t agree with this form of treatment and
```

After constructing document embeddings for the seed myth text, we constructed document embeddings for all social media posts in our data set. Using the mathematical representation of each post, we were able to identify posts similar to the seed myths and containing additional information useful for understanding MOUD myths. Specifically, we identified the 200 most semantically similar posts per platform for each seed myth using the k-nearest neighbor (KNN) algorithm [22], implemented in Python’s scikit-learn library [23]. The KNN algorithm assumes that similar things exist in close proximity. In other words, KNN uses the idea that similar things are near each other—in our case, it would compare how close posts are to the seed myths. This process provided us with candidate social media posts that were likely to be discussing MOUD myths or related topics. Additional details of our machine learning and NLP approaches are provided in Multimedia Appendix 1 [21,24-34].

Because not all posts identified through the methods described above may be directly discussing a MOUD myth and document embeddings could pick up some noise, we performed a second data processing step, in which we harnessed annotations from public health experts. The experts reviewed and evaluated whether each post in our now-filtered data set of 800 messages (200 per platform) was relevant to 1 of the seed myths, discussing a new myth, or neither. Specifically, a total of 3 public health experts (coauthors of this paper) reviewed each of the 800 social media posts to perform this qualitative assessment and reach a consensus on the topic discussed therein. Public health experts included 2 clinicians and 1 doctoral-level epidemiologist. The experts reviewed all posts and collectively came to a consensus across all posts in our data set. Our rationale for the qualitative annotation approach followed the guidelines given in the seminal research of McDonald et al [35]. The experts leveraged thematic coding, an iterative process that involves multiple coders developing, discussing, and refining codes through continual discussion. Our qualitative annotation, followed by consensus-building discussion, is situated in grounded theory [36,37].

This manual review resulted in a total of 303 posts identified as discussing potentially new myths. The pipeline for identifying these posts is outlined in Figure 1.

**Methods to Understand Discussions of New Myths Arising From the Seeds**

We developed additional machine learning–based techniques to better characterize the content of the 303 annotated posts. We leveraged an unsupervised machine learning technique known as hierarchical clustering [24]. This approach provides a probabilistic mechanism to group items (social media posts) into categories (discussion themes). Multimedia Appendix 1 describes this unsupervised technique in greater detail.

Hierarchical clustering was used to construct 10 categories from the 303 posts that are potentially indicative of new myths. All posts per theme were then presented to the above public health
experts to interpret and name the extracted themes. To give richer context to the experts and help with the generation of theme descriptors, we also provided the linguistic markers (n=1-grams or single words) present in the posts for each theme using a commonly used lexical analytic generative model known as Sparse Additive Generative Models (SAGE) of Text [25]. SAGE identifies distinguishing words in our topic themes, where the SAGE magnitude of a word signals the degree of its uniqueness. Previous work has shown that SAGE outperforms other topic models, such as latent Dirichlet allocation (LDA) models, by focusing on high-frequency terms with accurate counts, thus leading to learning more robust interpretable topics [25]. Using this information, the experts developed descriptions of each category and identified myths related to OUD. After careful inspection, the experts aggregated a few topically similar themes, with a final focus on seven themes.

Ethical Considerations
This study is considered exempt research since there are no human participants involved. As such, the study proceeded without obtaining informed consent from social media users. Moreover, social media users who authored posts in the data set were not compensated because the data were publicly available. Social media posts are anonymized by not including usernames in our analysis. All examples given in this study are slightly paraphrased from different social media platforms to further protect user confidentiality. The potential use of these findings by malicious actors cannot be overstated. Motivated actors perpetrating myths and misinformation surrounding OUD could use machine learning and NLP approaches to target susceptible people with OUD and redirect them toward clinically unverified treatments, leading to misinformation exacerbation. Additionally, people with OUD are often stigmatized on multiple levels. Individuals with OUD are perceived as dangerous, of moral failure, and called “addicts” [38]. In light of these possible negative outcomes, although we provided links to all open-source libraries associated with our computational analyses, we have not shared the text data from different social media platforms to minimize the possible identification of OUD social media users.

Results
Our analytics pipeline resulted in the identification of 7 clusters or discussion themes of social media posts related to MOUD. Textbox 1 shows paraphrased example posts that represent new myths or potentially harmful information identified from this data set, and Table 1 displays the salient keywords identified by SAGE for each category to help provide further context.

Textbox 1. Example posts from our data set (n=303) that represent inaccurate or harmful information identified by our human-machine mixed strategies. Themes (in bold font) are labeled by public health experts. The bullet points depict example posts from our data set for each identified type of misinformation. Posts are slightly paraphrased to prevent traceability and author identification.

The most prevalent category described and discussed treatments for opioid use disorder (90/303, 29.8%). Posts described several Food and Drug Administration (FDA)–approved medications for OUD, including buprenorphine and methadone, and nonapproved treatments such as kratom. Additional posts referenced a regulated supply of heroin to treat OUD, while other posts discuss the need for long-term use of buprenorphine or methadone. New myths present in this category perpetuated the notion that addiction is not a medical disease and discussed alternative therapies such as kratom.

The second category explored the nature of addiction (68/303, 22.5%). Posts discussed the definition of addiction and the distinction between dependence and addiction and debated whether addiction is a disease. Similar to the first category, misinformation found in this category included statements that addiction is not a medical disease and the promotion of alternative therapies, such as “Ibogaine cures addiction big time.”

The third category described the pharmacologic properties, effects, and addictiveness of substances (52/303, 16.9%). Posts included comments on how addictive substances were compared with each other (eg, nicotine vs heroin or fentanyl vs marijuana). Additional posts discussed drug metabolism and drug synthesis. Misinformation in this category included statements that “Buprenorphine is more addictive than opioids” and that “Fentanyl is less addictive than marijuana.”

The fourth category focused on intravenous or injection drug use (36/303, 11.9%). Posts covered drug injection techniques, advice, and the health consequences of such injections. Misinformation in this category included statements that “withdrawal from buprenorphine is worse than heroin” and that “willpower is the only way to quit.”

The fifth category centered on pain, opioid use, and addiction (28/303, 9.3%). Posts covered the use of opioids for chronic pain, the risk of addiction when using opioids for pain, and the stigma associated with using opioids for pain. Misinformation in this category included diverse statements such as “the only people overdosing are those taking illicit heroin,” “people with chronic pain are physically dependent on opioids like a normal person,” and “Who cares if people are addicted to kratom, it’s just like coffee, it’s good for you.”

The sixth category described physical dependence on medications (22/303, 7.2%). Posts commented on the distinction between dependence and addiction and specifically noted kratom as resulting in less addiction. Misinformation in this category included statements promoting alternate therapies.

Finally, the seventh category largely described tramadol use (7/303, 2.3%). Posts commented on tramadol dosing and administration. A discussion of the alternative therapy, ibogaine, was also present.

Each of the 7 categories included posts that contained some form of new misinformation that was not present in the initial seed myths we used to build our detection approach. Textbox 1 presents examples of misinformation or myth text. Further review of the misinformation resulted in classifying the misinformation into three themes, as shown in Textbox 1: (1) discussing addiction or addictiveness, (2) taking medication for addiction is not true recovery, and (3) alternative or nonrecommended treatments for addiction.

**Discussion**

**Overview**

The aim of this study was to develop and test a methodology for identifying new myths and misinformation related to MOUD. While health professionals are cognizant of the presence of misinformation and its effects on patient populations [39,40], there is currently no systematic approach for identifying potentially harmful information that individuals who use substances are actually exposed to and discussing. We developed a semiautomated pipeline that uses known myths as seed text and a sophisticated NLP approach to identify other misinformation that is circulating. The approach used a recent...
algorithm released by Facebook Research for measuring text similarity in social media postings [21] and then explored results through automated clustering and human expert review. We found that this approach identified new myths and forms of misinformation beyond those used as seed myths, suggesting that this approach may be useful in identifying new and emerging forms of potentially harmful information that may be circulating.

The posts we identified were grouped into 7 main themes related to MOUD, each revealing inaccuracies upon review by public health experts. The most common misinformation included statements endorsing alternative therapies such as kratom or ibogaine or discouraging medication use, favoring less effective abstinence-only approaches [41]. These are critical areas that require ongoing public health attention since alternative therapies such as kratom have been linked to fatal overdoses, and nonpharmacologic therapy for OUD is associated with higher rates of drug resumption and mortality. Our approach, using automatic data mining techniques, successfully flagged these types of misinformation, even uncovering subtler concerns that have not received sufficient attention, such as misinformed statements about the addictiveness of buprenorphine and unwarranted fears about buprenorphine withdrawal. These findings are significant as buprenorphine, a partial-opioid agonist, stands as one of the most effective treatments for OUD [7]. In light of the rising impact of health misinformation on patient populations, this study addresses the lack of tools for identifying potentially harmful information that spreads. We introduce an approach that quantitatively taps into extensive discussions about addiction across major communication platforms, contributing to misinformation identification. This is pivotal because, although patients seek health information from social media, it is also a breeding ground for false information dissemination [42], and there is a lack of systematic tools to assess health information related to addiction shared on these platforms [43]. Most closely related to this study is the work done by Sarker et al [13], Garett and Young [44], and Johnson et al [45]. Garett and Young [44] conducted a review on how inaccurate and false beliefs by both patients and providers can lead to stigma and serve as barriers to receiving appropriate treatment. This study comments on the consequences of 4 types of stigma, including structural stigma, public stigma, self-stigma, and stigma associated with treatment medications [44]. Similar to this study, Johnson et al [45] conducted a content analysis of 33 YouTube videos to identify and understand the lived experiences of parents and families impacted by the opioid crisis. In contrast to their work, we focused on social media posts and comments to identify new myths surrounding OUD. Most closely related to this study is Sarker et al [13], wherein the authors similarly leveraged NLP methods and built a classifier that identified whether a post’s language promoted 1 of the leading myths challenging addiction treatment: that the use of agonist therapy for MOUD is simply replacing one drug with another [13]. However, this study differs in the sense that it does not focus on 1 particularly known myth but rather on finding new pieces of misinformation.

To our knowledge, no studies report interventions directed at web-based misinformation on MOUD, yet lessons from analogous interventions during the COVID-19 pandemic are informative. One study of US-based Facebook users showed decreased distance traveled among those who viewed video messages from health professionals during the 2020 holiday season [46]. Another study found that journalistic fact-checks may be effective against COVID-19 misinformation [47]. Finally, a third study demonstrated the utility of accuracy nudges in addressing COVID-19 misinformation [48]. Taken together, these interventions suggest initial steps in building the evidence base for infodemic response across public health areas. Further study is needed to understand interventions that address MOUD-related misinformation.

The greatest strength of this study is that it is nonobtrusive and leverages a large-scale data set along with advances in machine learning and NLP to identify new pieces of misinformation that could exacerbate OUD health-related risks. Nevertheless, this study is subject to limitations. First, the qualitative assessment of myths and misinformation was conducted by only a limited number of health experts. As myths can be nuanced, further work should aim to codify definitions and guidance around opioid-related myths, particularly as this field of study grows. Second, while we demonstrate success at identifying misinformation beyond the seed myths we used to initialize the algorithm, the nature and scope of all misinformation related to MOUD are not known, and thus we are unable to assess the sensitivity of our approach to capturing all misinformation that may exist. Nevertheless, the ability to quantitatively and algorithmically identify misinformation related to addiction is still an important advancement. Third, although the approach we use harnesses machine learning and NLP techniques, a component of our pipeline still relies on public health expert review. While this necessitates some labor, human-in-the-loop designs are a leading framework for product development, have certain advantages, and can be particularly useful for complex areas such as health misinformation where expert judgment is required [14]. Finally, we acknowledge that there are a multitude of social media–based communication modalities, and this study is limited to those that are publicly available. It is possible that the nature of health misinformation may differ by platform, and further study of these differences is needed.

Our research demonstrates promise in identifying myths and misinformation related to treatment for OUD included in social media posts. With rapidly rising opioid overdose fatality rates, the initiation and adoption of MOUD are increasingly urgent to prevent additional loss of life. Attention by health and public health professionals to the health misinformation that may be affecting individual decisions related to OUD treatment engagement and retention can be a critical element in enhancing prevention.

Conclusions

Health misinformation regarding treatment for OUD is prevalent, contributing to the challenges of preventing opioid-related overdoses. However, a systematic and quantitative methodology to identify this misinformation is lacking. In response, we developed a multistage analytic pipeline to analyze social media posts from platforms such as Twitter, YouTube, Reddit, and Drugs-Forum for OUD-related misinformation. Our
methodology successfully identified 7 main clusters of misinformation related to MOUD. The most salient topics for these myths include treatments for OUD, the nature of addiction, as well as the pharmacologic properties, effects, and addictiveness of substances. Further understanding of the identified myths and continual monitoring of emerging myths are critical in the battle against the opioid overdose epidemic.

Acknowledgments
This research was supported through a contract by the Centers for Disease Control and Prevention (CDC; through the Department of Health and Human Services) with the Georgia Institute of Technology (Principal Investigator MDC). CDC investigators participated in the design and conduct of the study; the collection, management, analysis, and interpretation of the data; the preparation, review, or approval of the manuscript; and the decision to submit the manuscript for publication. ME and MDC had full access to all the data in the study and took responsibility for the integrity of the data and the accuracy of the data analysis. We thank Kenneth Kannampully for his help with the Drugs-Forum data collection.

The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the CDC.

Data Availability
The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors’ Contributions
SS, MDC, and ME designed the research. ME, SS, and MDC conceptualized and developed the analytic techniques. ME gathered and analyzed the data and designed the machine learning models. SS, VK, CJ, RL, AKO, and LS provided expert clinical review and annotations for the models and read, edited, and provided feedback on the paper. ME, SS, and MDC interpreted the results and drafted the paper.

Conflicts of Interest
None declared.

Abstract

Background: The use of web-based health information (WBHI) is on the rise, serving as a valuable tool for educating the public about health concerns and enhancing treatment adherence. Consequently, evaluating the availability and quality of context-specific WBHI is crucial to tackle disparities in health literacy and advance population health outcomes.

Objective: This study aims to explore and assess the quality of the WBHI available and accessible to the public on oral lichen planus (OLP) in Arabic.

Methods: The Arabic translation of the term OLP and its derivatives were searched in three general search platforms, and each platform’s first few hundred results were reviewed for inclusion. We excluded content related to cutaneous LP, content not readily accessible to the public (e.g., requiring subscription fees or directed to health care providers), and content not created by health care providers or organizations (i.e., community forums, blogs, and social media). We assessed the quality of the Arabic WBHI with three standardized and validated tools: DISCERN, Journal of the American Medical Association (JAMA) benchmarks, and Health On the Net (HON).

Results: Of the 911 resources of WBHI reviewed for eligibility, 49 were included in this study. Most WBHI resources were provided by commercial affiliations (n=28, 57.1%), with the remainder from academic or not-for-profit affiliations. WBHI were often presented with visual aids (i.e., images; n=33, 67.4%). DISCERN scores were highest for WBHI resources that explicitly stated their aim, while the lowest scores were for providing the effect of OLP (or OLP treatment) on the quality of life. One-quarter of the resources (n=11, 22.4%) met all 4 JAMA benchmarks, indicating the high quality of the WBHI, while the remainder of the WBHI failed to meet one or more of the JAMA benchmarks. HON scores showed that one-third of WBHI sources had scores above 75%, indicating higher reliability and credibility of the WBHI source, while one-fifth of the sources scored below 50%. Only 1 in 7 WBHI resources scored simultaneously high on all three quality instruments. Generally, WBHI from academic affiliations had higher quality scores than content provided by commercial affiliations.

Conclusions: There are considerable variations in the quality of WBHI on OLP in Arabic. Most WBHI resources were deemed to be of moderate quality at best. Providers of WBHI could benefit from increasing collaboration between commercial and academic institutions in creating WBHI and integrating guidance from international quality assessment tools to improve the quality and, hopefully, the utility of these valuable WBHI resources.
Introduction

The internet has revolutionized the visibility and accessibility of data [1]. Over half of today’s world population used the internet in 2021 [2]. Searching the internet for web-based health information (WBHI) was the third most frequent internet activity, and 6.75 million searches are performed daily for health information [3,4]. Often, WBHI is considered a “first aid” resource for health information and is used to compare diagnoses or treatment options [5,6], or to supplement insufficient time with a health care provider [6,7]. More seriously, some patients believe that WBHI is trustworthy and might defer or replace medical consultation or treatment from health care providers [6,8,9]. Lastly, recent evidence suggests that seeking WBHI could be associated with changes in health behavior or patient outcomes [6,8,9]. Therefore, ensuring the availability, accessibility, and quality of WBHI is essential to the well-being of individuals and the community.

The format and quality of WBHI vary substantially. The format ranges from health blogs/forums based on personal experiences offering unregulated information to peer-reviewed journal articles that provide complex data addressed to medical professionals [10,11]. Therefore, the quality of WBHI could vary considerably between the resources of WBHI. Some global research indicates that the quality of some WBHI targeting the public could be of low quality [10,11]. Evidence that examined Arabic WBHI often found that a considerable proportion of the WBHI had low quality, including but not limited to not disclosing the authorship of the information, outdated information, and lack of advice that WBHI should not replace a health care consultation [12-16]. Often, high-quality WBHI would require payment (ie, subscription) for access, exacerbating the inequalities in accessing WBHI for some individuals [10]. The evaluation of context-specific WBHI (ie, language) emerges as a public health priority that might address some health literacy inequality.

Oral lichen planus (OLP) is a prevalent chronic inflammatory mucocutaneous disease that frequently affects the oral mucosa. Between 0.5%–2% of the world’s population is affected by OLP [17-19]. In a review of studies conducted in Arab countries, OLP had a potential malignant transformation rate ranging from 0.4% to 6.5% [20]. Although there is no gold standard measure of the quality of WBHI, some international tools like the Journal of the American Medical Association (JAMA) benchmarks and Health On the Net (HON) are frequently used to examine the WBHI in different languages. Literature that evaluated the English content of WBHI regarding OLP using the aforementioned tools reported moderate accuracy and reliability [11]. A comprehensive evaluation of 122 Arabic health websites revealed that these websites varied substantially in meeting some industry benchmarks, like the HON code. For instance, 16% of the websites provided information on their advertising policies, while 73% provided justification for the content included within a website [21,22].

Though accessing high-quality WBHI can effectively increase the public’s knowledge, support health-related decision-making, and improve health-seeking behaviors or outcomes [8,23], no studies focused on evaluating OLP-related WBHI in Arabic. As such, the need arises to scrutinize the content and accuracy of Arabic WBHI related to OLP that is accessible to the public. This study assessed the availability and quality of OLP-related resources in Arabic.

Methods

Search Strategy

This study was a cross-sectional evaluation of Arabic WBHI on OLP. We searched for the Arabic translation of the keywords “oral lichen planus,” “treatment of oral lichen planus,” and their derivatives ( , , , ) in three main search engines, namely, Google, Yahoo, and Bing. We used the Boolean operator (OR) to link these terms but did not use any conditions of filters to mimic electronic research that patients or members of the public might perform on OLP.

We reviewed the first few hundred links on each platform for inclusion until links were no longer relevant to OLP. We included resources (ie, web pages) with information on OLP in Arabic. We excluded WBHI focusing on extra-oral lichen planus, scientific content requiring membership (eg, subscriptions) or directed to professionals (ie, specialty journals), community-based forums without professional guidance, social media posts, and results promoted or advertised by search engines. We also excluded resources that included video or audio content only with no accompanying text and results that were in .doc, .pdf, or .ppt format, as the public might be less likely to seek such resources. Two trained evaluators (AA and HA) simultaneously screened and evaluated the OLP Arabic WBHI resources and deferred to the senior author (AFA) in case of disagreement.

Domains and Tools for Evaluating WBHI

The WBHI resources were assessed for content and quality. The content of the resources was categorized as reported previously by Ni Riordan and McCreary [24] and attached in Multimedia Appendix 1 [24]. Briefly, results were grouped according to the affiliation of the web page (commercial, nonprofit, governmental, or university/medical center), specialization (if a web page is either entirely or partially related to the searched topic), content type (medical facts, clinical trials, human interest stories, or question and answer), and content presentation (text, images/graphs, videos, and audio). The quality of the web pages was assessed with the DISCERN

KEYWORDS

oral lichen planus; health information; Arabic; medical information; information seeking; quality; online information; Arab; oral; inflammatory; inflammation; chronic; mouth; mucous membrane; mucous membranes; reliable; reliability; credible; credibility; periodontontology; dental; dentist; dentistry

[JMIR Form Res 2024;8:e49198] doi:10.2196/49198
instrument [25], the JAMA benchmarks [26], and the HON code [27].

The DISCERN tool aims to empower consumers when making treatment choices by evaluating the quality of written health information (ie, publications). DISCERN is a validated 16-item instrument, with each item rated on a 5-point scale (1=did not fulfill item to 5=complete fulfillment of item) and is arranged in three sections. The first section (items 1-8) addresses the reliability of the publication, the second section (items 9-15) assesses the quality of the information related to treatment choices, and the third section consists of one item (item 16) that gives an overall quality rating of the content [25,28,29].

JAMA benchmarks assess the accountability of WBHI by examining the following domains of resources: authorship (providing authors and their affiliations), attribution (eg, citations) of the source of information provided, disclosure (revealing any ownership, sponsorship, or conflict of interest in providing the WBHI), and currency (ie, updates of the WBHI) [26].

The HON tool evaluates the reliability and credibility of health websites. HON asks reviewers to evaluate a given web page regarding eight sections: authority, complementarity, confidentiality, attribution, justifiability, transparency, financial disclosure, and advertising policy [30]. The reviewer will score each item from 0% (did not fulfill the specific item) to 100% (total fulfillment of that item), while the HON final score is an average of scores across the eight items.

Statistical Analysis

Data were extracted, coded, and cleaned in Excel (Microsoft Corporation), then analyzed using SPSS Statistics (Version 24.0; IBM Corp.). The data were summarized using frequency and percentage distribution for the categorical variables and means with SDs for the continuous variables. We classified WBHI by type of affiliation into commercial and academic (including nonprofit, medical center, and governmental), then compared the quality of WBHI across these groups using bivariate analyses. To facilitate comparison with previous literature, the HON score was categorized into an ordinal variable as such: scores <50% (low credibility), 51%-75% (moderate credibility), and scores >75% (high credibility). Fleiss κ was used to calculate the interrater reliability of the reviewers in assigning the HON score as a categorical variable [31]. Lastly, to synthesize information from all three quality measures, we created a composite variable as follows: high-quality WBHI means the resource satisfied at least 3 of the JAMA benchmarks, had a HON score ≥75, and had a DISCERN overall score ≥3; otherwise, the WBHI was considered low-quality.

Ethical Considerations

This study was exempt from ethical review since it used publicly available data sources that do not include any patient-identifying data.

Results

Overview

The keywords returned the highest number of hits in Google (n=56,770), followed by Yahoo (n=5188) and Bing (n=1910). We reviewed the first 400 results on Google, 300 on Yahoo, and 211 on Bing until the web pages were unrelated to OLP. After removing duplicated results, a total of 49 results were included in this study. The most frequent reason for exclusion was results about oral lesions other than OLP (Figure 1). The interrater reliability measure indicated a high agreement between the evaluators in assigning HON scores (κ=0.826, 95% CI 0.823-0.828).
Content Assessment

More than half of the web pages had commercial affiliations (n=28, 57.1%), that is, WBHI provided by for-profit clinics with clear advertisements for treatment or establishments (Table 1). Conversely, 43% (n=21) of the WBHI resources had academic affiliations (nonprofit, medical centers, and governmental affiliations). Only one-fifth of the web pages (n=11, 22%) were focused exclusively on OLP, rather than lichen planus in general. The vast majority of Arabic OLP WBHI was in the format of medical facts (n=42, 85.7%), and most WBHI included images of OLP (n=31, 63%; Table 1).
Table 1. Content assessment of Arabic web-based health information on oral lichen planus (OLP) using Ni Riordan and McCreary’s [24] method (n=49).

**Quality Assessment by DISCERN**

The overall mean score of DISCERN for the included WBHI was rather low (mean 2.61, SD 1); however, the average rating of single items varied substantially (Table 2). Items with the highest DISCERN scores described the publication’s aims and the alternative OLP treatment options. There was no evidence to indicate meaningful differences in the DISCERN scores between WBHI presented by commercial and academic affiliations.

**Quality Assessment by JAMA Benchmarks**

Only 22.4% (n=11) of the WBHI resources met all 4 JAMA benchmarks, indicating high quality, and another 24.5% (n=12) met 3 of the 4 benchmarks. Overall, most WBHI fulfilled the “Disclosure” criteria, while less than half of the web pages fulfilled the “Attribution” criteria (Table 3). Academic affiliations satisfied the authorship and attribution more often than commercial affiliations but were less current than commercial resources (Table 3).
Table 3. Overall and stratified distribution of the fulfillment of *Journal of the American Medical Association* (JAMA) benchmarks and Health On the Net (HON) scores among reviewed web-based health information (WBHI; n=49).

*aJAMA comparisons denote raw percentages comparing the relative contribution by affiliation type within each JAMA benchmark. bHON comparison denotes column contribution by affiliation type across levels of HON scores. cHigh-quality WBHI denotes a WBHI resource that satisfied at least 3 of the JAMA benchmarks, had a HON score >75, and had an overall DISCERN score ≥3; otherwise, a resource was labeled as low-quality.

Quality Assessment by HON

The average HON score was significantly higher for academic affiliation sources of WBHI than commercial affiliations (mean 71, SD 14 vs mean 56, SD 15; P<.001). When HON scores were examined as an ordinal variable, almost one-third (n=14, 29%) of the WBHI resources scored higher than 75, indicating high credibility of the WBHI, with more contributions from academic rather than commercial affiliations (Table 3).

Overall Quality Assessment

When WBHI information was classified by collective score combining all three quality instruments, it was found that 1 in every 7 resources (n=7, 14.3%) had high quality, and most of this high-quality evidence came from academic affiliations (n=5, 23.8% vs n=2, 7.1% from commercial affiliations; Table 3). However, the difference in the distribution of quality levels across affiliation types was not significant (Fisher exact test P=.12).

Discussion

Principal Findings

This study evaluated the content and quality of the Arabic WBHI on OLP available to the public using prevalidated standardized tools. The results indicated that approximately one-third of the WBHI had high scores, corresponding to higher quality, as indicated by the JAMA and HON tools. The Arabic WBHI on OLP was often presented as a narration of medical facts and frequently included audiovisual aids to enhance the consumer’s comprehension of health information, and most were provided by commercial affiliations. To the best of our knowledge, this is the first study to evaluate Arabic WBHI on OLP. As OLP can be a chronic condition with occasional atypical forms and a potential for malignant transformation, patients are likely to supplement their clinical consultations with WBHI [7,17,32,33]. Hence, this evaluation of the quality of WBHI on OLP in Arabic is essential and timely.

The Arabic WBHI on OLP in this study included a higher percentage of resources deemed to be of higher quality compared to Arabic WBHI on other diseases, including periodontal diseases and breast and oral cancers [12,14,34]. For instance, in this study, 1 in every 5 WBHI sources had fulfilled all 4 JAMA benchmarks, while recent results by Halboub et al [16] and Al-Ak’halili et al [34] found the same for 8% and 4%, respectively, of the websites they reviewed. The association of higher quality with resources classified as academic was noted in previous studies evaluating Arabic WBHI [34]. Lastly, DISCERN scores in this study were slightly higher than those reported by Alakhalili et al [14] on oral cancer. However, these studies evaluated different diseases, and the higher scores could reflect “better” WBHI on OLP compared to oral cancer or an inherent subjectivity in the DISCERN instrument by virtue of having a Likert scale.

Most of the WBHI resources we reviewed had more commercial affiliations than affiliations to medical or research centers. This generally agrees with the literature where commercial affiliations were the most prolific providers of WBHI [12,13,34]. This is consequential as the web pages with a commercial affiliation often include advertising of certain treatments or care providers. Some evidence suggests that advertising negatively affects the credibility of the information offered and individuals’ trust in the source of WBHI [35]. Moreover, compared to academic affiliations, we observed a lower quality among WBHI by commercial affiliations, as evidenced by the HON, DISCERN,
and JAMA benchmarks scores. While these differences in quality scores did not always reach statistical significance (possibly due to the relatively small sample size), they indicate a consistent trend among commercial affiliations across all the quality tools used.

Of the WBHI we reviewed, the authority and attribution were the least fulfilled JAMA domains—that is, resources rarely mentioned the authors and the references of the WBHI. This was in line with previous studies on Arabic WBHI on oral cancer, periodontal diseases, and epilepsy [13,34]. This highlights an area of potential improvement as the authority of the author (ie, the level of expertise of the person writing the information) was found to increase the credibility and trust in the content of the WBHI [35]. Moreover, other evidence from an Arabic-speaking country showed that participants prioritized information provided by health care professionals over other sources [9]. Our findings, along with conclusions from other Arabic WBHI, are useful for developers of WBHI resources to promote transparency when creating web-based content to maximize the benefit of WBHI to the public.

Enhancing the content and quality of Arabic WBHI is pivotal in optimizing its effectiveness and influence on patients’ well-being. For example, research reported that 49% of the participants in a US-based national survey used WBHI as a first resource to address health concerns [36]. Another study from Saudi Arabia reported that the patients who sought diabetes mellitus–related WBHI, compared to nonseekers, were more health conscious and showed a positive trend of better self-care [8]. Three critical issues must be highlighted when we combine evidence from this study with conclusions from similar research on Arabic WBHI. First, the quality of available resources in Arabic is moderate at best, leaving the public at a disadvantage as most of the evidence is deemed low-quality. Second, developers and providers of WBHI of digital health content must invest in the quality of WBHI in Arabic to empower the public [37]. This could be accomplished by benchmarking the finalized content against the quality tools frequently used in the relevant literature to build more robust, impactful WBHI. Third, it is imperative to establish policies and guidelines that guarantee the quality of Arabic WBHI that are produced, disseminated, or promoted for the benefit of the public.

Acknowledgments

Authors’ Contributions
AFA conceptualized the study. AA and HA acquired and curated the data. LAA performed the data analysis. AA, HA, and AFA wrote the initial draft. LAA and AFA edited and critically reviewed the draft. All authors have reviewed and agreed to publish the final version of this manuscript.

Strengths and Limitations
This study reviewed the content of three major search engines, potentially covering the majority of OLP-related WBHI that the public could find, access, and use. Additionally, we used validated and standardized tools to evaluate the quality and content of OLP health information on the web, enhancing the comparability with research elsewhere. However, this study could not assess Arabic readability due to some challenges related to the available tools and our belief that readability in Arabic is context specific and best explored through research that uses community participatory methods (ie, focus groups). Future efforts should strive to include the readability of the Arabic WBHI from both the providers’ and the consumers’ perspectives. Lastly, the WBHI we evaluated included published web pages up to mid-2020, coinciding with the height of the COVID-19 pandemic. The COVID-19 pandemic increased the demand for digital resources in general, which might have positively affected the quality of WBHI in general in response to the increased demand for web-based information. However, given the comparison of our results to other recent evidence on Arabic WBHI post COVID-19 [14,34,38], we assume that the Arabic WBHI content did not experience a change of a magnitude large enough to substantially alter our conclusions regarding the quality of Arabic WBHI related to OLP available to the public.

Conclusion
This study evaluated the quality of Arabic WBHI on OLP available to the public, using several validated and standardized tools, namely, JAMA, DISCERN, and HON. The results indicated that the quality of the WBHI is moderate at best, with only 1 in 7 resources scoring simultaneously high on all three resources. Commercial affiliations of the WBHI provided more content than academic affiliations; however, the content delivered by the former was of lower quality. Therefore, the collaboration between commercial and academic WBHI providers could improve the quality of the OLP resources offered to the public. Lastly, providers of WBHI in Arabic could benefit from integrating guidance from international quality tools to enhance the quality and, hopefully, the utility of these valuable WBHI resources.

Abstract

This study demonstrates that changes in mindfulness predict subsequent changes in well-being in a data set including individuals who recently engaged in psychedelic use. (JMIR Form Res 2024;8:e54632) doi:10.2196/54632

KEYWORDS
psychedelics; mindfulness; observational; web-based survey; psychedelic; meditation; mental health; anxiety; depression; survey; surveys; drug; drugs; substance use; hallucinogen; hallucinogens

Introduction

Psychedelics have been linked to improvements in depression, anxiety, and overall well-being in clinical trials and cross-sectional research [1-3]. Psychedelic use has also been linked to improvements in mindfulness [4,5], leading researchers to hypothesize that the link between psychedelic use and improvements in well-being may be driven in part by increased mindfulness [4,6,7]. Yet, there is a dearth of studies that directly explore this research domain.

This study uses a prospective data set of individuals who recently used psychedelics to examine, a priori, whether changes in mindfulness are linked to subsequent improvements in well-being, depression, and anxiety. Additionally, this study builds upon and addresses the core limitations of Mans et al [8], which found that psychedelic use was linked to improvements in mindfulness and well-being in the aforementioned data set. As Mans et al [8] did not control for major demographic and substance use confounds, include anxiety as an outcome in the analyses, nor assess how changes in mindfulness may potentially drive subsequent improvements in mental health, we aim to address these critical limitations within this study.

Methods

Overview

This study includes data that were collected in 2017 through a web-based platform called “Psychedelic Survey.” Haijen et al [9] provide further details on the data collection.

We used linear regression to assess whether changes in mindfulness from time 1 (baseline) to time 4 (2 weeks post psychedelic experience) were associated with changes in overall well-being, depression, and anxiety from time 1 to time 5 (4 weeks post psychedelic experience). We controlled for key demographic and substance use variables including age, gender, education level, and prior classic psychedelic use.

We used the Cognitive and Affective Mindfulness Scale–Revised to measure mindfulness, the Warwick-Edinburgh Mental Wellbeing Scale to measure overall well-being, the Quick Inventory of Depressive Symptomatology to measure depression, and the State-Trait Anxiety Inventory–6 (STA16) to measure anxiety. As the STA16 is commonly used to measure state (ie, momentary) anxiety, the scale was adapted to measure trait (ie, persisting) anxiety; these adaptations are included in Multimedia Appendix 1.
**Ethical Considerations**

The study was approved by the Joint Research Compliance Office and the Imperial College Research Ethics Committee (ICREC reference 18IC4346). Participant data is anonymous, and participants were not compensated for their responses. All participants provided informed consent before participation.

**Results**

Table 1 presents the demographics of our participants. Table 2 presents the results of our regression models. Changes in mindfulness (T1→T4) were associated with changes in overall well-being, depression, and anxiety (T1→T5). $R^2$ values ranged from 0.19 to 0.35, indicating moderate to strong effect sizes for our models. Multimedia Appendix 1 includes supplementary robustness analyses that assess the inverse relationship between well-being and mindfulness (ie, are changes in well-being from T1→T4 associated with changes in mindfulness from T1→T5?). Although these associations were significant, $R^2$ values for these models were lower than those for our main models assessing the relationship between mindfulness changes (T1→T4) and well-being changes (T1→T5; $R^2$ range 0.11-0.17). Thus, these additional results offer further evidence supporting the notion that mindfulness changes drove well-being changes in this study.

Discussion

Using a sample of individuals who recently used psychedelics, this study demonstrated that changes in mindfulness (T1→T4) were significantly associated with subsequent changes in mental well-being (T1→T5) [8]. Furthermore, models assessing the inverse associations between well-being and mindfulness (ie, assessing whether changes in well-being [T1→T4] predicted subsequent changes in mindfulness [T1→T5]) were weaker, strengthening the possibility that mindfulness drove improvements in well-being in this study.

Hill’s criteria for causation provide guidelines for evaluating the causal power of our results [10]. This study fulfills 7 of the 9 criteria: adequate strength of association, consistency with prior findings, specificity, plausibility, coherence (ie, biological plausibility), analogy (ie, comparability to related phenomena), and temporality (ie, the cause occurring before the effect). Additional research is needed to address the remaining criteria: biological gradient (ie, dose-response) and experimental evidence.

Limitations include the lack of a control group and the likelihood of bidirectional influence between changes in well-being and changes in mindfulness, both of which limit our ability to make definitive causal claims within this study. Another core limitation is our inability to control for important demographic factors in this study (eg, race/ethnicity, income, marital status). Future longitudinal studies and randomized trials can address these limitations. Overall, this study provides preliminary evidence that mindfulness may be a potential driver of the link between psychedelic use and salutary mental health outcomes.

Abstract

We addressed the limitations of subjective clinical tremor assessment by comparing routine neurological evaluation with a Tremor Occurrence Score derived from smartwatch sensor data, among 142 participants with Parkinson disease and 77 healthy controls. Our findings highlight the potential of smartwatches for automated tremor detection as a valuable addition to conventional assessments, applicable in both clinical and home settings.

(JMIR Form Res 2024;8:e51249) doi:10.2196/51249

KEYWORDS
Parkinson disease; tremor; smart wearables; smartwatch; mobile apps; movement disorders; tremor documentation; tremor occurrence; tremor score

Introduction

Clinical assessment of tremor is limited by its subjectivity, making it challenging to detect subtle tremors (<0.05 g) [1]. The need for technology-based evaluations led to extensive research on sensor-based tremor assessments [2-6]. However, the benefits of smart consumer devices for clinical documentation remain unaddressed. We aimed to bridge this research gap by comparing tremor documentation from routine neurological assessments with a Tremor Occurrence Score (TOS) derived from smartwatch sensor recordings. We included 142 participants with Parkinson disease (PD) and 77 healthy controls. During clinical visits, routine neurological assessments were conducted and wrist-motion data were captured using a previously established Smart Device System (SDS) in a controlled setting [1,7]. The SDS is based on consumer smartwatches and smartphones. The smartwatches were validated in a geophysical experiment for tremor analysis with comparison to a gold-standard seismometer [1]. We investigated the potential of complementing routine tremor documentation with tremor capture using smartwatches [8].

Methods

Overview
The SDS parent study [1] recruited 450 participants, including patients with PD and other movement disorders and healthy controls. The SDS implemented data capture through electronic questionnaires and app-guided movement tasks with smartwatch sensing. Varghese et al [7] provide a detailed description of the study. Of the 450 participants, 101 were excluded due to diagnoses other than PD. Moreover, 130 patients with PD without explicit information regarding tremor in routine documentation were excluded, resulting in 219 participants. Table 1 summarizes the age, sex, and years from diagnosis onset distribution.

aPD: Parkinson disease.
bHC: healthy control.
cN/A: not applicable.

Patients with PD were labeled as either (1) **TremorDocumented**: tremor was documented in routine documentation, regardless of type or amplitude (78/142, 54.9%), or (2) **NoTremorDocumented**: no information regarding tremor in routine documentation (64/142, 45.1%). We compared the routine tremor documentation to a Tremor Occurrence Score (TOS) from smartwatch recordings of a 20-second task, during which participants remained seated in an armchair. The TOS is normalized, from 0=no tremor occurrence to 1=tremor occurrence with a clear frequency peak, with 0.5 representing the average TOS of healthy controls. Details on calculations can be found in Multimedia Appendix 1 [9,10].

**Ethical Considerations**

The SDS parent study has been registered (ClinicalTrials.gov NCT03638479) and approved by the ethical board of the University of Münster and the physician’s chamber of Westphalia-Lippe (reference 2018-328-f-S). All participants gave written informed consent, and data were pseudonymized.

**Results**

Figure 1 shows boxplots of the TOSs according to participants’ routine tremor documentation. Overall, 16 (25%) out of 64 patients in the **NoTremorDocumented** group had a TOS ≥0.75 (the median TOS in the **TremorDocumented** group) and an average amplitude of 0.07 g. Particularly, 10 (16%) patients in the **NoTremorDocumented** group had a clear tremor (TOS >0.88, amplitude >0.10 g). The **TremorDocumented** group had a TOS ≥0.75 and an average amplitude of 0.11 g. Overall, patients with a clear but low-amplitude tremor (TOS ≥0.75, amplitude <0.05 g) were 1.59 times less likely to have a documented tremor (**NoTremorDocumented**) than those with a nonsubtle tremor (TOS ≥0.75, amplitude >0.05 g).
Figure 1. Boxplots of Tremor Occurrence Scores (TOSs) for all participants grouped by their routine tremor documentation. Each data point represents a participant of the respective group. Points are colored according to the average wrist amplitude in grams. The middle line is the median. The top and bottom sections are upper and lower quartiles, respectively. The box represents the middle 50% of TOSs for the group. The upper and lower whiskers represent scores outside the middle 50%. PD: Parkinson disease.

Discussion

Smartwatches can capture clear tremors in certain patients with PD, wherein the tremor was not documented during routine neurological assessments. Generally, patients with a clear but low-amplitude tremor (<0.05 g) were 1.59 times less likely to have a documented tremor than those with a strong tremor. We hypothesize that the tremor may not have been documented during the examination because of its small amplitude and difficulty of being seen. Moreover, a few patients (10/64, 16%) in the NoTremorDocumented group showed a clear tremor with visible amplitudes (>0.10 g), possibly due to the tremor being unnoticed or absent during routine examination. Likewise, tremors may not always manifest during smartwatch-based data capture, ultimately affecting the findings’ reproducibility.

Nevertheless, we suggest that integrating smartwatch-based data capture into routine neurological assessments enhances tremor documentation by providing objective numbers on frequency and amplitude for biomarker analysis. Smartwatch integration would further enable improved longitudinal assessment at home. The findings are not suitable for assessing the potential of diagnostic improvements, as routine manual documentation was only compared to smartwatch-based data capture. The parent study is currently evaluating a larger patient cohort, including differential diagnosis, to evaluate the diagnostic accuracy by using machine learning and more detailed tremor features, other movement characteristics, and nonmotor symptoms [1].

Abstract

Background: Digital phenotyping has seen a broad increase in application across clinical research; however, little research has implemented passive assessment approaches for suicide risk detection. There is a significant potential for a novel form of digital phenotyping, termed screenomics, which captures smartphone activity via screenshots.

Objective: This paper focuses on a comprehensive case review of 2 participants who reported past 1-month active suicidal ideation, detailing their passive (ie, obtained via screenomics screenshot capture) and active (ie, obtained via ecological momentary assessment [EMA]) risk profiles that culminated in suicidal crises and subsequent psychiatric hospitalizations. Through this analysis, we shed light on the timescale of risk processes as they unfold before hospitalization, as well as introduce the novel application of screenomics within the field of suicide research.

Methods: To underscore the potential benefits of screenomics in comprehending suicide risk, the analysis concentrates on a specific type of data gleaned from screenshots—text—captured prior to hospitalization, alongside self-reported EMA responses. Following a comprehensive baseline assessment, participants completed an intensive time sampling period. During this period, screenshots were collected every 5 seconds while one’s phone was in use for 35 days, and EMA data were collected 6 times a day for 28 days. In our analysis, we focus on the following: suicide-related content (obtained via screenshots and EMA), risk factors theoretically and empirically relevant to suicide risk (obtained via screenshots and EMA), and social content (obtained via screenshots).

Results: Our analysis revealed several key findings. First, there was a notable decrease in EMA compliance during suicidal crises, with both participants completing fewer EMAs in the days prior to hospitalization. This contrasted with an overall increase in phone usage leading up to hospitalization, which was particularly marked by heightened social use. Screenomics also captured prominent precipitating factors in each instance of suicidal crisis that were not well detected via self-report, specifically physical pain and loneliness.

Conclusions: Our preliminary findings underscore the potential of passively collected data in understanding and predicting suicidal crises. The vast number of screenshots from each participant offers a granular look into their daily digital interactions, shedding light on novel risks not captured via self-report alone. When combined with EMA assessments, screenomics provides a more comprehensive view of an individual’s psychological processes in the time leading up to a suicidal crisis.

(JMIR Form Res 2024;8:e55999) doi:10.2196/55999
Introduction

Background

In 2021, a total of 48,183 Americans died by suicide, with rates rising in the United States up to 2019 [1] and early indications of a continuing trend into 2022 [2]. While the number of suicides continues to increase, our ability to predict suicidal thoughts and behaviors (STBs) remains stagnant [3], underscoring the potential benefits of shifting focus from identifying who is at risk to when individuals are at risk for suicide. Studies using ecological momentary assessment (EMA) to collect data multiple times per day have demonstrated that key suicide risk factors, including suicidal ideation, change rapidly across the course of the day [4]. However, this research has been limited by the temporal granularity of assessments (ie, every 3-4 hours). It has yet to pay due attention to prospectively predicting suicidal behaviors (ie, suicidal planning and suicide attempts) [5]. Notably, the transition from contemplating suicide to deciding to act on such thoughts can transpire in as little as 10 minutes [6,7], making this decision-making process an ideal candidate for study in temporally intensive designs.

Intensive time sampling studies that use EMA have been shown to capture suicide risk processes effectively [8]; however, these methodologies carry a high participant burden, with the expectation that participants are willing and able to actively report on their experiences consistently throughout and across several days, including during times of distress. This contributes to the high rates of missing data within EMA designs, with compliance rates often around 60% in clinical populations [8]. Despite these limitations, asking self-report items at an intensive time scale has shed light on the dynamic nature of STB [4], with recent work becoming increasingly granular, prompting assessments every 10 minutes for an hour [9]. Furthermore, EMA research has also shed more light on the dynamic influence (both concurrent and prospective) of theoretically identified constructs [10], with a prominent focus on theoretically relevant risk factors, such as thwarted belongingness and perceived burdensomeness [11].

In contrast to active assessment approaches, the reliable detection of experiences within a relatively short window (eg, minutes) can be enhanced by technologically innovative methodologies that can passively and continuously capture the dynamic nature of factors contributing to suicide risk. This has provided, in part, the foundation for the surge in applications of passive sensing—including digital phenotyping [12]—in clinical research. Digital phenotyping is the use of data from smartphones and other personal digital devices to measure behaviors, cognitive functions, mood, and other psychological variables [13,14]. By collecting and analyzing data such as keystrokes, voice patterns, geolocation, social media activity, and other digital traces, digital phenotyping offers a real-time, high-resolution, yet low burden, approach to understanding and monitoring clinical phenomena.

Digital phenotyping has seen an increase in application across clinical research broadly, with the term being previously applied to suicide risk profiles based on active assessments (ie, EMA) [15]. However, little research has specifically targeted passive assessment approaches to suicide risk detection, with existing findings being mixed concerning its predictive validity. For example, in a recent study, Czyz et al [16] found that sensor-based assessments (resting heart rate, heart rate variability, step count, and sleep duration) did not add incremental validity to the prediction of near-term suicidal thoughts above and beyond EMA self-report questions among high-risk adolescents. Alternatively, it was demonstrated that psychological monitoring of electrodermal activity did improve fit upon EMA-only models in the prediction of suicidal ideation severity [17]. The limited work in this realm leaves open the possible use of passive assessment in better understanding suicide risk.

One of the most recently available methods in performing digital phenotyping is screenomics [18,19], wherein participants passively provide temporally intensive records of their psychological and social life as it manifests on the screens of their digital devices [19]. In this case, screenomes, or the record of experiences on digital devices with screens [19], are captured via software that takes screenshots of an individual’s smartphone screens every 5 seconds when the device is in use. Initial work using screenomics has described the timing and patterns of smartphone usage by extracting various textual and graphical features from screenomes, allowing for a mapping of app use and topic of content viewed [20], among other key use features such as the emotion valence of content viewed [21]. More recently, screenomes have informed the examination of digital communications, including differentiation between produced (ie, actively producing smartphone content) and consumed (ie, passive consumption) communication content [22], as well as the communication dynamics within relationships [23].

This Study

Following the possibility of using screenomes to learn about individuals’ emotional experiences and interpersonal dynamics, this study is the first, to our knowledge, to engage screenomics with a clinical population and, more specifically, for the study of suicide risk. This paper focuses on a comprehensive case review of 2 participants, detailing their passive (ie, obtained via screenomics screenshot capture) and active (ie, obtained via EMA) risk profiles that culminated in suicidal crises and subsequent psychiatric hospitalization. In our approach, we intentionally focused on building a qualitative, rather than quantitative, understanding of the data, purposely eschewing statistical modeling to capture the nuanced individual experiences and complexities inherent in suicide risk. Further, we iteratively followed inductive and deductive approaches.
[24,25] in deciding which variables to define (in passively collected data) and focus on (in actively collected data). Through this analysis, we shed light on the timescale of risk processes as they unfold prior to hospitalization, as well as introduce the novel application of screenomics within the field of suicide research. To underscore the potential benefits of this method in comprehending suicide risk, we concentrate on a specific type of data gleaned from screenshots—text—captured prior to hospitalization, alongside self-reported EMA responses.

**Methods**

**Overview**

This case review focuses on 2 participants who had suicidal crises and subsequent psychiatric inpatient treatment, coincident with their participation in an intensive time-sampling study that included both active and passive assessment approaches. To participate in the larger study, participants were required to have an Android smartphone, daily access to the internet (via Wi-Fi or cellular data), a past 1-month history of active suicidal ideation, and no history of being diagnosed with schizophrenia. Participants completed a baseline assessment, 28 days of active assessments obtained via signal-contingent EMA prompts, and 35 days of passive assessments obtained via screenshot collection. Participants were randomly assigned to 2 protocols where they provided the additional 7 days of passive screenshot collection (with no EMA prompts) in the week prior to the 28-day EMA+screenshot collection period (person A) or the week following the 28-day EMA+screenshot collection period (person B). For the 2 participants included in this study, data collection occurred before, during, and after an acute crisis and hospitalization spanning 38 (person A) and 51 (person B) days, respectively. A general overview of the data collected and how the screenshots were processed is depicted in Figure 1.

**Ethical Considerations**

All procedures were approved by the institutional review board of the University of Notre Dame (protocol number 21-12-6965). Prior to engaging in any study procedures, participants were provided a full description of the study and the opportunity to ask questions, including speaking with study principal investigators (BA and RJ) or the institutional review board if any concerns were expressed. All participants provided written informed consent. They were compensated up to US $215 for participation (ie, US $40 for baseline assessment, US $100 for a 28-day EMA period, US $20 for completing at least 75% of EMA surveys, and US $55 for a 35-day screenomics period). Self-reported data from this study are deidentified; screenshot data are coded with layered IDs, encrypted upon storage upload, processed to remove potentially identifying information (ie, names and addresses), and accessible only to core study team members.

**Active Assessment**

**Overview**

Across the 28 days, participants received 6 prompts each day to complete a short survey on their smartphone (ie, signal-contingent design); prompts were delivered randomly within 2-hour windows across a 12-hour participant-selected block (eg, 9 AM to 9 PM). When participants received a prompt, they had 30 minutes (with one 15-minute reminder) to complete the short survey (expected to take <3-4 minutes). The EMA protocol was administered via the LifeData software on participants’ smartphones. To improve compliance and data quality, participants completed a “practice” EMA signal-contingent prompt during the baseline session and were incentivized for completing ≥75% of EMA signal-contingent responses (determined every week); EMA compliance was calculated based on the number of prompts received versus the number of prompts completed. We identified “high” scores for

---

*Figure 1.* General overview of the study design. EMA: ecological momentary assessment; OCR: optical character recognition.
each variable depicted below by calculating whether an individual score was at or above the 90th percentile based on the person-specific empirical distribution.

Risk Factors
For this paper, we primarily focus on 2 key risk factors related to suicide: thwarted belongingness and perceived burdensomeness, as explained in the Interpersonal Psychological Theory of Suicide [26]. However, we also examined other important risk factors supported by prior research, including positive and negative emotions, urges, and behaviors related to nonsuicidal self-injury, alcohol and drug use urges, interpersonal conflict, self-reported sleep patterns, and physical pain [10]. The majority of these items were answered on a 5-point Likert scale, except interpersonal conflict, self-injurious and alcohol use behaviors, and nightmares, which were binary. Further, assessments of pain were reported on a 0-100 scale. Multimedia Appendix 1 [27,28] shows details for EMA questions to access risk factors.

Suicide Risk

Suicidal Ideation
Four questions assessed momentary (ie, “In this moment…”) passive (ie, “Life is not worth living for me”; “There are more reasons to die than to live”) and active (ie, “I want to die”; “I think about taking my life”) suicidal ideation, all items were answered on a 5-point Likert scale. Based on prior work by the study team, which showed that the 4 items form 1 factor (rather than 2 factors) [11], the item responses were summed to obtain a composite momentary suicidal ideation score.

Suicidal Planning
Three items assessed suicidal planning since the last prompt (ie, “Considered a specific suicide method”; “Identified how to acquire your suicide method”; “Made other preparations for your death”); these items were summed to create a composite suicidal planning score. All items were answered on a 5-point Likert scale.

Suicidal Desire
Two questions assessed momentary suicidal urges (ie, “How strong is your urge to make a suicide attempt?”; “How intense is your desire to kill yourself?”); items were answered on a 5-point Likert scale. These items were summed to create a composite suicidal desire score.

Passive Assessment

Overview
Continuous smartphone data collection was collected via the ScreenLife Capture [29] app, which is tailored for integration with HIPAA (Health Insurance Portability and Accountability Act of 1996)-compliant servers at the University of Notre Dame. This software passively captures screenshots of participants’ Android smartphone screens at 5-s intervals during smartphone use and stores the screenshots locally on the smartphone before bundling, encrypting, and transmitting them to research servers at intervals that accommodate bandwidth and device memory constraints. The screenshots are obtained continuously as the participant uses their smartphone in everyday life without requiring active engagement from the participant. In postprocessing, the screenshots’ content features are extracted using various image processing tools. In postprocessing, the text from each screenshot was extracted using EasyOCR, an open-source optical character recognition tool for Python, known for its efficiency in processing images containing text, even under less than perfect clarity or with intricate layouts. Optical character recognition technology converts various document types, such as scanned paper documents, PDF files, or images taken by a digital camera, into editable and searchable data. We removed any text extracted with a confidence value of less than 0.70. The text was then normalized by lemmatization, case reduction, and removal of punctuation and numbers and examined using a variety of dictionaries.

Risk Factor–Related Content

Linguistic Inquiry and Word Count
The first dictionary-based method that we tested is the linguistic inquiry and word count (LIWC) [30], which is implemented as a commercially available software program [31]. LIWC analyzes text according to a dictionary comprised of 6400 words, word stems, and emoticons, primarily related to psychological processes (eg, affective and social processes) [31]. The output contains scores on 90 dictionary components and linguistic or grammar dimensions of their data. For this paper, we only extracted components that we thought could be related to psychological processes or risk factors for suicide (eg, substances). Multimedia Appendix 2 [31] shows an overview of LIWC components. To display the scores, we opted to depict a ratio (score for each day/total) score for each instead of the absolute number of mentions for each category.

Topic-Specific Dictionaries
Since the specific words in the LIWC components are proprietary, we also created our own dictionary of common words likely associated with these components, particularly those crucial for understanding the suicide risk process. For example, we created a substances dictionary. Multimedia Appendix 3 contains words used in specific dictionaries.

Social Content
We identified which smartphone app was in use through the text portrayed when an app was in use. After examining participants’ screens to identify phone-specific app displays, we used the following words to identify text messaging (SMS): “text message,” “sms,” and “text,” while the following text for Meta: “write a comment,” “what’s on your mind,” “like,” “facebook,” and “Instagram.” We acknowledge that this dictionary will not perfectly distinguish between each app and similar apps, with a more robust method needed when extrapolating beyond these 2 individuals. Additionally, we used external data to train a model to identify whether the screenshot contained indicators of using a social app. We used the Rico data set [32], a repository of 66,261 screen images from Android operating systems. Each screenshot in Rico captures a momentary snapshot of a mobile app’s user interface. For our purposes, one of the crowdsourced annotations is “Is_Social” (4172 positive cases), which classifies whether or not a screen contains social media elements or functionalities. From this,
we randomly split the images into an 80/20 train-test split and fine-tuned ResNet18, which is a variant of the Residual Network family, a type of convolutional neural network architecture. The model was trained for 50 epochs, choosing a final model based on the test set area under the curve score, which was maximized at 0.89. We applied this model to each person’s screenshots, aggregating the predicted probabilities by day.

**Suicide Language**

We defined our dictionary to derive scores specific to suicide-related words (ie, “kill myself” and “end it all”) and a separate dictionary based on theoretically linked risk factors (ie, “trapped” and “crying”). These dictionaries were created through literature review and expert consultation. Multimedia Appendix 3 contains words used in specific dictionaries. Finally, we used the dictionary, termed crisis, which was developed by screening crisis chat messages [33]; this dictionary contains 227 words, ranging from specific states regarding suicidality (ie, “hurt myself” and “I just want this all to end”), suicide-related emotion states (ie, “hate my life” and “hopeless”), and potential suicidal behavior–related words (ie, “drown” and “rope”). To clean the text, we first removed screens that contained EMA prompts, namely, to avoid capturing suicide words that were used as a part of the EMA assessments.

**Results**

**Case Overview**

**Person: A**

**Overview**

Person A was a 37-year-old, straight, White, non-Hispanic individual born female and identifies as a woman. They reported being single, employed full-time, and with an annual household income of US $30,000–US $39,000. This participant’s diagnostic assessment revealed they met the diagnostic criteria for current major depressive disorder, panic disorder, agoraphobia, generalized anxiety disorder, posttraumatic stress disorder, and cannabis use disorder. They reported having engaged in prior individual counseling, as well as spiritual counseling, and that they were currently taking medication for psychiatric and medical reasons, including heart problems and epilepsy. Concerning suicide risk history, they reported chronic suicidal ideation, beginning at age 10 years and attempting suicide on 5 occasions, with the first attempt at age 11 years and the most recent 2 attempts in the year before study enrollment (1 in a month prior). In the week prior to enrolling in the study, they reported thinking about suicide 14 times and denied any suicidal planning.

**Provision of Active and Passive Data**

Person A responded to EMA prompts on 25 days; on these days, they, on average, only completed 4.04 prompts (SD 1.70), resulting in compliance of 60.1% (101 completed prompts out of 168 total prompts) or 67.3% counting only the days in which they responded at least once. They provided 139,276 screenshots. An average day involved 5.92 (SD 2.75) hours of screenshot data collection.

**Person B**

**Overview**

Person B was a 29-year-old, White, non-Hispanic individual who was born female and has a nonbinary gender identity; they reported questioning their sexual identity at the time of baseline assessment. They reported being employed full-time, living with a partner, and having an annual household income of US $40,000–US $49,000. This participant’s diagnostic assessment revealed they met current diagnostic criteria for bipolar I, as well as current panic disorder, social anxiety disorder, and substance use disorders (cannabis, amphetamine, and cocaine). They reported having previously engaged in several forms of outpatient treatment (ie, individual counseling, group counseling, couples counseling, and day treatment) and currently taking medication for medical and psychiatric reasons. Stated medical concerns included heart and respiratory problems. Concerning suicide risk history, person B reported chronic suicidal ideation, experiencing suicidal thoughts on 95% of days, beginning at the age of 7 years. They also reported having attempted suicide on 4 occasions, with the first being at the age of 13 years, and the most recent 5 years prior to study involvement. In the week prior to enrolling in the study, they reported thinking about suicide 7 times and planning for suicide 3 times.

**Provision of Active and Passive Data**

Person B completed EMA surveys on 23 days, responding to, on average, 2.7 (out of 6; SD 1.63) prompts per day, resulting in a compliance of 37.5% (63 completed prompts out of 168 total prompts) or 45.6% counting only the days in which they responded at least once. Participant B provided 58,098 screenshots. An average day involved 3.59 (SD 2.74) hours of screenshot data collection.

**Comprehensive Suicide Risk Assessments**

To ensure participant safety, EMA responses that indicated elevations in imminent suicide risk triggered comprehensive risk assessments by study staff. Information obtained during these calls is not presented among active assessment results but rather provided in the Results section to provide a more in-depth contextual understanding of each detailed participant. During study enrollment, person A’s responses resulted in a comprehensive suicide risk assessment 9 times. Through these calls, person A expressed feelings of being overwhelmed and hopeless; they also expressed difficulties with having limited social support. They engaged in means restriction pertaining to their most recent suicide attempt method. Suicidal ideation was reported on these calls; however, the participant denied suicidal planning or intent. Day 26 in the study was the last time person A’s responses triggered a suicide risk assessment (study staff unable to reach them after 3 attempts) prior to their choice for hospitalization; however, on day 29 of participation, the participant reported self-admitting for psychiatric hospitalization due to concerns of being unable to keep themself safe in the context of their suicidal thinking, and study staff spoke with them after they were on the way to the hospital due to EMA responses triggering a suicide risk assessment. They were hospitalized on days 29–32 of study participation.
Comprehensive Suicide Risk Assessments

During study enrollment, person B’s responses to the suicide-specific EMA questions triggered the study risk assessment protocol 8 times. During these calls, the participant expressed their suicidality was prompted by a panic attack, as well as interpersonal conflict that was impacting their housing stability. Suicidal ideation and suicidal planning were expressed in multiple calls; however, intent to act on these plans was low, and confidence in keeping themselves safe was high. They reported the use of several coping strategies, such as connecting with their care provider (resulting in adjustments to their psychiatric medication), means restriction, reviewing reasons for living, future planning, listening to music, sitting with their emotions, and deep breathing. However, on day 18 of participation, the participant attempted suicide and subsequently received inpatient psychiatric treatment from days 18 to 22; person B emailed the study staff to notify them of hospitalization after discharge (ie, day 22).

Comparative Analysis

In the following sections, we describe each person’s active assessment and passive assessment risk profiles surrounding their suicidal crises and subsequent hospital admission. The vertical red line in the visualizations represents the first day of each person’s hospitalization.

General Use Patterns

Active Assessment Compliance

For both individuals, we can see that EMA compliance was lowest surrounding their hospitalization. Particularly for person A (Figure 2), we see a decline in compliance with the active assessment protocol leading up to hospitalization, with a more precipitous decline for person B (Figure 3). For person A, the nonprovision of active assessments presents several problems for assessing suicide risk via EMA, as it suggests that some individuals may be less likely to respond to research survey prompts during periods when they are at the highest risk.

Figure 2. Person A: ecological momentary assessment compliance across the study. The vertical red line denotes the first day of hospitalization.

Figure 3. Person B: ecological momentary assessment compliance across the study. The vertical red line denotes the first day of hospitalization.
Phone Use

We see a different picture regarding phone use leading up to hospitalization, as depicted in Figures 4 and 5. While the number of passively collected screenshots stays relatively consistent leading up to the hospitalization for person A (Figure 4), we see an increase in phone use for person B (Figure 5) the day prior.

Phone use leading up to hospitalization can be further decomposed to look at the timing of when screenshots were collected within a given day; see Figures 6 and 7, where a horizontal red line denotes 50% phone use (ie, 30 minutes=360 five-second intervals) for that hour. For person A (Figure 6), we can see relatively consistent phone use during specific times of the day, along with periods in which their phone is not in use. Most days include at least 1 hour in which they were intensively using their phone (>50% time spent on the phone). In contrast, person B (Figure 7) was more variable in their phone use—some days included periods of intense use, while on others, phone use was sparse. Notably, neither person A nor B’s screenshot patterns indicate a consistent use pattern. The above phone use patterns do not suggest poor sleeping habits as revealed by periods of nonuse; however, we further examine this by considering phone use across hours of the day, aggregated across days. We calculated the percentage of each hour, on average, that each person used their phone (Figure 8: the horizontal red line represents 50% [ie, 30 minutes] average use for that hour). On average, neither person approaches using their phone 50% of the time. As mentioned earlier, person B (Figure 8: right) uses their phone less than person A (Figure 8: left). However, we see similar trends across individuals, with increasing phone use across the day. Notably, we also see some degree of either variable sleep schedules or sleep schedules being interrupted by phone use, as there are few hours of the day with no phone use for either person.

Figure 4. Person A: number of screenshots by day in study. The vertical red line denotes the first day of hospitalization.
Figure 5. Person B: number of screenshots by day in study. The vertical red line denotes the first day of hospitalization.

Figure 6. Person A: screenshot count across days and hours of each day. The horizontal red line depicts 50% phone use for that hour.
Active Assessment

Risk Factors

Self-reported sleep indicators were assessed each morning. Subjective quality of sleep (sleep quality: bottom panel) and the presence of nightmares (top panel: nightmares yes or no) are depicted in Figure 6 (person A: Figure 9 and person B: Figure 10).

Compliance was particularly low for this set of questions. However, there are clear trends for both. While person A had consistent nightmares leading up to the hospitalization, their sleep quality improved (5=very good night of sleep). This is in contrast to person B, where nightmares increased and sleep quality decreased prior to the hospitalization.

Of theoretically and empirically relevant variables that we assessed via EMA, we do not see any increasing trends in perceived burdensomeness, thwarted belongingness, negative affect, or positive affect in Figures 11 and 12 (notably, however, there are a few spikes in negative affect for person A immediately prior to hospitalization). Figures 11 and 12 depict the empirically supported risk factors that demonstrated change leading up to hospitalization. We can see that both individuals reported consistent interpersonal conflicts across the study. However, there were no clear increases leading up to the hospitalization. For person A (Figure 11), we do see a slight increase in urges to drink alcohol; however, when we look at the responses related to alcohol use, they only reported drinking alcohol on 2 days. Further, both individuals report consistent urges to use drugs, with person B exhibiting a slight increase.
in urges prior to hospitalization. Finally, person A reported moderate urges to self-injury, with reported self-injury engagement on 1 occasion. However, there is no clear pattern of changes in risk factors prior to hospitalization.

**Figure 9.** Person A: ecological momentary assessment sleep responses across days in the study. Nightmares (yes or no) in the top panel, subjective sleep quality in the bottom panel. The vertical red line denotes the first day of hospitalization.

![Graph showing sleep responses](image_url)

**Figure 10.** Person B: ecological momentary assessment sleep responses across days in the study. Nightmares (yes or no) in the top panel, subjective sleep quality in the bottom panel. The vertical red line denotes the first day of hospitalization.

![Graph showing sleep responses](image_url)
**Figure 11.** Person A: risk factor ecological momentary assessment responses across days in the study. The blue line is a loess curve, while the vertical red line denotes the first day of hospitalization.

**Figure 12.** Person B: risk factor ecological momentary assessment responses across days in the study. The blue line is a loess curve, while the vertical red line denotes the first day of hospitalization.

**Suicide Risk**

EMA responses related to suicidal ideation, planning, and desire for persons A and B are depicted in Figures 13 and 14, respectively; loess curves depict general trends, with red data points denoting higher relative values (ie, above the 90th percentile). For person A, we can see generally increasing trends for self-reported suicidal ideation and suicidal desire leading up to their hospitalization, with the highest reported values of suicidal ideation on the day of hospitalization. For person B, we can see elevated responses of self-reported suicidal ideation and planning leading up to their hospitalization. However, these elevations dissipate in the days immediately prior. As noted in Figures 2 and 3, we see lower response rates for surveys, including questions assessing suicidal ideation, planning, and desires in the days prior to hospitalization.
**Passive Assessment**

**Risk Factor–Related Content**

To assess passive assessment indicators of sleep, we attempted to link sleep and wake times, obtained via active assessment once per day, to screenshot collection timestamps. However, person A reported sleep and wake times on 16 days, while person B reported on 14 days. Given the small number of responses for each person (ie, approximately 50% missing data) and variability in their reported sleep and wake times, we did not feel confident calculating whether screenshots were collected during reported sleep times. Thus, we opted against reporting and visualizing this.

For person A (Figure 15), we see peaks in several components leading up to their hospitalization, potentially most evident for the death and conflict scores. Probing further into the screenshot content during this day, we found that person A spent most of the day watching the TV show with “murder” in the title, likely contributing to these peaks. We also see a clear peak in the substances score prior to hospitalization. We created a substance-specific dictionary to further examine this (Multimedia Appendix 3). In applying this dictionary, we identified the top 5 words, and plot their use across the time period in Figure 16. To contextualize these findings, we examined a random selection of 1000 screenshots from the day prior to hospitalization. From these screenshots, it is evident that person A was experiencing a high degree of pain; this was corroborated by active responses of self-reported daily physical pain: although there were only 15 responses, their mean response was 74.4 (SD 16.2). They also disclosed through a SMS text message that an over-the-counter painkiller was not enough,
and they could not get into a doctor to receive a prescription until the following month. Further, given the high identification of “weed” in screenshots the day prior to hospitalization, we extracted co-occurring text (i.e., text from screenshots where “weed” was identified), and it became evident that person A was viewing posts about the medicinal use of marijuana on Facebook.

For person B (Figure 17), we see a number of components peak in the day prior to hospitalization. To contextualize these findings, we examined a random selection of 1000 screenshots from the day prior to hospitalization. We saw that they spent a large amount of time on a dating app (increase in sexual score in Figure 17) and conversing with individuals from that app. Further, like person A, person B was struggling with physical pain (specifically, head pain) and spent considerable time looking at health care providers and trying to identify a diagnosis, thus explaining the spike in a number of LIWC categories (i.e., physical and health). Notably, they only completed 10 active responses of self-reported daily physical pain, making it hard to derive any conclusions from their average score of 26.8 (SD 23.5).

We further examined risk factor text content on the day prior to hospitalization, as presented in Figures 18 (person A) and 19 (person B). For person A, a number of spikes in several risk factors were seen during the evening, whereas for person B, similar spikes were seen earlier in the day.

**Figure 15.** Person A: Linguistic inquiry and word count scores across days in the study. Note that scores are displayed as a ratio, using the daily score divided by the sum of all time points. The vertical black line denotes the first day of hospitalization.

![Figure 15](image)

Figure 18. Person A: Linguistic inquiry and word count scores on the day before hospitalization.
Figure 19. Person B: Linguistic inquiry and word count scores on the day before hospitalization.

Social Content
Given the high amount of social contact for each person, we further examined changes in social behavior prior to hospitalization. Figure 20 shows the SMS text message and Meta (ie, Facebook, Instagram, and WhatsApp) use for person A. While the use of Meta apps does not show a clear change in the pattern of use relative to hospitalization, the use of text messaging peaks on the day of hospitalization. For person B (Figure 21), we see an increased use of Meta apps immediately prior to hospitalization, along with a slight increase in SMS text messaging in the days prior.

A similar conclusion can be drawn from the modeling of whether a screenshot contains social content in Figures 22 (person A) and 23 (person B). In examining a random sample of 1000 screenshots from the day of hospitalization, it appeared that person A was preparing for hospitalization by contacting friends to watch her dog and find a ride. Further, through disclosing her need for hospitalization, she was in frequent SMS text message conversations in which multiple individuals provided support for her decision. Alternatively, for person B, we see an increase in the use of social apps leading up to the day of hospitalization. However, on the day right before hospitalization, we do not see a large predicted total score of a number of screenshots containing social content.

Figure 20. Person A: SMS text message and Meta usage across days in the study. The vertical red line denotes the first day of hospitalization.
Suicide Language

In applying the suicide-specific dictionaries, for person A (Figure 24), we only see the clear spike related to viewing the TV show. This is unsurprising given the other information gleaned from this participant’s screenshots, as their hospitalization was often discussed relative to pain, rather than suicidal thoughts or behaviors. Similarly, for person B (Figure 25), we see more of a peak with respect to risk factors and crisis words as opposed to suicide-specific words.

We then examined the top 10 endorsed individual risk words in Figures 26 and 27. For person A (Figure 26), we unsurprisingly see a large spike in pain on the day prior to...
hospitalization. This is further seen in counting the word identification within the day prior to hospitalization (Figure 28). A peak in pain is followed by similar peaks in guilty and alone later in the day. Similar to person A, for person B (Figure 27), we see pain as peaking on the day before hospitalization, in addition to smaller, but noticeable peaks in anxiety, alone, and depression, as well as numb, in the few days prior. When examining the day prior to hospitalization (Figure 29), we see that the identification of pain primarily occurred earlier in the day, followed by smaller peaks in alone, depression, numb, and anxiety.

Discussion

The goal of this comparative case review was to detail risk profiles obtained from both actively and passively collected smartphone data in the days leading up to a suicidal crisis. Through this, we also aimed to introduce the novel application of screenomics in suicide research. Our preliminary findings underscore the potential of passively collected data in understanding and predicting suicidal crises. The vast number of screenshots from each participant offers a granular look into their daily digital interactions, which, when combined with EMA assessments, provides a more comprehensive view of an individual’s psychological processes in the time leading up to a suicidal crisis. While this variegated picture of each individual’s life, as captured through a phone, makes a clean summarization impossible, it is worth noting some of the common elements evidenced in the data.

The first was decreased EMA compliance leading up to one’s hospitalization, muddying our understanding of an individual’s risk state, including the presence of STB. Perhaps most notably, this highlights the potential downsides of relying solely on one’s ability and willingness to disclose their experiences in times of distress or crisis, having important implications for the prediction of, and intervention during, such risk states. We recognize this is conjecture based on the analysis of only 2 individuals and requires future research as, to our knowledge, this has not been previously assessed or tested in intensive longitudinal studies of STBs. However, if true, it has important consequences for the rising use of just-in-time interventions targeting suicide risk [34]. For example, relying on active (ie, EMA self-reported responses) may offer sufficient temporal granularity for intervening upon lower level risk states but may not be adequate for detecting crises given the burdensome design, particularly when in crises. Rather, as demonstrated in
our case examples, personalized phone use patterns might be a more reliable indicator of impending suicidal crisis than EMA-assessed suicidal ideation.

A second takeaway from our analysis is that screenomics captured the salient precipitating factors for each suicidal crisis, which were not detected via EMA, due to a variety of reasons (ie, nonresponse and ceiling effects). The first illustrative example is that of physical pain. Self-reports via EMA were able to capture the role of physical pain in suicide risk, to some extent, for person A, who responded to approximately 54% of daily questions about pain. However, for both person A and B, texts extracted from their screenshots were able to more fully portray the significant, and dynamic, nature of this experience leading up to one’s hospitalization. While we recognize this risk process may be specific to the individuals selected for inclusion in this report, an effect with similar implications was demonstrated for the theoretically relevant risk factor of thwarted belongingness. For example, EMA responses with regard to thwarted belongingness were elevated across the majority of the study period, preventing an observation of increases, or spikes, prior to hospitalization. Alternatively, for both person A and person B, we see that alone, a central aspect to the construct of thwarted belongingness (ie, “I am alone” [26]), represented one of the top 10 risk factors words used and also demonstrated a spike in use during the day immediately preceding hospitalization. Together, these examples underscore the potential of passive data collection, such as screenomics, to tap into risk processes that are not evident from, or demonstrated by, self-report assessments. Indeed, the low-burden nature of such passive assessment may allow for a more nuanced detection of a wide array of potential risk factors, lending to meaningful personalized risk detection.

Finally, and possibly the most surprising element was a general increase in phone use leading up to the hospitalization, including the increase in social use. It remains unclear as to whether this was a causal factor—that is, contributed to suicide risk—or was the result of seeking social support for their distress, making arrangements to be hospitalized (pet care or work), or other possible help-seeking behaviors, to cope with their escalating suicide risk. Further, the function of social phone use at or near times of suicidal crises may be person or situation specific (ie, idiographic). For example, person A appeared to be engaging in help-seeking behavior via SMS text message (eg, arranging rides) prior to hospitalization, while person B largely engaged in social and dating app usage, potentially contributing to acute interpersonal stressors. It will be useful to further develop our data processing pipeline to further explore the relationships between phone use, particularly social use, and suicide risk.

Of note, we purposely did not report any results from statistical models. While it is becoming more commonplace to apply linear models at the individual level [35], we opted against this. Our main focus for this comparative case report was on identifying risk patterns preceding hospitalization; the forgoing statistical models allowed us to explore a greater number of risk pathways in a more in-depth manner. Further, each participant had a limited number of assessments, with an increasing number of missed prompts leading up to the hospitalization (Figures 2 and 3), making the application of linear models difficult. Moreover, applying a longitudinal model to components derived from screenshots presents a number of challenges due to the high dimensionality, and uncertainty regarding forms of validity (eg, in naming components).

Within suicide research, and particularly intensive longitudinal research, ethical consideration of participant safety is a primary concern [36]. The incorporation of active assessments has the clear benefits of face validity to specific suicide questions (ie, “Are you planning to attempt suicide today?”), along with straightforward processing to derive risk score cutoffs that indicate required follow-up by study staff and the ability to readily access such data (ie, manually examining responses). As noted above, there are potential issues with relying on active assessment responses (ie, noncompliance [37,38]). However, the use of passively collected data (broadly defined) also presents a number of challenges for use in ascertaining risk. The first is the clear lack of published research on which data sources are valid markers of risk. Second, while some data points are easily calculated (ie, the number of screenshots and steps walked), others would require complex and expensive processing pipelines to process data in real time. For instance, in screenshots presented in this case study, this would require automatic decryption of uploaded images to a server that is integrated with a graphics processing unit (or central processing unit) architecture that can apply pretrained models to generate new data sources (eg, SMS text messages) or predictions (eg, suicide risk scores based on the text). Similarly, most smartwatches require manual syncing with software before data are uploaded to the cloud, thus precluding real-time analysis. Thus, a large degree of additional research is required before incorporating various types of passive assessment into real-time participant safety protocols.

A number of limitations to this paper should be mentioned. First, as this is the first comprehensive investigation of smartphone screenshot data to improve our understanding of suicide risk, aspects of our approach are preliminary in nature, including the use of specific (ie, suicide, risk factor, and substance) dictionaries. It will be important for further validation of these dictionaries prior to wide-scale applications. Our focus on studying 2 individuals with a complex case profile limits the generalizability of our findings across the wider spectrum of severity of suicidal ideation, planning, and behaviors. Consequently, our results may not fully represent the experiences of those at lower levels of suicide risk (ie, not experiencing a suicidal crisis). The findings may also not generalize to individuals at a similar risk level but do not consider psychiatric hospitalization as a treatment option. Further research with larger and more diverse samples is necessary to validate and extend our findings to a broader population. Finally, we only included one form of passive sensing, screenomics, while a number of other modalities, such as geo-location or watch-based assessments (ie, sleep, steps, and heart rate), have seen wide application in clinical research [39].

In conclusion, the primary aim of this paper was to provide an in-depth examination of both passive and active data modalities from 2 individuals who were hospitalized for suicidal crises. We hope this paper has introduced the value of collecting...
passive data, specifically screenshots, at an intensive timescale, as well as highlighting the potential of its ability to incrementally add to our understanding of suicide risk timescale and underlying processes.

Acknowledgments
This project was funded by the National Institute of Mental Health (1R21MH129688) awarded to BA and RJ.

Data Availability
The screenshot data set collected and analyzed during this study is not available from the authors at this time. However, it will eventually be accessible through the NIMH National Data Archive. Derivative data sets used to create each figure are available from the corresponding author on reasonable request.

Abstract

Background: Targeting reproductive-aged women at high risk for type 2 diabetes (T2D) provides an opportunity for prevention earlier in the life course. A woman’s experiences during her reproductive years may have a large impact on her future risk of T2D. Her risk is 7 to 10 times higher if she has had gestational diabetes (GDM). Despite these risks, T2D is preventable. Evidence-based programs, such as the National Diabetes Prevention Program (DPP), can reduce the risk of developing T2D by nearly 60%. However, only 0.4% of adults with prediabetes have participated in the DPP to date and reproductive-aged women are 50% less likely to participate than older women. In prior work, our team developed a mobile 360° video to address diabetes risk awareness and promote DPP enrollment among at-risk adults; this video was not designed, however, for reproductive-aged women.

Objective: This study aims to obtain feedback from reproductive-aged women with cardiometabolic disease risk about a 360° video designed to promote enrollment in the DPP, and to gather suggestions about tailoring video messages to reproductive-aged women.

Methods: Focus groups and a qualitative descriptive approach were used. Women with at least 1 previous pregnancy, aged 18 to 40 years, participated in one of three focus groups stratified by the following health risks: (1) a history of GDM or a hypertensive disorder of pregnancy, (2) a diagnosis of prediabetes, or (3) a BMI classified as obese. Focus-group questions addressed several topics; this report shared findings regarding video feedback. The 3 focus-group discussions were conducted via Zoom and were recorded and transcribed for analysis. Deductive codes were used to identify concepts related to the research question and inductive codes were created for novel insights shared by participants. The codes were then organized into categories and themes.

Results: The main themes identified were positive feedback, negative feedback, centering motherhood, and the importance of storytelling. While some participants said the video produced a sense of urgency for health-behavior change, all participants agreed that design changes could improve the video’s motivating effect on health-behavior change in reproductive-aged women. Participants felt a tailored video should recognize the complexities of being a mother and how these dynamics contribute to women’s difficulty engaging in healthy behaviors without stirring feelings of guilt. Women desired a video with a positive, problem-solving perspective, and recommended live links as clickable resources for practical solutions promoting health behavior change. Women suggested using storytelling, both to describe how complications experienced during pregnancy impact long-term health and to motivate health behavior change.

Conclusions: Reproductive-aged women require tailored lifestyle-change messaging that addresses barriers commonly encountered by this population (eg, parenting or work responsibilities). Moreover, messaging should prioritize a positive tone that harnesses storytelling and human connection while offering realistic solutions.
Introduction

Targeting reproductive-aged women at high risk for type 2 diabetes (T2D) provides an opportunity for prevention earlier in the life course [1]. This is especially important as a woman’s health status during her reproductive years may have a large impact on her future risk of T2D [2-5]. Her risk is 7 to 10 times higher if she has had gestational diabetes (GDM) [2,5]. Despite these risks, T2D is preventable. Evidence-based programs, such as the National Diabetes Prevention Program (DPP), can reduce the risk of developing T2D by nearly 60% [6,7]. However, very few adults with prediabetes participate in the DPP and reproductive-aged women are 50% less likely to participate than older women [8]. Our team earlier developed a 360° video to increase risk perception of T2D. The video helps participants conceptualize T2D complications throughout the lifespan and is designed to promote DPP enrollment among at-risk adults. It was developed with input from Hispanic community members and was not designed specifically for reproductive-aged women [9]. Because few studies have attempted to understand methods motivating reproductive-aged women to engage in healthy lifestyle change, this study aims to obtain feedback from reproductive-aged women with cardiometabolic disease risk factors in order to tailor messaging for this population.

Methods

Overview

Designed for middle-aged Hispanic men and women with prediabetes, the 360° video can be viewed with a man’s or woman’s voice and in English or Spanish. Viewers can move their phones around to look at the video’s world [10]. The video depicts an individual who has made unhealthy eating choices and has foregone dental care, thereby increasing their risk for T2D. It shows progression from prediabetes through diabetes leading to a heart attack. The video ends with a statement that diabetes can be prevented through the DPP.

Eligible participants included women who have had at least 1 previous pregnancy, were 18 to 40 years of age, and had one of the following three health risks: (1) history of GDM or hypertensive disorder of pregnancy, (2) diagnosis of prediabetes, or (3) BMI classified as obese. Those with GDM or prediabetes were eligible regardless of BMI. The 3 focus groups were conducted via Zoom by an interviewer from the University of Utah’s Center for Clinical and Translational Science Community Collaboration and Engagement Team (CCET) who had been trained in focus-group best practices and community-engaged research. Focus-group questions enabled key themes relating to the topic to be identified [11]. Focus-group participants were recruited by a CCET study coordinator using flyers. These were posted in the University of Utah cardiologist and obstetrics and gynecology offices, and in Facebook and LinkedIn groups within the CCET’s network. The coordinator screened for eligibility and reviewed the study’s consent cover letter with potential participants. The CCET supports community-engaged research that addresses investigator- and community-identified priorities with the goal of promoting community health needs [12].

Data collection included audio-recording the 1-hour-long focus-group discussions between February and April of 2022. Participants were asked to share their feedback on ways to modify the story, the voice-over content, and the imagery to make the video more impactful and appropriate for reproductive-aged women. The focus-group interviewer prompted participants to provide additional details about their perspectives and experiences. Additionally, the interviewer noted commonalities and differences between participant experiences to foster further insight. Members of the research team were present at the focus groups to answer questions and guide follow-up. The research team had no prior relationship with participants. Audio recordings of the focus groups were transcribed by a research assistant and verified for accuracy by additional team members.

Analysis was completed by 4 team members trained in qualitative methods and women’s health. Qualitative content analysis was used to examine the data. Deductive codes were used to identify concepts related to the research questions (eg, positive and negative feedback). Inductive codes were created for novel insights shared by participants (eg, importance of using storytelling and centering the video’s focus on family relationships). The codes were then organized into categories and themes. Lincoln and Guba’s trustworthiness criteria [13] were used, including weekly coding meetings with authors (AAB, SES, JK-M, and SSC) to discuss nuances in the data to ensure consistency in the application of codes. Coding across transcripts was compared to assess similarities and differences between participant experiences not only as women who had given birth, but also as women with differences in health risks. To address reflexivity during analysis, a group memo document was maintained and reviewed weekly. A member of the team audited group notes and coding to assess for consistency and accuracy. No members had a personal history of hypertensive disorder of pregnancy, GDM, or T2D, but all had clinical and research expertise. Our assumption was that participants would provide critical feedback on the video.

Ethical Considerations

Before the study’s initiation, waiver-of-consent documentation was received from the University of Utah Institutional Review Board (IRB 00146243). Participants received a consent cover letter containing information about the study’s purpose, and potential risks associated with participation; this information was reviewed with participants before focus-group sessions began, and the voluntary nature of participation was emphasized. Participants received a US $75 gift card for participation in a
demographic survey, pre-event Zoom technical session, and focus-group discussion. This amount was suggested by the CCET and was approved and deemed noncoercive by the IRB.

**Results**

**Overview**

In total, 20 women participated in the 3 focus groups (see Table 1 for demographics).

The main themes were positive video feedback, negative video feedback, centering motherhood, and the importance of storytelling. See Textbox 1 for exemplar quotes.
Table 1. Participant demographics (N=20).

Textbox 1. Themes and exemplar quotes.

Positive video feedback
- I thought the information was interesting. I knew that, like, eye doctors often catch diabetes, but I wasn’t aware about the dental connection. So, it was information that I... I personally didn’t realize that dentists would give that kind of information about diabetes, or potential risks.
  [Participant #5; obesity focus group; Hispanic or Latino]
- When I watched it, I was like, ‘Oh, I need to get my crap together and I don’t want to be that.’ ... I felt somewhat motivated to want to, like, improve my life. Like, I don’t know, but it’s more my personality just to be very direct.
  [Participant #3, pregnancy complication focus group; White, Asian, non-Hispanic]

Negative video feedback
- I don’t do well with scare tactics. And, so, it’s just... That kind of style is really off-putting to me. It kind of scares me away from it more.
  [Participant #1; obesity focus group; White, non-Hispanic]
- I think it lacks empathy. ... While I was watching it, I felt a lot of guilt and shame, um, which is something I think if you’re trying to reach women specifically of childbearing age that that should not be something that I think should be the first thing that ignites in someone.
  [Participant #7; prediabetes focus group; Hispanic or Latino]

Centering motherhood
- I would much prefer something that was like super fun and encouraging and saying, you know, like, about being excited about having energy to play with my kids, and being around, you know?
  [Participant #1; obesity focus group; White, non-Hispanic]
- I don’t think the fear tactic is gonna work. Um, like, that’s like, I feel like that’s somebody that’s like yelling at me to go to the gym, ‘You’re just being lazy.’ Like, ‘Just get up and go.’ Like, ‘Disregard your feelings and your postpartum depression and your postpartum anxiety and all of those other things’.
  [Participant #7, pregnancy complication focus group; White, non-Hispanic]

Importance of storytelling
- I think our just our innate human beings, like we really love connection. ... What really would have got me, is if I saw like a mother. ... and how she was given that news at the dentist. And saw her progress with her family.
  [Participant #5; prediabetes focus group; Native Hawaiian or Pacific Islander]
- Maybe a mother and daughter, where the mother is struggling with the beginnings of these issues and shares the information with her daughter to help prevent from developing issues in the future.
  [Participant #2, pregnancy complication focus group; White, non-Hispanic]

Positive and Negative Video Feedback
Feedback about the videos was generally negative. While some participants said the video produced a sense of urgency for healthy behavior change, all participants agreed that it did not motivate health-behavior change in reproductive-aged women.

Centering Motherhood
The participants felt that a tailored video should convey empathy for the complexities of motherhood and recognize how these dynamics contribute to women’s difficulty engaging in healthy behaviors. Participants emphasized that this tailored messaging should convey urgency. They recommended messages that avoided stirring feelings of guilt. Participants desired a video with a positive, problem-solving perspective. They suggested live links could be embedded within the video as clickable resources for practical solutions, helping to promote health behavior change (eg, links to the DPP website, food-preparation tips, and ways to incorporate children into physical activity).

Importance of Storytelling
One woman suggested that an optimal approach to the video would summarize a woman’s personal risk from her doctor’s point of view (eg, “you’ve had gestational diabetes, so this is what that means for your long-term health risk”), and then quickly pivot to a problem-solving tone: “Now here’s how we’re going to help you get to where you need to be.” Women across the 3 focus groups agreed that storytelling would be effective in describing how pregnancy complications impact long-term health. For example, a participant suggested the video could include a mother talking with her adult daughter about developing T2D and how she wishes she had acted earlier for...
prevention. The mother could also encourage her daughter to begin finding solutions while still young and able to maintain health. Other participants agreed that a focus on storytelling and human connection would improve the video’s effectiveness. Finally, the women suggested that it should end by illustrating the benefits of healthy behavior change (eg, being able to keep up with their kids).

Discussion

In focus group interviews with reproductive women at risk for T2D, participants were enthusiastic about the use of 360° videos to promote healthy-lifestyle change and DPP enrollment, but many found the video to be negative or guilt-inducing. Suggestions for change included positive messages and avoidance of guilt-based messaging. Additionally, participants felt that messaging should acknowledge the time demands and challenges faced by reproductive-aged women, including parenting and work demands, and should convey urgency without creating feelings of guilt.

Few efforts have been made at tailoring diabetes-prevention messaging for reproductive-aged women. An example is the Health-e mums study, which used smartphone app–based messaging to target women with a history of GDM. The app prompted women to improve their health behaviors through goal-setting, and personalized responses to the recording of body weights, diet, and activity. Women provided feedback on messages received through the app. As was true of our study, some Health-e mums participants disliked the use of “negative storytelling,” instead preferring positive, health-coaching messages [14]. Recently, the Centers for Disease Control and Prevention (CDC) released a 1-minute-long promotional DPP video entitled “More Energy Means More Family Fun” [15] that is tailored to reproductive-aged women. It is unclear if the video has been successful in motivating their target population to enroll in the DPP.

Study strengths include participant characteristics (eg, racial or ethnic diversity) and a range of cardiometabolic risk factors. Limitations include the small sample size and the homogeneity of the participants, including the fact that all were mothers. Thus, findings may not apply to women who are not mothers.

In sum, participants highlighted the importance of acknowledging shared experiences and struggles of motherhood, while also offering realistic solutions and a positive tone through storytelling. These findings underscore the importance of tailoring health behavior change messaging to address unique needs of reproductive-aged women and to motivate enrollment in lifestyle change programs. Such messaging is essential for engaging this population in lifestyle change so as to reduce disease burden.

Acknowledgments

The authors of this paper give thanks to the University of Utah’s Center for Clinical and Translational Science Community Collaboration and Engagement Team for their collaboration on this project and to Roger Altizer and Greg Stoddard for their assistance with developing the video. This study was supported by funding from the Educational Resource Development Council at the University of Utah. Additionally, author JK-M received support from the National Institute of Nursing Research of the National Institutes of Health under award number (F31NR020431). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. These funding sources had no impact on the study’s design and data collection, or the analysis, interpretation, and writing of the study’s results.

Authors’ Contributions

The conceptualization of the study is attributed to SES and BG. SES, BG, and JK-M created the interview guide for the focus groups. The design and implementation of the qualitative analysis was done by AAB. Data analysis was done by AAB, JK-M, SES, and SSC. The manuscript was written by AAB, JK-M, SES, BG, and SSC. All authors approved the final version for publication.

Conflicts of Interest

None declared.
