For those who don’t speak English, that’s another [issue]—because participants here, we have different languages spoken here, more than five, six, seven languages. For caregivers who don’t understand or don’t speak English well, that’s challenging as well. [ADC-AL]

Furthermore, some participants expressed concern that technology-based solutions may not be appropriate methods of communication for some clients due to low technology proficiency and preferences for traditional methods. While many of the features were easy to use, participants noted a few exceptions that were too complex and potentially confusing for them to navigate, particularly the appointment tracking feature. A staff member noted that while navigating the app was “pretty easy,” it might confuse caregivers who could “get mixed up on appointments, whether it’s outside or they’re coming here” (ADC-NF).

</tr>
</tbody>
</table>

**Table 2.** Qualitative subthemes for perceived ease of use.

Perceived Value in Clinical Practice

Perceived value in clinical practice is the degree to which CareMOBI could improve patient care and management within ADS. Thirteen questions in the survey assessed this domain (Figure 3). The mean score for this domain was 6.18 out of 7, indicating that participants generally rated the CareMOBI app well in terms of potential value to their clinical practice. The item with the highest average score was “The proposed mHealth app can facilitate the care of my patients/clients/loved ones” (mean of 6.55 or strongly agree). The item with the lowest average score was “The proposed mHealth app can facilitate the care of my patients/clients/loved ones” (mean of 5.70 or agree).

Data from the qualitative interviews suggested that staff felt there was immediate value to implementing the app in the day center (Table 3).

I know how it could help me and my family, so it just lights the torch for me the more. This is so huge because the next wave, they’re gonna be—they’re more technology savvy, so they’re gonna be wanting a lot of this information more so, so we have to keep evolving to be able to help make sure that we are communicating right away and training our staff to use it. Both the people were so excited, like, “Oh, my God, it’s so much easier,” and then they get an alert. I’m like, “Yeah, just to get an alert.” [ADC-NF]
Several features of the CareMOBI app would improve the staff’s ability to manage care for ADS participants. Specifically, study participants appreciated the alert and notifications feature for caregivers and staff and the built-in features that allow easy “communication on a daily basis” for members of the care team. The CareMOBI app has the capacity to track health progress (i.e., vital sign trends, medication management, and appointment reminders) beyond ADS through caregiver and health professional portals. These features were viewed as beneficial to augment the traditional emergency communications and to facilitate chronic disease management within the adult day centers. While most features received positive feedback, 1 staff participant noted that the behavioral assessment tool, which used emoticons (or “smiley faces”) to evaluate daily behavior was oversimplified. Generally, both the qualitative and quantitative data indicate that staff participants perceived the CareMOBI app as a potentially valuable clinical tool to augment their practice due to its ability to facilitate communication, consolidate patient information, and organize care management.

Figure 3. Quantitative survey answer distributions for perceived value in clinical practice. mHealth: mobile health.
Table 3. Qualitative subthemes for perceived value in clinical care.

<tr>
<td>Patient monitoring and management</td>
<td>“I know how it could help me and my family, so it just lights the torch for me the more. Both the people were so excited, like, ‘Oh, my God, it’s so much easier,’ and then they get an alert. I’m like, ‘Yeah, just to get an alert.’” [ADC-NF]</td>
</tr>
<tr>
<td>Real time communication among the care team</td>
<td>“I think that the real-time communication makes it useful. What we’re seeing on a daily basis, if we’re able to communicate on a daily basis as opposed to—right now, we have—we will call a family member if there is an acute episode. If there’s not an acute episode, we’re not gonna just be like, ‘Hey, this is what happened today. This is what we saw. Blah, blah, blah, blah, blah.”” [ADC-DT]</td>
</tr>
<tr>
<td>Updates on health progress</td>
<td>“Even though they might not be able to communicate on a consistent basis when I call, tell me what was happenin’ this week or this weekend. I could at least gather that information and, like I said, with the app there, I could say, ‘Per a neighbor who’s slash the caregiver, this is what they observed.’” [ADC-LSM]</td>
</tr>
<tr>
<td>Trends</td>
<td>“Then visually having the client on-site, it would be able to give me a better way of communicating. ‘Oh, yeah. This is not just a bump. [Laughter] It’s a big bump from the baseline.’ That’s the whole point, being able to look at the trend.” [ADC-LSM]</td>
</tr>
<tr>
<td>Assist caregivers</td>
<td>“We, at adult daycare center, we take care of not only participant, but the caregiver also. When caregiver’s wellbeing are good, our participant are good. They can have quality of life at home instead of ending up in a placement. It’s not their wishes and their goals. That’s very good that in the app.” [ADC-AL]</td>
</tr>
<tr>
<td>Schedules and reminders</td>
<td>“I think it’s very good to have [appointments] on the calendar. It’s forgetful for those who have cognitive impairment and caregiver busy with the schedule. When you have those in place, it’s very good for the keep ongoing with the appointment, with the medication, make sure they take medication on time, don’t miss any doses. That help both caregiver and participant to do the daily tasks appropriately.” [ADC-AL]</td>
</tr>
<tr>
<td>Patient profile information</td>
<td>“Then they sign up their loved one and their pictures, information about themselves, information about their loved one, the medication they’re on, what they, little bit about themselves, a little bit about their loved one’s background.” [ADC-EK]</td>
</tr>
<tr>
<td>Disliked features</td>
<td>“Sometimes behavior issues where someone is having extraordinary anxiety or—then I think that that might be able to be addressed. It would be challenging to properly do that with just the smiley faces, I think. I thought that was very surface-related, very cursory thing. I’m not sure how incredibly helpful that would be unless there’s some depth later somewhere. That would be my only concern about that.” [ADC-HK]</td>
</tr>
<tr>
<td>Health progress logs</td>
<td>“I found that it had, the activities part of it and how their morning started or how they slept, and things that I deal with, hands on here.” [ADC-LR]</td>
</tr>
<tr>
<td>Miscellaneous ways the app enhances care</td>
<td>“That is perfect, because then—in outcomes for us or if we utilize it regularly, it would help us with data collection too.” [ADC-BT]</td>
</tr>
</tbody>
</table>

**Fits Within the Workflow**

New technology should be compatible with the existing workflow of staff and patients and cause minimal disruptions to optimize adoption. A total of 9 questions assessed the extent to which the CareMOBI app could integrate into the existing health records and workflow of ADS staff (Figure 4). The mean domain score was 5.14 out of 7, indicating that most participants agreed that the CareMOBI app would fit within the workflow. The item with the highest average score was “I often use smartphone apps in my work or daily life” (mean of 6.38 or strongly agree), and the item with the lowest average score was “The use of the proposed app may interfere with the usual follow up of my patients” (mean of 3.36 or slightly disagree). Due to the wording of this item, a low rating has a positive implication for the compatibility of the CareMOBI app with ADS staff workflow.

However, data from the qualitative interviews highlighted several caveats that could preclude the successful integration of the CareMOBI app into the current staff workflow (Table 4). Staff recommended prioritizing the interoperability of CareMOBI with existing electronic health record systems (e.g., TurboTAR) to avoid duplicitous documentation and streamline their workflow. Congruent with the quantitative data, staff participants cited that the lack of existing mHealth apps used in their routine workflows meant that staff and caregivers were not familiar with this interface and could be problematic when initially integrating the app into use. To ameliorate this, the staff participants emphasized the need for sufficient training using videos and other methods for both staff and caregivers, as many described being intimidated by the complexity of emerging technologies. Participants (ADC-JL) also voiced concern that documentation in the CareMOBI app would just be “one more thing” that needs to be done and believed it could be challenging to “actually utilize it” given their other responsibilities. Many participants also imparted that the benefits provided by improved e-communication and information sharing could encourage integration into their workflows. One staff member stated that the app was “great [for] communication with physicians” and another remarked that the ability to be able to take pictures of medication bottles and export patient information “clears up so much confusion” for them. Both the qualitative and quantitative data show relative support for using the app in the workflow but the qualitative interview data reveal several barriers that could inhibit integration.
Figure 4. Quantitative survey answer distribution for how CareMOBI fits within the adult day service workflow. mHealth: mobile health.

Table 4. Qualitative subthemes for how CareMOBI fits within the adult day service workflow.

<table>
<thead>
<tr>
<th>Subthemes</th>
<th>Qualitative feedback</th>
</tr>
</thead>
<tbody>
<tr>
<td>Benefits of e-communication</td>
<td>&quot;I actually think it would help a lot, just because it would keep you—it would keep the family more informed, ’cause nowadays everybody uses their cell phones, so it would be right at—right in the palm of their hand. They wouldn’t have to worry about goin’ to their computer. I feel like it would be a great communication with the physicians, letting them know how our members are doing. Also, communication between the staff. Yeah, I thought it was a great tool. I work in another area with home care, and I was thinking how that would work out with that one really well, too. It just kinda would be a great communicator.&quot; [ADC-BW]</td>
</tr>
<tr>
<td>Information sharing</td>
<td>&quot;Also, for the medications where they’re seen, that’s huge ’cause they don’t know all the time, the majority of the time. Waiting for a doctor’s office to just snap that picture of the bottle, and the RN gets it right away, it clears up so much confusion.&quot; [ADC-NF]</td>
</tr>
<tr>
<td>Suggestions for integrating within existing workflows</td>
<td>&quot;The interoperability, I think that’s the biggie. That we’re entering information one time only so that once you do have your prototype, and it’s down pat, how it maps to the software and, I would say, specifically, TurboTAR ’cause I think it is the most broadly used in adult day healthcare in California, that whatever terminology you’re using on your app maps to sections within TurboTAR so that that’s automatically populating.” [ADC-DT]</td>
</tr>
<tr>
<td>Training caregivers to use app</td>
<td>&quot;This is so huge because the next wave, they’re gonna be—they’re more technology savvy, so they’re gonna be wanting a lot of this information more so, so we have to keep evolving to be able to help make sure that we are communicating right away and training our staff to use it.” [ADC-NF]</td>
</tr>
<tr>
<td>Feasibility of using app in practice</td>
<td>&quot;I think your issue and hurdle is gonna get people to actually utilize it, especially on the health care side because we already have a thousand things to document and a thousand things to click and a thousand buttons to do. This would just be one more thing. You said something—I—you could put an event in like an urgent situation, but would the caregiver still understand that I’m not sitting here with my cell phone watching for something like that to happen so that they’re still responsible for the care of the member. They’re still responsible for calling 911 in any situation like that.” [ADC-JL]</td>
</tr>
</tbody>
</table>

Likelihood of Adoption

This domain assesses the extent to which staff participants intended to include CareMOBI in their program and use it with clients and caregivers. Five items assessed this domain (Figure 5) and had a mean score of 5.77, a score that suggests most respondents agreed that they intended to use the app after its release. The highest rated item was “I would use the proposed app if I receive appropriate training” (mean of 6.10 or strongly agree) and the lowest rated item was “I have the intention to
use the proposed app routinely for the care of my patients/clients/loved one” (mean of 5.40 or slightly agree).

The qualitative data revealed that many staff participants were motivated to adopt the CareMOBI app (Table 5). One participant said, “we were already talking about how we would utilize it in our program,” reflecting the high quantitative score for the likelihood of adoption. The app was designed to reflect the interdisciplinary nature of ADS, and staff participants were appreciative of this aspect. One participant (ADC-LR) commented that they were “very impressed with it and how it touched on all of the different disciplines that we have to do with in an adult day health center, social work, health, activities.” To increase the likelihood of adoption, staff participants also suggested new features of the app to improve care and user experience, including the option to print reports and collect education-level data from patients to help allocate activities.

Figure 5. Quantitative survey answer distribution for overall likelihood of adoption of CareMOBI. mHealth: mobile health.

Table 5. Qualitative subthemes for overall likelihood of adoption of CareMOBI.

<th>Qualitative feedback</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overall high likelihood of adoption</td>
<td>“Yep, yep. Very much. I definitely see for those that will——and I...my co-director, so we were already talking about how we would utilize it in our program. By creating direction and maybe even assistance with family members and setting it up.” [ADC-BT]</td>
</tr>
<tr>
<td>Suggested additional features</td>
<td>“I think also, education level. That would help because we do a lot of brain work. If we need to know their education level as to which kind of work to give them. I think education level would be a good question too.” [ADC-EK]</td>
</tr>
<tr>
<td>General impression of the app</td>
<td>“I was very impressed with it and how it touched on all of the different disciplines that we have to do with in an adult day health center, social work, health, activities. Yeah, I touched on everything, so I was really impressed with that.” [ADC-LR]</td>
</tr>
</tbody>
</table>

Discussion

Principal Findings

The results of this study show that the CareMOBI app is highly acceptable to ADS staff, but there were questions about the feasibility of implementation. The high scores in all 4 domains of the survey—perceived ease of use, perceived value in clinical care, fit within existing workflows, and end users’ overall likelihood of adoption—demonstrate that ADS staff members generally considered that the app was easy to use; added clinical value; fit into their workflow; and that if given the option, would likely adapt the app into their system.

This high receptivity and likelihood of adoption may be attributable to the participatory design process, which engaged staff, caregivers, and providers to identify barriers to and facilitators of effective communication within the ADS setting. Prior to developing the app, members of the study team conducted qualitative interviews nationwide to identify facilitators of effective communication between ADS sites and primary care providers. Results indicated that ADS staff wanted to exchange information bidirectionally with other care team members. They sought technology that would reduce their reliance on fax and voicemail while enabling them to share serial observations of a person living with dementia’s day-to-day health with all members of the care team (eg, ADS staff, health care providers, and caregivers) [7].

In this study, qualitative interviews largely qualified the high scores from survey data; however, interviewees expressed practical concerns about the app’s feasibility, particularly about its fit within the existing workflow of ADS. The feasibility of CareMOBI was threatened by the added workload and documentation burden it has the potential to create, especially for overburdened providers who “already have a thousand things...
to document and a thousand things to click and a thousand buttons to do.” This concern is not limited to the ADS setting; other research has shown that increased documentation burden in hospitals is a contributing factor to clinician burnout [10,11]. Notably, cost was not mentioned by any of the participants as a concern or barrier to adoption. This is likely because, with low-cost subscriptions (<5 US $/month) and little to no investment overhead, mHealth apps are reputed as a cost-effective solution to meet the needs of complex patients.

The potential workflow disruption and incompatibility with existing technology infrastructures have been cited as one of the major barriers to successful eHealth implementation in a systematic review, and our study was no exception [9,12]. As another participant pointed out, “The interoperability, I think that’s the biggie. That we’re entering information one time only.” This could be mitigated by making CareMOBI interoperable with ADS billing software which is what most sites rely on for day-to-day practice management. In a future study, a back-end dashboard for CareMOBI will be designed to integrate with existing ADS practice management systems, like TurboTAR. This will avoid what 1 participant referred to as “double documentation.”

Another key priority for future development will be the translation of CareMOBI into different languages. ADS is the most diverse subset of long-term care, with nearly 60% of participants identifying as a racial or ethnic minoritized individual [13]. Studies show that ADS can deliver relevant, person-centered care to diverse populations [3]. Adaptations of CareMOBI into other languages will be necessary to improve adoption and inclusivity and ensure the technology reflects the population it is designed to serve.

Successful adoption of new technology in health care settings requires buy-in from staff. It is, therefore, imperative that technology adds clinical value and does not hinder efficiency. While barriers and facilitators of app use in certain health care settings have been well documented, our study is the first to explore the unique perspectives of staff in ADS settings. Resourcing this setting with low-cost mobile technology is especially innovative because ADS sites provide essential care to persons with dementia but are often resource-constrained and rarely embedded within health care systems.

CareMOBI was developed as a reaction to the overwhelming sentiment that methods of communication in ADS need to be modernized and streamlined to provide optimal care for their clients. Overall, our results from prototype testing show a high level of acceptability among ADS staff with a need for greater attention to feasibility. Recognized by many of the study’s participants, CareMOBI’s biggest strength is its ability to bring all the members of the care team—ADS staff, caregivers, patients, and health care providers—to the same digital table, managing the complex care of older adults as a true team. Previous research by the Agency for Health Care Research and Quality found that care models emphasizing collaborative care were the only effective, evidence-based care models for persons with dementia [14]. By emphasizing effective communication, CareMOBI, with ongoing refinement and enhancement, has significant potential to help streamline and improve care for participants with dementia and other chronic conditions.

Limitations
While this study is the first to our knowledge to document the perceived feasibility and acceptability of a mHealth app in the ADS setting, these results should be interpreted with some limitations. The participants of this study were only furnished with a prototype of the CareMOBI app with a limited set of capabilities. At times, this elicited frustration from the participants due to certain functions not working correctly. Conversely, testing with only a prototype precludes assessment of real-world functionality, particularly in the assessment of integration within the workflow. This study consisted of a relatively small, sample of exclusively women participants representing 3 states. Regulations and documentation requirements for ADS and other community-based services differ greatly between states, and preferences around the design and use of technology can be influenced by gender [15]. These findings, therefore, may therefore not be generalizable. A larger, more representative study sample would have potentially offered more robust results. However, these findings—the emphasis on minimizing disruptions to workflow, training, and institutional support—are consistent with other previous implementation studies in a broad array of health care settings [9,12,14].

Future Directions
The feedback gleaned in this study will guide future improvements to the CareMOBI app and on-site implementation of the app. Prior to implementation, the CareMOBI team will aim to develop interactive training modules personalized for each type of end user (ie, a caregiver-specific training module vs an ADS staff or nurse training module). Small-scale implementation studies will help develop a robust framework for successful CareMOBI adoption in ADS settings. Further technological development will be pursued to integrate CareMOBI’s interface with other prominent technologies, like TurboTAR, that are already required in ADS settings.

Conclusions
This mixed methods study assessed the feasibility and acceptability of ADS staff toward adopting the CareMOBI app in ADS settings. Overall, staff participants were motivated to integrate CareMOBI into their clinical settings because of its potential to ameliorate long-standing communication challenges between ADS staff and other key members of the care team. However, the qualitative interviews highlighted many important potential barriers to successful implementation that researchers will have to consider as they move forward to the next phase of CareMOBI’s development. The CareMOBI team will continue to leverage this important feedback to develop an app that is optimized to fit the needs of all end users and help bring ADS communication into the 21st Century.

Abstract

Background: Restorative dentistry plays a crucial role in dental practice, necessitating professionals to stay abreast with the latest advancements in the field. The advancement of technology has made web-based learning a widely used method of education delivery in dentistry, providing learners with extensive information and flexibility.

Objective: This study aims to evaluate how effective an online educational course in restorative dentistry is for dental graduates in Syria.

Methods: This study used a pre-experimental study design, with pretest and posttest assessments to measure changes in participants’ knowledge and skills. A total of 21 dental graduates completed the online course in restorative dentistry, which was hosted on Moodle, using the learning management system of the Syrian Virtual University. Participants were provided with a suggested learning sequence and had the flexibility to navigate the course on their own and at their own pace. The course was developed based on the principles of web course design and web-based course development using the ADDIE (Analysis, Design, Development, Implementation, and Evaluation) general instructional design model. The pretest and posttest assessments consisted of 50 multiple-choice questions with a single correct answer, aligning with the course content. Furthermore, participants were asked to complete a course acceptance survey upon finishing the course.

Results: The results showed a significant improvement in the participants’ knowledge of restorative dentistry, supported by a statistically significant P value of less than .05. The effect size of the difference between the pre and posttest indicated that the effect size, as indicated by ω², demonstrated a significant 62.1% difference between the pre and posttest, indicating a high and statistically significant effect. Furthermore, the value derived from the Haridy obtained work ratio formula indicated that the educational program was effective, with an effectiveness amount of 3.36%. Additionally, 93% (n=19) of respondents expressed confidence in having gained the expected benefits from the educational course upon its completion.

Conclusions: The findings indicated a notable enhancement in the participants’ understanding of restorative dentistry. The participants’ high satisfaction rate and positive feedback from the course acceptance survey further emphasize the favorable reception of the web-based learning approach. This study highlights the potential of web-based learning in dental education, opening the door for future research in this area. The findings of this study carry important implications for the design and implementation of web-based educational programs in dentistry, suggesting that such programs can serve as an effective tool for continuous professional development in the field.

(JMIR Form Res 2024;8:e51141) doi:10.2196/51141

KEYWORDS
restorative dentistry; online learning; dental education; dental graduates; Syria; education; dental; dentistry; dental practice; effectiveness; educational program; survey
Introduction

Restorative dentistry is a crucial aspect of dental practice, involving the use of various materials and techniques to restore the function and aesthetic appearance of teeth [1]. Continuous education, particularly in restorative dentistry, is essential for dental graduates and practitioners to stay updated with the latest developments in the field [2-4]. In recent years, web-based learning, also known as e-learning, has gained popularity as a method of delivering education in dentistry, thanks to technological advancements [5,6]. This approach provides learners with access to a wealth of information while offering the flexibility to learn at their own pace, overcoming the limitations of time and space [7]. In response to this trend, the dental profession has developed web-based dental courses and web-based continuing dental education programs [8]. The global implementation of web-based learning in dentistry has been further accelerated by the COVID-19 pandemic [9,10].

The transition to new education delivery models, such as web-based education, has reshaped teaching methods into a blended learning methods, particularly in dental education [11,12]. Studies have shown that web-based teaching is perceived as equally as effective as traditional classroom approaches in terms of knowledge acquisition and academic performance [1,13]. Web-based dental education programs and courses have been developed to enhance the knowledge of dental students and practitioners, providing them with easy access to a wide range of information and fostering empowerment [14-16]. Several universities and dental schools worldwide have integrated web-based education into their dental programs, acknowledging its advantages and potential to enhance patient health care outcomes through a patient-centered approach and continuous learning [17-19]. However, while web-based learning offers numerous advantages, careful consideration of technical and pedagogical factors is essential to ensure its effectiveness. Hands-on training with manikins during preclinical education remains crucial [19-21].

This study aims to evaluate the effectiveness of a web-based educational course in restorative dentistry in improving the learning outcomes for Syrian dental graduates. Through assessing the influence of this web-based course, we aim to contribute to the understanding of the benefits and effectiveness of web-based learning in dental education.

Methods

Ethical Considerations

The ethical approval of this study was obtained from the Syrian Virtual University Ethics Committee (237/0) on January 7, 2023. This study involved a pre-experimental web-based course with human participants. The course did not involve any harmful interventions or interactions that could harm the participants. There is a preprint version of this study [22].

Before their participation, informed consent was obtained from all participants. The consent form, written in Arabic, the first language of all participants, provided a clear description of the research objectives and procedures. Participants were assured that their information would be securely stored and used solely for this research. To ensure confidentiality and privacy, the study data collected from participants were anonymized and protected with appropriate security measures. Access to the participants’ identities was restricted to only one of the researchers involved in the study.

The participation questionnaire was indirectly distributed to approximately 50 graduates, and a voluntary and random selection process was conducted to include participants. Out of the 50 participants contacted individually, a total of 21 participants willingly agreed to take part in the study. The selection of participants was not influenced by any specific criteria or biases, ensuring a representative sample for the research. A total of 21 dental graduates completed the online course in restorative dentistry (OCR D) which used a pre-experimental study design with pretest and posttest assessments.

Overview

The course was asynchronous and hosted on Moodle, using the learning management system (LMS) of the Syrian Virtual University. Each participant had an account and full access to the course at any time. The course duration was 3 weeks, and it was available on LMS during this duration with full access for participants, it was divided into 4 thematic units with resources including documents, downloadable articles, presentations, short educational videos, examinations, and surveys.

The OCR D was developed by the principal researcher, RA, based on the principles of web course design [23,24], and web-based course development [25,26], using the ADDIE (Analysis, Design, Development, Implementation, and Evaluation) general instructional design model [27]. The course and its contents were reviewed by several experts from the Faculty of Dentistry at Damascus University.

The course primarily focused on theoretical aspects related to clinical topics. The course provided participants with a comprehensive understanding of various clinical topics within the field of dentistry. It aimed to enhance their theoretical knowledge and conceptual understanding of the principles and practices relevant to restorative dentistry. The course covered a wide range of theoretical aspects, including but not limited to dental materials, treatment planning, occlusion, tooth preparation, and aesthetic considerations. Participants were exposed to evidence-based theories, research findings, and best practices in the field. The course was theory about clinical topics and consisted of four main themes: (1) composite restoration including anterior and posterior composite restoration, (2) diastema closure, (3) direct composite veneer, and (4) tooth whitening.

In addition, we supported the course with clinical applications and clinical cases. The participants were given a suggested sequence for optimal learning but were allowed to access and navigate the course at their own pace. Participant contributions were reviewed daily to guide them in their studies and provide...
feedback. The daily feedback was given by the course tutor. Discussion of any issues related to the revised unit was also allowed, and any doubts were addressed. The study outcomes were based on the structure of the course, which was organized into units, lectures, and educational videos. Tools, methods, and resources were selected for use in the course, which included a set of presentations and related educational short videos.

The participants were informed about the pretest and posttest assessments that would be conducted as part of the study, and they were required to complete both assessments. The pretest was administered before the start of the course, while the posttest was conducted immediately after the course ended.

The study population comprised participants who had graduated from the Faculty of Dentistry. The invitation to the course was sent to a group of graduate students. A total of 21 participants agreed and accepted the invitation to participate in the course, and informed consent was obtained from those who accepted the invitation. The participants have been recruited according to the inclusion criteria including participants who had completed all restorative dentistry courses in their undergraduate studies, had access to a laptop, iPad, or smartphone, had good internet access, and had good knowledge of both Arabic and English, including medical terminology. Participants who did not complete the pretest were excluded from the study.

The pretest and posttest assessments were designed to measure the participants’ knowledge of restorative dentistry. The assessments were based on the course content. The assessments consisted of 50 multiple-choice questions with a single correct answer. The questions were designed to cover the 4 main themes of the course. Each multiple-choice question had 1 correct answer and 3 distractor options. A correct response received 2 points toward a total score of 100, while an incorrect response received zero points. The test was web-based, with limited time access. The duration of the test was 40 minutes.

In addition, participants were also asked to complete a course acceptance survey at the end of the course. The survey consisted of Likert scale questions and open-ended questions. The Likert scale questions were designed to measure the participant’s satisfaction with the course, the quality of the course content, and the effectiveness of the course in improving their knowledge of restorative dentistry. The open-ended questions allowed participants to provide additional feedback and comments about the course.

Data collected from the assessments were analyzed using SPSS (version 25.0; IBM). Descriptive statistics, including means and SDs, were calculated to describe the participants’ demographic characteristics and their pretest and posttest scores. The paired-sample 2-tailed t test was used to compare the mean scores of the pretest and posttest assessments. A P value of less than .05 was considered statistically significant.

Results

Overview

The study included 21 participants, of which 12 (57%) participants were female and 9 (43%) participants were male, with ages ranging from 23 to 30 years. Sixteen (76%) participants graduated from public universities and 5 (24%) participants graduated from private universities. The participants were distributed as follows: 12 (57%) participants were master candidates, 8 (38%) participants were general dentists, and 1 (5%) participant was a specialist. All participants had different years of experience in dental practice with 7 (33%) dentists having only 1 year of experience, 6 (29%) dentists having 2 years of experience, 6 (29%) dentists having 3 years of experience, and only 2 (10%) dentists having more than 3 years of experience.

A total of 21 participants completed the course, with course completion tracked by the LMS, and the time taken to complete the course ranged from 2 to 7 days. The pretest and posttest results were collected and stored in Google Forms and analyzed using SPSS. All 21 participants completed both tests without any significant lack of information. The change in knowledge between pretest and posttest results was analyzed using the paired-sample 2-tailed t test. A P value of less than .05 was considered significant. The P values, mean scores, and SDs for the precourse and postcourse tests for the entire test and each section are shown in Table 1.
Table 1. Results of paired-sample 2-tailed t test to test knowledge level change.

The normal distribution was tested using the 1-sample Kolmogorov-Smirnov test, which showed that the distribution of the sample was standard. The paired-sample 2-tailed t test was then applied, revealing no statistically significant difference in the post-course test results of the participants, regardless of their age group, gender, academic status, type of university, or prior experience with web-based courses.

**Acceptance Questionnaire**

The internal consistency of the user acceptance questionnaire items, as determined by Cronbach α, was demonstrated to be 0.924, indicating high reliability. In terms of user acceptance, all survey respondents (N=21) reported satisfaction with the web-based course when using a 5-point Likert scale. Moreover, the majority of survey respondents 93% (n=19) believed that they gained the expected benefit from the educational course after its completion.

The attendees showed the highest agreement with the well-employed materials and the enthusiasm of the instructor in presenting the web-based course, and the lowest agreement with the technical resources and communication methods required to attempt the web-based course as presented in Table 2.

### Discussion

#### Principal Findings

This study aimed to evaluate the effectiveness of a web-based educational program in restorative dentistry for increasing the knowledge of Syrian dental graduates. The course was designed based on the fundamental principles of web course design and web-based course development. A total of 21 participants completed the entire course. The results of the study showed a significant increase in the participants’ levels of restorative dentistry knowledge after completing the web-based course, as demonstrated by the postcourse test scores.

The course was also well-received by the participants, as indicated by their positive evaluations. These findings are consistent with previous studies that have investigated the effectiveness of web-based learning in enhancing participants’ knowledge and skills. This success of the course could be attributed to the well-structured presentation and content of the course, as well as the ease of use of the web-based platform (LMS-Moodle) and its flexibility in navigating the course content [29,30].

The highest score in the students’ precourse tests was obtained about composite restoration (first unit), which may be attributed to the fact that composite restoration is widely used and considered the most popular restorative material in dentistry. In contrast, the lowest score in the precourse test was obtained for tooth whitening (fourth unit), because tooth whitening lectures are only given in advanced dental practice programs and postgraduate studies. However, the students’ scores on specific knowledge areas in the postcourse tests showed a notable improvement in all units, including tooth whitening, despite the widespread use of tooth whitening in dental clinics to restore the aesthetic appearance of teeth [31]. This result ensures that the course has been focused on new concepts and interesting ideas that the participants had not been taught before, as well as influencing their daily practice.

The result of this study is consistent with those of Morales-Pérez et al [29], Absi et al [32], and Rosenberg et al [33] regarding the effectiveness of web-based learning and web-based courses in increasing the knowledge of participants.

The current situation in Syria makes attending traditional courses challenging, due to, for example, the lack of transportation, fuel, ...
and electricity; lack of sufficient and qualified places to hold the courses; and shortage of human resources and staff [34-36]. However, the course offered flexibility in terms of delivery and content review, allowing participants access to the platform 24 hours a day. This approach is similar to previous studies by Murphy et al [37] and Rosenberg et al [33]. Asynchronous web-based learning was also an option that enabled participants to revisit the course materials as needed, based on their commitments and social life as noted by Ruiz et al [38].

Asynchronous web-based learning is considered an attractive, flexible, and convenient option for learners, with lower costs and easy access to information. Similarly, Kenjrawi and Dashash [39] found that asynchronous electronic medical education is an effective and feasible approach for improving the knowledge and attitude of Syrian clinical practitioners [39].

The web-based course proved a valuable option for continuing medical education in Syria given the current circumstances in Syria and after the impact of the COVID-19 pandemic [40]. In dental education, computerized sources of information and virtual reality are increasingly being used as educational tools and have shown promise in training dental students [41]. These technological advancements have the potential to revolutionize dental education and enhance the learning experience of students.

The results of this study indicate that the participants expressed high levels of acceptance and satisfaction with the restorative dentistry course, as evidenced by the questionnaire results. The majority of the cohort (19/21, 93%) reported that the course provided the desired benefit, and all participants reported enjoying it. The well-designed course materials and the instructor’s enthusiasm for delivering the web-based course were also praised by participants. However, there were some areas of the course that needed improvement, such as technical resources and communication methods required to improve the web-based course.

To further assess the effectiveness of the web-based course, future research using larger sample sizes would be beneficial, to evaluate both knowledge and skills in each unit of restorative dentistry separately. Nevertheless, implementing web-based courses of restorative dentistry in continuous medical education programs in Syria is advisable, as it may help dentists stay up to date with minimal requirements.

**Limitations**
The study did not assess the long-term retention of knowledge or the impact of this web-based course on the participants’ clinical practice. Furthermore, the study focused only on an OCRD. The findings might not apply to other areas of dentistry or other forms of web-based learning.

**Conclusion**
This study provides evidence that web-based learning can be an effective tool in improving the knowledge and skills of dental graduates about restorative dentistry. The high satisfaction rate expressed by the participants and the positive feedback received through the course acceptance survey indicate that the web-based educational program was well-received by the participants. These findings support the potential of web-based learning in dental education and suggest that it can be a valuable tool for providing continuous education to dental professionals, as it can help dental professionals stay up to date with the latest advancements in their field, which can ultimately benefit the patients they serve.

**Acknowledgments**
The authors would like to thank Syrian Virtual University for its assistance and all the participants who agreed to take part in this study. All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided APF support for the publication of this article. Artificial intelligence was not used in writing this manuscript.

Abstract

Background: The artificial intelligence (AI) analysis of chest x-rays can increase the precision of binary COVID-19 diagnosis. However, it is unknown if AI-based chest x-rays can predict who will develop severe COVID-19, especially in low- and middle-income countries.

Objective: The study aims to compare the performance of human radiologist Brixia scores versus 2 AI scoring systems in predicting the severity of COVID-19 pneumonia.

Methods: We performed a cross-sectional study of 300 patients suspected with and with confirmed COVID-19 infection in Jakarta, Indonesia. A total of 2 AI scores were generated using CAD4COVID x-ray software.

Results: The AI probability score had slightly lower discrimination (area under the curve [AUC] 0.787, 95% CI 0.722-0.852). The AI score for the affected lung area (AUC 0.857, 95% CI 0.809-0.905) was almost as good as the human Brixia score (AUC 0.863, 95% CI 0.818-0.908).

Conclusions: The AI score for the affected lung area and the human radiologist Brixia score had similar and good discrimination performance in predicting COVID-19 severity. Our study demonstrated that using AI-based diagnostic tools is possible, even in low-resource settings. However, before it is widely adopted in daily practice, more studies with a larger scale and that are prospective in nature are needed to confirm our findings.
Introduction

Background

Humans have been learning to adapt to the COVID-19 pandemic. While vaccine development has mitigated the spread, mortality, and morbidity associated with COVID-19, waves of COVID-19 cases are still reported. The main driver of these cases is viral mutation, with the latest mutant, the XBB omicron subvariant, reported to be more virulent and responsible for another COVID-19 wave in Singapore [1]. As of November 1, 2022, a total of 4707 new cases have been reported throughout Indonesia [2]. This is the highest number of new cases reported since September 1, 2022, and might be attributed to SARS-CoV-2 variants. Importantly, at the time this study was conducted, the number of new daily cases reached 14,518 confirmed cases per day at its peak (January 30, 2021) [3].

Currently, the World Health Organization (WHO) endorses the use of the nucleic acid amplification test, including reverse transcription–polymerase chain reaction (RT-PCR), as the gold-standard diagnostic method for COVID-19 cases [4]. Nonetheless, at the height of the pandemic, the weaknesses associated with the test are accentuated, thus increasing the false-negative rates [5,6]. This is similar to the situation we experienced in Indonesia during our study period.

Therefore, another alternative is needed to help with the COVID-19 triage process. Imaging modalities, primarily chest computed tomography (CT) scan and chest x-ray (CXR), are widely available in most health care facilities. Lung CT is the most effective and sensitive method for diagnosing lung lesions during early disease progression [7]. While CXR is less sensitive than lung CT, it is easier to perform, is more cost-effective, is faster, is more portable, has less radiation exposure, has simpler decontamination, and is more widely distributed. Hence, the latter is the initial radiographic modality of choice amid COVID-19 pandemic [8].

Several scoring systems have been developed to increase CXR’s diagnostic accuracy and reliability in diagnosing COVID-19. The Brixia scoring system (BSS), one of the most commonly used scoring systems, is a semiquantitative CXR scoring system for COVID-19 diagnosis [9]. However, this system is complicated because of the issue of ground truth, which is influenced by rater experience, interobserver agreement, CXR quality, the facility, and the environment surrounding the scoring process. Moreover, additional work burden is imposed on the radiologists as the system relied on manual, subjective scoring and became a less-interesting option at the height of the pandemic [10].

Fortunately, artificial intelligence (AI) is available to ease the workforce burden amid the COVID-19 pandemic. In the past decade, AI has been advancing rapidly, especially in radiology, with applications mainly to diagnose respiratory diseases such as tuberculosis [11]. With the help of AI and machine learning, diagnostic precision can be optimized through computing algorithms for image identification and analysis, resulting in quantitative image scoring [12]. Another important AI role is to determine COVID-19 severity [13], especially in the setting of limited medical resources, equipment, and hospital beds. The correct identification of disease severity can facilitate efficient, adequate, and prompt treatment for those who need it the most.

One of the most used AI software in the COVID-19 pandemic is CAD4COVID x-ray, which detects and scores COVID-19 pneumonia through the color heat map method. This software has been shown to be significantly superior in diagnosing COVID-19 pneumonia through CXR in 454 participants compared with 6 radiologists with an excellent area under the curve (AUC) [14]. However, studies that examined this software utility for disease severity classification remained scarce, especially in low- and middle-income countries such as Indonesia.

Similar to the study mentioned earlier, our study aimed to compare AI performance against that of radiologists. However, in our study, the radiologists used the BSS.

Objectives

The research questions are two-fold: (1) How does the AI scoring system, using the color heat map methodology, compare to the BSS when assessing CXR in correlation with SARS-CoV-2 RT-PCR results among participants suspected of having COVID-19 pneumonia? (2) What is the effectiveness of the AI scoring system in comparison with the BSS for classifying disease severity in participants suspected of having COVID-19 pneumonia?

The rationale for our research questions is in alignment with the WHO’s guidelines, which recommend the use of chest imaging for the diagnostic evaluation of COVID-19 in scenarios where (1) RT-PCR testing is available but results are delayed or in cases where (2) initial RT-PCR testing returns negative results but there is strong clinical suspicion of COVID-19 [15]. Our practical experience indicates that these delays in RT-PCR results can extend up to a maximum of 2 weeks. In addition, during periods of high COVID-19 prevalence, the occurrence of false negatives in RT-PCR tests can be notably elevated. A meta-analysis revealed that under conditions of a 50% disease prevalence rate, the rate of misdiagnosis reached 290 out of 1000 participants [16].

Moreover, the wait for a positive RT-PCR result can significantly disrupt the triage system and the clinical flow for patients suspected with COVID-19 infection, consequently leading to delays in the allocation of appropriate treatments. To the best of our knowledge, this is the first study to examine these questions in an Indonesian population.
Methods

Study Design
This retrospective cross-sectional diagnostic study used secondary data from medical records and picture archiving and communication system chest radiography repositories. This study was conducted at the Rumah sakit Dr. Cipto Mangunkusumo (RSCM) National Referral Hospital, Jakarta. This study included adults (aged ≥18 years) hospitalized with suspected COVID-19 and RT-PCR–confirmed COVID-19 infection, with or without comorbidities, from April 2020 to April 2021. This study excluded cases with substandard chest radiography qualities, large lung cavities on CXR, concurrent mediastinal or lung mass, and an interval between RT-PCR and CXR acquisition of >7 days. Data were extracted from inpatient medical records from the RSCM department of internal medicine from April 2020 to April 2021 that met the inclusion criteria. Sampling was performed consecutively until the minimum number of samples was obtained.

Ethical Considerations
This study protocol was reviewed and approved by the Faculty of Medicine, University of Indonesia’s Ethical Board (approval number Nomor KET-588/UN2. FI/ETIK/PPM.00.02/2020). Written informed consent was waived because of the retrospective nature of the study and amid the COVID-19 pandemic. All medical records and CXRs were deidentified and anonymized to ensure patient confidentiality and compliance with privacy standards. No compensations were given to the participants because of the nature of the study.

Operational Definition
Vaccination data were ascertained from history taking and medical records and Ordinarily stratified into not vaccinated, vaccinated once, and vaccinated twice. COVID-19 disease severity was determined on hospital admission by emergency medical doctors and was stratified according to the local Indonesian guideline, which adopted the WHO COVID-19 disease severity stratification (Table S1 in Multimedia Appendix 1) [17]. Oxygen saturation data were measured using the transmittance pulse oximeter. They were Ordinarily stratified according to normal oxygen saturation (94%-100% on room air), mild to moderate hypoxia (90%-93% on room air), and severe hypoxia (<90% on room air). The RT-PCR data were ascertained from the medical records and used naso- oropharyngeal specimens. Specimen handling and processing for RT-PCR have been described elsewhere [18].

Diabetes was defined according to the American Diabetes Association and the Indonesian Guidelines for the Management and Prevention of Diabetes [19]. Hypertension was defined according to the Indonesian Society of Hypertension Guidelines and the Eighth Joint National Committee [20,21]. Chronic obstructive pulmonary disease and asthma were determined according to the Global Initiative for Obstructive Lung Disease and the Global Initiative for Asthma guidelines, respectively [22,23]. Finally, pulmonary tuberculosis was defined according to the WHO guideline. It was deemed positive if there was a previous history of tuberculosis or active pulmonary tuberculosis [24]. Acute respiratory distress syndrome was defined according to the Berlin criteria [25].

BSS Measurement
The BSS is a semiquantitative method used to measure the severity of lung lesions on CXR. The method has been described in detail elsewhere [9]. Briefly, the lung image on CXR is divided into 6 zones, and each zone can have a score of 0 to 3 with a total maximum score of 18. A total of 2 observers, both board-certified radiologists, measured the score. The third radiologist acted as the ground truth, with >20 years of experience. Every CXR was anonymized before the scoring was performed, and radiologists were blinded to the clinical data. In this study, we focused on the overall CXR score domain of BSS for comparison. We did not establish a predefined BSS cutoff for the classification of positive SARS-CoV-2 RT-PCR results and for the disease severity classification in advance.

AI System for CXR Interpretation
For AI-based CXR interpretation, we used the CAD4COVID x-ray software. It is an advanced AI system built upon deep learning techniques designed for the identification of COVID-19 indicators in frontal CXRs. This cutting-edge system, an extension of the commercially available CAD4TB software (version 6; Thirona), primarily developed for tuberculosis detection in chest radiographs, undergoes initial preprocessing steps, including image normalization and lung segmentation via U-net software. Subsequently, the system uses a patch-based analysis with a convolutional neural network and concludes with image-level classification using an ensemble of networks [14].

The following steps were performed on the software:
1. Digital CXR (Digital Imaging and Communications in Medicine) of patients suspected with COVID-19 infection was pseudoanonymized before image upload with the picture archiving and communication system INFINITT software (INFINITT Healthcare).

2. CXR scoring was performed in 4 consecutive steps, which are as follows:
   - Normalization: this step was to normalize the CXR scale from CXRs with larger or smaller sizes and to be generalized by AI so that it can be processed uniformly.
   - Lung fields segmentation: the AI automatically did this step to delineate the lungs and distinguish them from the rest of the image.
   - Texture analysis: this step was to determine relevant abnormalities in lung segments.
   - Finally, area analysis was done to estimate the percentage of involved lung parenchyma.

3. All filter weights were calculated. The average filter weight was used as a mask on the CXR image to generate a color heat map, which was visualized only in the lung area previously segmented by the previously trained model.

4. The color heat map produced different colors corresponding to its weight. Red, yellow, green, and blue correspond to high,
medium, low, and very low probability of abnormality on the CXR, respectively.

5. The digital CXR was uploaded to the CAD4COVID software to generate 2 AI scorings. First, the affected lung area (ALA) score, with a scale from 0 to 100, was determined according to the total lung volume with abnormalities detected on the CXR. A higher value indicates more lung area that is affected. Second, the COVID-19 probability score, with a scale from 0 to 100, was determined according to the average final weight of all layers. A higher value indicates a higher probability of COVID-19.

The CAD4COVID cutoff for a positive SARS-CoV-2 RT-PCR result and disease severity classification were determined during the study.

**Data Analysis**

**Descriptive Statistics**

We summarized baseline characteristics, presenting categorical variables as frequencies (n) and proportions (%). Continuous variables were described as means with SDs for normally distributed data and as medians with IQRs for nonnormally distributed data. The normality of continuous data was assessed using the Kolmogorov-Smirnov test.

**Interobserver Reliability**

Interobserver reliability was evaluated using the intraclass correlation coefficient (ICC) with a 2-way mixed-effect model (k=2) and consistency. We categorized ICC values as poor, moderate, good, or excellent reliability. Estimated means with their respective 95% CIs were reported for each respective ICC. ICC values of <0.50, 0.50 to 0.75, 0.75 to 0.90, and >0.90 were interpreted as poor, moderate, good, and excellent reliability, respectively. In addition, we also evaluated interobserver reliability based on CXR projections, that is, posteroanterior (PA) and anteroposterior (AP).

**Receiver Operating Characteristic Analysis**

To assess the diagnostic performance of both AI scoring and Brixia scoring, we used receiver operating characteristic curves and AUC analyses. AUC values of <0.60, 0.60 to 0.70, 0.70 to 0.80, 0.80 to 0.90, and 0.90 to 1 were classified as failure, poor, fair, good, and excellent, respectively. The results were calibrated and internally validated using the Hosmer-Lemeshow test and bootstrapping. A comparison between the AUCs was performed using the DeLong test. A P value of <.05 indicates significant difference.

**Optimum Cutoff Values**

We determined the optimum cutoff values for AI scoring (probability score and affected lung score) and the BSS to distinguish the RT-PCR results and classify disease severity. The Youden Index method guided our selection process, aiming for the highest sensitivity with a specificity of ≥50% (Tables S2 to S4 in Multimedia Appendix 1).

**Diagnostic Performance**

We calculated sensitivity, specificity, accuracy, positive predictive value, and negative predictive value based on the chosen cutoff values. The reference standard for COVID-19 diagnosis was RT-PCR, as it is the diagnostic modality needed to confirm COVID-19. The reference standard for disease severity classification was the BSS.

**Agreement Tests**

The agreement between AI and Brixia scoring in relation to RT-PCR results and disease severity was assessed using the kappa statistic. Kappa values of 0 to 0.20, 0.21 to 0.40, 0.41 to 0.60, 0.61 to 0.80, and 0.81 to 1 were classified as slight, fair, moderate, substantial, and near-perfect agreement, respectively.

We adhered to the Standards for Reporting of Diagnostic Accuracy statement in our reporting of results. Statistical analyses were performed using SPSS for Macintosh (version 27; IBM Corp), MedCalc for Windows (version 20.114; MedCalc Software Ltd), and Stata Statistical Software for Macintosh (version 14; StataCorp LP).

**Results**

From April 2020 to April 2021, there were 1145 hospitalized patients with COVID-19 in RSCM National Referral Hospital, Jakarta, with complete clinical data, CXR, and RT-PCR. Only 26.2% (300/1145) of the participants met the inclusion and exclusion criteria. The study outline is presented in Figure 1.
Baseline Characteristics

A total of 300 participants (refer to the Methods section) were enrolled in this study. Demographics, comorbidities, clinical data, and radiology scoring are presented in Table 1.

In this study, most hospitalized patients with COVID-19 were aged <60 years (211/300, 70.3%), with a median population age of 52 (IQR 39.0-61.0) years and male gender preponderance (159/300, 53%). In total, >two-thirds of the patients had a negative RT-PCR result (203/300, 67.7%). Moderate disease severity dominated COVID-19 disease severity. Moreover, the 3 most common comorbidities were hypertension, diabetes, and pulmonary tuberculosis.

Interobserver Reliability of Lung Lesion Severity on CXR With the BSS
The analysis showed no statistically significant difference for every lung zone evaluation and the total score in Brixia scoring between the 2 observers (Table 2).

The ICC score for the BSS for every lung zone was >0.75, with good to excellent reliability for zone A (right upper lobe [RUL]) and zone D (left upper lobe [LUL]). Excellent reliability was noted for zone B (right middle lobe), zone C (right lower lobe), zone E (left middle lobe), zone F (left lower lobe), and for the overall CXR score. The Brixia score for each lung zone and the overall CXR score had similar proportions for both AP (187/300, 62.3%) and PA (101/300, 33.7%) CXR projections. The AP had a lower ICC score with a wider 95% CI (Figure S1 in Multimedia Appendix 1).

Performance Comparison Between Color Heat Map–Based AI Scoring Performance and the BSS on CXR Against SARS-CoV-2 RT-PCR Results of Patients Suspected With COVID-19 Infection
Of the 300 participants suspected with COVID-19 infection, only 32.3% (97/300) had a positive RT-PCR result. Owing to the small number of RT-PCR–positive cases and its large measurement error, no scoring system was able to statistically discriminate between patients who had a positive RT-PCR result and those who had a negative RT-PCR result.

Performance Comparison Between Color Heat Map–Based AI Scoring and the BSS on CXR Against COVID-19 Disease Severity
All scores were higher among 86% (258/300) of cases of moderate to critical disease, when compared with 14% (42/300) of cases of mild disease (P<.001). The receiver operating characteristic analysis showed that the AI probability score, AI ALA score, and BSS had excellent discrimination against COVID-19 disease severity (Table 3; Figure 2).

Compared with the performance of BSS to discriminate disease severity (sensitivity 75.7% and accuracy 79.3%), the AI ALA score had better sensitivity and accuracy (Sn 84.5% and accuracy 83.0%), while the AI probability score did not (Sn 68.2% and accuracy 69.7%). The kappa statistic showed that there were moderate agreements between AI probability score (κ=0.271±0.050; P<.001), AI ALA score (κ=0.452±0.063; P<.001), and BSS (κ=0.456±0.053; P<.001) against COVID-19 disease severity (Table 3). However, there was no significant difference between the AUC for the AI probability score (AUC 0.787) and the BSS (AUC=0.863), with a difference of 0.076 (SD 0.034, 95% CI 0.010-0.142; P=.04). Similarly, no significant difference was observed between the AI ALA score (AUC 0.857) and the BSS, with a negligible difference of 0.006 (SD 0.023, 95% CI –0.039 to 0.052; P=.76), indicating that both AI scores were comparable to BSS in discriminating disease severity (Table 4).

The Hosmer-Lemeshow test shows good calibration and internal validation for the AI probability score ($P=.90$) and AI ALA score ($P=.99$). Calibration and internal validation of the BSS could not be performed.

**Discussion**

**Principal Findings**

In this study, we demonstrated that the BSS had excellent interobserver reliability (ICC>0.75) to determine the severity of lung lesions on CXR (ICC 0.950, 95% CI 0.937-0.960). Our findings are in agreement with previous studies by Mruk et al [26] (ICC=0.847, 95% CI 0.816-0.848) and Chaudhari et al [27] (ICC=0.920, 95% CI 0.880-0.950). Our study also aligns with that of Mruk et al [26], who reported that PA projection had higher interobserver agreement and reliability than AP projection. Thus, it can be assumed that PA CXR projection has better image quality and thus can affect the interpretation.

In the context of lung anatomy, zone A (RUL) and zone D (LUL) had lower ICC values than the other zones. These findings were similar to those of a previous study by Monaco et al [28], who also reported that LUL had the lowest ICC, followed by the right lower lobe and the RUL. A hypothesis explaining these findings is the left upper zone sparing phenomenon seen in COVID-19 pneumonia, that is, infiltrates rarely develop on the LUL and the RUL. Moreover, anatomical structure juxtaposition with the clavicles and scapula influences the scoring subjectivity of these zones.

Although the interobserver reliability was excellent and the mean difference in the overall CXR score was low, the interobserver score had a very wide range ($Δ_{CXR}$ Overall score=0.0-16.0). This difference was influenced by a myriad of factors that were not studied in this research. Similarly, van Assen et al [29] reported poor interobserver agreement when assessing disease severity. The disease severity classification was different in 82% of CXR, with 59% showing a 1° difference in disease severity. The differences were primarily observed in the intermediate group (mild and moderate severity), which can greatly affect clinical decision-making for patient management.

While the semiquantitative method may be seen as more convenient, the subjective nature of this scoring system can give rise to multiple problems, including how to determine the ground truth. Thus, supporting data is needed to justify its use [10]. Moreover, the BSS can contribute to health care workers’ burnout, especially radiologists, as the system relies on them to manually sum up the score.

No scoring system was able to statistically discriminate between which patients had a positive RT-PCR result and which ones had a negative RT-PCR result. These findings might be explained by the low prevalence of positive RT-PCR results (97/300, 32.3%), which might have been caused by a high false-negative rate, considering the true COVID-19 prevalence during the participant enrollment was 47.6% (143/300).

False-negative RT-PCR results can be explained by numerous factors, including exposure time, symptom onset, SARS-CoV-2 virulence, and specimen handling and processing [30-35].

Lai and Lam [31] showed that the interval between the day of exposure and the day of RT-PCR specimen sampling contributed to false-negative rates. False-negative rates of RT-PCR for the 0-, 5-, 8-, and 21-day interval were 100%, 35%, 20%, and 66%, respectively. Viral virulence also contributed to a false-negative rate, as reported in studies by Alteri et al [34] and Pietrollo et al [35]. They showed that the false-negative rates of participants infected with low viral virulence were approaching 20% to 30%.

Another possible contributor to an increased false-negative rate was specimen transportation, considering that the viral specimen should be kept at a minimum of −70 °C to maintain viral isolation and viability [36]. This factor is crucial owing to the unavailability of an in-house RT-PCR facility in our hospital because it was centralized in the early days of the COVID-19 pandemic. Our hospital is a national referral hospital, which might have led to referral bias. Therefore, most patients referred from lower-tier health care facilities with COVID-19 may have negative RT-PCR results as they may have passed the virulence period and many days have passed since the first onset of symptoms. Finally, according to the Indonesian COVID-19 guidelines, the RT-PCR test did not have to be repeated, contrary to the WHO and European Center for Disease Control guidelines, which state that before discharging patients, 2 negative RT-PCRs are needed [4,37].

Therefore, in our circumstances, solely relying on RT-PCR can lead to an underestimation of the COVID-19 diagnosis, which will impact the decision-making and clinical management of COVID-19. In retrospect, as the RT-PCR turnaround time is high with a high operating cost, at the height of the COVID-19 pandemic, another screening modality that is fast, inexpensive, practical, reliable, and noninvasive is needed for triaging, diagnosing, and quarantining suspected COVID-19 cases as measures to curb the pandemic. Nonetheless, this modality will act as an adjunct to conventional CXR and should be incorporated while waiting for the RT-PCR results [38]. Therefore, we preferred CXR rather than CT scan as the modality that we researched because it is widely available, inexpensive, and has low radiation exposure.

Although our findings found that AI and Brixia scoring were poor COVID-19 diagnostic modalities, they were similar to previous studies that also reported that AI and manual radiologist scoring had similar performance. Murphy et al [14] showed that the AI system (AUC 0.810) gave similar scoring results and was even superior compared with 6 radiologists ($P<.001$). This was likely because of the heterogeneous lung lesions seen on CXR in patients with COVID-19, including peripheral and diffuse opacities, which made distinguishing COVID-19 from other pulmonary diseases more challenging. In contrast, Chamberlin et al [39] stated that radiologists had a superior diagnostic ability for COVID-19 (AUC 0.936, 95% CI 0.918-0.960) compared to AI (AUC 0.890, 95% CI 0.861-0.920), despite similar discriminatory abilities between them.

However, the AI scoring system has several advantages over manual evaluation for CXR interpretation. First, an automated...
and quantified AI scoring system will decrease radiologists’ overall work burden. Second, with the help of the AI scoring system, radiologists can increase their accuracy up to 99.05%, which is comparable to that of RT-PCR [40,41]. Moreover, as nonradiologists, especially medical doctors who work on the front line, are the first ones to see the CXR before interpretation by the radiologists, AI use can increase the diagnostic agreement. Hwang et al [42] showed that AI scoring gave similar results to radiologists (AUC 0.714 vs 0.712) but was superior to nonradiologists (AUC 0.714 vs 0.584). Furthermore, hybrid AI use increased diagnostic agreement significantly for both groups (radiologists’ Fleiss κ=0.688, 95% CI 0.665-0.710; nonradiologists’ Fleiss =0.510, 95% CI 0.488-0.533) [42].

In our assessment of AI and BSS performance against disease severity in patients suspected with COVID-19 infection participants, the AI ALA score exhibited higher sensitivity and diagnostic accuracy compared with the BSS, although the difference was not statistically significant. This can be explained by the fact that CAD4COVID can eliminate the technical limitations of conventional CXR, such as its quality. Furthermore, before generating scores, the software normalized the CXR image and segmented lung fields, which optimized CXR image quality [14]. Considering the limited size of our data set, it is not possible to definitively assert the superiority of the AI system over human Brixia. Nonetheless, our analysis indicates a 95% CI that the AI system’s performance is not statistically distinct from that of human Brixia. This finding serves as a promising safety signal, warranting additional comprehensive testing and assessment of AI scoring systems in larger subsequent studies aimed at real-world implementation. Regardless, both had excellent discrimination without significant differences in AUC.

In the context of evaluating AI and Brixia scoring in assessing disease severity among patients suspected with COVID-19 infection participants, both AI scoring systems demonstrated notably higher sensitivity and diagnostic accuracy when compared with the BSS. This superiority can be attributed to the capacity of CAD4COVID to overcome the inherent technical limitations often associated with conventional CXR imaging, including variations in image quality. Notably, CAD4COVID effectively normalized CXR images and meticulously segmented lung fields before generating probability and ALA scores, thereby enhancing overall image quality. Notably, both AI and human Brixia scoring exhibited excellent discrimination without significant disparities in the AUC.

To the best of our knowledge, this is the first study to compare the AI scoring performance using the CAD4COVID software based on AI probability and AI ALA score with the BSS against disease severity in patients suspected with COVID-19 infection participants. Our findings align with those of Guiot et al [43], albeit with a different modality. In their research, CAD4COVID-CT, through the ALA and CT severity score (CT-SS), was able to predict the length of stay, the odds of intensive care unit admission, the odds of mechanical ventilation, and the odds of in-hospital mortality [43]. The cutoff value chosen for odds of intensive care unit admission was CT-SS 14 with an AUC of 0.84 (95% CI 0.79-0.90) and, for odds of mechanical ventilation, it was CT-SS 16 with an AUC of 0.71 (95% CI 0.63-0.78).

The sensitivity, specificity, and accuracy of the BSS were 75.6%, 100%, and 78.4%, respectively. These values were lower than reported by Abo-Hedibah et al [44]. In their study, the BSS sensitivity, specificity, and accuracy in diagnosing moderate disease were 90.4%, 100%, and 94.6%, respectively, whereas in diagnosing severe disease, they were 100%, 84.5%, and 86.7%, respectively. Nevertheless, they referred to disease severity stratified by the WHO, whereas our study referred to the Indonesian national guidelines.

The clinical implications of these findings are 2-fold. First, with the help of AI scoring, a clinician can more confidently exclude moderately to critically ill patients with COVID-19. However, the AI scoring system is image based and not clinically applicable. Thus, it will generate conflicting results when the disease severity classification relies on clinical criteria, as seen in the WHO and Indonesian guidelines [17,45]. In contrast, the US National Institutes of Health COVID-19 guidelines do not solely rely on clinical data [46]. For example, moderate COVID-19 infection can be diagnosed if there are pulmonary infiltrates on imaging. As COVID-19 pneumonia can be asymptomatic or without typical signs and symptoms of pneumonia, we argue that disease severity should be stratified according to the National Institutes of Health guideline [46].

Second, minimal pulmonary lesions on the CXR that are sometimes undetected by manual readers could be identified by AI. The AI probability and the ALA score had higher sensitivities than the BSS to rule out moderate to critical disease. The AI probability and the ALA score can mitigate drawbacks when relying on clinical judgment and conventional radiographs. These findings are significant, as the downstream effect will include patient management, that is, outpatient or inpatient treatment.

According to our study results, we propose the incorporation and clinical application of AI use on CXR as an ancillary diagnostic tool for patients suspected with COVID-19 infection in a structured algorithm. We hope that for future COVID-19 outbreaks, this algorithm can shorten triage and diagnostic time and shorten clinical decision-making as to whether the patients need to be quarantined or hospitalized. As AI and Brixia scoring did not have discriminatory ability against RT-PCR results in suspected COVID-19 cases, we hope that with the addition of clinical and laboratory data, a more precise diagnostic model can be developed. In contrast to the RT-PCR results, the AI and Brixia scoring had an excellent ability to discriminate disease severity in patients suspected with COVID-19 infection, with superior sensitivity and accuracy observed for the former. Thus, AI scoring can be considered for CXR interpretation because of the clinical–radiological incompatibility that can sometimes be observed in patients with COVID-19 pneumonia.

Our study showed that the AI scoring system has the potential to become a disease severity classifier for patients with suspected COVID-19 infection. As the AI scoring system was generated through machine learning, with more data available to train the system, the AI scoring accuracy will continue to increase. We proposed an algorithm for AI incorporation and...
AI application on CXR as an ancillary diagnostic test for patients with COVID-19 (Figure 3).

**Figure 3.** Proposed algorithm of artificial intelligence (AI) incorporation and AI application on chest x-ray as an ancillary diagnostic test on patients with COVID-19. ALA: affected lung area; CXR: chest x-ray; Prob: probability; RT-PCR: reverse transcription–polymerase chain reaction.

**Limitations**

Our study has several limitations. First, the study population is relatively small compared with the COVID-19 prevalence during the participant’s enrollment, owing to missing data and the study’s exclusion criteria. Second, as our hospital is a national referral hospital, most patients came with moderate to critical disease and presented with other pulmonary lesions. Furthermore, several study variables could not be retrieved as they were not incorporated into the patient’s medical record. Finally, in the early days of the pandemic, our hospital did not have an in-house RT-PCR facility because of the centralized specimen processing, so the specimen had to be delivered to another facility, which could further compromise RT-PCR results.

**Conclusions**

The AI score for the ALA and the human radiologist Brixia score had similar and good discrimination performance in predicting COVID-19 severity. Our study demonstrated that using AI-based diagnostic tools is possible, even in low-resource settings. However, before it is widely adopted in daily practice, more studies with a larger scale and prospective in nature are needed to confirm our findings.

Abstract

Background: Polycystic ovary syndrome (PCOS) represents a significant global health burden requiring urgent attention. This common chronic endocrine and cardiometabolic condition affects around 1 in 10 women and individuals assigned female at birth, with significant adverse effects on well-being, quality of life, and mental health, as well as serious and complex long-term health consequences. International guidelines for best health care practice recommend the provision of comprehensive cognitive behavioral interventions to support self-management and improve health outcomes for those living with PCOS. Web-based health interventions have the potential to meet this need in an accessible and scalable way.

Objective: We aim to identify barriers to self-management and psychological well-being in women with PCOS and adapt a web-based self-management program to provide a prototype digital support intervention for them.

Methods: We adapted an existing support program (HOPE) for PCOS using the antecedent target measure approach. We conducted qualitative interviews with 13 adult women living with PCOS, 3 trustees of a patients with PCOS advocacy charity, and 4 endocrinologists to identify “antecedents” (barriers) to self-management and psychological well-being. Framework analysis was used to identify potentially modifiable antecedents to be targeted by the novel intervention. At a national conference, 58 key stakeholders (patients and health professionals) voted for the antecedents they felt were most important to address. We used research evidence and relevant theory to design a prototype for the PCOS intervention.

Results: Voting identified 32 potentially modifiable antecedents, relating to knowledge, understanding, emotions, motivation, and behaviors, as priorities to be targeted in the new intervention. A modular, web-based prototype HOPE PCOS intervention was developed to address these, covering six broad topic areas (instilling HOPE for PCOS; managing the stress of PCOS; feeding your mind and body well; body image, intimacy, and close relationships; staying healthy with PCOS; and keeping PCOS in its place).

Conclusions: We identified barriers to self-management and psychological well-being in women with PCOS and used these to adapt a web-based self-management program, tailoring it for PCOS, which is a comprehensive group intervention combining education, empowerment, lifestyle management, peer support with cognitive behavioral tools, and goal-setting (to be delivered by peers or codelivered with health care professionals). The modular structure offers flexibility to adapt the program further as new clinical recommendations emerge. The intervention has the potential to be delivered, evaluated for feasibility, and, if effective, integrated into health care services. Self-management interventions are not designed to replace clinical care; rather, they serve as an additional source of support. The HOPE PCOS program conveys this message in its content and activities. Future research should evaluate the prototype intervention using primary outcomes such as measures of psychological well-being, self-management self-efficacy, depression, anxiety, and PCOS-related quality of life. They should also assess the intervention’s acceptability, scalability, and cost-effectiveness.
Introduction

A Complex Condition With Serious Physical and Mental Health Consequences

Polycystic ovary syndrome (PCOS) represents a significant global health burden requiring urgent attention [1]. It is a common chronic cardiometabolic condition affecting around 1 in 10 women and individuals assigned female at birth. PCOS has diverse symptoms, for example, acne, alopecia, hirsutism, obesity, impaired glucose metabolism, menstrual disturbances, and subfertility [2-4]. It has significant adverse effects on well-being, quality of life, and mental health. For example, compared with healthy controls, women with PCOS have lower health-related quality of life and higher scores on symptoms of depression and anxiety [5-9], and appear to be at risk for disordered eating [10-14] and unhealthy weight management practices [15]. There is also evidence that women with PCOS may experience impaired sexual satisfaction [16], which may impact relationship satisfaction for those in intimate relationships [17]. The adverse mental health impact of PCOS may have been worsened during the COVID-19 pandemic, as patients faced an uncertain risk of contracting COVID-19, more limited access to health care services, and barriers to using their normal support strategies [18].

PCOS has serious and complex long-term health consequences [19,20]. Women with PCOS are at increased risk of sleep disturbances [21] and obstructive sleep apnea [22,23] and appear to have an elevated risk for postpartum depression [24]. They also have an increased risk of developing type 2 diabetes and cardiovascular complications [4]. Hospital admission rates for patients with PCOS have been reported to be twice as high as those without the condition [25].

The Need for Self-Management Support

PCOS is a long-term condition with no cure, having a wide range of treatment options but no single treatment that targets every symptom or concern. Treatments are often complex and multifaceted and often include recommendations for lifestyle change, for example, altering diet and increasing physical activity [4]. Considerable self-management is required on the part of those living with PCOS, including adherence to treatment. There are wide disparities in adherence, with 1 review suggesting adherence rates ranging from 21.7% to 86% [26]. A large-scale survey suggests women with PCOS are open to adjusting their diet and physical activity to improve their health, but few achieve their goals [27].

Recent qualitative research [28-33] has identified that women with PCOS face a range of barriers to following health professionals’ lifestyle advice, including limited access to credible information, time, cost, and lack of access to safe exercise spaces, with some women lacking adequate social support, having unsupportive partners, or struggling to prioritize their own health because of responsibilities for feeding children [29]. In addition, women’s motivation and capability to adhere to recommended lifestyle changes may be impacted by the complex and multifaceted nature of PCOS, including fatigue, anxiety, depression, difficult emotions, disordered eating, the impact of stress, sleep disturbances, and a lack of critical health literacy [28,29,31-33]. Features of PCOS itself may add to the burden of following lifestyle advice, especially around weight management. For example, altered regulation of gut hormones and energy expenditure may affect women’s capability to follow diet and exercise regimes [28].

The Need for Comprehensive, Evidence-Based, Coproduced Interventions

Patients with PCOS value specialized, integrated health care services [34], and it has been argued that the ideal model of care would be “evidence-based, patient-centered, codeveloped by consumers and health professionals” [35]. International guidelines advise (in addition to appropriate medical treatment) “Comprehensive health behavioral or cognitive behavioral interventions could be considered to increase support, engagement, retention, adherence, and maintenance of a healthy lifestyle and improve health outcomes in women with PCOS.” [4]. There is therefore scope for developing new interventions that combine education and cognitive behavioral approaches with peer support to promote physical activity, healthy eating, and emotional well-being in women with PCOS. This multifaceted approach reflects the tradition of long-term self-management that is well established in other endocrine conditions, such as diabetes [36]. Self-management is arguably broader than lifestyle change, referring to what patients must do to manage their own health in collaboration with health professionals [37,38]. This may include behavior change but also requires emotional regulation, coping, and maintaining general well-being, such as self-worth, a positive outlook, and hope [39].

Objectives for This Study

The first aim of the study was to identify barriers to self-management and psychological well-being in women with PCOS. The second aim was to combine insights from these data to cocreatively adapt an existing web-based program to offer a prototype peer-delivered, self-management intervention to empower and support women with PCOS to enhance their psychological well-being and, if they chose to, to make appropriate lifestyle changes to self-manage their condition.

To develop our novel self-management intervention for PCOS, we selected an existing intervention that has been researched and evaluated with multiple patient groups. The HOPE program [40] is a complex intervention for long-term condition self-management with a distinctive theory and evidence base from positive psychology [41]. The HOPE program has reduced anxiety and depression and increased positive well-being for...
people with a range of health conditions and support needs, for example, people living with multiple sclerosis [42], parents of children with developmental disorders [43], and people living with and after cancer [44].

**Methods**

**Approach to Intervention Development**

The UK Medical Research Council’s (MRC) guidance on developing complex interventions [45,46] recommends that intervention development should be “a dynamic iterative process, involving stakeholders, reviewing published research evidence, drawing on existing theories, articulating program theory, undertaking primary data collection, understanding context, paying attention to future implementation in the real world, and designing and refining an intervention using iterative cycles of development with stakeholder input throughout” [46].

The most recent framework commissioned by the National Institute of Health Research and the MRC [47] further emphasizes the importance of developing interventions that are “implementable, cost-effective, transferable, and scalable in real-world conditions.” This may include adapting existing interventions and using existing, for example, digital infrastructure, rather than developing wholly new interventions ab initio. We chose to adapt and tailor an existing intervention to build on its previous successes and use its proven, scalable digital infrastructure to offer a PCOS intervention that would be as implementable, transferable, and scalable as possible.

The HOPE cancer program from which this intervention was adapted [44] was developed following the MRC recommended processes and continues to undergo refinements as each cohort or variant of the program is completed. In adapting HOPE for PCOS, we conducted an initial needs assessment with key stakeholders, reviewed published research evidence from primary sources, review papers, and international clinical guidelines, and drew on established and emerging theories about psychological well-being to produce a prototype digital intervention [48] that could be subjected to feasibility testing.

**Underpinning Theory and Evidence: Self-Management Versus Behavior Change**

Interventions in the field of health behavior are more likely to be successful if they are theory-based [49]. A number of different approaches were considered for adapting the existing HOPE program, including the behavior change wheel [50] and intervention mapping [51]. However, both of these approaches require very clear specification at the outset of the intervention design of what the target behavior is that the intervention seeks to increase, decrease, promote, or modify. “Lifestyle change” is recommended as a first-line treatment in relation to the management of PCOS, and this often refers to changes to diet and physical activity. However, there is as yet no international consensus as to what precise optimal self-management behaviors might be in PCOS, and it was felt that the groundwork was lacking for the development of a behavior change intervention per se. Given the diversity of the PCOS population, for example some are lean, some are living with overweight and obesity, some are trying to conceive, others are not, some are physically active, some are more sedentary, some have issues around eating, and others are not, the development of a behavior change intervention to meet the needs of all these was beyond the scope of this study. As our objective was to adapt the existing HOPE program to support self-management, reduce depression and anxiety, and promote psychological well-being rather than develop a completely new intervention from scratch, we used the design process outlined in the following sections.

**Cocreation Process**

An iterative process of cocreation was used to develop the intervention, using a mixed methodology. An initial needs assessment was conducted with key stakeholders, following the antecedent target measure (ATM) approach [52,53]. This is a flexible model that has been used in the development of previous self-management interventions, for example, for people living with cancer or dementia [54,55].

**Initial Data Collection**

Semistructured interviews were conducted with women living with PCOS, trustees of the Verity UK PCOS charity who themselves had PCOS, and endocrinologists who provided services to patients with PCOS at a large publicly funded teaching hospital.

**Participant Characteristics**

Those with lived experience of PCOS were 13 adult women recruited through purposive sampling from social media. All had received a formal diagnosis of PCOS from health professionals at least 6 months before the study and took part in individual interviews. The Verity trustees were 3 adult women, all diagnosed with PCOS by National Health Service (NHS) clinicians, who volunteered to be interviewed to assist with the “cocreation” of the new intervention. The health professionals interviewed in December 2016 were 4 endocrinologists working for a large UK NHS teaching hospital, which has a specialist clinic for PCOS.

**Procedure**

Interviewees were presented with the problem statement “Some women with PCOS struggle to cope and self-manage effectively” and asked if they agreed and, if so, to give all the reasons why. The reasons given (“antecedents” in the terminology of ATM) were typically difficulties women experience with PCOS and in self-managing their condition. Interviews continued until participants felt they had exhausted all the antecedents they viewed as relevant for PCOS. Antecedents and the conversation through which they were generated were audio recorded and transcribed verbatim for the patient interviews. Antecedents were transcribed contemporaneously for the trustee and health professional interviews.

**Analysis**

All the antecedents generated across interviews were collated and analyzed thematically following the framework analysis approach to theme development [56] to identify potential targets for intervention. When targets were chosen for intervention, only those considered to be potentially amenable to change by a self-management intervention were selected. For example,
the following antecedents were excluded: endocrine characteristics of PCOS itself, social and environmental factors such as stigmatizing behavior from others, and issues with the health care system such as general practitioners’ awareness of PCOS. Once antecedents judged to be unsuitable targets for the intervention were excluded, 36 potentially modifiable antecedents remained.

**Stakeholder Voting on Priorities for Intervention**

A web-based survey was created listing the 36 modifiable antecedents, and delegates at a national public engagement conference were asked to rate each of these on a 5-point scale of how important they would be to target in a self-management intervention (0=not at all important, 1=somewhat important, 2=important, 3=extremely important, and 4=crucial). Conference delegates included patients with PCOS and advocates and some health professionals treating PCOS, of whom 58 voted in the survey. All modifiable antecedents scoring 2.5 or above were retained as intervention targets; antecedents scoring below 2.5 were discarded.

**Literature Searches for Intervention Targets**

Literature searches were conducted, and clinical guidelines were consulted to generate further intervention targets. Review and systematic review papers [2,16,57-68] were reviewed alongside an international clinical guideline for the management of PCOS [4]. No new targets were generated from the literature, which confirmed the findings from the needs assessment with key stakeholders.

**Adaptation of Existing Digital Intervention and Consultation With Stakeholders**

The existing HOPE program has previously been specified using the Practical Reviews in Self-Management Support (PRISMS) self-management intervention taxonomy [69], and new intervention components were mapped onto or added to the program specification. New program content specific to the prototype PCOS program was created to complement the existing HOPE program materials. A paper prototype was presented to key stakeholders from the PCOS support charity, and following discussion, the new program materials were created and uploaded into the secure web-based platform that hosts the HOPE program. This produced a 6-week web-based intervention ready for feasibility testing.

**Ethical Considerations**

This study received clearance from the Coventry University Research and Ethics Governance Committee (approvals P40730, P44631, and P45355). For the data collection from health care professionals, NHS Research Ethics Committee approval was not required. A letter of access for research was provided by the Research, Development, and Innovation office of the University Hospitals Coventry and Warwickshire NHS Trust. Participants provided written, informed consent before being interviewed. Patients with PCOS and health care professionals at the public engagement event completed a digital informed consent statement before completing the web-based voting survey. Interview transcripts were anonymized for analysis. No personally identifiable data were collected in the voting survey. No compensation was offered to any participants.

**Results**

**Stakeholder Needs Assessment and Voting**

Table 1 shows the list of modifiable antecedents presented in the next stage of the intervention design. Figure 1 shows a diagrammatic representation of the logic model developed from the PCOS self-management needs assessment done with stakeholders.
Table 1. Modifiable antecedents of polycystic ovary syndrome (PCOS) self-management and psychological well-being in order of priority, as voted on by patient and health care professional delegates at the public engagement event.

</tbody>
</table>

Potential antecedents scoring below 2.5 were discarded as intervention priorities. This left 32 antecedents that were targeted by the new intervention, 10 of which were thematically categorized in the framework analysis under behaviors, 9 under emotions, 8 under knowledge and understanding, 8 under motivation, and 1 under skills.
In a typical ATM design, logic models are often presented as linear processes in which 1 antecedent, such as knowledge or understanding, is represented as preceding another, such as motivation or behavior. We have selected the metaphor of interlocking gears for our schematic logic model on the assumption that knowledge, understanding, skills, motivation, emotions, and behavior interlock and may drive or impede each other, at times facilitating or hampering effective self-management. For example, a person might gain helpful knowledge about their condition, but without developing skills to apply this to practice, they might be unable to engage in effective self-management behaviors. Similarly, a person might have adequate knowledge, understanding, and skills to manage their condition, but difficult emotions might adversely impact their motivation and prevent effective self-management. This logic model was used to inform the adaptation of the existing HOPE program framework to produce a specific version for PCOS.

Mapping Modifiable Antecedents Onto Intervention Content

Table 2 shows how the antecedent “problems” derived from the logic model were mapped onto solution-focused content across 6 sessions of the prototype intervention.
Table 2. Mapping of antecedents of polycystic ovary syndrome (PCOS) self-management and psychological well-being onto new PCOS self-management intervention session content.

Choosing Theory- and Evidence-Based Intervention Components to Address Modifiable Antecedents of Self-Management

The HOPE program framework used to develop the PCOS intervention includes the following self-management intervention components: information about available resources, safety netting, training and rehearsal to communicate with health care professionals, training and rehearsal in psychological strategies, social support, and lifestyle advice and support [69]. Below, we outline how specific intervention content was selected to address the antecedents identified in the logic model for PCOS self-management.

Information and Activities to Target Knowledge and Understanding for Self-Management

Women with PCOS have unmet information needs [63,70-72] and may lack knowledge of how to manage their condition, for example, how to eat well to manage insulin resistance [33,73]. Unmet information needs may adversely impact...
self-management, including adherence to treatment [26,28,32,74,75]. PCOS-specific information is valued by patients with PCOS and may address unmet psychosocial needs [76-78], potentially enhancing understanding, reducing anxiety, and promoting quality of life [79]. There is a plethora of information sources available on the web, of varying quality, making it difficult for women with PCOS to select trustworthy material [71,80-83]. Signposting to trustworthy information sources may support patient activation and self-management. In the prototype intervention, factual information is provided about PCOS, including androgen excess and food intake, blood sugar and insulin resistance, eating well, and managing weight.

The needs assessment and previous research [84,85] indicate women may have concerns about the long-term health sequelae of PCOS. Motivation to adopt healthy lifestyles may be impacted by perceptions of the health risks associated with PCOS [28]. In the prototype intervention, content is provided on focusing on future health and ways to manage emerging health concerns and worries. Information about specialist health professionals, the range of support, and some potential treatment options is designed to empower participants to be active partners in their health care. The intervention seeks to empower participants to engage in health protective behaviors, for example, exercise, healthy eating, self-monitoring of their health, managing worries to alleviate health anxiety, and future help-seeking as any new health issues arise. Links to further information and resources are provided, for example, Verity (a UK PCOS charity), the NHS Choices website, the NHS Improving Access to Psychological Therapies service, and the AskPCOS app [86].

**Goal Setting and Feedback to Target Self-Management Motivation and Behavior**

Women with PCOS may struggle to achieve the goals they set for lifestyle change [27], may lack the ability to identify and resolve barriers [32], experience tiredness, feel unrewarded, or have depressive and defeating thoughts that act as barriers to achieving their goals [29]. Goal setting is a widely used and effective component of self-management support [87,88]. Goal-oriented care, emphasizing patient priorities and values, may be particularly appropriate for patients with chronic or multifaceted health concerns [89]. Goal-setting theory and research recommend paying attention to multiple goal factors and multiple phases in the goal process [90].

Goal setting and solution-focused goal feedback are included in every session of the prototype intervention, with weekly and long-term goals chosen by participants themselves based on their personal priorities and values rather than set or recommended by program facilitators. The goal-setting and feedback processes are facilitated by peer facilitators, with attention to goal difficulty, goal specificity, goal proximity, goal commitment, and solution-focused feedback.

**Psychoeducation and Activities to Target Emotions**

Women with PCOS are prone to higher perceived stress [91], and stress may also impact women with PCOS differently and have an impact on the physiology of the condition [92,93]. Stress may be a barrier to lifestyle change [32]. Mindfulness-based stress reduction activities have been effective in reducing stress, depressive, and anxiety symptoms in PCOS [94] and in increasing self-efficacy for physical activity and nutrition behaviors [95]. Physical activity has well-recognized benefits for mood and perceived stress [96,97], including in women with PCOS [98,99]. In the prototype intervention, content is provided on managing stress, including mindfulness, soothing rhythm breathing, guided imagery, and “get active, feel good.” Because interviews with health professionals during the needs assessment suggested that some women with PCOS may exercise in dysfunctional ways in order to lose weight, the PCOS prototype intervention does not promote exercise for weight loss per se but rather for stress management and general well-being.

Psychological comorbidities may be a barrier to lifestyle change [32]. Interventions using aspects of cognitive behavioral therapy (CBT) have shown promise for improving fatigue, quality of life, weight loss, and depressive symptoms in women with PCOS [100-103]. In the prototype intervention, CBT-informed content is provided on managing common unhelpful thinking patterns. Compassionate mind approaches (sometimes referred to as part of a “third wave” of CBT) are particularly relevant to disordered eating, emotional eating, and weight management [104-107]. In the prototype intervention, a compassionate mind approach is taken to eating well, including eating mindfully, overeating, binge eating, and self-soothing.

Self-compassion activities, compassionate mind training, and compassion-focused therapy have been demonstrated to be particularly beneficial in improving anxiety, depression, shame, and self-criticism [106,108-111]. These issues have been identified as common in populations with PCOS. In the prototype intervention, content is provided on self-compassion, including, for example, compassion for perceived flaws, toward feelings of embarrassment or shame, and “getting to know your inner critic.”

Women with PCOS may have reduced relational and marital satisfaction [17,112], sexual satisfaction, function, and sense of sexual attractiveness [16,113-119]. Body dissatisfaction may be a barrier to lifestyle change [28]. The prototype intervention discusses and seeks to normalize the topic of common body changes and associated distress, for example, acne, alopecia, hirsutism, obesity, and associated low self-esteem, frustration, and depression, which have been identified in previous research [84,120-123], and in the needs assessment. Content is provided on common body changes in PCOS and associated difficult emotions. The potential impact of PCOS on intimate relationships and sexuality is explored, along with suggestions for ways to cope and adjust.

The population with PCOS is diverse, including women who will be more or less concerned about visible or invisible body changes. Interventions may empower them to respond and adjust in ways that are personally appropriate, including accepting changes, making adaptations, or seeking treatment, for example, for obesity or hirsutism. Previous research, including the needs assessment, indicates that embarrassment or shame may lead women to conceal the extent of their bodily changes, even from health professionals [124-127]. In the prototype intervention,
content is provided on responding to change, including acceptance, treatments and adaptations, and overcoming embarrassment to get help for body changes. The PCOS intervention takes an autonomy or body acceptance approach [128,129]. Unrealistic female body standards and body-positive activism are discussed in the program materials.

Women may struggle to manage and control their PCOS symptoms, especially if they have comorbidities, sometimes feeling controlled by their condition [84]. Motivational imagery interventions are widely used in sports psychology, with benefits for motor performance, motivational outcomes, and affective outcomes [130] and found to be motivating by a number of different populations, including people trying to manage their weight or type 2 diabetes [131,132]. Emotional mental imagery interventions have shown promise for reducing anxiety and depression [133,134]. Prospective (future-focused) mental imagery interventions are particularly relevant to fostering optimism in people with depression [135]. In the prototype intervention, content is provided on life priorities and motivational imagery—“keeping PCOS in its place”—and future-focused mental imagery.

Positive psychology interventions, such as character strengths and gratitude diaries, which focus on function rather than dysfunction, have shown promise in treating anxiety, depression, low mood, and low self-esteem and in promoting positive well-being [136-138]. In the prototype intervention, content is provided on maximizing psychological resources, for example, by focusing on character strengths and gratitude diaries rather than focusing purely on psychological deficits and dysfunctions.

**Activities for Development of Self-Management Communication Skills**

Being able to communicate the need for practical and social support is essential for effective self-management. Communicating with friends, family, peers, and health professionals may be particularly difficult for women with PCOS because of its sometimes visible, sometimes invisible nature and associated taboos and stigma [139-142]. In the prototype intervention, content is provided on communication, including communicating concerns with friends, family, peers, and health professionals.

The intervention explicitly acknowledges the issue that some women with PCOS may lack trust in, or feel dismissed or stigmatized by, health professionals [70,71,143-147]. Some health professionals treating PCOS recognize that “lifestyle change,” especially around weight, is a sensitive topic [148], but some patients report a lack of trust in and perceived lack of empathy from health professionals. Intervention materials in the prototype explore and deconstruct health communication around weight to foster shared understanding and trust.

People with long-term health conditions need a range of knowledge and skills to navigate health care systems and participate actively in consultations and care [149]. In the prototype intervention, content is provided on maximizing support from health services and health professionals, including health care specialists who treat PCOS, treatments, “why it may sometimes sound like health professionals are being preachy or judgemental,” summarizing concerns and requesting a referral, shared agenda setting at health care appointments, and communicating clearly and assertively with health professionals.

**Building on Therapeutic Peer Group Factors and Collective Advocacy**

Women with PCOS are interested in group education interventions [150]. Group psychosocial and psychoeducational interventions provide particular therapeutic factors, for example, instillation of hope, universality, imparting of information, and opportunities for altruism and catharsis [151]. A lack of social support may be a barrier to lifestyle change [32,33]. Group and peer support, provided face-to-face or on the web, have been beneficial for those living with PCOS [76,78,152-154]. Peers delivering interventions may be well placed to express empathy and to act as realistic role models, supporting self-management [155-157].

Peer group factors are emphasized and facilitated throughout the prototype PCOS intervention, including, for example, self-management, “your PCOS journey,” getting peer support, open space forums, support from health professionals, peers, and the UK PCOS charity, and signposting to ongoing participation with PCOS-related groups and networks. The intervention is delivered in a web-based group format with secure digital social sharing features, for example, a gratitude wall, hopes and dreams, goal sharing, and delivery by trained peer facilitators who themselves had PCOS. Group delivery allows the intervention to be made available to multiple participants, saving time and resources for facilitators.

Improving health care access and outcomes for PCOS is not simply a matter of individual patient assertiveness. Collective collaborative action between patients, health professionals, and powerful others is needed to bring about change. In the prototype intervention, content acknowledges the limits of personal assertiveness and emphasizes the value of collective action. For example, we signpost to activism by Verity [158] and other women’s health organizations.

**Modular Web-Based Format for Accessibility And Scalability**

Digital health interventions offer considerable scope for accessibility and scalability [159]. The prototype PCOS intervention is designed to be delivered digitally through a secure social platform developed by the social enterprise community interest company Hope for the Community (H4C) [160]. The social enterprise company hosts the intervention and delivers interventions may be well placed to express empathy and to act as realistic role models, supporting self-management [155-157].

Improving health care access and outcomes for PCOS is not simply a matter of individual patient assertiveness. Collective collaborative action between patients, health professionals, and powerful others is needed to bring about change. In the prototype intervention, content acknowledges the limits of personal assertiveness and emphasizes the value of collective action. For example, we signpost to activism by Verity [158] and other women’s health organizations.

**Program Specification**

Textbox 1 shows the content of the 6-week prototype intervention program. Solution-focused goal setting and feedback, open forum discussions, and further resources are provided in every session.
The H4C team uploaded the additional content and created a working prototype intervention that was checked and tested, ready for a pilot study with women living with PCOS.
Textbox 1. Content of polycystic ovary syndrome (PCOS) intervention.

Session 1: Instilling HOPE for PCOS
- Welcome and introductions
- Responsibilities and ground rules
- Instilling HOPE
- Diaphragmatic breathing
- Gratitude diary
- Your PCOS journey
- Support from health professionals, peers, and Verity (UK PCOS charity)
- PCOS basics: androgen excess & insulin resistance
- Test your PCOS basics: quiz
- Factual information about PCOS
- Self-management
- Self-compassion

Session 2: Managing the stress of PCOS
- Gratitude diary
- Managing stress
- Mindfulness
- Physical activity for stress management: “get active, feel good”
- Managing common unhelpful thinking patterns (cognitive behavioral therapy [CBT])
- Mindfulness: and am I doing this “right”?;
- Why self-compassionate mindfulness?
- Compassion-focused therapy

Session 3: Feeding your mind and body well
- Gratitude diary
- Eating well in PCOS: role of food intake, blood sugar, and insulin
- Why being insulin resistant is a problem for the whole body
- Why it may sometimes sound like health professionals are being preachy or judgmental
- Eating well without depriving yourself, losing weight in PCOS
- Eating mindfully to eat well in PCOS
- Overeating and binge eating in PCOS: some helpful tips for reducing the chances of overeating
- Feeding your mind and body well
- Feeding your mind: three systems regulating our emotions
- Ways to soothe yourself without over- or undereating
- Getting to know your inner critic, developing a compassionate ideal

Session 4: Body image, intimacy, and close relationships
- Gratitude diary
- Body changes, sexuality, and intimacy
- Communication
- Common body changes in PCOS
- Difficult emotions that can come with body changes
- Getting ready to be self-compassionate
- Compassion for your perceived flaws
Overcoming embarrassment to get help for body changes
- Getting ready to be self-compassionate toward feelings of embarrassment or shame
- Responding to change: acceptance, treatments, and adaptations
- Treatments

Session 5: Staying healthy with PCOS
- Gratitude diary
- Focusing on your future health
- Ways to manage emerging health concerns and worries about your future health
- Getting peer support
- Maximizing your psychological resources
- Maximize the support you get from health services and health professionals
- Health care specialists who treat PCOS
- Activity: Summarizing concerns and requesting a referral
- Communicating clearly and assertively with health professionals
- Activity: Shared agenda setting at health care appointments
- When communicating clearly and asking assertively do not get you what you want

Session 6: Keeping PCOS in its place—your strengths and life goals
- Gratitude diary
- Character strengths
- Life priorities
- Motivational imagery
- Sharing our successes
- Self-compassion
- Activity: self-compassionate letter
- Signposting to ongoing participation with PCOS related groups and networks

**Discussion**

**Principal Results**

We cocreatively identified and prioritized barriers to self-management and psychological well-being to adapt a successful web-based self-management program and tailor it for the needs of adult women with PCOS. We developed a web-based prototype program for the PCOS program, ready for testing with this population.

**Comparison With Previous Work**

Women with PCOS value specialized, integrated, evidence-based, patient-centered health care services, ideally codeveloped with consumers and health professionals [34,35]. The new HOPE PCOS intervention has been codeveloped by combining input from patients, patients with PCOS’ advocates, and health care professionals. It is a comprehensive intervention integrating education and empowerment with lifestyle management, cognitive behavioral tools, and peer support, ready to be delivered by trained peer facilitators or codelivered by peers and health care professionals.

Developed following MRC guidance for the development of complex interventions [45,47], the intervention is evidence-based, underpinned by relevant theory, and designed to support a collaborative approach to care. Subject to evaluation, the new intervention could be integrated as part of PCOS services to support self-management and the model of collaborative, patient-centered health care advocated by international guidelines [4,161].

The intervention deploys an existing secure web-based social platform that has been used successfully to scale up other self-management support programs for other populations and conditions [40,44]. The multicomponent and modular structure of the program offers flexibility in adapting it further as new clinical recommendations and patient information emerge. The intervention is therefore well placed to be delivered and evaluated at scale.

The HOPE PCOS intervention is designed to support self-management and promote psychological well-being, rather than as a behavior change intervention per se. Since we started the process of cocreating the HOPE PCOS intervention, a different team has undertaken development work for a behavior change lifestyle intervention using a different intervention design.
model [28,31-33]. That work has not yet, to our knowledge, resulted in a prototype intervention. However, the findings from the needs assessment work conducted by that team for their lifestyle intervention concur considerably with our own needs assessment results, showing that women living with PCOS may often experience barriers of capability, opportunity, and motivation, for example, a lack of credible information, difficulty managing multiple health conditions, limited access to resources, adequate social support, and issues such as health expectancies and emotional eating affecting their motivation to engage in lifestyle change [33].

Limitations
The current HOPE PCOS intervention is based on a needs assessment conducted with adult women. As part of the iterative cocreation process, further needs assessments may be required to adapt and tailor future versions of the intervention for other populations, for example, adolescents with PCOS, as concerns, distress, and intervention format preferences may differ [162]. There is scope to develop variants of the intervention for specific adult populations, for example, perimenopausal, menopausal, or postmenopausal women with PCOS who may have specific concerns [163-165]. The intervention might also be tailored to support trans and nonbinary people with PCOS, those with particular concerns such as weight management, comorbid conditions, or those actively trying to conceive. More cocreation and development work could be done to ensure the intervention is culturally appropriate. The intervention is intended to provide extra support and not to bypass what is recommended by a clinician. Women with PCOS are not advised to rely fully on this self-management intervention and are advised to consult a clinician as appropriate.

Cocreative intervention development is an iterative process, and, in addition to tailoring the HOPE PCOS intervention for different populations, future iterations may need to develop new content or place greater emphasis on some components, depending on how participants and health professionals evaluate the program. If consensus emerges about specific target behaviors for self-management in PCOS, it may be necessary in the future to adapt the intervention to promote specific behavior change. For example, the current content promoting physical activity could be modified and refined to promote a target level of physical activity, or the current material on healthy eating could be modified to promote specific changes in eating behavior.

Although the prototype intervention has been collaboratively co-designed to support self-management and psychological well-being, further feasibility research is needed with patients with PCOS using the program. This should evaluate the program’s acceptability as well as its impact on key outcomes such as measures of self-management, depression, anxiety, and psychological well-being. Future work is also needed to assess the intervention’s scalability, cost-effectiveness, and suitability for integration with standard care.

Conclusions
The development of the novel HOPE PCOS intervention contributes to ongoing efforts to support patients with long-term conditions to self-manage effectively and is, to our knowledge, the first such program for patients with PCOS. This study has demonstrated that comprehensive intervention programs can be codeveloped with patients with PCOS, patient advocates, and health care professionals to address multiple barriers to self-management and psychological well-being. A person-centered, holistic approach, organized around the self-reported needs and priorities of patients, may produce interventions that complement services provided by health care professionals and patient advocacy and support organizations. This study demonstrates that the use of a remote digital platform with preloaded, evidence-based intervention content may offer economies of scale in that complex self-management support interventions might be delivered to many patients in parallel, potentially saving clinic resources for one-to-one care. A key message for those working to develop lifestyle or self-management support interventions is the potential value of adapting an existing program and reusing existing digital infrastructure to provide a tailored intervention without the additional resource implications of developing an entire intervention from scratch.

Acknowledgments
The HOPE Program is delivered by Hope for the Community, a community interest company of Coventry University. The intervention development work for this polycystic ovary syndrome intervention was supported by a short-term temporary research sabbatical for CP funded by Coventry University. The patient interviews were conducted by CO as part of her master’s study in Health Psychology at Coventry University.

Data Availability
The data sets generated or analyzed during this study are not publicly available due to participants’ consent being given for anonymized extracts only (not whole transcripts) to be used in published reports, but data are available from the corresponding author upon reasonable request.

Conflicts of Interest
AT is the co-inventor of the original HOPE Program, co-founder, and nonexecutive director of Hope For The Community (H4C).

Abstract

Background: Vancomycin pharmacokinetics are highly variable in patients with critical illnesses, and clinicians commonly use population pharmacokinetic (PPK) models based on a Bayesian approach to dose. However, these models are population-dependent, may only sometimes meet the needs of individual patients, and are only used by experienced clinicians as a reference for making treatment decisions. To assist real-world clinicians, we developed a deep learning–based decision-making system that predicts vancomycin therapeutic drug monitoring (TDM) levels in patients in intensive care unit.

Objective: This study aimed to establish joint multilayer perceptron (JointMLP), a new deep-learning model for predicting vancomycin TDM levels, and compare its performance with the PPK models, extreme gradient boosting (XGBoost), and TabNet.

Methods: We used a 977-case data set split into training and testing groups in a 9:1 ratio. We performed external validation of the model using 1429 cases from Kangwon National University Hospital and 2394 cases from the Medical Information Mart for Intensive Care–IV (MIMIC-IV). In addition, we performed 10-fold cross-validation on the internal training data set and calculated the 95% CIs using the metric. Finally, we evaluated the generalization ability of the JointMLP model using the MIMIC-IV data set.

Results: Our JointMLP model outperformed other models in predicting vancomycin TDM levels in internal and external data sets. Compared to PPK, the JointMLP model improved predictive power by up to 31% (mean absolute error [MAE] 6.68 vs 5.11) on the internal data set and 81% (MAE 11.87 vs 6.56) on the external data set. In addition, the JointMLP model significantly outperforms XGBoost and TabNet, with a 13% (MAE 5.75 vs 5.11) and 14% (MAE 5.85 vs 5.11) improvement in predictive accuracy on the inner data set, respectively. On both the internal and external data sets, our JointMLP model performed well compared to XGBoost and TabNet, achieving prediction accuracy improvements of 34% and 14%, respectively. Additionally, our JointMLP model showed higher robustness to outlier data than the other models, as evidenced by its higher root mean squared error performance across all data sets. The mean errors and variances of the JointMLP model were close to zero and smaller than those of the PPK model in internal and external data sets.
Conclusions: Our JointMLP approach can help optimize treatment outcomes in patients with critical illnesses in an intensive care unit setting, reducing side effects associated with suboptimal vancomycin administration. These include increased risk of bacterial resistance, extended hospital stays, and increased health care costs. In addition, the superior performance of our model compared to existing models highlights its potential to help real-world clinicians.

Introduction

Vancomycin is frequently used for severe infections caused by gram-positive bacteria (including methicillin-resistant *Staphylococcus aureus*), such as pneumonia, skin and soft tissue infections, and other sepsis or septic shock in patients with critical illnesses. For vancomycin, because of the narrow therapeutic range and individual differences in pharmacokinetic parameters, therapeutic drug monitoring (TDM) is recommended to minimize toxicity and improve therapeutic efficacy. Although various pharmacokinetic indicators related to the antibacterial action of vancomycin have been suggested, the most recent guideline [1] recommends that a ratio of the area under the curve (AUC) over 24 hours to the minimum inhibitory concentration (MIC) of ≥400 should be the primary pharmacokinetic and pharmacodynamic (PK/PD) predictor of vancomycin activity [2]. However, in the real world, especially in intensive care units (ICUs), a more practical method of vancomycin monitoring is evaluating with trough concentrations since calculating the AUC requires multiple blood samples per patient [3-5]. There are different methods to determine the vancomycin AUC, such as the Bayesian approach or equation-based methodologies such as the trapezoidal model. The Bayesian approach uses population data to estimate individual patient pharmacokinetic parameters, called Bayesian priors. However, this method requires complex mathematical calculations to estimate the posterior distribution of model parameters and relies on certain assumptions, such as the normality of errors and data independence. Violating these assumptions can result in biased results, and using the Bayesian approach requires expensive commercial software programs [6,7]. On the other hand, equation-based approaches, like the trapezoidal model, do not require specialized software but need multiple blood sampling to achieve 2 steady-state levels. Since it is done under steady-state conditions, it cannot account for potential changes in AUC due to ongoing acute physiological changes. The pharmacokinetic profile of vancomycin exhibits linear pharmacokinetics over a range of therapeutic doses, is highly variable, especially in older people or people with critical illnesses, and is different for adults with normal renal function [8,9].

Population pharmacokinetic (PPK) models of vancomycin required to determine the AUC have very limited robustness beyond the specific population studied. The training and experience of the clinician or clinical pharmacist are still vital in achieving adequate vancomycin TDM, especially in patients with critical illnesses with high heterogeneity. A more multidimensional and consistent decision-making system is needed in such a clinical decision-making system because differences inevitably influence the results of individual clinicians’ abilities. Machine learning algorithms have emerged as a promising approach for improving decision-making on specific questions related to rich multidimensional data and for medical research and clinical care [10-12]. In previous studies, machine learning techniques such as decision trees [13] and extreme gradient boosting (XGBoost) [14,15] were used to make better predictions on vancomycin concentrations. In addition, various deep learning models have had great success in various fields [16], including clinical practice. These might help solve more complex clinical problems. In this study, we aimed to establish an ideal model by comparing and integrating methods that have been successful so far in the decision-making system that predicts the vancomycin TDM level in patients in the ICU.

Methods

Study Population

This retrospective study involved 2406 patients with critical illnesses admitted to medical ICUs, including 1 each at Dongguk University Ilsan Hospital (DUIH) and Kangwon National University Hospital (KNUH) between January 1, 2010, and February 28, 2022. We used the data collected from DUIH and KNUH as the internal and external validation data sets. The internal validation data set contained 977 patients, while the external validation data set contained 1429 patients. Patients with critical illnesses (>18 years) with intravenous vancomycin treatment history and who had at least 1 test for vancomycin TDM were eligible for this study. Vancomycin TDM was investigated for trough-level information. If the TDM was checked multiple times, only the first TDM value was selected. However, in patients with normal renal function, if the interval between stopping vancomycin and readministering it was 2 weeks or more, it was considered an independent TDM value and used for analyses. Patients who received oral vancomycin or were aged 18 years or younger were excluded. The total serum vancomycin concentrations were determined using a fluorescence immunoassay (VANC3, Cobas c 702; Roche Diagnostics).

The data set was split into training and testing groups in a 9:1 ratio, with 879 and 98 cases representing the internal data set, respectively. For external validation, 1429 cases from KNUH were used. To evaluate the model’s generalization and the range of expected errors of the classifiers, 10-fold cross-validation was performed on the internal training data set, with a 9:1 ratio and 791 and 88 cases, respectively. The model was tested on
both the internal and external test data sets for each fold and the metrics obtained were used to calculate the 95% CI over the 10 folds. The internal and external data sets remained constant across all folds. To evaluate the generalization ability of the joint multilayer perceptron (JointMLP) model, we used 2394 cases from the Medical Information Mart for Intensive Care–IV (MIMIC-IV) [17] as a US critical care database used for large-scale multi-institutional research for external validation.

Experimental Model

We proposed a JointMLP to predict the vancomycin TDM level in patients in the ICU. The JointMLP model is an ensemble model, meaning it combines the predictions of multiple individual MLPs (multilayer perceptrons) to generate a final prediction. The MLP is an artificial neural network. The MLP consists of multiple layers of interconnected nodes (also known as neurons) that perform mathematical operations on the input data to generate an output. In the case of the JointMLP model proposed for vancomycin TDM prediction, each MLP in the ensemble consists of 3 hidden layers with a hidden unit size of 32, and the LeakyReLU activation function is used to introduce nonlinearity into the model (Figure 1). Using an ensemble helps reduce the risk of overfitting and improves the accuracy and robustness of the model. In this case, the JointMLP model comprises 100 different MLPs, each with its own set of weights learned during the training process. To find the best set of hyperparameters for the JointMLP model, grid search is used, which systematically tests different combinations of hyperparameters to find the combination that yields the best performance on a validation data set. In this case, the tuned hyperparameters included the number of MLPs, the number of hidden layers, and the size of the hidden units. In a JointMLP model, the MLPs are trained independently in parallel. During training, each MLP in the ensemble receives a randomly selected subset of the training data and learns to make predictions based on that subset. The individual MLPs are then combined to generate a final prediction, typically by taking the average of their outputs or using a weighted combination. The MLPs are trained independently of each other and in parallel. Our JointMLP model is available on the websites [18] for predicting TDM levels and recommending the frequency and dose.

Figure 1. The architecture of joint multilayer perceptron (JointMLP). The JointMLP model was built with 100 different multilayer perceptrons (MLPs) consisting of 3 hidden layers with a hidden unit size of 32 and LeakyReLU as an activation function.
We compared 4 other models: the PPK model [19], XGBoost, TabNet, and 300-layer MLP. The PPK is a pharmacokinetic model used to assess the relationship between drug concentration and time in the body. XGBoost is an open-source library for decision tree–based gradient-boosting machine learning. The XGBoost model especially works well on tabular data learning. It is a vital model for distributed training or regularization. TabNet is a deep learning model specialized for tabular data set analysis. TabNet could be optimized by automatically transforming input variables and using additional validation data to select the required variables.

For XGBoost, the hyperparameters are eta (learning rate), gamma (minimum loss reduction required to make a further partition on a leaf node of the tree), and max_depth (maximum depth of a tree). The grid search was performed to find the best combination of these hyperparameters. The eta, gamma, and max depth values were 0.2, 0.001, and 6, respectively.

For TabNet, the hyperparameters are n_d (width of the decision prediction layer), n_a (width of the attention embedding for each mask), n_steps (number of steps in the architecture), gamma (coefficient for feature reusability in the masks), and verbose (verbosity for notebook plots). The grid search was performed to find the best combination of these hyperparameters. The values chosen for n_d, n_a, n_steps, gamma, and verbose were 8, 8, 3, 1.3, and 0, respectively.

The 300-layer MLP model was constructed to verify the performance of the JointMLP model. The hyperparameters for the MLP model were chosen to have the same depth as the JointMLP model, which is 100 horizontal MLPs times 3 hidden layers. The number of hidden layers was set to 300, and the number of hidden units was set to 32. 

Data Processing

Variables that are associated with vancomycin PK/PD were selected. These variables included the total dose of vancomycin from start to end, the usage of the loading dose at the first use, the total number of vancomycin infusions, the dose of vancomycin per infusion, the mean infusing interval of vancomycin, the interval from the start of vancomycin administration to the measurement of vancomycin serum levels, age, sex, height, weight, serum creatinine levels, serum vancomycin levels, dialysis, and the total volume of transfusion from the start of vancomycin administration to the measurement of vancomycin levels. Patients with impaired kidney function may have issues with the metabolism and elimination of vancomycin. The estimated glomerular filtration rate (eGFR), which represents renal function, was calculated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula and used as a variable. For the normalization of the data, for both the input and target variables, all values were scaled in the range (−1 to 1) using the minimum-maximum scaler. Moreover, we only had binary categorical variables in the model. Therefore, no special categorical variable encoding was performed in the model but a simple change to 0 and 1. To select significant input variables, we grouped variables into 5 categories. Each variable was classified as (1) baseline demographics—age, sex, body weight, and height; (2) drug administration-related variables; (3) variables related to the volume of distribution; (4) eGFRs using serum creatinine levels; and (5) variables related to the amount of transfusion. With the above-grouped categories, first, we have selected the default variables that would be used throughout all scenarios: the baseline demographics and the drug administration–related variables. Then, from the remaining 3 categories, with the clinician’s consultation, we tried to minimize the redundancy of the variables that would have the same meaning. Moreover, in accordance with the feature importance of each variable, we were able to find the best combination of model input variable sets. Furthermore, the contribution of the input data to the model in the test set was determined through the Shapley value of Shapley Additive exPlanations (SHAP) [19]. A high mean absolute estimated Shapley value indicates that the variable has a stronger impact on the output value.

Statistical Analysis

The primary end point was the predictive performance of the vancomycin level within the therapeutic range. The baseline variables and patient characteristics of internal and external data sets were presented as frequencies with percentages or mean values with SDs. Between–data set comparisons were performed using the paired 2-tailed t test for continuous variables or the chi-square test for categorical variables. The measured serum vancomycin levels were used as true values. The predictive abilities of 4 kinds of models for vancomycin trough concentrations, using the PPK model on the website of the infectious diseases management program at the University of California, San Francisco [20], machine learning models (XGBoost) [21], and deep learning models (TabNet [22] and JointMLP), were evaluated for bias and precision by calculating the mean absolute error (MAE), root-mean-square error (RMSE), $R^2$, and adjusted $R^2$. The paired t test on MAE was used [23,24] to confirm significant differences in prediction performance between models. P values of <.05 were considered statistically significant. All analyses were performed with R software (version 3.4.4; R Foundation for Statistical Computing) and Python (version 3.8.12; The Python Software Foundation) using the SciPy 1.9.1, PyTorch 1.10.2, and PyTorch Lightning libraries.

Ethical Considerations

This study involved a retrospective analysis of medical records and did not involve collecting prospectively obtained data. As such, the study was considered to pose minimal risks and did not directly affect patients’ rights, welfare, or clinical care while offering recognized social benefits. To protect patient confidentiality during data collection and record review, all investigative records were securely stored in an encrypted database, and published results did not include any participants’ names or identifiers. The study received ethical approval from the institutional review board of Dongguk University Hospital (DUHI 2021-08-015) and Kangwon National University Hospital’s Institutional Review Board (KNUH-2022-03-020). This study was performed per the principles of the Declaration of Helsinki.
Results

Overview

Out of the 977 patients included in the DUIH data set, the testing data set was composed of 98 (10%) patients, with the other 879 patients belonging to the training data set. All 1429 patients included in KNUH were for external validation. The baseline characteristics did not differ significantly between the testing and training groups (Table 1). However, there were more older patients and shorter heights in the external validation set. The estimated renal function by the CKD-EPI method was worse in the patients for external validation. The patients included in MIMIC-IV showed significant differences in sex distribution compared to internal data sets or patients in other ICUs in Korea, and the proportion of non-Hispanic White patients was over 66.4% (n=1591).

XGBoost (1 of the Machine Learning Models) Versus PPK Model

Compared to the PPK model, the XGBoost model only significantly improved the predictive performance of external data sets (20.43 vs 11.59, a 76% change by RMSE and 11.87 vs 8.75, a 36% change by MAE; Table 2) when evaluated by RMSE and MAE. Although statistical significance could not be determined, the predictive power of internal data sets also improved by 8% (10.38 vs 9.58 by RMSE) and 16% (6.68 vs 5.75 by MAE).

<sup>a</sup>RMSE: root mean squared error.  
<sup>b</sup>MAE: mean absolute error.  
<sup>c</sup>PPK: population pharmacokinetic.  
<sup>d</sup>XGBoost: extreme gradient boosting.  
<sup>e</sup>MLP: multilayer perceptron.  
<sup>f</sup>JointMLP: joint multilayer perceptron.

The proposed JointMLP model significantly outperformed XGBoost and TabNet with a 13% (5.75 vs 5.11) and 14% (5.85 vs 5.11) improvement in predictive accuracy under MAE on the internal data set, respectively. Additionally, our trained JointMLP showed better performance not only on the internal data set but also on the external data set that consisted of 1429 patients with critical illnesses by 34% (8.75 vs 6.56) and 14% (7.50 vs 6.56) when compared with XGBoost and TabNet. Furthermore, JointMLP’s RMSE performance is higher than that of other models on all data sets, which means that the proposed model is more robust than theirs against outlier data.

Within the external data set, we clearly see that all models are statistically significant among themselves (Figure 2). However, the P value of JointMLP within the internal data set expressed a trend more robust than all other models while showing statistical significance only when compared with PPK with MAE. The mean error and variance of the JointMLP model were nearer to zero and smaller in both internal and external data sets than in the PPK model (Figure 3).
Figure 2. $P$ value heat map by paired t test on all the combinations of prediction models. The $P$ value for each comparison of the mean absolute error for predictive performance on (A) the internal validation data set (B) and the external validation data set. 300MLP: 300-layer multilayer perceptron; JointMLP: joint multilayer perceptron; PPK: population pharmacokinetic; XGB: extreme gradient boosting.

Figure 3. Comparisons of the population pharmacokinetic (PPK) and joint multilayer perceptron (JointMLP) models on the internal and external validation sets. Scatter plots of (A) the internal data set and (B) the external data set with the predicted value against a target value. The error histograms of (C) the internal data set and (D) the external data set with a predicted value against a target value. TDM: therapeutic drug monitoring.

The most influential variables in TDM prediction were eGFR CKD-EPI, the average dose of vancomycin, and the average volume of distribution in both internal and external data sets. These variables consistently had high SHAP values in both data sets (Table 3).

**JointMLP Versus 300-Layer MLP**

The purpose of Table 2 was to compare the predictive performances of the 300-layer MLP model and the proposed JointMLP model. The results showed that JointMLP outperformed the 300-layer MLP model in both the internal (8.27 vs 9.94, a 23% improvement by RMSE, and 6.98 vs 5.11, a 37% improvement by MAE) and external (9.50 vs 9.94, a 5% improvement by RMSE, and 7.45 vs 6.56, a 14% improvement by MAE) data sets, indicating the effectiveness of the boosting ensemble approach used in JointMLP. Figure 2 shows the P value analysis of the comparison between JointMLP and the 300-layer MLP model. The analysis revealed that the difference between the 2 models was statistically significant (P<.001) within the external data set. However, compared to other models, the difference between JointMLP and the 300-layer MLP model was not statistically significant (P=.09) within the internal data set.

**Model Comparisons in the MIMIC-IV Data Set**

The findings presented in Table 4 clearly indicated that the JointMLP model performed better than both the PPK and 300-layer MLP models by a significant margin of 160% and 25%, respectively, when evaluated using the RMSE metric. This improvement in predictive performance was observed even in the MIMIC-IV data set, which included patients from multiple centers and races. The JointMLP model also demonstrated superior performance compared to the XGBoost and TabNet models, with improvements of 5% and 4%, respectively. When examining the MAE metric, the JointMLP model significantly outperformed the PPK model by 90%, with further improvements of 8%, 6%, and 5% over the XGBoost, 300-layer MLP, and TabNet models, respectively.

<sup>a</sup>MIMIC: Medical Information Mart for Intensive Care.

<sup>b</sup>RMSE: root mean squared error.

<sup>c</sup>MAE: mean absolute error.

<sup>d</sup>PPK: population pharmacokinetic.

<sup>e</sup>XGBoost: extreme gradient boosting.

<sup>f</sup>MLP: multilayer perceptron.

<sup>g</sup>JointMLP: joint multilayer perceptron.

All models, except for the 300-layer MLP, were statistically significant in the MIMIC-IV data set (Figure 4A). The most influential variables in TDM prediction using the JointMLP model were consistent with eGFR CKD-EPI, average vancomycin dose, and average distribution volume, which were variables identified in the internal data set (Figure 4B). The 300-layer MLP was statistically significant ($P<.001$) compared to the PPK model. Additionally, the JointMLP model had a mean error and variance that were close to zero and smaller than those of the PPK model in the MIMIC-IV data set (Figure 4C and D).

Discussion

Principal Findings

The PPK method is widely used for predicting vancomycin TDM levels. However, it is population-dependent, leading to inappropriate results for some patients. Therefore, this study proposes a consistent decision-making system that is population-independent and unaffected by clinicians’ abilities by applying a joint MLP model that integrates various successful deep learning models and decision trees. The proposed JointMLP showed the best performance for predicting vancomycin trough concentration in all data sets compared to other models. Significantly, in the MAE metric, the JointMLP model improved performance by 90% over the PPK model. Results mean that the proposed model can be applied to predict appropriate vancomycin trough concentrations in patients with critical illnesses who require vancomycin treatment in various situations.

Comparison to Machine Learning Model

In our study, we compared the performance of 3 machine learning models for predicting vancomycin levels: JointMLP, XGBoost, and TabNet. XGBoost is a popular gradient-boosting algorithm known for its high accuracy and flexibility, while TabNet is a newer deep-learning model [22] specifically designed for tabular data. Compared to XGBoost and TabNet, our JointMLP model outperformed both in terms of predictive accuracy. One of the main reasons for this is that our model was designed to handle noisy data samples, a common characteristic of medical data sets. A deep neural network architecture accomplishes this with multiple layers, which allows the model to learn complex relationships between the input features and the output variable. In contrast, XGBoost and TabNet are both tree-based models, which may need to be more effective at handling noisy data.

Compared to previous studies [15,24-26], our proposed JointMLP model performs better in accurately predicting vancomycin levels. Specifically, our model outperforms XGBoost and TabNet, 2 well-known models in analyzing tabular data and predicting drug concentrations. Moreover, our JointMLP model is designed to handle noisy data samples effectively, a crucial feature for real-world applications in the medical domain where data quality can be highly variable. Our model’s robustness is demonstrated by comparing it to a...
300-layer MLP, confirming the effectiveness of our model structure in handling vancomycin TDM predictions. Importantly, our model is trained on a larger and more diverse data set than previous studies and tested on an unseen data set, demonstrating its generalizability and suitability for predicting drug concentrations. Overall, our findings highlight the potential of deep learning models in improving the accuracy and reliability of drug concentration prediction, which can lead to better treatment outcomes and improved patient health. Overall, our findings suggest that the JointMLP model is a promising approach for predicting vancomycin levels, particularly in the presence of noisy data. However, the choice of which model to use may depend on the specific characteristics of the data set being analyzed and the goals of the analysis.

Limitations and Future Work

When considering implementing our approach in clinical settings, there are several factors to consider. First, although we extended our model to validate across diverse patient populations, including patients from Asia and other regions in the MIMIC-IV data set, we acknowledge that there is still room for improvement in this regard. We used a larger data set than previous studies, with 977 samples as the internal data set and 1429 samples as the external data set. Additionally, we sought to develop a generalized model by applying the MIMIC-IV data set, which includes 2394 samples. However, additional validation with external data sets is necessary to enhance further the generalizability of our model for predicting vancomycin levels. Second, our comparison of the predictive performance with the PPK method was based on the trough-based target method, which is easily used in the treatment of patients with critical illnesses, rather than the AUC/MIC-specific range that is currently recommended. Therefore, further research is needed to compare the AUC/MIC range with our approach.

Despite these limitations, our deep learning model, if implemented in actual clinical practice, could significantly improve the treatment outcomes of ICUs by supporting clinical decision-making in a more standardized and consistent manner. Our proposed JointMLP model will continue to evolve and update its performance to mimic the human brain better and determine the optimal vancomycin dose.

Conclusions

In this study, proposing the JointMLP approach in clinical settings has significant implications for public health, as it can help optimize treatment outcomes for patients with critical illnesses in ICUs. By providing a more accurate and consistent method for predicting vancomycin levels, the model can reduce adverse events associated with suboptimal vancomycin dosings, such as the increased risk of bacterial resistance, longer hospital stays, and higher health care costs. Furthermore, the ongoing development and improvement of the JointMLP model through continuous learning and updating can lead to more effective treatments and better health outcomes for patients, improving the accuracy and reliability of other clinical prediction models in the future. Overall, the implementation of the JointMLP approach has the potential to improve public health outcomes and benefit patients worldwide.

Acknowledgments

We would like to thank Jihye Han for helping us with data mining. This study was supported by the National Research Foundation of Korea Grant and the Korea Health Technology R&D Project through the Korea Health Industry Development Institute, funded by the Korean Government (HI21C1074).

Optimization of Using Multiple Machine Learning Approaches in Atrial Fibrillation Detection Based on a Large-Scale Data Set of 12-Lead Electrocardiograms: Cross-Sectional Study

Abstract

Background: Atrial fibrillation (AF) represents a hazardous cardiac arrhythmia that significantly elevates the risk of stroke and heart failure. Despite its severity, its diagnosis largely relies on the proficiency of health care professionals. At present, the real-time identification of paroxysmal AF is hindered by the lack of automated techniques. Consequently, a highly effective machine learning algorithm specifically designed for AF detection could offer substantial clinical benefits. We hypothesized that machine learning algorithms have the potential to identify and extract features of AF with a high degree of accuracy, given the intricate and distinctive patterns present in electrocardiogram (ECG) recordings of AF.

Objective: This study aims to develop a clinically valuable machine learning algorithm that can accurately detect AF and compare different leads’ performances of AF detection.

Methods: We used 12-lead ECG recordings sourced from the 2020 PhysioNet Challenge data sets. The Welch method was used to extract power spectral features of the 12-lead ECGs within a frequency range of 0.083 to 24.92 Hz. Subsequently, various machine learning techniques were evaluated and optimized to classify sinus rhythm (SR) and AF based on these power spectral features. Furthermore, we compared the effects of different frequency subbands and different lead selections on machine learning performances.

Results: The light gradient boosting machine (LightGBM) was found to be the most effective in classifying AF and SR, achieving an average $F_1$-score of 0.988 across all ECG leads. Among the frequency subbands, the 0.083 to 4.92 Hz range yielded the highest $F_1$-score of 0.985. In interlead comparisons, aVR had the highest performance ($F_1=0.993$), with minimal differences observed between leads.

Conclusions: In conclusion, this study successfully used machine learning methodologies, particularly the LightGBM model, to differentiate SR and AF based on power spectral features derived from 12-lead ECGs. The performance marked by an average $F_1$-score of 0.988 and minimal interlead variation underscores the potential of machine learning algorithms to bolster real-time AF detection. This advancement could significantly improve patient care in intensive care units as well as facilitate remote monitoring through wearable devices, ultimately enhancing clinical outcomes.

Introduction

Atrial fibrillation (AF) is the most prevalent cardiac arrhythmia, impacting an estimated 33.5 million people worldwide [1]. This severe cardiac condition heightens the risks of stroke and heart failure [2]. Clinicians typically detect and diagnose AF through the noninvasive electrocardiogram (ECG) method. However, ECG interpretation relies heavily on the expertise of the medical professional, creating a need for automated ECG classification to support clinicians. Machine learning, a subset of artificial intelligence, has shown great potential in improving the detection and management of AF through automated ECG analysis [3], risk stratification [4], or treatment planning [5].

The 2020 PhysioNet Challenge data sets offer 12-lead ECG recordings that can be used to evaluate machine learning techniques for ECG interpretation [6]. Compared to machine learning approaches based on small and homogeneous data sets, algorithms using PhysioNet data are likely to be more representative of realistic clinical scenarios, thereby making them better suited for practical implementation. Various machine learning techniques have been used to detect AF using ECG data. Some of the widely explored methods include support vector machines, decision trees, random forests, and deep learning approaches like convolutional neural networks and recurrent neural networks. These techniques have demonstrated promising results in classifying normal sinus rhythm (SR) and AF, with fair accuracy and $F_1$-scores [4].

The performance of machine learning algorithms depends on the quality of the input features. Common feature extraction methods in AF detection include time-domain analysis, frequency-domain analysis, and wavelet transform. Power spectral density (PSD) is a popular frequency-domain feature that has been used to differentiate SR from AF. PSD analysis reveals information about the distribution of a signal’s power and frequency components. An ECG signal comprises various frequency components, including those related to the sinus heartbeat as well as atrial and ventricular activity. The PSD distribution of these frequency components may alter heart conditions that affect the cardiac contraction cycle, making it a potential indicator for identifying cardiac arrhythmias. Consequently, we developed an automated machine learning algorithm based on PSD to differentiate normal SR from AF based on a large-scale data set from PhysioNet 2020.

Methods

ECG Data

We used the 2020 PhysioNet Challenge data sets (Table 1) [6], comprising the China Physiological Signal Challenge (CPSC) Database (men: n=3699, women: n=3178, total: n=6877, and sampling rate: 500 Hz), CPSC-Extra Database (men: n=1843, women: n=1610, total: n=3453, and sampling rate: 500 Hz), St Petersburg Institute of Cardiological Technics INCART 12-lead Arrhythmia Database (total: n=72 and sampling rate: 257 Hz), Physikalisch Technische Bundesanstalt (PTB) Diagnostic ECG Database (men: n=377, women: n=139, total: n=516, and sampling rate: 1000 Hz), Physikalisch Technische Bundesanstalt extra large (PTB-XL) electrocardiography Database (men: n=11,379, women: n=10,458, total: n=21,837, and sampling rate: 500 Hz), and Georgia 12-lead ECG Challenge Database (men: n=5551, women: n=4793, total: n=10,344, and sampling rate: 500 Hz). The PhysioNet Challenge data sets can be accessed publicly [7], and data access is licensed under the Creative Commons Attribution 4.0 International Public License [8].

From these data sets, we initially selected data featuring a 500 Hz sampling rate. Next, we identified ECG diagnoses using the Systematized Nomenclature of Medicine—Clinical Terminology codes 426783006 and 164889003 for SR and AF, respectively. This led to the identification of 20,766 SR and 3458 AF ECG recordings. After excluding recordings corresponding to multiple diagnoses, the final data set comprised 9102 SR and 1088 AF ECG recordings.

**Ethical Considerations**
This study was approved by the institutional review board of Taipei Veterans General Hospital (2022-04-004BC).

**ECG Preprocessing and Feature Extraction**
The ECG patterns associated with AF exhibit greater variability compared to those of SR. To explore this distinction, we used the Welch method [9,10] to estimate PSD and determine the frequency composition of the ECG signals. The recording durations of the ECG data ranged from 6 to 60 seconds, with 10 seconds being the most common. This variability could lead to differences in PSD resolution. To address this issue, we used the frequency bin method to ensure consistent frequency resolution across our PSD features. We set the frequency resolution to 1/6 Hz and calculated the arithmetic mean of the PSD frequencies within this resolution to represent the midpoint of each envelope. The data we used had a sampling rate of 500 Hz. Based on Nyquist-Shannon sampling theorem, the highest frequency information we can get is 250 Hz. After observing several data plots of the original PSD graph, we can see that most of the power of the signal is within 0 to 25 Hz. Thus, for a 10-second ECG recording, we selected a frequency of 0 to 25 Hz which was converted to 0.083 to 24.92 Hz. Figure 1 presents an example of original PSD plots and explains why we chose the PSD from 0 to 25 Hz. For further segmentation, it was just reasonable to separate the whole frequency segment into 5 smaller segments since the whole frequency ranges from 0 to 25 Hz. Figure 2 presents example ECG signals and PSD plots, highlighting notable differences in PSD between SR and AF; narrower harmonic frequency components can be observed in SR, while AF patterns display more erratic frequency components. We used these PSD features as inputs for our machine learning algorithm.

**Figure 1.** Initial results of PSD for SR and AF in lead 1. The original frequency information we got from PSD is 0 to 250 Hz. From the figure, we can see that the power of the signal concentrates within 0 to 25 Hz. Thus, we selected 0 to 25 Hz as our main frequency band. AF: atrial fibrillation; PSD: power spectral density; SR: sinus rhythm.
Figure 2. A comparison of the ECG and PSD for SR and AF in lead V4. While there is a discernible difference between SR and AF in the ECG representation, it remains challenging to distinguish them in this format. In contrast, the PSD figure demonstrates the harmonic nature of SR and the chaotic nature of AF, making it much easier to differentiate between the two. As a result of these observations, we have chosen to use PSD as the primary feature for our machine learning algorithms. This decision is based on the enhanced clarity and distinction provided by the PSD representation, which allows for more accurate and effective differentiation between SR and AF in our analysis. AF: atrial fibrillation; ECG: electrocardiogram; PSD: power spectral density; SR: sinus rhythm.

Machine Learning Methods

Supervised machine learning is a type of machine learning where the algorithm is trained on a labeled data set, and the goal is to make predictions for new, unseen data. There are several types of supervised machine learning methods used in this study, including (1) discriminant analysis: a method for modeling the relationship between a dependent variable and one or more independent variables (used for continuous target variables); (2) logistic regression: a method for modeling the probability of a binary outcome based on one or more independent variables; (3) decision trees: a method for making predictions by creating a tree-like model of decisions and their potential consequences; (4) random forests: an ensemble method that combines multiple decision trees to make a prediction; (5) support vector machines: a method for classifying data by finding the best boundary (or “hyperplane”) that separates the classes; (6) neural networks: a method inspired by the structure and function of the human brain (can be used for a wide range of tasks, including classification and regression); and (7) naive Bayes: a probabilistic method for making predictions based on Bayes’ theorem (often used for text classification).

Additionally, we used a gradient boosting decision tree algorithm, namely light gradient boosting machine (LightGBM) [11]. It is one of the most efficient algorithms in recent years, known for its speed and accuracy. Boosting is an approach for combining multiple base models into a composite one. One of the ensemble tree algorithms of LightGBM is a “leaf-wise” tree algorithm, wherein the tree grows vertically; most of the others are “level-wise” tree algorithms, wherein the trees grow horizontally. The leaf-wise structure reduces time complexity and offers a favorable balance of accuracy and efficiency, especially for large-scale, high-dimensional data. Thus, it is useful in classification problems.

Perceptrons are single-neuron models and the precursors to larger neural networks; now, they are the building blocks of neural networks. A deep neural network (DNN) is a supplement of a feed-forward neural network and consists of 3 types of layers: the input layer, the output layer, and the hidden layer. The input layer receives the input signal to be processed. The output layer performs the required task, such as prediction or classification. The true processing engine is the hidden layers, placed between the input and output layers. In a DNN, data flow from the input layer to the output layer, just as in feed-forward neural networks. The neurons are trained through back propagation. DNNs are widely used in various applications, including automated diagnosis using ECG data [12].

Statistical Analysis

Data Imbalance

We used the synthetic minority over-sampling technique [13] to filter the data and reduce the imbalance between the numbers of SR and AF recordings (n=9102 and n=1088, respectively).

$F_1$-Score

To mitigate bias resulting from data imbalance, we used the $F_1$-score as the primary metric for evaluating machine learning models. $F_1$-scores treat false-positive and false-negative errors equally and are more useful than accuracy in cases of class
imbalance. The $F_1$-score is the harmonic mean of precision and recall, which measures the errors contributed by false positives and false negatives, respectively.

**Training, Validation, and Testing Data Sets**

We divided our data sets into training, validation, and testing sets. The training set was used to develop the models, the validation set for model tuning, and the testing set for model assessment. In this study, 60% of the data comprised the training set, 20% the validation set, and 20% the testing set. For model tuning, we used ensemble learning to identify optimal parameters for each model based on the validation set.

**Results**

**Comparison of the Performance of Various Machine Learning Algorithms**

We evaluated various machine learning methods, including extra tree, LightGBM (Microsoft Corporation), CatBoost (Yandex), XGBoost (The XGBoost Contributors), decision tree, k-nearest neighbors, stochastic gradient descent, gradient boosting, random forest, naïve Bayesian, logistic regression, and DNN. Our analysis reveals that machine learning algorithms with boosting methods outperform those without boosting. In particular, LightGBM outperformed the other methods, achieving the highest average $F_1$-score of 0.988 across all 12 ECG leads and the lowest computation time for features within the entire frequency range (0.083–24.92 Hz). Conversely, our results indicate that the naïve Bayesian algorithm performs poorly in classifying SR and AF. Despite its simplicity, naïve Bayesian appears to be less suited for this specific task, and alternative approaches should be considered for better accuracy and reliability. Thus, we focused solely on LightGBM for subsequent analyses.

**Effect of Frequency Band on Model Performance**

We examined the contributions of various frequency subbands of ECG PSD features to model performance in detecting AF (Table 2). The entire frequency range was divided into 5 subbands (0.083-4.92, 5.083-9.92, 10.083-14.92, 15.083-19.92, and 20.083-24.92 Hz). The highest overall $F_1$-score was achieved by the model using the full frequency range (0.083-24.92 Hz), and the frequency subband of 0.083 to 4.92 Hz yielded the highest $F_1$-score among the subbands. Generally, the $F_1$-score for each subband was around 0.9, indicating that every subband contains valuable information for ECG classification.

**Discussion**

**Principal Findings**

In this study, we found that the LightGBM algorithm was the most effective machine learning model for our purposes. Notably, all frequency subbands contained distinct information, achieving independent $F_1$-scores of approximately 0.9. Consequently, using the entire frequency range (0.083-24.92 Hz) provided the most comprehensive features and yielded the highest $F_1$-score of 0.988. Interestingly, among the limb leads, aVR produced the best result, which was marginally superior to the outcomes of chest leads and lead II. This finding is unexpected, as lead aVR is rarely used in real-world scenarios for detecting arrhythmia. The contributions of different frequency bands to classification performance showed that even though each subband contains unique features, the dominant frequency subband (0.083-4.92 Hz) is sufficient for distinguishing AF from SR.
In terms of the contributions of frequency bands to classification performance, it is important to note that the normal human heart beats between 60 to 100 times per minute (1-1.67 Hz), whereas the dominant frequency in AF ranges from 3.8 to 8 Hz [14]. Given the differences in frequency components between SR and AF, they can be used to distinguish one from the other. As demonstrated in Figure 1, multiple frequency peaks are observed within the 0 to 25 Hz range for both SR and AF. Consequently, frequency subbands containing distinct features may yield different results.

Initially, we hypothesized that the subband containing the dominant frequency (0.083-4.92 Hz) would result in the optimal classification of SR and AF, similar to the whole frequency range (0.083-24.92 Hz), while other subbands would struggle to classify SR and AF effectively. Indeed, models using the dominant frequency subband performed well, with results closely resembling those of models using the whole frequency range. However, other subbands also demonstrated high performance independently (Table 2), with F1-scores exceeding 0.854. The dominant frequency subband (0.083-4.92 Hz) yielded an F1-score of 0.985, which is comparable to that of the whole frequency range (F1-score=0.988). These findings suggest that although each subband contains unique features and cannot be replaced by other subbands, the dominant frequency subband alone is sufficient for differentiating AF from SR.

In this study, we explore the variations in AF classification performance across different ECG leads. Each ECG lead has unique physiological applications, which in turn influence the preference of medical professionals in identifying specific types of arrhythmias. For instance, lead 1, aVF, or V1 are frequently used in diagnosing right ventricular hypertrophy. Routine clinical practice suggests that lead 2, which is typically the focus of medical professionals when examining AF, would yield the most accurate results. Surprisingly, our findings revealed that all leads, within the frequency range of 0.083-24.92 Hz, generated F1-scores in close proximity to 0.985. Among these, lead aVR achieved the highest F1-score at 0.993. We believe this can be attributed to the visibility of AF in the majority of leads and the comprehensive features encompassed by the entire frequency range.

Contrary to our initial expectations, lead aVR, which is not a common choice in clinical settings, produced the most optimal results when using subbands [15]. This finding may potentially shed light on the reentry mechanism that underlies AF [16,17]. It is worth noting that lead aVR captures data from the right ventricle outflow tract and the basal portion of the septum, whereas AF predominantly manifests in the left ventricle. Consequently, the reentry mechanism emerges as the most plausible explanation for this observed phenomenon.

In a prior study [18], the 2020 PhysioNet Challenge data sets were used alongside the LightGBM machine learning algorithm. However, the approaches to signal extraction and processing in that study differed from those used in our research. The previous study implemented filtering techniques and wavelet multiresolution analysis, while our investigation used PSD and the Welch method. Another key distinction between the 2 studies is the scope of the classification task. While our research focused solely on differentiating AF from SR, the previous study attempted to identify 24 different diseases. Due to the varied physiological information provided by each ECG lead, we opted to compare the performance of LightGBM for each individual lead, rather than inputting data from all 12 leads into the LightGBM simultaneously. Furthermore, our study identified the most critical frequency subband within the total frequency range. We determined the dominant frequency subband to be 0.083-4.92 Hz, which played a significant role in our analysis.

There are several limitations to be addressed in this study. One notable constraint is our selection of 10-second ECG recordings, which may not accurately represent the full spectrum of real-world clinical scenarios. The data sets used in this study were predominantly clean, while actual clinical situations may involve data contaminated by noise, potentially affecting the results. Moreover, our study focused exclusively on single-diagnosis data, representing either AF or SR. This approach, however, does not account for the possibility of a patient experiencing multiple arrhythmias concurrently. Consequently, our findings were derived under simplified conditions that may not fully reflect the complexity of real-life cases. In light of these limitations, it is essential to interpret our results with caution and consider further research that incorporates a broader range of ECG recordings, addresses potential noise-related challenges, and examines cases with multiple coexisting arrhythmias to enhance the generalizability and applicability of our findings to real-world clinical settings.

In summary, LightGBM proves to be a highly effective algorithm for distinguishing AF from SR. Our study demonstrated that when dividing the entire ECG frequency range into subbands with fewer features, lead aVR delivered the best performance. This outcome could potentially be associated with the underlying pathological mechanisms of AF. By incorporating adequate frequency band features, lead 2 ECG data can achieve an F1-score of approximately 0.99. This level of accuracy and efficiency of the LightGBM model renders the algorithm suitable for implementation in clinical practice and integration into commercialized electronic devices, such as the smartwatch with the ECG functionality, for a range of health care applications. This study’s findings suggest that leveraging the power of LightGBM could enhance arrhythmia detection and monitoring, ultimately improving patient care and outcomes.

**Literature Review**

In this review, we will talk about studies that introduce techniques for AF detection, analyzing their methods, results, and potential implications in the field of cardiology. First, one study [19] proposed a feature extraction method based on a gradient set for AF detection, which features simplicity, noise tolerance, and adaptability to various classifiers. However, we can still improve the feature extraction method in the future, such as improving AF detection performance by proposing a more representative feature set or combining it with other types of features. This approach shows the potential for streamlined, efficient feature extraction, providing a solid foundation for further research in the domain.
Next, the Transposed Projection–Convolutional Neural Network (TP-CNN) method was introduced in another study [20], aiming to use “compressed ECG signals” for AF detection. The approach demonstrates promising results in accurately detecting AF in wearable application scenarios while addressing energy consumption concerns. It shows the effective use of compressed signals and a highly accurate algorithm. Yet, its data sources only contain 25 patients. More patients should be included in further studies.

Another study [21] demonstrates a unique method using multiple parameters, including the average number of f waves in a TQ interval, showing robust real-time AF detection capabilities. This approach not only differentiates between AF and normal ECGs but also outperforms distinguishing AF from other arrhythmias. However, they can discuss more about how their algorithms will be implemented in clinical situations.

There is another study [22] focusing on low-complexity algorithms for AF detection, a method based on RR interval features. This approach demonstrated reasonable feature selection while maintaining a low computational cost, making it suitable for low-power devices. However, in future studies, it should focus on getting a better $F_1$-score.

In addition to ECG AF detection, there is also a signal called photoplethysmography common in wearable devices for AF detection, while we usually use ECG in clinical situations. This Fitbit Heart study [23] provides an algorithm that exhibited a high positive predictive value for concurrent AF, highlighting the potential of consumer wearables for large-scale AF identification. Though the result is nice, we hope we can know more about photoplethysmography comparison with ECG.

In conclusion, these studies collectively contribute to the evolving landscape of AF detection methods. While each approach offers unique advantages, further research should focus on refining these methods, exploring real-time applications, and enhancing the overall accuracy and efficiency of AF detection algorithms. Potential limitations should also be emphasized in future studies.

Abstract

Background: The unmet need for mental health care affects millions of Americans. A growing body of evidence in implementation science supports the effectiveness of task sharing in the delivery of brief psychosocial interventions. The digitization of training and processes supporting supervision can rapidly scale up task-shared interventions and enable frontline health workers (FLWs) to learn, master, and deliver interventions with quality and support.

Objective: We aimed to assess the perceived feasibility and acceptability of a novel mobile and web app designed and adapted to support the supervision, training, and quality assurance of FLWs delivering brief psychosocial interventions.

Methods: We followed human-centered design principles to adapt a prototype app for FLWs delivering brief psychosocial interventions for depression, drawing from an app previously designed for use in rural India. Using a multimethod approach, we conducted focus group sessions comprising usability testing and group interviews with FLWs recruited from a large health system in Texas to assess the feasibility and acceptability of the app. The positive System Usability Scale was used to determine the app’s overall usability. We also calculated the participants’ likelihood of recommending the app to others using ratings of 0 to 10, yielding a net promoter score. Focus group transcripts were coded and analyzed thematically, and recommendations were summarized across 4 key domains.

Results: A total of 18 FLWs varying in role and experience with client care participated in the study. Participants found the app to be usable, with an average System Usability Scale score of 72.5 (SD 18.1), consistent with the industry benchmark of 68. Participants’ likelihood of recommending the app ranged from 5 to 10, yielding a net promoter score of 0, indicating medium acceptability. Overall impressions of the app from participants were positive. Most participants (15/18, 83%) found the app easy to access and navigate. The app was considered important to support FLWs in delivering high-quality mental health care services. Participants felt that the app could provide more structure to FLW training and supervision processes through the systematic collection and facilitation of performance-related feedback. Key concerns included privacy-related and time constraints regarding implementing a separate peer supervision mechanism that may add to FLWs’ workloads.

Conclusions: We designed, built, and tested a usable, functional mobile and web app prototype that supports FLW-delivered psychosocial interventions in the United States through a structured supervision mechanism and systematic collection and review of performance measures. The app has the potential to scale the work of FLWs tasked with delivering these interventions to the...
Introduction

Background

In the United States, 22.8% of adults have a mental illness, and 5.5% have a serious mental illness [1]. Following the COVID-19 pandemic, the percentage of adults with symptoms of anxiety or depressive disorders has increased substantially, with preliminary data reporting a prevalence of 20% to 32.3% [2,3], although the extent of the increase is still unclear [4]. In 2021, in the United States, only 65.4% of adults with serious mental illness and 47.2% with any mental illness received mental health services [1], and the proportion receiving “minimally adequate” treatment [5], defined as treatment minimally sufficient for common mental disorders, is low [6,7]. In addition to the direct impact on health and well-being, the economic cost of mental illness is high [8]. Worldwide, 418 million disability-adjusted life years and an economic burden of US $5 trillion are associated with mental health disorders [8]. In the United States, the federal government spent US $280 billion on mental health services in 2020 [9]. Despite significant efforts, access to mental health services remains highly limited owing to barriers such as cost and availability of services [9].

The rate of untreated mental health conditions is a major concern. Although psychosocial interventions have shown remarkable effectiveness in supporting individuals with mental conditions [10,11], barriers to accessing services limit the number of people benefiting from such interventions [12]. Access to mental health support varies widely across the country. According to a 2018 study, over 60% of rural counties reported lacking access to a psychiatrist or psychologist [13]. Studies have reported long delays in appointment scheduling [14], with clients sometimes having to wait many months before they are seen; this is especially true for scheduling first-time appointments [15] and has thus become a common issue for mental health care [16,17]. The COVID-19 pandemic has exacerbated the gaps between a need for and access to mental health services [18], with renewed calls to address the shortage of mental health professionals in the United States [19].

To address the gap in providing adequate services for mental health conditions, the World Health Organization and other institutions have advocated for task-sharing approaches, including screening and treatment protocols that frontline health workers (FLWs) can follow to extend the role of mental health specialists wherever possible, particularly in areas where specialist support is nonexistent or inaccessible [20]. Worldwide, there is growing evidence of the effectiveness of psychosocial interventions delivered by FLWs who are not behavioral health specialists [21-24]: frontline interventions have demonstrated effectiveness and cost-effectiveness in addressing mental health in high-income and low-income countries worldwide [25-29].

Task-sharing programs with trained FLWs were initially pioneered and have since been broadly evaluated across various low- and middle-income countries, many with <1 psychiatrist per 100,000 people, rendering specialist access a near impossibility for much of the world’s population [30-33]. Following the concept of “reciprocal innovation,” in which mutual benefit and learnings are derived from innovations demonstrated to be effective in low-income settings and then applied to high-income settings and vice versa [34], task-sharing programs are now being advocated for use in high-income countries experiencing critical shortages of mental health providers and a need for equitable, culturally competent, and value-based care [21,25,35]. Task-sharing programs show great promise for increasing the health system’s capacity to meet the overwhelming demand for mental health care in the United States, particularly in areas with already limited access to specialized care. They can further allow specialists to focus on more complicated cases, potentially reducing delays for those who require more specialized care [36,37]. Scaling up such task-shared programs requires innovative strategies to ensure quality delivery of interventions and support FLWs’ skill enhancement. Using digital tools for training and supervision of FLWs is a promising next step [21] to enhance FLW skills, deliver psychosocial interventions effectively, and provide supportive supervision. Here, we define an FLW as any health worker without specialized training in mental health care who may be tasked with providing mental health support to clients in their communities, which in the United States can include primary care providers, physician assistants, community health workers (CHWs), lay therapists, peer navigators, nurses, midwives, and health coaches [38]. FLW-delivered interventions often have brief core elements (eg, behavioral activation [BA] [21,39]) and are intended to be conducted during FLW visits with clients in the community or primary care settings.

We built an app prototype guided by the principles of measurement-based care and supportive supervision based on an earlier app designed to facilitate supervision for CHWs in rural India [40] to facilitate skill enhancement of FLWs and effective delivery of FLW-led interventions in Texas. Measurement-based care includes methods of monitoring and improving the quality of psychosocial intervention delivery through objective, measurable metrics generated through systematic data collection to monitor client progress and directly inform care decisions [41-43]. Supportive supervision shifts the focus from the supervisor-supervisee dyad to the entire workforce by including self-assessments and assessments by peers, community members, and supervisors [44]. By digitally supporting measurement-based care and supportive supervision, the app can provide scalable access to measurable, evidence-based metrics that can guide assessments by peers as well as oneself and one’s supervisor. The app is designed to

https://formative.jmir.org/2024/1/e55205
support FLWs trained to implement a psychosocial intervention and who can benefit from a metrics-driven, supportive supervision approach to enhance individual performance and ensure intervention fidelity.

**Goal of This Study**

In this study, we aimed to assess the feasibility and acceptability of an adapted version of this prototype app in preparation for potential implementation in the United States following the technology acceptance model [45] and learnings from prior work using similar technology in India and other global settings [46].

**Methods**

We used human-centered design principles to adapt an app for FLWs in the United States and used a multimethod approach combining usability testing and group interviews to yield collective interpretations of the feasibility and acceptability of the app among potential target end users [47].

**Prototype Design**

The design of the app was based on learnings from implementing an existing app in the Promoting Effective Mental Healthcare Through Peer Supervision (PEERS) project built on the CommCare platform and developed as part of a large-scale randomized controlled trial in India to understand whether the quality of mental health care offered by FLWs can be improved through a scalable measurement-based peer supervision model [46,48]. This study builds on evidence that an allied peer supervision model can provide a scalable approach to improve the quality of mental health care available to populations in low-resource settings [46,49]. As of late 2023, over 200 nonspecialist providers or lay counselors in Madhya Pradesh and Goa with appropriate training and supervision in mental health care but no formal mental health qualifications continue to use the app to support the peer supervision component of their work.

In this study, following the PEERS model, we adapted an Android and web app using an iterative prototype design with feedback from an advisory panel of stakeholders and subject matter experts with backgrounds in clinical professional development education, mental health policy, clinical social work, and development and implementation of CHW programs in Texas. Members of the study team held 4 rounds of discussions with 5 advisory panelists to assess face validity and help ensure that potential target users’ input was directly incorporated throughout the design and development process. Through a series of in-depth interviews, advisory panel members initially provided commentary on the original PEERS app, current supervision practices in the United States, and the app’s potential to support the supervision process. Subsequent in-depth interviews probed feedback on the usability of the prototype and considerations for its implementation within the United States. The advisory panel’s feedback included inputs for the design and development of the app and considerations for future implementation.

After incorporating preliminary advisory panel feedback, a final app prototype and study materials were created and prepared for usability testing with target end users. The final app was designed to support the following FLW activities: (1) registering clients, conducting and audio recording intervention sessions, and entering session-related notes; (2) reviewing and rating audio-recorded intervention sessions they conducted themselves using a validated scale (eg, the Behavioral Activation Quality Scale [44]); (3) reviewing and rating audio-recorded intervention sessions conducted by peers; (4) reviewing data visualizations of self-ratings as well as those given by their peers and supervisors for reviewed sessions; and (5) accessing related training materials. A screenshot of the app’s menu and the details of each module are shown in [Figure 1](#).
Previous Mental Health Training

To assess the feasibility and acceptability of this prototype app, we identified participants who had completed a 2-part training on foundational skills and BA interventions for depression and received access to measurement-based peer supervision training developed by a nonprofit program, EMPOWER, that leverages digital tools for training and supervising FLWs worldwide [46]. The FLWs in this study had been trained as part of efforts to build workforce capacity and scale up access to brief psychosocial interventions for depression in primary care and community settings across Texas [46].

Recruitment

FLWs from a large health system in Texas (ie, Baylor Scott & White Health) were recruited via email by an experienced human subjects–trained member of the study team to participate in remote focus group sessions. Candidates who met the following eligibility criteria were invited to participate: (1) aged ≥18 years, (2) fluent in English, and (3) having completed training on foundational skills and BA interventions for depression and having access to the measurement-based peer supervision training course developed by EMPOWER. Informed consent was obtained before participation.

Onboarding to the App

After completing the aforementioned training courses, which included a brief introduction to the app and brief video tutorials on how to use it, participants were invited to join a remote focus group session comprising usability testing and a group interview. All sessions were conducted via Zoom (Zoom Video Communications) and lasted approximately 1.5 hours. Participants who did not own an Android device were mailed a study tablet with the app preinstalled for use during the usability testing portion of the focus group session. Study team members trained in user experience and qualitative methods moderated the sessions (YXH and DML).

Usability Testing

To assess the app's usability, a set of 11 usability tasks and related scenarios were created based on tasks we anticipated FLWs would commonly perform if they were to use the app in practice (see the task list in Multimedia Appendix 1). One moderator (DML) introduced each task to the participants, who then performed each task independently at their own pace. The next task was introduced once everyone had completed the preceding one unless the task took much longer than anticipated, in which case the moderator then moved participants to the next task. Moderators observed and noted participants' task performance while providing minimal assistance with task instructions when needed.

Surveys

In addition to usability testing, each participant independently completed a series of surveys via Qualtrics (Qualtrics International Inc) to collect information on participant demographics; experience with technology; and perceived ease of use, usefulness, and user satisfaction. We used the positive System Usability Scale (SUS) [50], a 10-item Likert scale survey to assess general usability, with possible scores ranging from 0 to 100, where higher scores indicate higher usability. We also calculated the net promoter score (NPS) [51], a single-item user-reported questionnaire to rate the likelihood of recommending the app to others to assess market viability. To generate an NPS, respondents provide scores between 0 (not at all likely) and 10 (extremely likely); scores of 9 or 10 are considered “promoters,” scores of 7 or 8 are considered “passives,” and scores of 0 to 6 are considered “detectors.” The NPS is then derived by subtracting detractors from promoters (both calculated as the percentage of total respondents), with possible NPS scores ranging from −100 to 100.

Group Interviews

All participants engaged in semistructured interviews following usability testing and survey completion. An interview guide was developed and used to collect feedback on user experience with probes on the overall impressions of the app, current supervision mechanisms, and barriers to and facilitators of the broader implementation of the app. A trained and experienced moderator (YXH) followed the guide to probe feedback on the app’s perceived feasibility, acceptability, and usefulness.

Data Analysis

The focus group sessions were audio recorded, transcribed, and anonymized before coding and analysis. The COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist is included in Multimedia Appendix 2 [52]. We used both deductive and inductive approaches to coding. We first defined usability, feasibility, and acceptability following definitions published by Ginsburg et al [53]. In total, 2 coauthors (YXH and DML) who moderated the focus group sessions independently read 2 transcripts and generated codes from the data. YXH, AP, and DML then finalized the codebook, which was used to direct the coding process. We used a systematic thematic coding approach [54] to generate key themes based on a priori codes and emergent codes: (1) perceived feasibility of the app, (2) acceptability of the app, (3) perceived usefulness of the app, and (4) barriers to and facilitators of scalability. Textbox 1 summarizes the definitions of the themes as used in this paper.

Following thematic coding, we developed code summaries or preliminary narratives describing each theme. YXH, AP, and DML then discussed and refined the code summaries to ensure depth and breadth across all participants. The final code summaries were used to describe the findings in this paper. An intercoder agreement was calculated between 2 coders (YXH and DML) on a portion of coded data until a κ value of 0.61 was achieved. All interview transcripts were double coded and analyzed using the qualitative research software Dedoose (version 9.0.107; SocioCultural Research Consultants) [55]. SUS and NPS scores were calculated following the focus group sessions.

The institutional review boards at Baylor Scott & White Health (388136) and Harvard Medical School (IRB22-0692) approved the study.

Results
Overview
A total of 18 FLWs—including clinical managers, CHWs, social workers or social work students, research assistants, nurses, and medical assistants—participated in 1 of 6 focus group sessions. Participants were aged between 21 and 70 years. Most identified as female (15/18, 83%), were not Hispanic/Latino (11/18, 61%), and had bachelor’s degrees (8/18, 44%). Table 1 summarizes the demographic characteristics of the participants.

Most participants (11/18, 61%) did not have mental health training before the EMPOWER training but interacted with individuals with mental illness regularly during their work (Table 2). None of the participants had experience delivering structured BA therapy.

Table 3 summarizes the participants’ current technology use. Less than half (7/18, 39%) of the participants owned Android-supported devices. Participants were provided with Android tablets if they reported not having or being able to use an Android device during the focus group session; 28% (5/18) of the participants installed the app on their own devices, and the remaining participants were provided with Android tablets for this study.

Overall, participants found the app usable, with an average SUS of 72.5 (SD 18.1) compared with the industry benchmark of 68, which has been found to be the average SUS for digital health apps and used in previous digital health studies [56,57]. The average SUS scores from older participants (aged >50 years) were lower than those from younger participants (Table 4). The NPS was 0 (neutral), with an equal distribution of promoters, detractors, and passives (6/18, 33% per NPS category).

### Perceived Feasibility of the App

In this section, we discuss the perceived feasibility of the app, which includes structural factors such as the current administrative and operational capabilities of health systems that could influence the introduction of the app. The participants discussed their current client-provider engagements and supervision mechanisms that could affect the potential introduction and incorporation of the app into current workflows and across the existing health system.

### Client-Provider Engagement

Participants described how they worked with clients, which revealed potential considerations of how the app may need to be flexibly designed to support the ways in which FLWs meet with clients today. First, although in-person visits were still common, many participants shared that they engaged with their clients via telehealth. Furthermore, when meeting remotely with clients, participants shared that they may not necessarily have a quiet, private space to speak with clients and connectivity may be less reliable. Thus, obtaining high-fidelity recordings of sessions conducted in settings with frequent disruptions is an important consideration. Second, FLWs have limited time to interact with clients, and some participants shared that additional time would be needed to deliver a brief psychosocial intervention. Third, in some cases, screenings such as the Patient Health Questionnaire–9 for depression are currently administered and updated in electronic health record (EHR) systems such as Epic, and it may not be the FLW’s role to access, collect, or update these data even though such screening data may be needed for the delivery of a psychosocial intervention such as BA. When discussing client engagement, one participant noted the following:

> ...the social worker is the first person that meets with the patient because she talks to the patient to see what barriers they have to their personal care, which would involve depression screening, and any kind of behavioral health barriers that they may have going on. So that’s how we get our information about what the patient is kind of going through and what they need as far as behavioral health management. [P04; nurse]

The integration of the app into existing EHR systems was reported as another important consideration.

Finally, although we did not specifically collect feedback on supervisors’ perceptions of the app, participants in supervisory roles suggested that additional time would be needed not only to review all the recordings but also to actually deliver the intervention—time that FLWs may not have:

> From my role, like I said before, I don’t know that I would have the time to incorporate something like this into a patient encounter just because, like I said, we’ve got about 15, 20 minutes to see a patient for whatever issue is happening. And generally, when I see a patient for depression, anxiety, or something mental health, we certainly talk about it, talk about the role of treatment, maybe some options for counseling, not necessarily just medication. But I feel like when they get to me, it’s more about treatment and not so much about talking through things just because they’re not going to have as much time with a physician or a nurse practitioner because of their schedules. [P08; nurse practitioner]

### Supervision Structure

According to the participants, the current supervision structure includes structured supervisor-supervisee meetings scheduled as a part of annual performance reviews. In most settings, although they are not perceived as part of supervision and are not standardized, peer support groups are also available. Although the existing peer support mechanisms are informal and do not follow a structure similar to the supervisor-supervisee meetings, they function as a good support mechanism for team members in which “a doctor can support a doctor, a manager can support a manager, or even their employees” (P06; clinical manager). A participant noted the following:
We do huddles where we kind of discuss different things that are going on and changes within our settings and our clinical practice that are similar, but we don’t necessarily do any ratings. [P16; certified medical assistant]

Thus, introducing the app would mean integrating these traditionally siloed supervisor-supervisee and peer support mechanisms and potentially introducing a new workflow that allows additional time and resources to be invested in supporting FLWs.

Acceptability of the App

On the basis of feedback from the focus group sessions, participants’ overall impressions of the app were mainly positive. Participants reported that they found the app “easy,” “useful,” and overall “important” to their current workflows. The app could provide a much needed structured platform to support peer supervision and overall training of FLWs. A participant with no training in mental health care delivery before the BA training program noted the following:

I don’t have to be a licensed professional counselor, and I can actually use it myself to help and...get supervision from my other peers to help me along the way. [P07; certified medical assistant]

Another participant described the app and process as an “objective way to actually hear the session and hear how much each person reacted, how they delivered the information to the person, how the patient received it” (P08; nurse practitioner). She added that, as a supervisor, she could instruct the trainee to “go ahead and go do it, and then we’ll listen, and we can talk about feedback together.”

Even though most participants did not necessarily review or remember information from the app-related training materials provided to them before the focus group sessions, they considered the app easy to use. Participants who accessed the app on their devices found it easy to install. Most respondents also found the app navigation to be easy and self-explanatory. Nonetheless, it was noted that it could be a bit confusing at first “because you don’t know where to click,” (P02; social worker or social work student) and there were a few features within the app that the participants found more challenging to navigate than others (eg, navigating and interpreting different graphs and reviewing self-ratings). Participants needed time to familiarize themselves with the app and use it comfortably as they had never used a similar app before. One FLW reported:

I watched the (training) videos a long time ago and didn’t remember exactly everything that was talked about in the videos. And so, there’s a little bit of difficulty at first, but it’s pretty intuitive [as to] where everything is and how to use it. Or at least for me, it was, and so I could be able to grasp onto it pretty easily. [P03; social worker or social work student]

The features that participants needed the most time to navigate included accessing recordings, graphs, and self-ratings.

Perceived Usefulness of the App

Participants generally perceived the app to be potentially useful for a few reasons. One respondent shared that such an app would be useful to have now to address gaps in care because of limited access to and availability of mental health specialists:

For me, it would be a great thing to refer someone to if this was—if this was available because I think right now our psychiatrists are scheduling out next year. I think it’s a year before you can get the next appointment. So obviously, mental health is a big problem. [P08; nurse practitioner]

The app could also help enhance FLWs’ job performance, highlight their areas for growth, and ensure overall intervention fidelity. The app’s ability to record and allow users to review and rate sessions can allow for more tailored feedback on performance enhancement, highlighting areas of growth:

I think as a supervisor, being able to record sessions could be really impactful if you have group supervision that you’re doing. Because if you have the consent from the patient and you’re able to kind of play this recording for everybody, you could kind of talk about what things went good [sic], areas of growth, basically. And so being able to use a recording, I think, could be helpful, as well as peer ratings and getting the ratings from your supervisor to kind of also see what areas of growth that you might have for behavioral activation or any other skills that you’re using at your place of employment. [P03; social worker or social work student]

In addition to individual performance enhancement, the app could ensure intervention fidelity. A CHW shared that counseling sessions were often interrupted in the hospital setting; therefore, audio recording or rating could verify that the sessions were comprehensive despite disruptions. Reviewing the recording asynchronously could also help FLWs ensure that their sessions adhere to the intervention protocol.

Finally, most participants mentioned how their current peer support groups lacked structure and did not use systematic guidance or frameworks such as ratings for peer supervision. Respondents highlighted the potential of this app to fill that gap; however, the challenge would be in how to systematically incorporate the use of the app across the health systems currently implementing or planning to implement task-shared mental health interventions. As aptly summarized by a CHW, “to say that we need something like this, we definitely do. It’s just ‘where-do-we put-it type’ of situation” (P17; CHW).

Barriers to and Facilitators of Scalability

Following discussions on the app’s perceived feasibility, usefulness, and acceptability, we probed considerations that could help the app’s broader implementation, including its fit into the FLWs’ current workflows and recommendations for future implementation.

Addressing Privacy Concerns

Protecting client privacy was expressed as a top priority for most respondents. Although feedback was mixed about clients’
apprehension toward audio-recorded sessions, it was generally agreed that obtaining proper client consent before recording was critical and necessary. Participants shared that consent from both FLWs and clients would be essential to ensure transparency and that all parties were informed of and agreed to how recordings would be used. Suggestions for increasing client comfort and obtaining adequate consent included building a trusted relationship with the client before asking to record sessions. By doing this, clients may be less hesitant to be recorded and more comfortable sharing their potential concerns.

Finally, regarding physical infrastructure, as noted previously, there is not always a private, physical space for FLWs to engage with clients and conduct peer supervision activities. One participant shared the following:

"...we would probably talk about a lot of stuff that people would really want to be kept private with no real chance of anyone else hearing it, but that space is a big issue. We have a lot of shared offices—a lot of people in the same room at the same time...it might be better for us to, say, record a session so that we can make sure we’re getting everything, make sure I’m not missing something because that person’s over here, this person’s doing this, this person interrupted me, that person bumped into me. Yeah, we would just need to find a way to do it where we could minimize distractions, interruptions, and that kind of stuff." [P17; CHW]

Another participant agreed, stating the following:

"I’m in a room that can accommodate 25 people. And I have people all around me, and we’re all talking about different things. And it’s really hard." [P18; CHW]

**Ensuring the App Fits Workflow and Time Capacity**

Although the app was perceived as an important addition to support their work, some participants raised concerns about finding time to deliver brief interventions and reviewing and discussing self- and peer performances. It was suggested that the ability to review and rate recordings anytime and anywhere is an advantageous feature of an app accessible from any device and that FLWs may prefer different device types depending on their environment or workflow. For example, one FLW noted the following:

"I think mostly it would be done at a computer because we have very set clinic hours where I’m at. But in some other environments, I could see somebody trying to access it from a car or something like that." [P16; certified medical assistant]

Another commented that, for her role, "...these (tasks) would be more flexible in very small devices, like iPad or phone, rather than recording it and everything, doing it in a computer” [P10; nurse]. Asynchronous review would also allow for more flexibility in completing these follow-up activities:

"I think being able to kind of reference the sessions that you’ve recorded will kind of allow for being a little more flexible in the schedule. Right now, you just have to go with each patient as it is, but this will allow...you to refer back. So, you don’t always have to just do it all at one time." [P16; certified medical assistant]

Collecting and managing data offline would also be critical for FLWs working in areas with limited connectivity.

**Providing Structured, Supportive Supervision**

Respondents noted how the app could help supervisors give structured feedback to their staff, identify and highlight growth areas, and delegate appropriate tasks to FLWs based on their performance and expertise. Similarly, peer supervision could allow for more structured feedback from peers in workplaces that currently have informal peer support groups. Respondents confirmed that structured supervisor feedback could help with performance enhancement and quality assurance, particularly during the training phase, when workers need the most support. One participant noted the following:

"...it would be good to be able to listen to how we interact with the patients. And it would be good to listen to it with the provider so...the nursing staff would know what we could do different, if we did well, just to get an idea of how we’re doing and how the patients are reacting to what we do." [P09; medical assistant]

Participants felt that current app-supported supervision could allow for a more consistent feedback mechanism, systematic tracking of gradual performance improvement, and a constant feedback loop to enhance learning opportunities for FLWs.

Similarly, although respondents reported that informal peer feedback is available in some settings, it is largely unstructured. Most participants agreed that having their peers listen to their sessions and provide feedback is beneficial. Respondents were generally receptive to their peers being involved in supervisory processes, primarily as the participants viewed peer supervision more as “feedback” rather than a performance appraisal. However, it was suggested that it would be important, if not critical, to ensure that peers provide constructive and positive feedback to each other; concerns were raised about how the care team culture may be affected by peers giving and receiving negative ratings and critiques on performance. When asked how they would feel about their peers listening and rating their sessions, one participant noted that it is “beneficial to have another set of ears as long as it’s constructive criticism or constructive help” [P18; CHW]. Regarding constructive criticism, "I think it’s all in bettering us so that we can better our patients, so that’s good." [P16; certified medical assistant]. For some, ratings were only associated with yearly performance reviews with a supervisor. Respondents emphasized the importance of a nurturing and supportive peer group rather than a competitive one. Finally, participants agreed that the app had the potential to help with more structured self-assessments as well. The ability to record and review sessions could allow for more flexible self-evaluation and help with self-improvement and retrospective performance assessment.
**Discussion**

**Principal Findings**
We conducted this study to assess the feasibility and acceptability of a prototype app developed for FLW supervision using objective, metric-based performance evaluation and supportive feedback mechanisms in the United States. Participants found the app easy to use and acceptable. It was considered useful for supporting task sharing of mental health care services, enhancing FLWs’ skills, ensuring intervention fidelity, and providing structure to the traditionally unstructured peer support groups by introducing peer ratings and structured feedback mechanisms. Some key feasibility issues revealed in discussions with FLWs and stakeholders included (1) how the ability to record sessions with high fidelity may depend largely on the nature of the client encounter, (2) the potential need to integrate the app into an existing EHR system (eg, Epic), and (3) the introduction and integration of a new app-supported peer supervision workflow into existing supervisor-supervisee processes and peer support mechanisms. Among areas of improvement for scalability were privacy considerations both on recording and rating the session and ensuring the availability of private space in the health facility to conduct the mental health intervention successfully. Other areas of improvement included focusing on the additional time commitment required of FLWs and supervisors when introducing the app, including time to record and rate the sessions. Findings from our study highlight the app’s potential to catalyze the existing traditional supervisor-supervisee dyad model by shifting focus to a supportive supervision model that incorporates feedback not just from supervisors but also from peers and through self-assessments [44].

We would like to highlight 2 key findings that affect the scalability of the current app and similar digital tools that aim to support the monitoring of psychosocial intervention delivery through objective, measurable metrics. The first is the utility of the current app for supportive supervision of FLWs in the United States. Given the current focus on the scalability of task-shared mental health interventions and the need to ensure the quality delivery of task-shared psychosocial interventions, digital solutions such as the one proposed in this study are crucial [46,58]. Worldwide, digital interventions have shown great promise in supporting FLWs [59], and studies are now exploring digital supportive supervision more extensively [60,61]. The current app can rapidly scale this process, standardize performance measures, and account for evolving training needs with great flexibility. In this study, we demonstrated that an app based on work with nonspecialist providers in Madhya Pradesh and Goa, India, was found to be usable and potentially useful for FLWs in Texas and shows promise for supporting the scale-up of services delivered by FLWs in similar settings across the United States.

Another key finding of this study is the potential of the app to help merge traditionally siloed supervisor-supervisee and ad hoc peer feedback approaches to build a more unified, structured supervision process across existing health systems. This requires effort beyond adding the app to the existing workflow; rather, it may be necessary to develop a new workflow entirely. Participants expressed concerns about the additional time commitment required to use the app as a part of their job. However, it is important to note that the time constraints mentioned were not necessarily related to the use of the app itself but to adding objective, measurable metrics to assess FLWs’ performance. Introducing measurable metrics to evaluate performance requires recording, rating, and discussing sessions; additional time; and skill sets often beyond the FLWs’ job description. The time commitment required can constrain effective supervision in task-shared projects [29]. Therefore, the app’s scalability depends greatly on creating a workflow that benefits FLWs and communicating its need to support FLWs and task-sharing mental health care across health systems. Creating protocols that outline how to record sessions safely and securely for quality assurance is also critical, particularly in light of the privacy concerns associated with recording internet-based sessions [62]. Ensuring readiness for a systematized supportive supervision process guided by infrastructure and protocols contextualized for a particular type of setting is crucial for the success of task-shared mental health care delivery [63]. More importantly, the current app must flexibly align rather than conflict with existing supervision models and diverse FLW workflows to ensure that it truly supports FLW skill enhancement, effective feedback mechanisms, and adequate fidelity in task-shared interventions [64-66].

**Recommendations for Future Implementation**
On the basis of the feedback collected in this study, there are several key considerations, challenges, and proposed solutions for the future implementation of this app. Table 5 summarizes the key considerations raised during the preliminary prototype design of the app, including advisory panel discussions, usability testing, and focus group session interviews. We propose solutions for each consideration that can inform future studies aimed at introducing similar digital tools to assist FLWs. These recommendations will also facilitate organizations’ development of supportive and structured supervision mechanisms.

</table>

<sup>a</sup>FLW: frontline health worker.
Conclusions
In summary, we demonstrated the feasibility and acceptability of a usable and functional mobile app prototype to support FLW-delivered psychosocial interventions in the United States. However, the success of future implementation hinges on further development of the app to ensure its adoption by both FLWs and their supervisors and overall readiness to adopt a novel peer supervision model of care. Feedback from stakeholders and target end users (FLWs) suggests that the app can help structure supervision mechanisms and systematize the collection and review of performance metrics in task-shared mental health interventions. With appropriate organization- and system-level support coupled with strong FLW training programs, the proposed app has the potential to scale up the delivery of high-quality, evidence-based mental health interventions in the United States through the critical role of FLWs who are already connected with and best positioned to serve some of the hardest-to-reach communities with the greatest needs for psychosocial support and care.

Acknowledgments
The authors would like to thank their colleagues at Dimagi, Akshita Sharma, and Surabhi Dubey, who assisted with app building and provided helpful inputs throughout this study. They would also like to thank Dr Daisy Singla, who has been leading the related study in rural India on which this study is based. Finally, they express their deepest gratitude to their advisory panelists from the Meadows Mental Health Policy Institute, Baylor Scott & White Health, the University of Texas at Arlington, and all the study participants for their time and contributions to this work. This project was supported by the National Institute of Mental Health award R43MH130305-01A1. AP has received support from the National Institute of Mental Health T32 on Social Determinants of HIV (T32MH128395-01). The development and testing of the app previously deployed in rural India were supported by Grand Challenges Canada under grant TTS-2109-47591 in collaboration with Sangath and the Sinai Health System.

Data Availability
The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Conflicts of Interest
YXH, DML, LM, and NL are employed by Dimagi, Inc, whose revenue is derived from the open-source platform on which the digital app described in this paper was built and studied. VP is a co-founder of the EMPOWER At Scale company in the US. He has zero income from this company.

Abstract

Background: The construction, chemical, aviation, medical, and health care industries have used serious games for safety training. To our knowledge, serious games have not been developed focusing on behavioral change to improve safety through the use of verbal commands and instilling players with heightened awareness of their spatial proximity to other people in their surroundings.

Objective: We aimed to develop a theory-driven serious game for improving safety behavior using verbal commands and validate the implementation of the theoretical frameworks used for game development. The game developed, KitchenSpeak, was a first-person character (FPC) game where users respond to in-game prompts to use loud verbal commands when they are approaching another employee’s blind spot.

Methods: In addition to using the SERES framework in guiding the general game design and development, and the Reflection, Engagement, Choice, Information, Play, Exposition (RECIPE) framework to inform the design of the game mechanics, we also applied gestalt laws of perception for graphic design to guide the design of the game’s user interface. We conducted 2 evaluative tests (alpha and beta) to collect end user and stakeholder feedback on the implementation of the theoretical frameworks, as well as to collect relevant information for full-scale implementation and a future validation study.

Results: The alpha and beta tests had 8 and 40 participants, respectively. The alpha test results revealed that the theoretical frameworks were adequately applied; however, suggestions were also made to modify and improve the game. The beta test results suggested further improvements for the game design and found no differences in the perception of ease of play between participants with and without previous FPC gaming experience ($P=.47$; Kruskal-Wallis). Results suggested that the game met its design and theoretical requirements, and it would be easily playable by all players regardless of their previous experience in FPC games.

Conclusions: A theory-driven and evidence-based FPC game titled KitchenSpeak was developed to teach the use of kitchen-speak terms in commercial kitchens. Evaluative tests were conducted to validate the implementation of the theoretical frameworks. Our main contributions are creating and validating game-based training to improve behavioral-based safety in the workplace and the incorporation of gestalt laws of perception for graphic design in the game’s user interface.

Introduction

Overview

In recent times, serious games have been used in industries and various occupations as training tools for employee safety. Serious games combine elements such as visual and auditory effects and the euphoria of completing challenges to facilitate user engagement to motivate the user to transfer gained knowledge to real-life experiences [1]. Serious games are effective tools to improve safety knowledge in the construction [2-8], chemical [9-11], medical and health care [12-15], and aviation [16-18] industries. However, to our knowledge, serious games have not been used in improving behavioral-based safety. In addition to acquiring safety knowledge, behavioral-based safety requires employees to repeat safe behavior over a period of time. Using verbal commands to alert fellow employees of their proximity is a safety practice that is important in high-traffic workplaces, where struck-by injuries can occur. Consistently using verbal commands is a behavior-based safety practice.

Verbal commands are used in various work settings, and this study used a commercial kitchen as a representative workplace to develop and validate our serious game. Verbal commands given in a commercial kitchen environment are generally called “kitchen-speak,” and they are widely used in commercial kitchens as a safety behavior aimed at reducing the risk of accidents due to collisions between employees. Existing methods to train employees to use verbal commands in the workplace using traditional training methods (lectures or videos with quizzes) have been ineffective. This study developed a theory-driven and feedback-based serious game for teaching and training employees to use verbal safety commands within a commercial kitchen.

KitchenSpeak Game Overview

KitchenSpeak is a first-person character (FPC) game where users respond to in-game prompts to use loud verbal commands when they are approaching another employee’s blind spot. These verbal commands to alert other employees of their proximity are called kitchen-speak, the namesake of this game.

Commonly used verbal commands in a commercial kitchen include “corner,” “behind,” “hot,” “sharp,” and combinations of these commands, such as “hot corner” and “sharp behind.” In our game, the player will use the keyboard and mouse to navigate the game environment. Whenever a scenario to use a verbal command occurs, a pop-up text message will inform the player of the verbal command required to be yelled. Upon successful yelling of the command, the game will display another pop-up to inform the player. The player will not be able to proceed through the scenario until the proper command is verbally completed.

KitchenSpeak game consists of 4 stages, where players will progressively learn a new command in every stage while applying the commands learned in previous stages. The last stage is a free-roam stage, where players will have to use a combination of the commands they have learned without any pop-up window to indicate the place of use. The players should now be able to identify the safety situation and act without a prompt. In each stage, a minimum of 4 verbal commands are required for completion, and the players are allowed 1 manual override per stage to minimize frustration and game abandonment.

Prior to starting the game, the player will have to enable the microphone on their computer. The voice recognition module used in this game is Google’s speech-to-text application programming interface which is trained with Google’s speech recognition models. The players do not calibrate or train the speech recognition module.

Significance of the Research

This study contributes to the body of knowledge on serious games by focusing on behavioral change to improve safety through the use of verbal commands and instilling the player with a heightened awareness of their spatial proximity to other people in their surroundings. Existing research in using serious games to improve safety has mainly focused on knowledge such as the proper use of tools [4,5] and proper procedures to perform high-risk tasks [19]. None of the existing serious games for safety focus on behavioral change and using verbal commands. The development and beta testing of the game from this study can be adapted to other training scenarios where behavioral change is needed and incorporate verbal commands as part of the gameplay.

Methods

Ethical Considerations

This study was reviewed by Oregon State University (OSU) institutional review board (IRB-2021-1174) and was determined to be exempt from review.

Methods Overview

The SERES framework [20] for developing serious games was used to guide KitchenSpeak’s development. Nicholson’s [21] Reflection, Engagement, Choice, Information, Play, Exposition (RECIPe) framework was used to guide the design of the game mechanics within the design foundation stage of the SERES framework. KitchenSpeak’s user interface (UI) was designed according to the 6 gestalt laws of perception as proposed by Smith-Gratto and Fisher [22]. An effective UI is important for game development as it ensures that the game players engage with the game in the intended manner [23].

SERES Framework

Overview

The five stages in the SERES framework are (1) scientific foundations, (2) design foundations, (3) development, (4)
validation, and (5) implementation. This study applies the first 3 stages of the framework to KitchenSpeak game development. The last 2 stages of the framework involve evaluating the effectiveness of the training tool, which is planned for a follow-up study. The following subsections present a summary of how the first 3 stages of the SERES framework were applied, as well as the plan for implementing the last 2 stages.

Scientific Foundations
There were 4 aspects of this stage. First, the target audience was Marketplace West Dining Center (MWDC) student employees (84% of the MWDC employee population). Second, the outcome objectives were to increase the use and knowledge of kitchen-speak among student employees. Third, the theoretical basis was our hypothesis that kitchen-speak use and knowledge will increase among people who play the game. Fourth, the tool evaluation will be performed in future work prior to implementation.

Design Foundations
Game Mechanics
We designed the game mechanics according to the RECIPE framework for gamification. Please see the RECIPE Framework for Game Mechanics section for further details.

Design Requirements
We modeled the virtual environment after the real-world MWDC environment to motivate reflection and foster immersion. A plug-in was used to transcribe verbal inputs from the players. For easy access, KitchenSpeak was designed for a web browser platform. MWDC management advised that the game’s completion time should be between 5 and 10 minutes.

Figure 1. Prompt to use kitchen-speak in the Corner stage.

Game Authoring Tools
Based on the design requirements, the following software and services were used to develop the game: (1) Unity-3D game engine for WebGL, (2) Autodesk 3ds Max for object modeling, (3) Google’s speech-to-text plug-in for speech transcription, and (4) PHP database hosted on OSU servers for game data storage.

Trial Design
Two validation tests (alpha and beta tests) were used to validate the implementation of the theoretical frameworks.

Development
Genre
KitchenSpeak was modeled to be a FPC game. The FPC perspective camera model was used since it encourages user immersion more than games in the third-person camera perspective [24].

Content
KitchenSpeak had 4 game stages: Corner, Behind, Hot Corner, and Free Roam stages. Each user must use kitchen-speak terms at least 3 times in the Corner and Behind stages, and at least 5 times in the Hot Corner and Free Roam stages. Each stage has a simple narrative where users are asked to complete tasks assigned by their supervisor. While navigating the virtual kitchen to complete tasks, the player is prompted to use kitchen-speak in blind areas. Figure 1 shows the “yell corner” prompt shown to a user as they approach a blind area. Learned kitchen-speak words cascade in each stage, that is, the Behind stage includes “corner” and “behind” kitchen-speak, the Hot Corner stage includes “corner,” “behind,” and “hot-corner,” and Free Roam includes all previously used kitchen-speak, with an additional “sharp-corner” kitchen-speak.
Rules
There are three general rules: (1) All game stages must be completed to complete the game. (2) Within the Corner, Behind, and Hot Corner stages, a player must use kitchen-speak terms when prompted; otherwise they do not advance through the blind area and cannot complete their assigned task ("enforced-use rule"); the Free Roam stage does not have this rule. (3) In the Corner, Behind, and Hot Corner stages, users are allowed to override the prompt to use kitchen-speak if they are stuck in the blind area for over 30 seconds; users are allowed a maximum of 3 overrides throughout the 3 game stages (override rule).

Visuals and User Experience
Gestalt laws of perception for graphic design were applied to guide the design of the UI elements. User experience was tested and modified through the alpha test.

Validation and Implementation
Validation and implementation, the last 2 elements of the SERES framework, will be performed in future work.

RECIPE Framework for Game Mechanics
The six elements of the RECIPE framework were implemented in KitchenSpeak game mechanics as follows.

Reflection
This was implemented by modeling KitchenSpeak environment and activities after the MWDC kitchen environment, as well as the activities that occur within the MWDC kitchen. Figure 2 shows a scene of the virtual environment from KitchenSpeak compared to the MWDC environment.

Exposition
This was implemented by including simple narratives, such as “Your colleague John put some Teriyaki chicken into the oven, and it is now ready to be checked and served. Go and pick up the chicken from the oven.”

Choice
This was implemented by (1) allowing users to choose different navigating routes to complete an activity and (2) giving users the ability to choose when they want to complete a task. They may decide to free-roam within the game before completing the task.

Information
This was implemented by creating 3 tutorial stages that allow the user to practice the game controls before the main game stages. Informational texts highlighting the objectives of each stage are displayed at the start of each stage. A quick message is also shown to alert the player if they correctly use kitchen-speak, and if they have started, completed, or are in the process of completing a task.

Play
This was implemented by allowing players to restart each stage from within the game. If a user fails to complete certain tasks within a stage, the user is permitted to restart that stage an infinite number of times until they have completed the stage or feel satisfied with their progress. A player is always informed on their progress through the informational text during task progress and completion. Allowing the user to fail and restart within the learning environment creates an opportunity for the user to self-reflect and discuss their experiences with other players, thus improving long-term learning [25].

Engagement
This was implemented through interaction by including activities within the game that require the user’s response. The user is made to provide verbal input as a form of response to the kitchen-speak prompts and is asked to provide keyboard input while completing activities.

Gestalt Laws of Perception for Graphics Design
Gestalt laws of perception for graphics design leverage the laws of perception to develop a comprehensible screen design that is aimed at aiding viewers to interpret and remember the
presented materials [22,23]. The gestalt laws were applied to the UI elements within KitchenSpeak; however, the Controls menu and Stage Select menu in Figure 3 are used as examples to show how the laws were applied. The 6 gestalt laws of perception for graphics design applied in this game are as follows.

**Figure 3.** Controls and stage select menus.

**Figure-Ground Contrast**
This law states that the figure and background must be distinct so that viewers can easily distinguish the figure from the background. In the Controls and Stage Select menus, the primary background color is dark orange (#FF8000) while the text color on the primary background is white (#FFFFFF). This color combination creates high contrast, which improves its legibility.

**Simplicity**
This law states that people simplify their perceptions based on previous experiences. The UI should be designed with simple and familiar designs so that viewers may easily understand it. In KitchenSpeak, unrelated information is shown in separate UI objects, while related information is shown in a single UI object.

**Proximity**
This law states that objects that are close together in space are generally perceived to be grouped together. Similar game UI objects were placed together to reduce the mental load that a player uses to identify game objects. In the Stage Select menu, the game stages and tutorial stages buttons are arranged in close proximity so that the player can easily identify that those buttons represent the game stages and training stages, respectively.

**Similarity**
This law states that objects that possess similar characteristics are generally perceived as a whole. KitchenSpeak game objects that were similar in function were designed to have similar appearances. In the Controls menu, the same background color was used for the subheadings Controls and Stages to signify that these 2 texts were subheadings and not parts of the instructions. In the Stage Select menu, the game stage buttons are made the same color apart from the Free Roam stage button. The Free Roam stage button turns green after the player successfully completes the 3 other stages.

**Symmetry**
This law states that objects with an unbalanced symmetry are perceived to be incomplete and could be distracting to viewers.

In the Controls menu, the white vertical line between the Controls and Stage subheadings was designed to create a symmetrical design in the UI. Symmetry was also applied in the Stage Select menu to guide the arrangement of the game stage buttons.

**Closure**
This law states that open shapes are perceived as incomplete. Important figures should have closed shapes so that viewers do not have to be distracted from trying to close the shape. In the Controls menu, the message “Successfully complete all stages to finish the game” conveys information that is different from the information that the other UI objects convey. As a result, its UI object was designed to have a closed red rectangular figure that distinguished it from the other UI objects, thus reducing ambiguity and making the information easier to read.

**Trial Design**
Two evaluation tests (alpha and beta tests) were conducted. The alpha test was conducted as a qualitative test in the form of an open-ended discussion where participants played KitchenSpeak version 1.0 and were asked to provide their verbal feedback on their gameplay experiences. Our focus for the alpha test was the game content, navigation, UI, speech recognition, realism of environment, narrative, choice, information, and the restart and override rules.

The beta test was conducted by releasing KitchenSpeak version 2.0 to MWDC staff and collecting their (1) game completion times, (2) perception of ease of play, (3) gameplay engagement, and (4) experience with bugs and glitches during gameplay. A 5-point Likert scale survey was used to collect user perception of ease of play, while a survey with predetermined questions was used to collect users’ experience with bugs and glitches.

**Results**

**Alpha Test Results**
We recruited 8 participants, including 5 MWDC management staff and 3 nonmanagement staff with varying gaming experience, who were recruited by MWDC management.
Participants played the game one after another with the debugging window opened to observe how the speech recognition model transcribed the participant’s speech input. The results from this qualitative test are provided in Table 1.

### Table 1. Results from the alpha test.

<table>
<thead>
<tr>
<th>Aspects of the game</th>
<th>Results</th>
<th>Suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Realism of game environment</td>
<td>Participants deemed the game environment design was similar in appearance to the MWDC(^a) kitchen.</td>
<td>Include more details to reflect real-world execution of activities, for example, while a player is picking up a hot pot from the gas oven top, they should turn off the gas and use heat-resistant gloves.</td>
</tr>
<tr>
<td>Content and narrative</td>
<td>Game narratives were perceived as short, but it was explained that they were intentionally kept short to avoid confounding the narrative with the game’s purpose. All participants agreed that the content and narrative were sufficient.</td>
<td>No suggestions for improvement.</td>
</tr>
<tr>
<td>Navigation</td>
<td>Difficulty in navigating for participants with no previous FPC(^b) gaming experience.</td>
<td>Limit the vertical camera viewing angle such that it cannot go above the game character’s horizontal line of sight. That is, FPC cannot look up, but only downwards.</td>
</tr>
<tr>
<td>Information</td>
<td>Instructions in the Stage Select menu were not easy to understand, and participants did not know how to start playing a stage.</td>
<td>Include descriptive instructions on how participants could access game stages.</td>
</tr>
<tr>
<td>UI(^c)</td>
<td>UI elements were without clutter, simple, and easy to understand.</td>
<td>No suggestions.</td>
</tr>
<tr>
<td>Speech recognition usability</td>
<td>Single-word kitchen-speak (ie, “corner” and “behind”) was transcribed correctly, but the “hot corner” phrase was often transcribed as “hot burner” and “hot porter.”</td>
<td>Include “hot burner” and “hot porter” phrases into a similar keyword dictionary such that they will be accepted as correct alternatives to “hot corner” when transcribed.</td>

### Beta Test Results

#### Overview

Feedback from the alpha test was used to release version 2.0, which was used for the beta test. The beta test had 40 participants; 34 of them played and responded to the FPC experience and the ease of play surveys, and 32 responses were valid. A total of 21 participants indicated they were in the 15-to-24-year age group, while 11 participants did not respond to the age question; 7 participants were male, 11 were female, 1 was nonbinary, and 13 did not indicate their gender. The age group and gender proportions were representative of the student population in MWDC. A total of 13 participants responded to the Bugs and Glitches questionnaire.

#### Ease of Play

We looked at the difference in perception of ease of play between participants with previous FPC experience and those without previous FPC experience. Table 2 shows the summary of the ease of play results. The average ease of play of all 32 participants was 3.91 (SD 1.12). There was no significant difference in the user’s perception of ease of play between players who had previous FPC experience and players who had no previous FPC experience at a .05 significance level.

Game Completion Time

We evaluated the average time it took a player to complete game stages and the difference in completion time between participants with FPC gaming experience and no FPC gaming experience. Table 3 shows a summary of the game completion time test. The Kruskal-Wallis test for game completion times indicated that there was a significant difference in the median time it took to complete the game between users with FPC experience and users without FPC experience.

*aSignificant at 5% significance level.

Gameplay Engagement

At least 160 prompts were shown to all 32 players (minimum of 5 kitchen-speak prompts per player). We measured disengagement by the ratio of the number of times a user did not use kitchen-speak when prompted to the minimum number of times a prompt to use kitchen-speak was shown in the Free Roam stage (5 prompts). The results revealed that out of more than 160 prompts that were shown to all 32 players, 11 (6.9%) prompts did not receive valid user responses, while at least 149 (93.1%) prompts received valid user responses.

Bugs and Glitches

A total of 13 participants completed the Bugs and Glitches questionnaire. A total of 8 reported no issues, 5 had bugs in the Free Roam stage, and 2 had speech recognition issues. One participant found the game realistic. While the speech recognition module was adjusted to reduce recognition errors after the alpha test, issues with speech recognition were still expected.

Discussion

Overview

As part of this discussion, we will examine implications of this study and implications for future game developers based on our results. The major topics of discussion will be the frameworks used for game development, the results of the alpha and beta tests, and the development of serious games for behavioral safety.

Frameworks for Game Development

The frameworks used for our game design were SERES and RECIPE frameworks. In addition, we used gestalt laws of perception to design an effective UI for a serious game. In evaluating our implementation of the RECIPE framework, we found that evaluating player engagement was challenging. We measured engagement through the lack of disengagement, and we found our approach to be lacking. Engagement is a multiconstruct measurement [26] and as such must use a triangulation method using more than 1 input. For future game development, developers should consider including multiple measurements for engagement during the design phase.

Effective UI design can improve the gaming experience for inexperienced players, and the gestalt laws of perception can bridge the gap for game developers in designing an effective UI. Previous gaming experience affects user experience as inexperienced players report less positive experiences than experienced players [27]; however, effective UI design can be used to improve user experience and aid effective learning in electronic learning platforms [23]. Gestalt laws of perception for UI design are effective because they provide a holistic perspective that considers humans' perception and interpretation of information [23]. We applied gestalt laws of perception to design the UI and evaluated the UI’s usability. The alpha test results showed that the UI design was without clutter, simple, and the information was easy to understand. We encourage serious game developers to incorporate the laws of perception to improve their game design by reducing clutter and improving information retention with players.

Alpha and Beta Testing

The alpha tests showed us the importance of receiving feedback to improve the game. Including the players, the most important stakeholders, is key to successful game deployment. In our case, we used a qualitative method that provided rich feedback for version 2. Our methods here show that a full testing regime that includes quantitative methods such as A/B testing is not always required. Receiving qualitative feedback to make quick improvements is an effective and agile methodology we suggest for serious game developers.

Our analysis of game completion time showed players without FPC gaming experience completed the game significantly more slowly than those with prior experience. Even though we had a tutorial for inexperienced players, the difference in completion time results was significant. This shows that additional training is required. Players with no prior FPC experience must be eased into gameplay by observing player behavior and receiving real-time feedback. Failure to ease players into the game may cause frustration and game abandonment.

In terms of bugs and glitches, voice recognition was an area of interest. There was variability due to factors such as background noise levels and user-specific characteristics. User accent and voice pitch are factors that will inherently affect the accuracy...
of a speech recognition module. Accent recognition is a problem of particular interest that requires further exploration.

KitchenSpeak game used the Unity3D WebGL. We used Unity3D’s profiling tool to review game assets and memory usage. The results showed that CPU memory was mostly used by rendering game object textures and audio data. To improve overall game performance, similar textures were applied to different game objects to reduce the number of times a type of texture was rendered. We encourage game developers to consider this aspect while developing a game and to use this technique to promote game performance.

Serious Game for Safety Behavior

Prior work in serious games for safety mainly focused on safety knowledge training. There are a few challenges in developing a serious game for behavior change from the safety behavior theoretical perspective. Safety behaviors are defined as acts that can be observed by other employees. Existing theories on changing safety behaviors are rooted in changing values, attitudes, and motivations, and emphasize providing consequences for not practicing the behavior [28].

The first challenge we encountered was finding the balance between providing sufficient exposition in the game to affect the value, attitude, and motivations of the players and managing the length of the gameplay. Our current approach to exposition is a pop-up text box to provide context. If the pop-up window is text-heavy or if we use too many consecutive pop-up windows, based on our own gameplay experience, it can lead to players skipping the pop-up windows or abandoning the game. We have opted to minimize the text in exposition, but have the player repeat the same behavior (verbal commands) multiple times for each play, each with a different exposition.

Second, the literature on safety behavior states that behavior must be observable by other employees; we included nonplayer characters (NPCs) into the scenes within our game. For future work, we plan to collect the gameplay information of actual players and create NPC movements based on actual players’ gameplay data to increase the realism of the NPCs. In either case, we are still looking into methods to assess whether the NPCs create the effect of observers.

Third, in terms of consequences to players when they did not perform the safety behavior, we considered adding consequences, and we evaluated two potential approaches. One is to create and display virtual scenes of accidents such as the spilling of hot food content after the collision and another is to use a pop-up window to inform the player that an accident had happened due to them not providing verbal commands. We decided against the pop-up window as we used it for exposition and did not want to overload the players and have them ignore it. Due to time constraints, we were not able to implement the actual scene of the accident for this study.

For safety behavior, using verbal commands consistently throughout an entire work shift is a relatively new concept to many employees who have never worked in a commercial kitchen. The behavior change we initiated through this study can serve as the baseline for future work to assess whether a change in value or attitude or motivations, a need for observers, and a need for consequences are necessary in a serious game to initiate behavior change.

Conclusion and Future Work

Serious games and other e-learning modules could be used as a cost-effective method for training as employers do not have to deal with the costs of face-to-face in-person training [29]. A serious game is a game that achieves an additional goal that is not for entertainment purposes [30]. By this definition, KitchenSpeak is a serious game. This study aimed to advance the serious games research field by developing a game aimed at changing behavior, specifically, instilling the behavior of consistently using verbal commands in blind areas within high-traffic workplaces.

KitchenSpeak development was successful; however, a new study should evaluate its effectiveness in improving the use of verbal commands and its effect on accidents that lead to struck-by injuries. In order to assess how effective KitchenSpeak is in enhancing the use of verbal commands, we need to compare the frequency of verbal command terms used in a commercial kitchen where the game is deployed to the frequency of kitchen-specific terms used in a commercial kitchen where the game is not deployed. To evaluate KitchenSpeak’s effect on accidents that lead to struck-by injuries, we will compare safety records on struck-by injury frequency before and after the game’s deployment in a commercial kitchen.

In this study, we discussed and validated the implementation of 3 theoretical frameworks that were used to develop the KitchenSpeak serious game for commercial kitchen safety. A serious game’s effectiveness is improved by incorporating theoretical concepts and principles that intend to achieve the desired results [30]. While theoretical concepts and principles serve as relevant tools for guiding serious game development, their effectiveness is linked to their success in application and implementation. In addition to testing the effectiveness of a serious game in achieving its desired outcomes, developers may also evaluate the implementation of their foundational theoretical principles, as they may provide relevant information on the cause of their game’s effectiveness or ineffectiveness.

Acknowledgments

We are grateful to Christopher Anderson, Kent Hildebrandt, Suzi Kritikos, and Michael Meeker of University Housing and Dining Services at Oregon State University for their assistance and input in the game’s development and validation. We are also grateful to Dan Kemoyan, MPH, and Tom Doyle, MBA, of Environmental Health and Safety at Oregon State University. There was no funding for this study. We used Google’s speech-to-text plug-in for transcribing users’ speech input to text, as well as a PHP database hosted on OSU’s servers for gathering all game-related data. The authors attest that there was no use of generative artificial intelligence technology in the generation of text, figures, or other informational content of this study.
**Data Availability**

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

**Authors' Contributions**

EHN was responsible for the conceptualization of this study. CA wrote the study, developed the game, and provided data for all tables in the study. EHN and GN provided administration and supervision of the project. All authors reviewed the final study.

Abstract

Background: Primary care plays a key role in the management of type 2 diabetes. Sodium-glucose cotransporter 2 (SGLT2) inhibitors have been demonstrated to reduce hospitalization and cardiac and renal complications. Tools that optimize management, including appropriate prescribing, are a priority for treating chronic diseases. Future Health Today (FHT) is software that facilitates clinical decision support and quality improvement. FHT applies algorithms to data stored in electronic medical records in general practice to identify patients who are at risk of a chronic disease or who have a chronic disease that may benefit from intensification of management. The platform continues to evolve because of rigorous evaluation, continuous improvement, and expansion of the conditions hosted on the platform. FHT currently displays recommendations for the identification and management of chronic kidney disease, cardiovascular disease, type 2 diabetes, and cancer risk. A new module will be introduced to FHT focusing on SGLT2 inhibitors in patients with type 2 diabetes who have chronic kidney diseases, cardiovascular diseases, or risk factors for cardiovascular disease.

Objective: The study aims to explore the barriers and enablers to the implementation of an SGLT2 inhibitor module within the Future Health Today software.

Methods: Clinic staff were recruited to participate in interviews on their experience in their use of a tool to improve prescribing behavior for SGLT2 inhibitors. Thematic analysis was guided by Clinical Performance Feedback Intervention Theory.

Results: In total, 16 interviews were completed. Identified enablers of use included workflow alignment, clinical appropriateness, and active delivery of the module. Key barriers to use were competing priorities, staff engagement, and knowledge of the clinical topic.

Conclusions: There is a recognized benefit to the use of a clinical decision support tool to support type 2 diabetes management, but barriers were identified that impeded the usability and actionability of the module. Successful and effective implementation of this tool could support the optimization of patient management of type 2 diabetes in primary care.

Introduction

Type 2 diabetes places a significant burden on both people with this condition and the Australian health system. An estimated 1.3 million Australians older than the age of 15 years have diabetes [1], with an associated Aus $14 billion (US $12.9 billion at 2010 rates) [2] of health spending. This creates an enormous social and economic burden. General practitioners...
Future Health Today (FHT) is a co-designed quality improvement and clinical decision support technology platform aimed at the detection and management of conditions in general practice. FHT integrates with the electronic medical record to provide two components: (1) a clinical decision support tool active at the point of care (PoC) and (2) a web-based dashboard that facilitates practice-wide audit and quality improvement activities, including patient recall. Wraparound activities are also included with links to the latest guidelines and access to educational resources. Following initial optimization in 12 general practices, using guidelines for CKD, CVD, and cancer prevention, it is now in use in 55 general practices across Australia. A new module was introduced to FHT practices in July 2022 recommending SGLT2 inhibitor prescribing in patients with type 2 diabetes who also have CKD, CVD, or risk factors for CVD consistent with the Australian Evidence-Based Clinical Guidelines for Diabetes [5]. If a patient is suitable for prescribing, the statement “Consider initiation of SGLT2 inhibitor to reduce CVD and CKD risk” will appear in the PoC. The objective of this paper is to report on the evaluation of the implementation of this new SGLT2 inhibitor module in FHT.

Methods

Study Design

Fifty-two practices in Victoria (n=51) and Tasmania (n=1) had access to the SGLT2 module between July 2022 and January 2023. A qualitative evaluation exploring the use of the module was undertaken using the Clinical Performance Feedback Intervention Theory (CP-FIT), a theory for designing, implementing, and evaluating feedback [15]. CP-FIT was chosen as it incorporates and builds on 30 pre-existing theories and was developed specifically for the health care context. The theory proposes 42 variables that influence a feedback cycle with each step vital for successful feedback to occur. The theory postulates that the cycle is affected by 3 variables: feedback, recipient, and context. In the context of FHT, CP-FIT outlines the steps that users move through when guideline-based recommendations are communicated to users. Algorithms are applied to electronic medical records (data collection and analysis); recommendations are delivered to users (feedback); and they are received (interaction), interpreted (perception), and interrogated (verification). If users find the recommendations appropriate (acceptance), they will respond to them (intention and behavior) and ultimately leads to changes in patient care (clinical performance improvement).

Participants were recruited through expression of interest to participate in semistructured interviews, from those who had at least 1 month access to the SGLT2 inhibitor module. Expressions of interest were sent via email to practices encouraging participation in an interview. Advertisements in the department and practice-based research network newsletters were also used to promote the study. Interviews were conducted between September and December 2022. All participants had access to the FHT software for between 6 and 18 months prior to the use of the SGLT2 inhibitor module in clinical practice.

Data Collection

Semistructured interviews using CP-FIT as a guide were conducted with GPs, general practice nurses (GPNs), and clinical health assistants (CHAs) to explore their perspectives on using the module and recommendations for improving the tool. CHA are administrative staff who use patient data for health research and quality improvement. The aim was to gather as many perspectives as possible until saturation was reached. Participants participated in one-to-one interviews that occurred via telephone or Zoom (Zoom Technologies). Interviews were conducted by MS, a male academic GP registrar with the University of Melbourne. An interview guide was developed to focus on questions regarding the clinical usefulness of the recommendations, the impact on clinical workflow, and perceived changes in clinical performance. Data were uploaded to NVivo (version 12; QSR International) and coded by MS to identify themes using CP-FIT as a coding framework. A second researcher (CM) reviewed the data to ensure the reliability of the analysis.

Ethical Considerations

This study was approved (23269) by the Faculty of Medicine, Dentistry and Health Sciences Human Ethics Subcommittee at The University of Melbourne. Consent was taken through a signed consent form prior to the interview, and verbal consent was also gained to record the audio component of the interview. Participation was voluntary, and participants were compensated with an Aus $50 (US $32) voucher for their time. Participants’ names and practice locations were deidentified and replaced by a pseudonym only known to MS and CM to ensure the protection of their privacy.

Results

Overview

Invitations for interviews were sent out to clinics that had at least 1 month of experience with the SGLT2 inhibitor module. There was interest from 14 general practice clinics, and 16 interviews were completed with participants from 11 clinics (Table 1). The sex of the interviewee was confirmed during the interview. A further 3 interviews were not completed as the
Interviewees used FHT and previous modules but not the SGLT2 inhibitor module. Interviews ranged from 15 to 42 minutes. The themes were mapped across the 3 variables: context, feedback, and recipient. Barriers and facilitators related to these variables are summarized in Figure 1.

Feedback Variables

Goal: Evidence-Based Nature, Relevance, and Importance

Common across all interviews were goals relating to the importance, relevance, and evidence-based nature of the SGLT2 recommendations. Users had confidence that the recommendations were accurate knowing they were based on the latest guidelines. Some incorporated FHT and the module in their conversation with patients by highlighting and explaining to patients the background and concept of FHT to install patient confidence and acceptance of SGLT2 inhibitor prescribing.

I can say to people that the reason I’m suggesting the change in medicine or the increase in dose is because there is a little point of care prompt, it’s telling me there are advantages in doing this, in making a change. [GP2]

Feedback Delivery: Active Delivery, Frequency, and Function

Active delivery was demonstrated through the PoC but not the dashboard. Participants found the PoC user friendly as it would automatically pop up once the patient file was opened. They also enjoyed the flexibility of being able to minimize and scroll through the recommendations in the PoC. In contrast, a majority indicated the need to log in to the dashboard to access it was a barrier to its use.

Well it [PoC] comes up automatically every time we enter a patient where it’s relevant and it’s a very good prompt to double check that we’re following the guidelines. [GP8]

Practices using the SGLT2 inhibitor module also had access to over 20 recommendations within FHT relating to other chronic diseases. With the multiple modules available, prompt fatigue was highlighted as a barrier, especially with time constraints during consultations. Several participants highlighted the possibility of a behavioral norm of not checking the PoC recommendations when they pop up. Despite this, most still believed the recommendations were helpful in identifying patients who would not have been highlighted if it was not for the prompt, reiterating the tool as an additional safety net.

It comes up on every patient when we open the file but because we’re so busy during a consultation...and it comes up so often. [GP2]

Context Variables

Organization and Team Characteristics: Workflow Fit, Intraorganizational Networks, and Competing Priorities

Many users reported using the PoC function before or during the consultation to guide clinical decision-making when talking broadly about FHT. They indicated that they referred to it when the consultation was diabetes focused but would otherwise flag it for future reference or disregard it. “I have a look at the point of care and see what kind of recommendations are popping up” (GP1).

The SGLT2 module encouraged collaboration between the staff. With the use of the cohort function, CHA and GPNs were able to generate recall list and book appointments for GPs to review patient suitability. This reduced the workload for GPs. In addition, GPNs felt comfortable initiating a conversation about the benefits of the medications, although they also acknowledged the final decision lay with the GP.

The autonomy is given to be able to do recalls without having to have the GP absolutely check through every little detail of the patient. [CHA1]

Competing priorities were identified as barriers to fully use FHT with a flow on effect to the SGLT2 inhibitor module, especially with the use of the dashboard. Multiple GPs commented that they used the PoC as the recommendations came to them once the patient file was open. This is in contrast with the dashboard which involved creating patient lists, recalling patients, and filling quality improvement forms. Time pressure was highlighted as a barrier, with many GPs commenting about having time constraints and an increased in workload due to workforce shortages, particularly in rural and regional clinics.

As with all of those things in a busy practice, the catch is putting time aside [to use FHT]. I never get around to doing so. [GP8]

Participants believed a lack of familiarity and knowledge with SGLT2 inhibitors hindered their use of the module. This stemmed from a lack of time for users to upskill. They were aware of the education resources and support offered through FHT, but time pressures did not allow them to review these resources. For the feedback cycle to be completed, GPs must show leadership in engaging with the module as they are the ones that make the decision on whether the recommendation is clinically appropriate. Practice staff have commented that due to time constraints and competing priorities, GPs were unable to prioritize the use of FHT.

I think our GPs, you need to actually show them and go through it with them [FHT], then there’s always that “I’m time poor, not right now, can’t do it too much.” [CHA1]

Patient Population: Clinical Appropriateness and Choice Alignment

Participants recognized that the recommendations were a guide only and still required the use of clinical acumen. Although they acknowledged the accuracy, they may not be clinically appropriate at the individual patient level due to factors such as age, health literacy, comorbidities, and likely compliance.

They’re [GPs] not willing to introduce stricter control for a 70 year old that’s got diabetes and he’s well controlled and everything else.... It’s just a little bit reassessment and the individualisation of the knowing your patients. [Practice nurse 7]

Implementation Process: Cost, Training, and Support

The main cost attributed to the use of FHT was time. For GPs, the time spent on the use of PoC before and during consultations was appropriate for the benefit given as the recommendations...
could be actionable at the time or delayed. However, the dashboard was unused by GPs as they did not have time to use it. In contrast, practice nurses and the CHA found the dashboard function useful to create recall lists and as a quality improvement tool.

Would I love to have more of an opportunity to look at the online module and setting up cohorts and doing things? I’d love to have more time doing that. [GP2]

Participants reported that more support and training would increase their familiarity of confidence in discussing and prescribing SGLT2 inhibitors. They were aware of the educational materials offered to them through FHT, but time constraints prevented them from using them. Practice nurses noted that the resources provided specifically for the SGLT2 inhibitor module were tailored more to GPs for prescribing with broader education on the topic likely to be more beneficial for them. While feedback for these resources was positive, participants believed other modes of education would be beneficial for the broader use of FHT.

I suppose maybe just some how to put it into practice, maybe. Like some scenarios or that type of thing. See while these patients come in, this has popped up, this is what we should be talking about and discussing. [Practice nurse 6]

Recipient Variables

Many found it useful to prompt and raise awareness of the benefits of prescribing SGLT2 inhibitors but found the overcapture of patients an issue. While commenting they were confident with the accuracy of the recommendations, the guideline-based recommendations did not take the patient’s personal history and suitability into account. Participants believed that to maximize the potential of the module, they are still needed to use their own clinical judgment to interrogate and decide if the recommendations were appropriate. Some commented that by following the recommendations blindly, it would reduce the “patient centredness” of the clinical decision and remove shared decision-making with the patient. “I wouldn’t have thought of it without the popup…. It’s making medicine more recipe-like” (GP3).

After seeing the recommendations, users identified their own need for further education on SGLT2 inhibitors and diabetic management in general. This stemmed from the need for more knowledge on the topics for them to confidently discuss these medications with patients. While they were aware of the resources offered through FHT, time constraints for education were again noted.

It’s improved my ability...my little areas of where I need to hone my education skills... I probably didn’t do it that well until we had the popup that forced me to think about why am I telling this patient. [Practice nurse 2]

The recommendation is shown every time the patient file is opened independent of the reason for presentation. Users have commented that it would be difficult to introduce the recommendations if the patients presented for a nondiabetes-related consultation and to steer the conversation toward diabetes. Some users would take note of it and often suggest making a subsequent appointment to discuss SGLT2 inhibitor prescribing. Others used the recommendation as a prompt to change their consultation style to incorporate the module in their consultations.

If I was to see a diabetic who wasn’t on a SGLT2 and had cardiovascular risks, then I would - I would in time change my plan. But as you would well know, best practice is hard to change because you’ve got to learn a new mental routine. [GP6]

Discussion

Principal Findings

The overall response to the use of the SGLT2 inhibitor module in FHT was positive. Enablers and barriers to the use of this module were explored. Enablers of the module’s use included users’ confidence about the accuracy of the recommendations and that they found it easy to incorporate into appropriate consultations and comfortable introducing the topic to patients. They felt the recommendations were proactive and a useful prompt for users to consider prescribing the medication. Unfamiliarity with SGLT2 inhibitors is a known barrier to its prescription [16], and GPs’ awareness of the nonglycemic benefits is low [14]. The inclusion and presentation of SGLT2 inhibitors in guidelines are relatively new, and they have also encouraged users to upskill on knowledge for them to feel more comfortable discussing it with patients.

The role of the GP and GPN and both vital to the management of diabetes in the primary care setting [17], and the module has helped define these roles. GPNs used the module to create lists from the dashboard to recall patients to initiate a conversation about possible SGLT2 inhibitor prescribing and optimization of diabetes management in general with the final decision made by the GP to determine suitability. The main barrier to the use of the module was time pressure and competing priorities during the consultations. Many users stated that the heavy workload prevented them from using the full function of FHT.

By mapping against the CP-FIT framework, the PoC function allowed users to move through the feedback cycle successfully. It has led to better recordkeeping (data collection and analysis) to maximize the efficacy of the algorithms to produce accurate recommendations. They still required to use their clinical acumen to decide whether the recommendation was appropriate for the patient (feedback, interaction, and perception). If appropriate (acceptance), they would initiate a conversation with the patient about prescribing SGLT2 inhibitors and discussing the benefits of improved glycemic control and better patient outcomes (clinical performance improvement). The expanding number of modules has led to prompt fatigue causing users to reduce their interaction with PoC and not initiating the feedback cycle.

There were several limitations to this study. Approximately half of the users of this module were the practice champions for FHT in their workplace. This may lead to responder bias with their enthusiasm for FHT making them more likely to participate and have a better understanding of the program. The study was
conducted during the COVID-19 pandemic, which may prevent potential users from engaging with the program as the effects of the pandemic caused disruption to workflow, especially with staff and resource shortages. We aim to conduct follow-up interviews in the future to see if the pandemic had any significant effect on the use of FHT.

The use of clinical decision support systems (CDSSs) in diabetes has previously been shown to improve patient outcomes [18], although studies are focused on the hospital setting and glycemic control [19,20]. Literature has consistently reported a gap between optimal diabetes care practice and recommended care standards. Previous CDSS studies have found high clinician satisfaction with its use to facilitate the intensification of glucose control [21]. There is strong evidence that users of CDSS consistently recommend its use to others [22] and is appropriate for general practice use [23].

Previous barriers with CDSSs previously reported include increased workload and time constraints [24], which align with the findings of this study. A previous study showed that the implementation of a CDSS alone did not improve quality of care but required multifaceted strategies including continuing education and feedback mechanisms, organizational changes, and patient-orientated strategies [25]. While these strategies were made available to participants, engagement and uptake of the SGLT2 inhibitor module recommendations were variable.

With the increasing burden of type 2 diabetes on the Australian health care system, early diagnosis and treatment will no doubt reduce the risk of developing and delaying comorbidities and improve the quality of life for diabetics. CDSS can assist clinicians in diagnosing and optimizing the management of chronic disease beyond type 2 diabetes.

Conclusions
This study highlights the benefit of a clinical decision support tool to improve appropriate prescribing and increase clinician awareness of SGLT2 inhibitors for their diabetic and cardiorenal effects. Successful implementation of this module could be used to detect patients who will benefit from the effects of SGLT2 inhibitors in primary care and assist in reducing all-cause mortality and morbidity with guideline-concordant prescribing.

Acknowledgments
The authors would like to acknowledge the contributions of the Future Health Today project team and investigators. We would also like to acknowledge the time and commitment of all participants. The project was supported by the Australian Government’s Targeted Translation Research Accelerator program and the Paul Ramsey Foundation.

Characteristics of Users of a Digital Hypnotherapy Intervention for Hot Flashes: Retrospective Study

Morgan Snyder¹, PhD; Gary R Elkins¹, PhD

Department of Psychology and Neuroscience, Baylor University, Waco, TX, United States

Abstract

Background: Hot flashes are associated with a lower quality of life and sleep disturbances. Given the many consequences of hot flashes, it is important to find treatments to reduce them. Hypnotherapy, the use of hypnosis for a medical disorder or concern, has been shown in clinical trials to be effective in reducing hot flashes, but it is not routinely used in clinical practice. One solution to close this implementation gap is to administer hypnotherapy for hot flashes via a smartphone app. Evia is a smartphone app that delivers hypnotherapy for hot flashes. Evia has made hypnotherapy more widely accessible for women who are experiencing hot flashes; however, the app has yet to undergo empirical testing. Additionally, research on user characteristics is lacking.

Objective: This study aims to (1) determine the average age, stage of menopause, and length of menopause symptoms for users of the Evia app; (2) determine the characteristics of hot flashes and night sweats for users of the Evia app; (3) determine the self-reported sleep quality of users of the Evia app; (4) determine the self-reported mental health of users of the Evia app; and (5) determine the relationship between hot flash frequency and anxiety and depression for users of the Evia app.

Methods: This study analyzed data collected from participants who have downloaded the Evia app. Data were collected at 1 time point from a self-report questionnaire that assessed the demographic and clinical characteristics of users. The questionnaire was given to users when they downloaded the Evia app. Users of the Evia app fill out a questionnaire upon enrolling in the program and prior to beginning the intervention. This included 9764 users.

Results: Results showed that the mean age of users was 49.31 years. A total of 41.6% (1942/4665) of users reported experiencing 5 or more hot flashes per day, while 51.2% (1473/2877) of users reported having difficulty falling asleep each night and 47.7% (1253/2626) of users reported their sleep quality to be terrible. In addition, 38.4% (1104/2877) of users reported that they often feel anxious or depressed. There was a small, significant, and negative correlation between hot flash frequency and self-report frequency of anxiety and depression ($r=-0.09$).

Conclusions: This study showed that the average age of app users is in line with the median age of natural menopause. A large percentage of users reported experiencing 5 or more hot flashes per day, while 51.2% (1473/2877) of users reported having difficulty falling asleep each night and 47.7% (1253/2626) of users reported their sleep quality to be terrible. In addition, 38.4% (1104/2877) of users reported that they often feel anxious or depressed. There was a small, significant, and negative correlation between hot flash frequency and self-report frequency of anxiety and depression ($r=-0.09$).

**Introduction**

Hot flashes are common during menopause, which is marked by 12 months of amenorrhea or absence of the menstrual period. It is estimated that approximately 75% of women experience hot flashes during menopause [1]. During the transition into menopause, hormone levels fluctuate, and this leads to many physical changes and symptoms, with hot flashes being known as the “hallmark” symptom of menopause. Hot flashes are distressing for women who experience them, and they are associated with a lower quality of life [2] and psychological well-being [3]. Hot flashes are also associated with sleep disturbances [4-6]. Given the many consequences of hot flashes, it is important to find treatments to reduce them.

The most effective treatment for reducing hot flashes is hormone therapy; however, this has been shown to increase the risk of breast cancer and its use is contraindicated in many situations such as in breast cancer survivors [7]. Other treatments for hot flashes such as selective serotonin reuptake inhibitors, selective norepinephrine reuptake inhibitors, clonidine, gabapentin, cognitive behavioral therapy, and mindfulness-based stress reduction have not been found to be as effective as hormone therapy, and they often include side effects that make their long-term use undesirable [8-13]. Therefore, effective and safe nonpharmacological treatment options are needed to relieve hot flashes.

Hypnotherapy, the use of hypnosis for a medical disorder or concern, has been shown to be effective in reducing hot flashes [14,15]. In a clinical trial that examined the efficacy of hypnotherapy for reducing hot flashes among breast cancer survivors, it was found that hypnotherapy reduced hot flashes by approximately 68% from baseline to intervention end point and this was significantly greater than controls [14]. In another clinical trial that examined the efficacy of hypnotherapy for reducing hot flashes among postmenopausal women, hot flashes were reduced by approximately 80% from baseline to week 12 and these reductions were significantly greater than the structured attention control condition [15].

Although hypnotherapy has been shown to be effective in clinical trials, it is not routinely used in clinical practice. Very few clinicians are trained to administer hypnotherapy for hot flashes. One solution to close this implementation gap is to administer hypnotherapy for hot flashes via a smartphone app. Evia is a smartphone app that delivers hypnotherapy for hot flashes. It is based on a hypnotherapy protocol that has been rigorously tested in randomized clinical trials [14,15] and was developed in consultation with an expert in the field of hypnotherapy for hot flashes. Evia includes a 5-week hypnotherapy intervention with daily tasks that include listening to the audio-recorded hypnotherapy session, tracking hot flashes, and psychoeducational readings. Evia has made hypnotherapy more widely accessible for women who are experiencing hot flashes; however, the app has yet to undergo empirical testing. Additionally, research on user characteristics is lacking. This is the first study to report the characteristics of users of Evia. The information gathered from this study will allow for the Evia app to be tailored and optimized toward its users. This study will also tell us whether individuals who seek relief from hot flashes via a smartphone app are different from those who seek treatment in a clinical setting or a clinical trial, and will allow us to better understand who is downloading and engaging with the digital hypnotherapy intervention. Some previous research has shown that smartphone app users are generally younger [16], and this study will explore whether users of Evia are younger than women who seek treatment in a clinical setting or clinical trial. Additionally, the study will explore how app users may differ in the length of time they have experienced menopause symptoms or symptom severity. In addition, this study is a first step to conducting further research on the Evia app, including clinical trials to evaluate efficacy.

This study analyzed data collected from participants who have downloaded the Evia app. These data were collected by Mindset Health, the developers of the Evia app. Users of the Evia app fill out a questionnaire upon enrolling in the program and prior to beginning the intervention. These data will be analyzed to achieve the study’s aims. This study aims to (1) determine the average age, stage of menopause, and length of menopause for users of the Evia app; (2) determine the characteristics of hot flashes and night sweats for users of the Evia app; (3) determine the self-reported sleep quality of users of the Evia app; (4) determine the self-reported mental health of users of the Evia app; and (5) determine the relationship between hot flash frequency and anxiety and depression for users of the Evia app.

**Methods**

**Overview**

Data were collected at 1 time point from a self-report questionnaire that was given to users when they downloaded the Evia app between October 5, 2021, and July 8, 2022. Users filled out the self-report questionnaire directly on the Evia app. These data were collected prior to the user beginning the intervention and were analyzed retrospectively.

**Participants**

Participants included individuals who downloaded the Evia app between October 5, 2021, and July 08, 2022. Participants are users of the Evia app and were recruited via Facebook advertisements and the app. Any person who downloaded the Evia app during this time period was prompted to fill out a questionnaire with demographic and clinical information prior to beginning the intervention. This included 9764 participants.

**Measures**

**Aim 1**

Participants were asked to fill in their age. Participants were asked, “How would you classify your stage of menopause?” Response options included “perimenopause,” “menopause,” “postmenopausal,” “I’m not menopausal,” and “I’m not sure.” To determine the amount of time that users have been experiencing menopause symptoms, participants were asked, “How long have you been experiencing menopause symptoms?” Response options included “0-6 months,” “6-12 months,” “1-2 years,” “2-3 years,” “3-5 years,” “5-10 years,” and “10+ years.”
Aim 2
Participants were asked, “How many hot flashes do you experience each day?” Response options ranged from “0” to “5+.” To assess the severity of hot flashes that users are experiencing, participants were asked, “How severe are your hot flashes?” Response options included “very mild”, “mild”, “moderate”, “severe”, and “very severe.” To assess the characteristics of users’ hot flashes, they were asked, “What do your hot flashes feel like?” Response options included “sudden feeling of warmth,” “perspiration,” “flushed appearance,” “rapid heartbeat,” “anxiety/an aura,” “dizziness/weakness,” “nausea,” and “other.” Users were able to select multiple responses for this item. To assess the number of night sweats that users experience, they were asked, “How many night sweats do you experience each night, on average?” Response options ranged from “0” to “5+.”

Aim 3
Users were asked to report sleep difficulty with 1 self-report item that reads, “Many women also struggle with sleep during menopause. Do you find it difficult to fall asleep each night?” Response options include “no,” “a little bit,” and “yes.” Users were also asked to rate their sleep quality with 1 self-report question that read, “How would you rate the quality of your sleep?” Response options included “terrible,” “fair,” “good,” and “excellent.”

Aim 4
Users were asked 1 self-report question that read, “Some women also struggle with mental health during menopause. How often do you feel anxious or depressed?” Response options included “never,” “sometimes,” “often,” and “constantly.”

Aim 5
Users were asked, “How many hot flashes do you experience each day?” Response options ranged from “0” to “5+.” Users were asked, “Some women also struggle with mental health during menopause. How often do you feel anxious or depressed?” Response options included “never,” “sometimes,” “often,” and “constantly.”

Ethical Considerations
This study was reviewed by the institutional review board at Baylor University and was considered to be exempt. The institutional review board determined the study to be secondary research for which consent is not required. The data analyzed were deidentified.

Data Analyses
Descriptive statistics (means, SDs, and frequencies) were calculated for the variables of interest. For aim 5, which was to determine the relationship between hot flash frequency and self-report frequency of anxiety and depression, a Pearson correlation analysis was used.

Results
Aim 1: Age, Stage of Menopause, and Length of Menopause Symptoms
The mean age of users was 49.31 (SD 6.693) years. Out of 9103 valid responses, 0.5% (n=49) of users reported being not menopausal, 31.2% (n=2837) of users were perimenopausal, 14.2% (n=1293) of users were menopausal, 13.1% (n=1188) of users were postmenopausal, 7.6% (n=688) of users were uncertain, and 33.5% (n=3048) of users reported unknown (see Table 1). Out of 3127 valid responses reporting length of experiencing menopause symptoms, 20.4% (n=639) of users reported 0-6 months, 20.9% (n=655) of users reported 6-12 months, 20% (n=624) of users reported 1-2 years, 13.5% (n=421) of users reported 2-3 years, 11.3% (n=354) of users reported 3-5 years, 9.3% (n=290) of users reported 5-10 years, and 4.6% (n=144) of users reported 10+ years (see Table 1).
Table 1. Stage of menopause and length of menopause symptoms for Evia users. This table lists the frequencies and percentages of Evia app users who are in each stage of menopause and their length of menopause symptoms. These data were collected from Evia app users who downloaded the Evia app. Data were collected via a questionnaire given on the Evia app to users prior to beginning the intervention and were analyzed retrospectively. These data were collected between October 5, 2021, and July 8, 2022. The Evia app includes a hypnotherapy intervention to help reduce hot flashes.

**Aim 2: Hot Flash Characteristics**

Out of 4665 valid responses, 13.5% (n=630) of users reported experiencing 0 hot flashes per day, 9.4% (n=437) of users reported experiencing 1 hot flash per day, 13% (n=607) of users reported experiencing 2 hot flashes per day, 12.8% (n=595) of users reported experiencing 3 hot flashes per day, 9.7% (n=454) of users reported experiencing 4 hot flashes per day, and 41.6% (n=1942) of users reported experiencing 5+ hot flashes per day (see Table 2). Out of 4183 valid responses, 1.9% (n=80) of users reported that their hot flashes were very mild, 30.4% (n=1273) of users reported that their hot flashes were mild, 40.9% (n=1710) of users reported that their hot flashes were moderate, 20.3% (n=851) of users reported that their hot flashes were severe, and 6.4% (n=269) of users reported that their hot flashes were very severe (see Table 2). Out of 4180 valid responses, 83% (n=3469) of users reported that their hot flashes felt like a sudden feeling of warmth, 59.2% (n=2474) of users reported perspiration, 47.5% (n=1987) of users reported a flushed appearance, 34.5% (n=1442) of users reported rapid heartbeat, 32.7% (n=1367) of users reported anxiety or an aura, 24.5% (n=1023) of users reported dizziness or weakness, and 16.4% (n=686) of users reported nausea (see Table 2). Out of 321 valid responses, 13.4% (n=43) of users reported experiencing 0 night sweats, 25.5% (n=82) of users reported experiencing 1 night sweat, 23.1% (n=74) of users reported experiencing 2 night sweats, 21.8% (n=70) of users reported experiencing 3 night sweats, and 16.2% (n=52) of users reported experiencing 4 night sweats (see Table 2).
Table 2. Number, severity, and characteristics of hot flashes for Evia users. This table lists the frequencies and percentages for Evia app users’ number of hot flashes, severity of hot flashes, hot flash characteristics, and number of night sweats. These data were collected from Evia app users who downloaded the Evia app. Data were collected via a questionnaire given on the Evia app to users prior to beginning the intervention and were analyzed retrospectively. These data were collected between October 5, 2021, and July 8, 2022. The Evia app includes a hypnotherapy intervention to help reduce hot flashes.

**Aim 3: Sleep**

Out of 2877 valid responses, results demonstrated that 18% (n=519) of users reported no to having difficulty falling asleep each night, 30.8% (n=885) of users reported a little bit of difficulty falling asleep each night, and 51.2% (n=1473) of users reported yes to having difficulty falling asleep each night. Out of 2626 valid responses, results also demonstrated that 47.7% (n=1253) of users reported their sleep quality to be terrible, 44% (n=1155) of users reported their sleep quality to be fair, 7.8% (n=206) of users reported their sleep quality to be good, and 0.5% (n=12) of users reported their sleep quality to be excellent.

**Aim 4: Mental Health**

Out of 2877 valid responses, 5.9% (n=169) of users reported that they never feel anxious or depressed, 38.4% (n=1104) of users reported that they often feel anxious or depressed, and 16.2% (n=465) of users reported that they constantly feel anxious or depressed.

**Aim 5: Relationship Between Hot Flash Frequency and Anxiety and Depression**

There was a small, significant, and negative correlation between hot flash frequency and self-report frequency of anxiety and depression ($r(2875) = -0.09, P<.001$).
Discussion

Principal Findings

Results demonstrated that the average age of app users (49.31 years) is in line with the median age of the beginning of perimenopause (47.5 years) and the median age of natural menopause (51.3) [17]. Although previous studies have shown that, overall, app users are generally younger [16], users of Evia are the age we would expect based on the age of menopause onset and symptoms emerging. Additionally, a large percentage of users (2837/9103, 31.2%) reported being in perimenopause, and this is oftentimes when menopause symptoms, including hot flashes, begin. An unexpected finding in this study was that a large percentage of users did not know their stage of menopause (3048/9103, 33.5%). This shows that users of Evia may not be aware of the various stages of menopause and what the menopause transition entails. This suggests that it may be beneficial for the Evia app to include some psychoeducational components about the menopause transition and stages of menopause. These psychoeducational components may help users of Evia better understand their menopause transition and experiences. Many users reported experiencing menopause symptoms for 0-6 months (639/3127, 20.4%), 6-12 months (655/3127, 20.9%), or 1-2 years (624/3127, 20%) with users less commonly reporting experiencing menopause symptoms for 5-10 years (290/3127, 9.3%) or 10+ years (144/3127, 4.6%). These results demonstrate that users are starting to use Evia toward the beginning of menopause symptoms. It is possible that those who have been experiencing symptoms for longer have learned how to cope with or treat their symptoms.

The largest percentage of users reported experiencing 5 or more hot flashes per day and reported that their hot flashes were moderate intensity. This finding is in line with previous studies that assessed hot flash frequency at baseline [15]. In a clinical trial by Elkins et al [15], participants experienced approximately 10 hot flashes per day on average at baseline. This study showed that, on average, Evia app users experience 5 or more hot flashes per day, which is in line with participants in previous clinical trials.

In line with previous studies regarding hot flashes and sleep, a majority of users (1473/2877, 51.2%) reported difficulty falling asleep each night and reported their sleep quality to be terrible (1253/2626, 47.7%) or fair (1155/2626, 44%). Previous studies have shown that menopausal women generally have poorer sleep than those not in menopause [18]. In addition, previous studies have also shown that hot flashes are associated with worse sleep outcomes [4-6]. Therefore, the finding that Evia users are reporting sleep problems is in line with previous research. Hypnotherapy interventions have been shown to improve sleep in menopausal women [15,19]. Evia includes components to address sleep problems and this study suggests that those components should be kept or additional components should be added in order to help users who are reporting difficulty falling asleep and poor sleep quality.

A majority of users reported that they sometimes (1139/2877, 39.6%) or often (1104/2877, 38.4%) feel anxious or depressed. This is also in line with previous research which has shown associations between hot flashes and symptoms of anxiety or depression [20,21]. However, this study found that there was a small, negative correlation between hot flash frequency and frequency of anxiety and depression, and this did not support the hypothesis that there would be a positive correlation between hot flash frequency and frequency of anxiety and depression. As mentioned above, previous research has found positive associations between hot flashes and symptoms of anxiety and depression; therefore, this finding is not in line with previous research. The correlation of –0.09 is also very small and near zero. It is likely only significant due to the large sample size. There are a couple of reasons that this finding may have occurred. First, users were not able to report the true number of hot flashes that they may have been experiencing and were limited to selecting 0, 1, 2, 3, 4, or 5+. Therefore, we measured a limited range of measurement of number of hot flashes. If users were able to report the exact number of hot flashes they were experiencing, there may have been more variation in this variable, and this may have affected the correlation. Second, the measurement of the frequency of anxiety or depression symptoms with a single item is not optimal. If a validated scale that measures depression or anxiety had been used, the measurement of this variable would have been improved. There may have been greater variability in this variable and the correlation may have been different. In addition, validated scales generally ask about the frequency of specific symptoms experienced whereas the single-item measure in this study asked solely about how often one was feeling anxious or depressed. Therefore, by using the single-item scale, the construct may have not been fully captured.

Limitations

This study has several limitations that should be addressed. First, several characteristics of users remain unknown and were not addressed by this study. For example, information about geographic location and race or ethnicity was not reported. The study was not able to describe several important demographic factors of the sample, including race or ethnicity and education level.

There were also limitations regarding how variables in the study were measured. For example, sleep quality and frequency of anxiety and depression symptoms were measured using single items. There are limitations to using single-item scales, including that they may not accurately or fully capture the construct. In addition, the items may have been worded in a suggestive manner. For example, “Many women also struggle with sleep during menopause. Do you find it difficult to fall asleep each night?” By starting the item with, “Many women also struggle with sleep during menopause...” it may be suggested for the individual to respond in a certain way. By identifying these limitations of measurement, this study will help to inform the optimization of data collection and measurement with the Evia app.

Future Directions

The results of this study will inform the optimization of the hypnotherapy intervention delivered via the Evia app. The results of this study will also inform the optimization of data collection via the Evia app. Once the Evia app is optimized,
further research is warranted. Future studies should first examine the feasibility of the Evia app in a randomized controlled trial design. Then, future studies should examine the efficacy of the Evia app in comparison to a control group or even a face-to-face delivery.

Conclusions
This was the first study to report on the characteristics of users of the Evia app, which delivers hypnotherapy for hot flashes. Results showed that the average age of app users is in line with the average age of menopause onset. Results also showed that the largest percentage of users reported experiencing 5 or more hot flashes per day and reported that their hot flashes were moderate intensity. In line with previous research regarding hot flashes and sleep, a majority of users reported difficulty falling asleep each night and reported their sleep quality to be terrible or fair. In addition, a majority of users reported that they sometimes or often feel anxious or depressed. The results of this study will help to inform the optimization and tailoring of the hypnotherapy intervention delivered via the Evia app.

Abstract

Background: The high prevalence of mental illness is a critical social problem. The limited availability of mental health services is a major factor that exacerbates this problem. One solution is to deliver cognitive behavioral therapy (CBT) using an embodied conversational agent (ECA). ECAs make it possible to provide health care without location or time constraints. One of the techniques used in CBT is Socratic questioning, which guides users to correct negative thoughts. The effectiveness of this approach depends on a therapist’s skill to adapt to the user’s mood or distress level. However, current ECAs do not possess this skill. Therefore, it is essential to implement this adaptation ability to the ECAs.

Objective: This study aims to develop and evaluate a method that automatically adapts the number of Socratic questions based on the level of detected psychological distress during a CBT session with an ECA. We hypothesize that this adaptive approach to selecting the number of questions will lower psychological distress, reduce negative emotional states, and produce more substantial cognitive changes compared with a random number of questions.

Methods: In this study, which envisions health care support in daily life, we recruited participants aged from 18 to 65 years for an experiment that involved 2 different conditions: an ECA that adapts a number of questions based on psychological distress detection or an ECA that only asked a random number of questions. The participants were assigned to 1 of the 2 conditions, experienced a single CBT session with an ECA, and completed questionnaires before and after the session.

Results: The participants completed the experiment. There were slight differences in sex, age, and preexperimental psychological distress levels between the 2 conditions. The adapted number of questions condition showed significantly lower psychological distress than the random number of questions condition after the session. We also found a significant difference in the cognitive change when the number of questions was adapted based on the detected distress level, compared with when the number of questions was fewer than what was appropriate for the level of distress detected.

Conclusions: The results show that an ECA adapting the number of Socratic questions based on detected distress levels increases the effectiveness of CBT. Participants who received an adaptive number of questions experienced greater reductions in distress than those who received a random number of questions. In addition, the participants showed a greater amount of cognitive change when the number of questions matched the detected distress level. This suggests that adapting the question quantity based on distress level detection can improve the results of CBT delivered by an ECA. These results illustrate the advantages of ECAs, paving the way for mental health care that is more tailored and effective.

Introduction

Background

Cognitive behavioral therapy (CBT) is an established and effective therapeutic approach for treating a wide range of mental illnesses, including depression and anxiety disorder [1,2]. This approach, rooted in the cognitive model of emotional responses, posits that our thoughts, feelings, and behaviors are interconnected. Its central principle asserts that negative automatic thoughts must be corrected because they deleteriously affect emotions and behaviors [3]. CBT has been widely adopted in clinical practice and in preventive health care for the general public [2,4]. Despite its efficacy, broad dissemination faces challenges [5,6]. The World Health Organization [5] asserts that factors such as a shortage of trained therapists, geographical and financial limitations, and societal stigma toward mental health contribute to a substantial treatment gap.

Researchers have attempted to provide CBT through embodied conversational agents (ECAs) to address social issues [7-9]. ECAs are computer-programmed interfaces that simulate human-like conversations with users by using natural language processing techniques. Examples include messaging app-like chatbots [10,11], robots [12,13], and ECAs displayed as computer graphics on a screen [14]. Text-based agents or chatbots are especially widespread and commercially available as smartphone apps. Inkster et al [11] and Fitzpatrick et al [10] are 2 examples of such agents whose ability has been extensively validated for targeting and helping individuals who are experiencing mild to moderate symptoms of depression and anxiety. These agents provide therapy for daily mental health care rather than intensive clinical treatment. Studies have shown their effectiveness in reducing symptoms of depression and anxiety, increasing mental well-being, and fostering user resilience [15].

ECAs, or chatbots, increase accessibility, affordability, and anonymity, potentially reaching a broader population that might benefit from CBT. However, the effectiveness of these digital therapies depends on several factors, including therapeutic techniques, empathy, user interface, and personalization. Asay and Lambert [16] categorized the factors affecting therapy effectiveness into four major groups: (1) extratherapeutic changes, which include clients' personality and environmental factors that support recovery, independent of therapy participation; (2) common factors such as empathy and therapeutic alliance, which are found in various therapy approaches; (3) expectancy, which involves improvement resulting from clients' anticipation of assistance and their belief in the therapy's rationale and effectiveness; and (4) techniques, which are specific factors unique to particular therapies and adjusted to address specific issues. Among these 4 groups, the techniques are crucial for enhancing the quality of therapy. One critical CBT therapeutic technique strategically uses Socratic questioning [17]. On the basis of the pedagogical style of the ancient Greek philosopher Socrates, this method is a form of guided discovery that encourages clients to critically examine and articulate their thought patterns to facilitate cognitive change and distress reduction [18,19]. Socratic questioning helps clients deeply contemplate their problems and perspectives. Questions such as “Why do you think that way?,” “What evidence supports this perspective?,” and “Have you considered other perspectives?” can be adjusted to specific problems or situations. These flexible templates can be applied to various concerns and situations. The process involves carefully considering the content, timing, and sequence of questions adjusted to an individual’s cognitive processes and emotional state, emphasizing the quality of queries when engaging the client in Socratic questioning [2,4,20]. Therapists observe the content of clients’ utterances, changes in their voices, and facial expressions to understand changes in their mood [2,4].

Recent studies have started to investigate the application of Socratic questioning in automated CBT systems such as ECAs. Kimani et al [14] and Shidara et al [21] explored ways to implement Socratic questioning in CBT delivered by ECAs. The former work provided Socratic questions according to a dialogue context using a flowchart of selectable inputs and reduced the specific anxiety about giving a presentation. The latter study set up 2 dialogue scenarios, with and without Socratic questioning, and evaluated them in a comparative experiment. The group with the scenario containing Socratic questioning showed a larger reduction in negative moods. Both studies suggest that Socratic questioning by ECAs promotes cognitive changes and distress reduction.

However, there is a significant gap in current research. Existing studies have not explored how to automatically adapt Socratic questioning. Ideally, ECAs should adapt CBT strategies according to users’ psychological states, just like human therapists do. Specifically, there is limited research on this topic. We must focus on the adjustment of the number of questions or its types. Therefore, we set our goal to personalize CBT strategies based on an individual’s current psychological state.

This study addresses this gap by introducing an adaptive method to improve the effectiveness of CBT using ECAs. This method adjusts the number of questions during a therapy session based on the detected level of psychological distress. The main goal is to provide questions according to the user’s level of distress to improve the therapeutic interaction. To achieve this goal, we formulated the following research questions:

1. Research question 1: Can modifying the number of questions based on the user’s level of psychological distress lead to better therapeutic outcomes?

To address this question, our system uses a machine learning model with natural language processing techniques to estimate a user’s psychological state during a CBT session. Our system can automatically detect psychological distress, allowing it to adapt to the user’s mental state without using psychological
scales such as the Kessler Psychological Distress Scale (K6) in each session. Furthermore, by integrating the distress detection model, our system can estimate the user’s distress in real time during the CBT session. This functionality is intended to improve the effectiveness of CBT with an ECA. In this sense, we present the hypothesis 1.

Hypothesis 1: In a condition with the adaptive number of questions, improvement in distress and emotion and cognitive change will be better than in a condition with a random number of questions.

2. Research question 2: Is there a clear benefit to modifying the number of questions to match the user’s specific psychological state rather than setting a fixed optimal number for all?

For this question, we emphasized the value of customization, recognizing that the most effective balance of questions may vary from user to user. Therefore, we aimed to clarify the therapeutic benefit of determining the distress reduction moments. Through this investigation, we aimed to identify the most effective strategy: changing the number of questions or setting a user-specific number of questions. Therefore, we propose hypothesis 2.

Hypothesis 2: The adapted question amount has better improvement than both the too few questions amount and the too many questions amount in terms of the users’ distress improvement, emotion improvement, and cognitive change.

To validate these hypotheses, we tested it experimentally by comparing 2 conditions: the adapted number of questions condition and the random number of questions condition. We assessed the reduction of psychological distress and negative emotional states and cognitive changes in both conditions. We also analyzed the influence of deviations in the number of questions from the model’s estimated value on the effectiveness of the ECAs.

The incorporation of a distress detection model into an ECA system is essential to our method. In the Psychological Distress Detection and Conversational Scenario section, we describe our psychological distress model and the design of the agent architecture.

**Psychological Distress Detection and Conversational Scenario**

**System Overview**

Figure 1 shows the overview of our system, including the abstract scenario. The detailed scenario can be found in Multimedia Appendix 1. This ECA uses an ECA toolkit called Greta (Institut des Systèmes Intelligents et de Robotique in Paris) [22]. Its animation’s appearance uses a version identified as more acceptable to Japanese people [23]. We used the ja-JP-Wavenet-B of Google’s Text-to-Speech service to generate the synthesized speech of a Japanese female voice. We used a laptop (i7, 32GB RAM, Dell Inc) for the ECA implementation and recorded the participants’ facial expressions and speech with its built-in camera. A microphone and a speaker were built into a headset (Sennheiser). Figure 2 shows a conversation between a user and our ECA.
In this study, we developed a question scenario based on the principles of cognitive restructuring [2,4], a key component of CBT. The scenario was supervised and reviewed by a psychiatrist to ensure clinical accuracy and relevance. The CBT process involves 3 main steps: identifying automatic thoughts, correcting them, and examining new balanced thoughts.

The first step in the scenario involves identifying automatic thoughts by describing the situation, the mood, and the automatic thoughts themselves. Typically, the situation and mood are described first, followed by identifying the automatic thoughts that occur between the situation and the mood. When describing mood, participants also report the intensity of their moods using a score, which is a percentage ranging from 0 (not stressed at all) to 100 (the most stressed they have ever felt). In this step, the users select their strongest automatic thought. Although multiple automatic thoughts may arise from a single situation, focusing on the strongest thought allows for the largest reduction of mood score.

In this study, we incorporated a classification model developed by Shidara et al [21] that determines whether automatic thoughts are expressed. Their model, which helps users accurately identify their automatic thoughts, was integrated into the response selection component of the ECA. When the ECA asks the user about his automatic thoughts, the model takes the response as input and determines whether the answer is a thought or something other than a thought, such as a mood or situation. If the response is deemed to be something other than a thought, the agent asks another question to elicit an automatic thought. If the answer is a thought, the agent proceeds to the thought-correction section. The model, constructed using Bidirectional Encoder Representations from Transformers [24], demonstrated a high estimation $F_1$-score of 0.81.

Once the automatic thoughts have been identified, participants correct their thoughts by comparing them with the facts of the situation. The CBT system poses questions designed to increase participants’ awareness of overlooked facts and provides distance from their automatic thoughts to view them more objectively. After correcting their automatic thoughts, the participants were asked to state their new balanced thoughts. This step involved considering the insights gained while correcting automatic thoughts and generating new balanced thoughts. At the end of this process, participants reported their mood score again to confirm a reduction of their negative mood scores after deriving new balanced thoughts.

**Adaptation of Number of Questions**

In our developed scenario, multiple questions were included for correcting automatic thoughts. This step ensured that the standardized scenario effectively improved participants’ mood by incorporating multiple questions. In actual CBT sessions, questions are adjusted according to an individual patient’s condition and level of distress.

Our ECA posed questions aimed at helping participants notice overlooked facts and gain distance from their automatic thoughts.
to view them more objectively. In the developed scenario, multiple Socratic questions were included for correcting automatic thoughts. This step ensured that the standardized scenario effectively improved participants’ mood by incorporating multiple questions. The number of questions posed for correcting automatic thoughts was adapted based on the detected level of the participant’s psychological distress. After posing questions that correct an automatic thought, the participant’s responses were used to identify their current psychological distress state. If distress is detected, the system continues to pose additional questions that prompt the participants to correct their thinking from various perspectives. This process gently nudges participants to reconsider their automatic thoughts, offering them the opportunity to alter their perspective and reduce their distress. The system was designed using a pool of 21 Socratic questions to prompt the correction of automatic thoughts. If a participant continues to exhibit high levels of psychological distress, the agent can pose up to 20 additional questions to assist them in working through their distress.

If the estimated value of the detection model is nondistressed, the agent proceeds to the next step, where the participant composes a balanced alternative thought. This step was based on the insights gained in the previous step, which is the correction of automatic thoughts. After this process, the participant again reported a negative mood score, which was expected to confirm a less negative mood.

Pretraining of Detection Models to Address Japanese Conversation

In our quest to dynamically adapt the number of questions asked during a CBT session, psychological distress in users must be accurately detected. In this context, machine learning models have been developed to estimate psychological distress [25-29], often using publicly available data sets, such as the Distress Analysis Interview Corpus/Wizard-of-Oz (DAIC-WOZ) database [30]. Unfortunately, this data set primarily contains English language data focused on assessing depressive tendencies rather than providing mental health care. Therefore, our challenge is to adapt these models to suit a Japanese language context, especially for the CBT domain.

To address this challenge, we first applied a deep learning architecture of the depression detection model proposed by Li et al [31]. Their model identifies depressive tendencies in interactions with ECAs by classifying presence or absence into 2 categories. It combines recurrent neural network and long short-term memory networks and uses multitask learning for depression detection. Multitask learning enables simultaneous training on multiple tasks, leveraging shared knowledge to improve generalization, use relationships between tasks, and reduce overfitting. In the study by Li et al [31], the model achieved a high $F_1$-score of 0.71.

Figure 3 [30,32] shows the training flow of the psychological distress detection model [30,32]. For the training process, we used a combination of pretraining and transfer learning. First, we translated the original training data in the study by Li et al [31] from English into Japanese using machine translation software and pretrained the model with reference to the settings in the study by Li et al [31]. We then constructed a Japanese CBT data set using crowdsourcing and conducted transfer learning on the detection model.

In the pretraining, we used data from 2 sources: the DAIC-WOZ data set [30] and the DailyDialog data set [32]. The DAIC-WOZ data set consists of 189 two-party English interviews between participants and Ellie, an animated ECA interviewer. Participants were evaluated using the Patient Health Questionnaire-8 scale [33]. Participants with a Patient Health Questionnaire-8 score
≥10 were considered depressed [33]. The DailyDialog data set [32] is an English dialogue collection containing 13,118 two-party daily life conversations. The data set included 3 expert-annotated information layers; 7 categorical emotions [34], 4 dialogue acts, and 10 dialogue topics. We maintained the original separation into training, validation, and test sets for both data sets. We used a transformer translation model, implemented with HuggingFace transformers [35], for the English-Japanese translation of both data sets.

We retained the original implementation details of the study by Li et al [31]. We trained the model for a maximum of 100 epochs with early stopping based on the macro $F_1$ metric for depression classification. We used cross-entropy loss and a batch size of 1 for the DailyDialog and DAIC-WOZ. Tokenization was performed using the MeCab library [36], and we constructed word embeddings with a default dimension of 128. The turn-level encoder consisted of 1 hidden layer and 128 output neurons. We tuned the document-level recurrent neural network layers within a range of {1, 2, 3} and the hidden size within a range of [128, 256, 512]. The model parameters were optimized using the Adam optimizer [37] with a learning rate of 0.001. Dropout rates were set to 0.1 for both the turn and document encoders.

**Transfer Learning for Real-Time Distress Detection in CBT**

After pretraining the model with the translated data, we implemented transfer learning by replacing the fully connected layer. This transfer learning process allowed us to leverage the original model architecture while shaping it to our specific distress detection task in CBT. In this transfer learning phase, we incorporated only 3 types of user utterances corresponding to the situation, mood, and automatic thought responses within the CBT process. This approach was adopted to enable real-time distress detection during CBT sessions with the ECA. When the detection model makes inferences, it inputs the 3 most recent utterances. In this way, the distress detection model enables real-time detection in a CBT session.

Our crowdsourced data set was initially collected from 100 crowd workers from the general public. However, upon visual inspection of the data, it became apparent that the responses from some participants were not adequately informative or valid for our purpose. Therefore, we excluded data from 6 participants as likely outliers or nonresponsive. Thus, the final data set for our analysis consisted of responses from 94 participants. In the data collection, we assessed the level of psychological distress in our crowdsourced data set with the Japanese version of K6 [38] (Japanese version [39]). This scale is a concise and reliable self-report tool that assesses the level of psychological distress experienced by individuals in the previous 30 days. This 6-item scale measures the frequency of symptoms related to anxiety and depression, making it a valuable instrument for detecting and evaluating mental health disorders in both clinical and research settings. The items are rated on a 5-point Likert scale, from 0 (none of the time) to 4 (all of the time), leading to a total score range of 0 to 24. Higher scores indicate greater psychological distress. In this study, following Sakurai et al [40], a K6 score of ≥5 was considered distressed, and a score of <5 was considered nondistressed. We constructed a psychological distress detection model that classified these 2 classes. Of the 94 participants, 63 (67%) were categorized as distressed (K6 score of ≥5) and 31 (33%) as nondistressed (K6 score <5). We used stratified sampling to automatically split the data into training, validation, and testing subsets. We used 55% (52/94) of the participants for training, 19% (18/94) of the participants for validation, and 26% (24/94) of the participants for testing.

**Methods**

**Ethical Considerations**

The research ethics committee of the Nara Institute of Science and Technology reviewed and approved this study (2019-I-24-3). We engaged a human resources company to advertise and recruit participants. All participants provided written informed consent before participating in the experiment. The participants were compensated with an honorarium, which was paid by the human resources company. Study data were anonymized.

**Participants**

This study was conducted in February and March 2023. Eligibility criteria for the experimental participants were as follows: (1) aged between 18 and 65 years, (2) having no hearing impairments, and (3) ability to speak Japanese. For the analysis of this research, 49 participants were allocated into 2 conditions to assess the impact of varying the number of Socratic questions based on detected levels of psychological distress during CBT sessions with an ECA.

In addition to these participants, a separate group (of 26 participants) was involved in a distinct experimental condition, designed for a different research focus. Although data for this separate group were collected concurrently with the main study, the data from this separate group are not relevant to the current analysis and have not been included in this paper. The objective of collecting the data from this separate group was to analyze whether an extreme number of questions were stressful and discouraged cognitive changes. It is expected that participants in this separate group might experience or perceive the system rather than personal emotional challenges such as depression or anxiety. Specifically, participants may be dissatisfied with how the system works or interacts rather than with their internal struggles. Although this system-related dissatisfaction is also important, it is beyond the scope of this study. Only the 2 conditions were used in this study to focus on the person’s nonadaptive thoughts and moods regarding their problems.

Table 1 shows the demographics and baseline characteristics of the participants who were recruited through an external participant recruitment service. We also included 1 participant with a history of a mental health issue in the adapted number of questions condition. This participant was currently in remission and not taking any medication. This participant was recruited through a company that provides employment transition services for people with a history of mental health issues.

\textsuperscript{a}K6: Kessler Psychological Distress Scale.

To confirm whether there was any bias in the age of the participants and the preexperiment K6 scores between the 2 conditions, we conducted a 2-sided Welch $t$ test and calculated Cohen $d$ values. As a result, for age, Cohen $d$ was 0.21 and the $P$ value was .48; for preexperiment K6 scores, Cohen $d$ was −0.08 and the $P$ value was .78. These results indicate that there was no significant bias in age and preexperiment K6 scores between the 2 conditions.

**Experimental Conditions**

Figure 4 illustrates the conversation scenarios for our 2 experimental conditions: the adapted number of questions and the random number of questions. In the adapted number of questions condition, the ECA used a distress detection model. This model continuously estimated the participant’s level of distress after each answer for a thought-correction question. If the model detects distress, it prompts the agent to ask a new question to correct the automatic thought. This process is repeated until the model detects no distress or the maximum number of questions is reached. In contrast, the condition of a random number of questions does not use the distress detection model. Instead, the system randomly determines the number of questions without considering the participant’s distress state. In both conditions, the number of questions asked to correct automatic thoughts varied from a minimum of 1 to a maximum of 21.

![Diagram of the experimental conditions. The adapted number of questions condition, which includes the psychological distress detection model, versus the random number of questions condition, which does not include the distress detection model.](image_url)

The condition assignment was not concealed from the experimental examiner. Participants were automatically assigned to conditions based on their age, sex, and K6 scores (a self-reported psychological distress scale). The day before the experiment, the participants responded to these 3 items using a questionnaire administered through Google Forms. On the basis of the questionnaire results, the conditions were divided such that no imbalance existed between the conditions in terms of K6, age, and sex. The participants conducted the experiment according to their predetermined condition assignments. They were unaware of their condition assignment and were not informed of the differences between the conditions.
Before the experiment, an experimenter explained this to the participants who signed the consent forms. They then completed the K6 questionnaire and read a publicly available leaflet explaining CBT [41]. The experiment consisted of the same questions as those in the ECA dialogue scenario created in our previous study [21]. The experiment was completed within 1 hour, including its briefing and preparation.

**Measures**

**Psychological Distress**

K6 was used as the rating scale to assess the psychological distress of our participants. Before the experiment, we obtained the K6 results for the previous 30 days. After the experiment, the participants were asked if any of the K6 items had changed after the CBT. The postexperimental measures differed from the original protocol, and we asked about the changes solely for analyzing our experiment. We calculated the change in psychological distress using equation 1.

\[
\text{Change in psychological distress} = \text{K6 score (pre)} - \text{K6 score (post)} \quad (1)
\]

Before the session, we measured the Quick Inventory of Depressive Symptomatology [42] (Japanese version [43]), which assesses depressive tendencies.

**Cognitive Change**

The Cognitive Change-Immediate scale [44] is a 5-item self-report measure that assesses the extent of the cognitive changes experienced by users during a single CBT session within therapy sessions. Items were rated on a scale from 0 (not at all) to 6 (completely), yielding a total score ranging from 0 to 30. Higher scores indicate a greater degree of cognitive change experienced by the participants.

**Mood Change**

A mood score is a numerical representation of the intensity of self-reported negative emotions experienced by the participants. The scores ranged from 0 to 100, with higher scores indicating more severe distress. Participants verbally provided their mood scores at 2 time points during scenarios involving CBT sessions with the ECA. The initial mood score was used for prethought correction, and the subsequent score was used for postthought correction. Specifically, participants were asked, “On a scale of 0 to 100, where 0 is no problem at all and 100 is a huge problem, how intense is that feeling?” These questions are commonly used to assess relief from negative moods [2,4]. Participants provided their responses verbally during the CBT. The participants’ moods were characterized using such language as anxiety, depression, sadness, feelings of inferiority, and fatigue. In this study, these negative emotional states were collectively assessed under an umbrella term, negative mood, which focuses exclusively on mood scores to evaluate the changes in these states. This approach allowed us to assess mood change. Following a previous methodology [45], mood change was calculated using equation 2.

\[
\text{Mood change} = \frac{\text{Mood score (pre)} - \text{Mood score (post)}}{\text{Mood score (pre)}} \quad (2)
\]

This calculation is a measure of the degree of change in a participant’s mood, where a larger positive value indicates a decrease in negative mood.

**State–Trait Anxiety**

The State–Trait Anxiety Inventory [46] (Japanese version [47]) is a validated, self-report questionnaire that assesses both state anxiety (temporary and situational anxiety) and trait anxiety (general and stable anxiety) in adults. The State–Trait Anxiety Inventory consists of two 20-item scales: the State–Trait Anxiety Inventory-State (STAI-S) and the State–Trait Anxiety Inventory-Trait (STAI-T). The STAI-S measures the respondent’s current anxiety levels and feelings of apprehension, tension, and nervousness. It assesses the extent to which an individual is experiencing anxiety in response to a specific situation or event. Items are scored from 1 (not at all) to 4 (very much), where higher scores indicate more severe state anxiety. The STAI-T evaluates a respondent’s general tendency to experience anxiety as a stable personality characteristic. It focuses on the feelings of anxiety that are not associated with a particular event or situation; instead, it reflects an individual’s overall tendency to become anxious. Items are scored from 1 (almost never) to 4 (almost always), where higher scores represent greater trait anxiety levels. Both STAI-S and STAI-T scores can range from 20 to 80, and higher scores denote greater anxiety. We calculated the change in STAI-S using equation 3.

\[
\text{Change in STAI-S} = \text{STAI-S (pre)} - \text{STAI-S (post)} \quad (3)
\]

This calculation is a measure of the degree of change in a participant’s state anxiety, where a larger positive value indicates a decrease in state anxiety.

**Statistical Analysis**

We conducted an investigation to address hypothesis 1. This hypothesis states that an adaptive selection of the number of questions based on detected psychological distress would have superior effects in improving mental states. This approach was compared with the one in which the number of questions was randomized. For this investigation, we focused on several metrics, including K6 scores, mood scores, STAI-S, and cognitive change. Both within-condition and between-condition comparisons were conducted within these metrics. Owing to the inability to confirm the normal distribution of these measures in both the adapted number of questions condition and the random number of questions condition, we chose to use nonparametric tests for our analyses. For within-condition comparisons, we assessed the differences in scores before and after the CBT session for each measurement in both conditions. The Wilcoxon signed-rank test was used to analyze these within-condition differences, illustrating the effect of the session on the adapted and random number of questions conditions individually.

For between-condition comparisons, we compared the pre- and postsession scores for each measurement between the adapted and random number of questions conditions. The Mann-Whitney U test was used for this analysis. In addition, we conducted a comprehensive analysis across 4 key parameters: change in psychological distress, cognitive change, mood change, and...
change in the STAI-S. This analysis involved multiple 1-sided Mann-Whitney U tests under the assumption that the adapted number of questions condition would show higher effects on each measure than the random number of questions condition.

We conducted a subgroup analysis to examine hypothesis 2, which asserts that adapting the number of questions according to the participant’s psychological distress is more effective. We categorized the participants into 3 subgroups based on the difference between the number of questions asked and the distress detection model’s estimation: the same group (participants who were asked the same number of questions as determined by the distress detection model), the fewer group (fewer questions were asked than determined by the distress detection model), and the more group (more questions were asked than determined by the distress detection model). In this analysis, we combined participants from both the adapted number of questions condition and the random number of questions condition. We did this because we expected too few participants in the same group within the random number of questions condition. We compared the same group with the fewer and more groups, expecting superior outcomes for the same group. This comparison used a 1-sided Mann-Whitney U test to compare the cognitive change, mood change, change in K6 scores, and change in the STAI-S across the subgroups.

In addition, we conducted further analysis to validate hypothesis 2. In this step, we examined the differences in various measurements across question counts. We focused on groups divided by question amount, such as 10, in the condition of a random number of questions. These were then compared with the participants in the adapted number of questions condition. Owing to the limited sample size in each category, we restricted our examination to qualitative analysis. In this comparative analysis, we did not conduct statistical testing. Furthermore, we reported the number of nondistressed and distressed values automatically detected for each individual question. These analyses aimed to demonstrate the effectiveness of a flexible approach to the number of questions presented.

Although we collected usability questionnaires and subjective evaluation feedback from the participants, this information was not included in the primary analysis of this study.

Results

Model Construction Results

Pretraining our detection models to address Japanese conversation yielded the following results: for the English data set (original condition and reproductive experiment), the accuracy was 0.72, precision was 0.67, recall was 0.58, and $F_1$-score was 0.62. When the data set was translated by an automatic translation model into Japanese, the models achieved an accuracy of 0.64, precision of 0.59, recall of 0.60, and an $F_1$-score of 0.59, demonstrating that we maintained equivalent performance levels despite the change in language.

We further applied transfer learning to the pretrained model with Japanese conversation for real-time distress detection in CBT. The results of implementing this transfer learning are as follows: In the condition where only pretraining was applied, the model achieved an average accuracy of 0.55, precision of 0.47, recall of 0.48, and an $F_1$-score of 0.48 across 5 evaluation trials. When both pretraining and transfer learning were implemented, the average scores improved, with the model achieving an accuracy of 0.70, precision of 0.60, recall of 0.63, and an $F_1$-score of 0.61. The model that demonstrated the highest performance during these trials, exhibiting an accuracy of 0.75, recall of 0.69, precision of 0.72, and an $F_1$-score of 0.70, was selected for integration into the conversational scenario.

Experimental Results

Table 2 presents the pre- and postsession scores for both the adapted and random number of questions conditions across various metrics.

aK6: Kessler Psychological Distress Scale.

bNot available.

cSTAI-S: State–Trait Anxiety Inventory-State.

dQIDS: Quick Inventory of Depressive Symptomatology.

eSTAI-T: State–Trait Anxiety Inventory-Trait.

The average time spent on the dialogues in the adapted number of questions condition was 494.96 (SD 161.10) seconds, whereas the random number of questions condition spent an average of 661.40 (SD 289.20) seconds. However, it should be noted that owing to system issues, we were unable to record the time spent by one participant in each condition. As a result, the reported mean and SD for time spent exclude the data from these 2 participants. All other measurements were successfully recorded for these participants.

The average number of questions asked to correct an automatic thought was 4.76 (SD 4.48) for the adapted number of questions condition and 8.83 (SD 6.52) for the random number of questions condition.

We evaluated the distress detection model’s performance in the adapted number of questions condition. Specifically, we evaluated its accuracy in correctly identifying the nondistressed states, indicating when to stop asking Socratic questions. The model’s performance was measured by comparing its output (0 denoting nondistressed) with the participants’ actual postexperiment psychological distress states. The model correctly identified nondistressed state in 72% (18/25) of the instances.

In the presession phase, the K6 scores did not significantly differ between the 2 conditions. However, a significant difference was observed in the postsession phase; the adapted number of questions condition recorded a notably lower K6 score, indicating a substantial reduction in distress compared with the random number of questions condition. On other measures, the pre- and postsession scores were not significantly different between the 2 conditions.

A closer look at the within-condition comparisons revealed that the adapted number of questions condition experienced a decrease in scores across several metrics following the session, albeit to varying degrees. The adapted number of questions condition showed more marked improvements, especially in the K6 and mood scores, with significant reductions after the session, as evidenced by Cliff delta values of -0.49 (P=.01) and -0.66 (P=.001), respectively. In contrast, although the random
number of questions condition also showed a reduction in the mood score, characterized by a medium effect size (Cliff delta=−0.44; \( P=0.03 \)), the change in the K6 score was negligible between the pre- and postsession periods.

Table 3 presents the comparative results of changes in each measurement. We conducted a 1-sided Mann-Whitney \( U \) test to compare the cognitive change, mood change, change in the K6 scores, and change in the STAI-S between the adapted number of questions condition and the random number of questions condition. The results indicated that there was no significant difference in the change in psychological distress, mood change, and change in STAI-S between the 2 conditions, with \( P \) values of .11, .16, and .54, respectively. However, for cognitive change, a relatively large effect size was observed with a Cliff delta of 0.12, and the \( P \) value was .07, showing a trend toward significance, suggesting that the adapted number of questions condition exhibited a tendency for greater cognitive change compared with the random number of questions condition.

### Table 3. Comparative results of changes in each measurement using nonparametric analysis of 1-sided Mann-Whitney \( U \) test for differences between conditions.

\(^a\)STAI-S: State–Trait Anxiety Inventory-State.

To investigate hypothesis 2, we conducted a subgroup analysis as described in the Statistical Analysis subsection. We categorized the 49 participants from the adapted and random number of questions conditions based on the deviation between the differences in the questions asked and the estimated value of the model. Of the 21 participants, 7 (14%) received fewer questions than estimated and 14 (29%) received more questions than estimated, and for 28 (57%) participants, the number of questions matched the estimated value, denoted as the same group.

Table 4 shows the mean and SD for each subgroup. For cognitive changes, comparisons between the same and fewer groups showed a small effect size (Cliff delta=0.08; \( P=0.46 \)), indicating no significant difference. For the change in psychological distress, the comparisons between the same and fewer groups showed a negligible effect size (Cliff delta=0.00; \( P=0.96 \)), indicating no significant difference. Similarly, comparisons between the same and more groups showed a negligible effect size (Cliff delta=0.07; \( P=0.77 \)), indicating no significant difference. For the change in mood, the comparisons between the same and fewer groups showed a negligible effect size (Cliff delta=0.04; \( P=0.77 \)), indicating no significant difference.

\(^a\)STAI-S: State–Trait Anxiety Inventory-State.

Table 5 illustrates the mean changes in various measurements such as distress, cognitive change, and mood change across different numbers of questions. As indicated in Table 4, the mean changes for the adapted number of questions condition were 1.04 for change in psychological distress, 16.3 for cognitive change, 0.22 for mood change, and 3.00 for change in STAI-S. The bar graphs of these data can be found in Multimedia Appendix 2. For the random number of questions condition, it was observed that in most instances, the mean change was lower compared with the overall average of the adapted number of questions condition. However, a notable exception was observed at a question count close to the average question count for the adapted number of questions condition (mean 4.76, SD 4.48), specifically at 5 questions. At this count, the random number of questions condition exhibited
slightly higher scores in both distress change and cognitive change compared with the adapted number of questions condition. Furthermore, a trend was observed in cognitive change, where an increase in the number of questions correlated with a larger change, indicating a potential area for further exploration and validation in subsequent studies. Despite these observations, it was consistently found that the adapted number of questions condition manifested superior effectiveness across various numbers of questions, indicating robustness in its application regardless of the question count.

Table 5. Mean change in each questionnaire across different numbers of questions posed to participants in the random number of questions condition. Instances where the mean is “not available” indicate that the number of participants (n) is 0. Instances where the standard SD is “not available” are due to the number of participants (n) being either 0 or 1.

<sup>b</sup>Not available.

Table 6 displays the number of detected values classified as nondistressed and distressed for each question aimed at correcting automatic thoughts. The bar graphs of these data can be found in Multimedia Appendix 3. In the adaptive question amount condition, questioning concluded with the detection of a participant’s first nondistressed value. Conversely, the process continued regardless of the values detected in the random question amount condition. Consequently, the total number of participants decreased as the number of questions increased. A significant proportion of participants were identified with nondistressed values, particularly within the initial 4 questions. However, as the number of questions reached a certain amount, the frequency of nondistressed value detection decreased, with none identified from questions 16 to 21. Meanwhile, distressed value detection persisted, with at least 1 individual exhibiting distressed values through the 21st question.

Discussion

Principal Findings

The primary aim of this study was to evaluate a method that adapts the number of questions in a CBT session based on the user’s level of distress, aiming to enhance the session’s effectiveness.

Hypothesis 1 posited that an adaptive approach to the number of questions selection, based on detected psychological distress, would lead to superior cognitive change and reduce psychological distress as well as negative emotional states compared with the random number of questions condition. The results partially supported this hypothesis. We observed a reduction in psychological distress from before the session to after the session in the adapted number of questions condition, whereas no such reduction was evident in the random number of questions condition. Furthermore, the level of distress after the session was significantly lower in the adapted number of questions condition than in the random number of questions condition. In contrast, no significant difference was observed in the changes in each measurement between the 2 conditions. These findings overall indicate that our approach contributed to optimizing the health care process and its outcomes.

A plausible reason for the significant improvement observed only in distress is that the deep learning model incorporated in this study was designed to detect the presence or absence of psychological distress. This suggests that although the CBT system’s adjustment of the number of questions was adjusted for distress, it was not necessarily adjusted for other measures. In cognitive models, cognition, including automatic thoughts, and reactions such as distress are considered distinct entities [2]. Relevant studies [19,44,45] explore the ways in which cognitive shifts can influence stress levels. Moving forward, it might be necessary to analyze the content of CBT and propose methods that enhance both cognitive and distress changes.

Hypothesis 2 proposed that better improvement would occur when the number of questions corresponded with the model’s estimated value. The data partially supported this, indicating more significant cognitive changes when the number of questions was aligned with the model’s estimate compared with when fewer questions were asked. This insight suggests the importance of precision in the number of questions selected to enhance the effectiveness of CBT delivered by ECAs. It was also implied that a large number of questions does not necessarily work effectively. Table 6 (Multimedia Appendix 3) shows that none of the participants were detected as nondistressed from questions 16 to 21. This result suggests that further questioning might not lead to significant improvements when there is no improvement in distress after a certain number of questions. Therefore, it would be prudent to set an upper limit on the number of questions that the system can ask.
We personalized the therapeutic process by ensuring a timely adjustment of the number of questions when the distress alleviation was projected to be insufficient. Our experimental data suggest that this approach significantly bolsters the effectiveness of ECAs in integrating thought-correction techniques into the therapy process. The data also revealed that maintaining a balance in the number of questions was critical for improving CBT’s effectiveness. Our findings highlight the potential of dynamic and personalized strategies in enhancing mental health care.

**Comparison With Prior Work**

The field of mental health care has significantly evolved owing to advancements in artificial intelligence. Among these advancements, using ECAs to deliver mental health care services is particularly promising. Influential studies in this domain, including the work of Fitzpatrick et al [10], DeVault et al [48], and Fulmer et al [49], investigate the effectiveness of these text-based conversational agents or ECAs in mental health care. Furthermore, research by Inkster et al [11], Ghaneharioun et al [50], and Murali et al [51] has revealed the importance of these agents’ ability to convey empathy.

These empathetic elements are crucial for creating a therapeutic alliance and supportive mental health care. Among these advancements, using ECAs to deliver mental health care services is particularly promising. Influential studies in this domain, including the work of Fitzpatrick et al [10], DeVault et al [48], and Fulmer et al [49], investigate the effectiveness of these text-based conversational agents or ECAs in mental health care. Furthermore, research by Inkster et al [11], Ghaneharioun et al [50], and Murali et al [51] has revealed the importance of these agents’ ability to convey empathy.

In addition, research endeavors by Kimani et al [14] and Shidara et al [21] initiated the exploration of the application of Socratic questioning in CBT delivered by ECAs. These studies have shown promising results in fostering cognitive changes and reducing distress. However, they have not explored the dynamic adjustment of Socratic questioning based on users’ psychological states. This study aims to address this gap.

The integration of such adaptive strategies in mental health care, as demonstrated by our study, underscores the substantial contribution of our research in advancing the field. Our study introduces a novel component that modulates the number of questions according to the degree of the user’s psychological distress. The results of our study indicate that adapting to a user’s psychological distress by modulating the number of questions significantly reduced psychological distress compared with a random number of questions. This finding is in alignment with psychiatric insights suggesting that the modification of automatic thoughts through questioning may not yield sufficient effectiveness if such thoughts remain superficial [2].

**Limitations**

When interpreting the results of this study, several limitations must be addressed. First, the cross-sectional design used in our research did not capture the long-term effects of ECAs on psychological distress. A long-term experiment is important to gain a deeper understanding of the lasting effects of ECAs and their potential role in improving mental health outcomes. Another limitation of our study is the small number of participants who exhibited high depressive tendencies. To enhance the generalizability of our findings, future research should involve a more diverse sample of participants, covering a broad range of psychological distress levels. This sample should include individuals with varying degrees of depression and other mental health concerns, ensuring that the results are more widely applicable to different populations that are experiencing various psychological issues. In addition, further research is needed on the effective selection of the number of Socratic questions to maximize the effectiveness of CBT. Techniques such as the WOZ method, in which a therapist operates an ECA, might shed light on this aspect [52].

**Conclusions**

Our study provides evidence that adjusting the selection of questions based on an individual’s distress levels can significantly enhance CBT effectiveness. This adjusted approach allows for a more personalized health care, which can improve the therapeutic outcomes for individuals who are struggling with mental health issues, including anxiety and depression.

Our research highlights the importance of timely and appropriate reactions when an individual’s distress levels improve during therapy. By carefully monitoring and responding to these changes in distress, the ECAs can better support users’ progress. Overall, our study highlights the value of personalized and adaptive approaches in CBT, paving the way for more effective and responsive mental health care.

Abstract

Background: People living with multiple sclerosis (MS) face a higher likelihood of being diagnosed with a depressive disorder than the general population. Although many low-cost screening tools and evidence-based interventions exist, depression in people living with MS is underreported, underascertained by clinicians, and undertreated.

Objective: This study aims to design a closed-loop tool to improve depression care for these patients. It would support regular depression screening, tie into the point of care, and support shared decision-making and comprehensive follow-up. After an initial development phase, this study involved a proof-of-concept pilot randomized controlled trial (RCT) validation phase and a detailed human-centered design (HCD) phase.

Methods: During the initial development phase, the technological infrastructure of a clinician-facing point-of-care clinical dashboard for MS management (BRIDGE) was leveraged to incorporate features that would support depression screening and comprehensive care (Care Technology to Ascertain, Treat, and Engage the Community to Heal Depression in people living with MS [MS CATCH]). This linked a patient survey, in-basket messages, and a clinician dashboard. During the pilot RCT phase, a convenience sample of 50 adults with MS was recruited from a single MS center with 9-item Patient Health Questionnaire scores of 5-19 (mild to moderately severe depression). During the routine MS visit, their clinicians were either asked or not to use MS CATCH to review their scores and care outcomes were collected. During the HCD phase, the MS CATCH components were iteratively modified based on feedback from stakeholders: people living with MS, MS clinicians, and interprofessional experts.

Results: MS CATCH links 3 features designed to support mood reporting and ascertainment, comprehensive evidence-based management, and clinician and patient self-management behaviors likely to lead to sustained depression relief. In the pilot RCT (n=50 visits), visits in which the clinician was randomized to use MS CATCH had more notes documenting a discussion of depressive symptoms than those in which MS CATCH was not used (75% vs 34.6%; $\chi^2=8.2$; $P=0.004$). During the HCD phase, 45 people living with MS, clinicians, and other experts participated in the design and refinement. The final testing round included 20 people living with MS and 10 clinicians including 5 not affiliated with our health system. Most scoring targets for likeability and usability, including perceived ease of use and perceived effectiveness, were met. Net Promoter Scale was 50 for patients and 40 for clinicians.
Conclusions: Created with extensive stakeholder feedback, MS CATCH is a closed-loop system aimed to increase communication about depression between people living with MS and their clinicians, and ultimately improve depression care. The pilot findings showed evidence of enhanced communication. Stakeholders also advised on trial design features of a full year long Department of Defense–funded feasibility and efficacy trial, which is now underway.

Trial Registration: ClinicalTrials.gov NCT05865405; http://tinyurl.com/4zkvr9x

Introduction

Background

Approximately 50% of people with multiple sclerosis (MS) have a depressive disorder, and people living with MS are 2-3 times more likely to be diagnosed with a depressive disorder than the general population [1]. However, depression in MS remains underreported, underevaluated [2], and undertreated [3,4], despite the prevalence of depression in people living with MS, low-cost tools available to screen for depression, and evidence-proven, society-recommended pharmacologic and nonpharmacologic treatment modalities [5,6]. In clinical practice, common barriers to these clinical goals include time constraints during clinical visits (Nelson, M, unpublished data, August 2020), stigma and discomfort discussing psychiatric symptoms [7], insufficient antidepressant medication dose, duration or mechanism of action [8], inadequate attention to other MS symptoms (fatigue, cognitive impairment, and urinary retention) that could interfere with mood and worsen symptom burden [2,9], and patient difficulty following treatments owing to difficulties with access, insurance, or finding specialists close to home [10], as well as the many competing demands on their time. Solutions to address these gaps in reporting, screening, and treatment are needed.

A closed-loop intervention could close these gaps in care and represent a pragmatic approach to address the suboptimal treatment of depression in real-world MS settings. Closed-loop interventions in health care refer to systems that minimize gaps in communication between patients and clinicians; these have been implemented effectively for a number of medical conditions [11-13]. For the purpose of improving depression care in MS, such an intervention would support relevant clinical information flow from patients to clinicians at the point of care and back to patients to support patient-centered care. Such a system would not focus on a specific “one size fits all” treatment or intervention modality (eg, social intervention) or on a specific proprietary mood app, but could support developing a complex plan individualized for each patient’s symptoms, goals, and capability. To accomplish this, the tool should efficiently deliver patient-reported mood symptoms to clinicians in line with the “5 rights” [14] (right information, to the right person, in the right format, through the right channel, and at the right time in the workflow). Further, the tool must promote the behaviors (eg, reporting, screening, treatment recommendations, and following through with timely refills or referral scheduling) that are likely to lead to mood improvements. Finally, this tool should seek to streamline workflows and streamline care in an existing care team (neurologist, nurse, and interprofessional staff) and system of care (informatics, care delivery, and payment structure). Once developed, even after extensive multidisciplinary stakeholder input, a digital health solution must be thoroughly socialized within a health system to increase adoption.

Some prior studies support the feasibility of monitoring patient mood longitudinally in people living with MS as well as the possible effectiveness of a closed-loop approach. There is good concordance between patient reports and clinical depression, supporting the use of patient-reported tools for depression monitoring [15]. The 3-month pilot CoachMS randomized controlled trial (RCT; NCT03335618; n=21; people living with MS [16]) showed that it was feasible, and acceptable, to monitor patients’ bothersome symptoms (mood, ambulation, and bladder) and to act on them clinically in near real time (coaching patients to address these) [16]. This intervention showed some preliminary efficacy in supporting behavioral change [17,18] likely to address depression, including in one case, recognition of and urgent hospitalization for suicidality. A proposed closed-loop intervention could further deliver data on patient function directly to the clinician at the point of care to support effective response.

Objectives

This study details a 3-phase endeavor designed to develop a comprehensive, closed-loop system for monitoring and thoroughly treating depression to be tested in real-world clinical settings: MS CATCH (Care Technology to Ascertain, Treat, and Engage the Community to Heal Depression in people living with MS). In phase I, a prototype was developed. In phase II, it was piloted in a clinical setting to obtain preliminary cross-sectional efficacy data on a fundamental premise, namely that visualization of patient mood during the clinical encounter would improve clinical attention to mood during that visit. In phase III, having ensured that the tool was satisfactory to patients and clinicians and that its use did indeed improve attention to depression in the pilot study, the tool was then refined using an extensive process of human-centered design (HCD) [19,20].

Methods

Phase 1: Initial Technical Build

Overview

Members of the primary research team led earlier engagement efforts that informed MS CATCH development, namely,
creating the BRIDGE dashboard concept [21], testing the acceptability of patient-reported outcomes (PROs) in a point-of-care MS clinical dashboard (MS NeuroShare; 19]), and developing a closed-loop reporting system that collects and synthesizes data at the point of care (MS Falls Insight Track; MS-FIT); [22]). Each of these design processes informed the current technical build.

**BRIDGE**

BRIDGE [21] is a technologically scalable, institutionally approved, workflow friendly, cross-disease, modular precision medicine platform [23]. BRIDGE launches from within a patient’s encounter from the Epic electronic health record (EHR) at the University of California, San Francisco (UCSF) using industry standard integration (Figure 1; Table S1 in Multimedia Appendix 1 [24]), delivering a seamless experience for clinicians [21]. BRIDGE was designed using an extensive process of HCD [19,20]. The tool accesses and visualizes data that are currently available in various disparate sources (EHR, patient diaries, and publicly accessible websites), with the substantial innovation that they are presented here in one comprehensive and streamlined format. A disease-specific version of BRIDGE is live within multiple clinics at the UCSF, with the MS clinic BRIDGE used as a point-of-care dashboard for the current project.

**Figure 1.** Components of the MS CATCH (Care Technology to Ascertain, Treat, and Engage the Community to Heal Depression in people living with multiple sclerosis) tool, including the (A) patient-facing survey and log, (B) the clinician-facing dashboard, and (C) the closed-loop system, with in-basket alerts for the clinician.

**MS NeuroShare**

This closed-loop prototype designed for a collaborative health system integrated a patient-facing PRO app with an EHR-based clinician-facing dashboard [25]. Patient participants cited the perceived value of thinking about and recording information before their appointments, noting how it impacted discussions with their clinicians, adding that coviewing information with the physician put physicians and patients on the same page and promoted a conversation of equals. Clinicians perceived patients’ prospectively collected mood scores as more sensitive, accurate, and comprehensive than a patient’s recall during the visit, and felt that these could improve value and promote clinician engagement [25].

**MS-FIT Tool**

A closed-loop system to prospectively record, report, and prevent falls in people living with MS was designed using HCD in a process analogous to that intended for MS CATCH [22]. MS-FIT includes low-burden regular falls ascertainment that patients can access with one click from any computer, tablet, or device, triggering a clinician’s inbox message for new or serious falls. Clinicians can then access and launch, from the medical record, a comprehensive version of BRIDGE refined
to support multimodal falls assessment and prevention [22]. The MS-FIT development process informed the feasibility of a closed-loop approach as well as specific needs and concerns of intended users, people living with MS, and MS care teams.

**MS CATCH Prototype**

The prototype for MS CATCH used in this study was refined for the specific purposes of depression monitoring and treatment by the study team using the BRIDGE and MS-FIT technical scaffolding, and informed by the MS NeuroShare and MS-FIT design processes and experiences. The MS CATCH prototype used in this study is shown in Figure S1 in Multimedia Appendix 1.

**Phase 2: Proof-of-Concept Pilot Randomized Controlled Trial**

**Research Setting and Participants**

**Design**

This was a cross-sectional, randomized controlled pilot study.

**Setting**

The primary clinical setting was the UCSF Center for MS and Neuroinflammation, which specializes in providing care to >5000 adults with MS annually, and has an extensive track record of pivotal trials for MS [26,27], remote monitoring [28,29], and treatment [16].

**Participants**

MS clinicians were invited to participate in the study during the center’s monthly research meeting, and a convenience cohort of 6 clinicians was enrolled using a signed electronic consent form. Then, from the participating neurologists’ practices, adult patients with an MS diagnosis scheduled for upcoming in-person and video neurology visits were contacted before the clinic visit by the study coordinator via email and phone call. Interested patients were scheduled for an enrollment visit whether in-person, or via telephone, or Zoom (Zoom Video Communications, Inc; an institutionally approved, Health Insurance Portability and Accountability Act–secure, televideo platform). During this visit, they provided detailed informed consent via DocuSign (DocuSign, Inc). Once patients signed the informed consent form, they were asked to complete a series of PROs, including the 9-item Patient Health Questionnaire (PHQ-9) scale, via a secure REDCap (Research Electronic Data Capture; Vanderbilt University) link. Patients with scores of ≥5 (mild depression: 5-9, moderate: 10-14, moderately severe: 15-19, and severe: 20-27) met the study criteria and were then enrolled in the pilot study. All participants were computer literate. Enrollment was capped at 50 individuals meeting criteria. Full inclusion criteria are summarized in Table S1 in Multimedia Appendix 1.

**Study Procedures**

The PRO data obtained from the patient participants populate the BRIDGE dashboard in real time. Patient visits were randomized 1:1 using a simple randomization scheme in which the clinician was informed by the study team to launch BRIDGE during the patient’s visit. For those who did not use BRIDGE, the visit proceeded as a usual clinical visit. Clinicians were reminded to launch BRIDGE via text or email before the patient appointment when applicable, and neither clinician nor patient participant were blinded to the intervention. Patients continued to be recruited until a target (n=50) had met the inclusion criteria and were seen in the clinic. For participants with PHQ-9 scores of ≥19, even if their clinician was not asked to use BRIDGE, the clinician was informed of their score near the conclusion of the clinic visit to ensure safe treatment of the patient. At the conclusion of the study visit, both clinician and patient feedback regarding the tool were solicited. During the proof of concept pilot, MS CATCH was used once during the visit in real time. For the full RCT, the patient-facing mood survey will be completed monthly, as described in the results for phase III.

**Trial Outcomes**

**Usability: Participant Feedback on Tool**

At the end of the study visit, patients were asked to provide feedback on the tool. There were 2 main prompted questions: “Tell us (with illustrative examples) of what worked well and what didn’t, with regards to BRIDGE, during your appointment.” This question was asked to both patients and clinicians, whereas “Please explain in detail, why it was or wasn’t useful for you to report your mood symptoms before the visit” was just addressed to the patients. Then, 2 questions informed from the System Usability Scale [30,31] and the health IT usability evaluation model [32] were completed, assessing likeability and perceived usefulness of the tool.

**Efficacy: Effect of the Tool on Attention to Depression**

At the end of the study, each clinical encounter was reviewed by a team member with an eye to whether mood was mentioned during the clinical visit. After the review was completed by one team member, another team member blinded to the treatment assignment audited the report. Only the second team member was blinded to treatment assignments. Any disagreements were resolved by a third party.

**Ethical Considerations**

This study was approved by the UCSF institutional review board (#18-26148).

**Statistical Analysis**

The participant demographics and usability outcomes were analyzed using descriptive statistics. The main efficacy outcome, percentage visits where depression was mentioned in the clinic notes, was compared for visits with and without the use of MS CATCH using chi-square analysis [33].

**Phase 3: MS CATCH Tool Refinement (Stakeholder Engagement and Intended User Input Over 6 Months)**

**Study Design**

HCD is a process that holds at its center the needs of the intended users. During the MS CATCH refinement phase, the overall goal was to fine-tune and optimize the intervention by partnering with patient and clinician users and multidisciplinary stakeholders in a sequence of iterative feedback sessions to inform and validate design decisions (Figure 2). To our knowledge, features assembled into the MS CATCH prototype

 JMIR Form Res 2024 | vol. 8 | e52809 | p.1313
 (page number not for citation purposes)
had never before been available at the point of care in a clinically actionable format for depression treatment in MS. It was important to verify that the workflow and displays promoted behavioral change likely to improve depression care and to simplify the display into the features most likely to drive adoption of the tool and support depression care. Here, the “capability, opportunity, and motivation model for behavioral change” (COM-B) [18] was used. COM-B is a hub in the center of Michie’s behavioral change wheel [18] and can help inform a patient’s intention to engage in a planned behavior, which is considered the best predictor of that behavior [34,35]. The COM-B approach, and individual intervention functions, have been successfully applied to facilitate behavioral change in people living with MS [17].

<tbody>
<tr>
<td>Stakeholder Advisory Group</td>
<td>Meeting 1 at study kickoff: Refine project goals, inform patient and clinician engagement protocols, and advise on potential clinical, technological, or ethical challenges.</td>
</tr>
<tr>
<td></td>
<td>Meeting 2 when tool is ready for clinical trial: Review the tool optimization and feedback scores (see below) and confirm that the intervention is ready for launch in the trial.</td>
</tr>
<tr>
<td></td>
<td>Meeting 2 following trial start: Review enrollment and early qualitative feedback once clinical trial activated and develop a roadmap for the transition plan.</td>
</tr>
<tr>
<td>Discovery Interviews</td>
<td><strong>Process:</strong> Members of the primary research team with expertise in engagement and HCD conducted 1:1 interviews with patients and clinicians separately, via the UCSF Zoom platform. The sessions were recorded to ensure that all feedback was captured. <strong>Goals:</strong> To ideate new features and map all features and data types to COM-B principles to facilitate behavioral outcomes (reporting, evaluating, treating) [15] likely to support depression reduction. <strong>Outcomes:</strong> Feedback was used to generate a list of features to be modified (e.g., enhanced, clarified, removed, and simplified) by the developer. Clarifying feedback was also elicited on perceived ease of use and usefulness to ensure that only the components most likely to be effective would be used.</td>
</tr>
<tr>
<td>Thinkaloud Session</td>
<td><strong>Process:</strong> Members of the primary research team conducted 1:1 sessions where the tool was launched and tested with patients and clinicians. Patients were presented with specific scenarios for entering data into the platform (e.g., using the tool after a difficult life event vs. for monitoring during periods of emotional stability) and the way they engaged with the tool was observed. Clinicians were exposed to interactive live demonstrations. <strong>Goals:</strong> Validate modifications made following discovery interviews and further refine and clarify each feature. <strong>Outcomes:</strong> Both patients and clinicians were asked to prioritize the individual data types by scoring their “perceived usefulness,” so that only the key drivers of behavioral changes were retained. If any specific data scored low (i.e., not perceived as useful), then they were either removed or modified in the visualization.</td>
</tr>
<tr>
<td>Final Tool Scoring</td>
<td><strong>Process:</strong> The final version of MS CATCH was scored by 20 diverse patients with MS and 10 MS clinicians using established scales such as the SUS, Health ITUES, and NPS. <strong>Goals:</strong> Assess clinician perception of usability with the System Usability Scale (SUS). Assess patient and clinician perceptions of usefulness and ease of use with Health ITUES-based questions, and perceptions of likeability with a single-item question and the Net Promoter Score (NPS). [26, 27, 28] <strong>Outcomes:</strong> Any domains scoring below target as defined in Table 3 would trigger another round of iterative edits, with input from the Stakeholder Advisory Group.</td>
</tr>
</tbody>
</table>

To maximize the likelihood that the tool would be adopted and effective, it was evaluated using the health IT usability evaluation model [32]. This model integrates multiple usability theories including the Technology Acceptance Model and evaluates both subjective and objective outcomes. Although refining the critical data and visualization elements, as well as technological and clinical workflow aspects, the 4 key variables proposed by Mathews et al [36] for digital health tool validation were examined to determine whether the tool (1) reflects HCD principles and (2) is likely to engage patients. These factors include usability, effectiveness, learnability or ease of use, and likeability. Usability was defined using the System Usability Scale, learnability and ease of use were measured with a subset of the Health Information Technology Usability Evaluation Scale–based questions, and likeability was assessed with a single Likert scale question: “Do you like the tool?” and the net promoter score (NPS). Effectiveness was determined based on the pilot study visit notes outcomes.

**Sequential Methods With Iterative Technological Modifications**

Over a 9-month period between September and June, sequential activities were conducted as outlined in Figure 2.
Stakeholder Advisory Group

This group was convened and led by members of the primary research team. The primary research team comprised investigators with a track record of collaboration as well as expertise in both scientific and technological aspects of this project, including MS clinical trials (RB), digital tools to evaluate and treat cognition and mood in MS (RB and AF), psychiatric care for underserved populations and innovations in treatment of psychiatric conditions in diverse settings (CM) [37-44], implementation science (CM), statistics (Ann Lazar), patient engagement (RB and JR) [20,21,25], HCD of digital tools (JR, RB, NS, and NM) [20,21,25], and launching an institutionally and technologically sophisticated, scalable, cross-disease platform from the EHR at UCSF (RB and BRIDGE team). The stakeholder advisory group included the research team listed above, as well as a patient champion JS, patient advocacy group leader Linda Glassel, National Multiple Sclerosis Society, Northern California Chapter President, MS nurse expert AM, Registered Nurse, social worker MD licensed independent clinical social worker, and MS neurologist CYG.

Participants

MS clinicians and other experts (degrees including Doctor of Medicine, Nurse Practitioner, Registered Nurse, and Masters in Social Work) were identified within the UCSF MS clinic and the investigators’ broader professional network. Adults with MS were recruited from the UCSF MS center by the study team (convenience sampling). All participants provided informed consent to test the tool and provide preliminary data. Furthermore, 31% (10/32) of the patients participated in the phase II pilot study.

Ethical Considerations

Activities during this phase (HCD phase) were approved by the UCSF institutional review board (#22-36620).

Results

Phase 1: Initial Technical Build

The MS CATCH prototype used for the current phase II and phase III study phases, informed by prior HCD processes (BRIDGE, MS NeuroShare, and MS-FIT), is shown in Figure S1 in Multimedia Appendix 1. A patient-facing mood survey was selected to be administered via a secure REDCap link that could be accessed on any device with Wi-Fi or cellular data capabilities. The validated, self-administered PHQ-9 scale was selected to be administered via a secure REDCap link that could be accessed on any device with Wi-Fi or cellular data capabilities. The PHQ-9 survey was then connected to the BRIDGE platform so that it could be visualized at the point of care and interpreted in BRIDGE in addition to the other elements of the patient’s MS history, as well as a list of resources including psychotherapy and psychiatry, available in the patient’s home area (California only). The PHQ-9 survey also triggered a clinician’s inbox message for worsening mood. The mechanism by which MS CATCH is postulated to work is by facilitating communication flows that are likely to support intended users’ COM-B behaviors (patient: reporting and follow through and clinician: evaluating and recommending) likely to lead to symptom improvement. With regard to usability, the intended users, that is, both clinicians and patients, can each access it with one click.

Phase 2: Proof-of-Concept Pilot Randomized Controlled Trial

Participants

Of the 200 patients contacted, 106 (53%) agreed to participate in this study. Of these, 50 (47.2%) met the inclusion criteria of a PHQ-9 score >4 and were cared for by 6 participating physicians. Distribution of PHQ-9 scores was as follows: 52% (26/50) mild depression (5-9); 32% (16/50) moderate depression (10-14); 10% (5/50) moderately severe depression (15-19); and 6% (3/50) severe depression (20-27). Patients were then randomized to visits where the BRIDGE dashboard was used (24/50, 48%) or not used (26/50, 52%). All participants were contacted before their clinical visit, which was conducted between May and December, 2021. This visit was where the MS CATCH intervention was used. The cohort included 40 (80%) females and 10 (20%) males, aged 25-75 (mean 50.46, SD 13.0) years, including individuals with all MS subtypes (32 relapsing remitting MS, 9 primary progressive MS, 1 progressive relapsing MS, 6 secondary progressive MS, 1 unspecified, and 1 MS likely).

Tool Usability

The mean likeability score was 4.3/5 for patients (93% of the patient participants agreed or strongly agreed that they liked the tool) and 4.4/5 for clinicians (100% of the clinicians agreed or strongly agreed that they liked the tool).

For perceived usefulness [30,31], among clinicians, 100% of them reported that the tool increased their attention to the patient’s mood, particularly for patients with mild to moderate symptoms that might otherwise have been missed. Clinicians provided some specific feedback on how to further customize the dashboard, suggesting that it would be better to have the categorical components of the PHQ-9 rather than just the raw score (3/6, 50%).

Among patients, 71% (20/28) reported feeling that it was useful to report their mood-related symptoms before the visit. In qualitative feedback, many patients reported that filling out the mood survey ahead of time gave them the opportunity to reflect on their own feelings: “It set the tone, upfront, about how I was feeling.” “It’s helpful for me to think about assessing my mood in a structured way,” “was useful because it made me stop and reflect;” and “it opened the door to explain how...new MS symptoms are affecting my mood.”

Tool Effectiveness

For the patients with a PHQ-9 score of ≥5, visit notes documented a discussion of depressive symptoms in 75% of the visits where MS CATCH was used versus 35% of the visits where it was not used (N=50; \( \chi^2 = 8.2; P = .004 \); Table 1). One patient was referred to a psychiatrist for suicidal ideation.
Table 1. MS CATCH (Care Technology to Ascertain, Treat, and Engage the Community to Heal Depression in people living with multiple sclerosis) pilot randomized controlled trial cross-sectional effectiveness. Visit notes documented a discussion of depressive symptoms in 75% of the visits where MS CATCH was used versus 34.6% of the visits where it was not used (N=50; χ² = 8.2; P = .004).

Discovery and Think-Aloud Sessions: Selected Findings

Detailed findings and scores from each round of engagement, as well as iterative development steps, are presented in Multimedia Appendix 1 and summarized here. During the discovery interviews (N=5 patients, N=5 clinicians), each tool component was found to be useful and usable. A number of features and data types were identified that mapped to the COM-B principles of behavior change, and these resulted in design changes and interventions promoted to address potential boosters or blockers (Table S2 in Multimedia Appendix 1). For example, patients universally felt that the PHQ-9 should be delivered monthly if not more often, despite concerns by the study team that it would be too burdensome. The patient-facing survey was edited to support free-text entry and addition of language at end of survey informing patients who scored >15 to seek care urgently, as their care team may not see the score for 36 hours, and instructing patients to seek immediate care if experiencing a mental health crisis. During the think-aloud sessions (N=7 patients, N=5 clinicians), some patients articulated concern for how answers might be interpreted by their clinicians, for example, concern about sending up unnecessary “red flags” with their survey answers as symptoms addressed on the survey can overlap with MS symptoms.

Relatedly, the free text box proved to be a popular design feature as it presents an opportunity to offer context for potentially concerning or MS symptom-related survey answers. Additional features were noted to be of value; for example, neighborhood walkability was specifically identified by patients as useful context for their clinicians to have within the clinical decision support view. Patients also universally expressed interest in having dashboard views available in a summary display for reference following appointments. All surveyed participants preferred an electronic summary format distributed through the patient portal (MyChart) as opposed to an alternative format that was not integrated with their EHR portal. Clinician feedback led to a reduction in the visual “wordiness” of the original clinical decision support widget. One decision that could not be accommodated was the ability to include patient insurance information, which substantially influences prescribing choices and referral decisions, as there is unfortunately no “ground truth” source for this information.

Final Changes Made to Tool Before Scoring

The patient survey was further developed to include an in-survey pop-up directing patients who screened positive for suicidal intent to seek immediate medical care (with contact information), a catalog of mental health resources at the end, and...
and a companion patient-facing mood tracker displaying the patient’s longitudinal mood survey results. On the dashboard side, the clinical decision support screen was further refined to be less “visually overwhelming.”

**Qualitative Feedback on the Closed-Loop System**

Clinicians’ qualitative feedback on the potential impact of MS CATCH on the care delivery experience and quality of conversations with patients and caregivers ranged from appreciation for the intervention’s holistic approach to concern that limited visit times will constrain the dashboards’ seemingly limitless potential.

- “Patients will feel empowered to make decisions using the information.”
- “The value comes from physicians being able to see the patient’s trajectory, and from patients being able to have a longitudinal view.”
- “It will allow me to come into visits with more of a plan.”
- “While [BRIDGE] may not be useful for every problem, it can be valuable for high stakes symptoms (depression, falls).”
- “Feel like it gives me more to offer my patients.”
- “Reinforces what we should do.”
- “Helps to have an objective measure of symptom worsening. Is more reliable than past notes.”

**Description of the Final MS CATCH Prototype**

The final prototype is displayed in Figure 1. The patient-facing survey is easily accessible via email. Along with receiving the short monthly survey via email, the patient’s response history and resources relevant to depression self-management can be viewed at the end of the survey (Figure S2 in Multimedia Appendix 1). PHQ-9 scores of 15 or higher or any suicidal intent trigger an alert to the patient’s MS clinician’s EHR in-basket. This is a critical feature allowing for timely follow-up within the usual care workflow, including an urgent referral to psychiatry. The clinician-facing dashboard (Figure 1) has a comprehensive mood evaluation and treatment dashboard that launches from the EHR. This dashboard can be copied and pasted into the clinical notes as well as the patient’s after visit summary to be accessed at the end of the visit and between visits. The tool uses a closed loop system, diagramed in Figure 1, which integrates the patient survey, in-basket messaging, and clinical dashboard tools.

**Final Tool Scoring**

A convenience sample of adults with MS (n=20) and clinicians (n=10) participated in the final tool testing. Of the participating clinicians, 5 (50%) practiced at external (non–UCSF-affiliated) institutions, and 5 (50%) were affiliated with UCSF. The target and achieved results are presented in Table 3.

Patient assessment ratings exceeded the goals in approximately all categories. Despite a patient NPS of 50, which is considered one point below excellent, slightly fewer (75%) than the goal of 80% agreed or strongly agreed that the tool was likeable (mean 4.25, SD 1.12). Of those (n=5) who scored the tool ≤4 with regard to likeability, approximately all (n=4, 80%) were neutral (score=3). Reasons varied from lack of personal applicability, “Mood symptoms are due to MS, not depression,” and “I have a lot of anxiety, but not depression”; to survey design, “I don’t like the multiple-choice options”; and to formatting, “Font is small.” Concrete follow-on actions taken by the development team in response to this feedback were as follows:

- Increasing the default survey font size, in addition to giving patients the option to adjust the font independently.
- Adding a note above the free text box indicating it can be used to add comments or clarify answers.
- Coaching physicians on how to communicate with patients about the survey, including how it can help detect anxiety and mood symptoms that may or may not be MS-related.

Similarly, clinician ratings exceeded the goals in approximately all categories. A clinician NPS of 40 indicated strong favorability in terms of recommending to peers. Perceived usefulness was slightly under goal at 95%. Although all but 1 clinician agreed or strongly agreed that the tool was useful (mean 4.35, SD 0.75) and 1 rated the tool ≤4 citing concerns about limited bandwidth and lack of financial incentives or reimbursable mechanisms for clinicians to address mood between clinical encounters. This feedback echoes concerns noted during discovery interviews about visit time limitations and the need for complementary workflows to ensure that patient mood issues can be monitored in a timely fashion, with the assistance of multidisciplinary staff (registered nurse and masters in social work) and elevated to physicians as needed.
and better integration is associated with improved psychiatric care [51]. In this study, we showed that viewing patients’ self-reported mood at the point of care improved attention to depression in the clinical notes. This course does not inform follow through on this intention. To that end, our 3-month pilot CoachMS RCT (NCT03335618; 21 people living with MS) showed that monitoring and responding to patients in real time [16] was feasible, acceptable, and showed preliminary effects on behavioral change [17,18] suggesting that sustained monitoring and feedback can promote behavioral change [16].

After development, implementation into clinical workflows represents the final goal of health-related tools. From prior experience in developing platforms for the clinical encounter, it was clear that socialization of a tool is a critical step. For patients, knowing that information about their mood will tie back to their care team and translate into improved attention to their care is an important component of tool use, as is the ability to self-monitor using the survey results. Furthermore, direct actionable steps were implemented based on patient feedback, such as providing a list of resources at the end of the survey to reduce the activation energy required to access resources during a depressive episode. Similarly, clinicians are more likely to use and recommend a tool if they know that patients will have completed their surveys [25] and are more likely to want access to patient-generated data if it is clinically actionable. Integrating comprehensive management resources will support individualization of the treatment plan rather than “one size fits all” treatment interventions.

Many treatment trials for depression have to date focused on “one size fits all” approaches testing a specific intervention or combination of interventions. Novel approaches tested within

Discussion

Depression is a serious comorbidity in MS that is associated with an increased risk of disability progression [47], yet it remains severely undertreated; by one estimate, two-thirds of individuals meeting the clinical criteria for major depressive disorder receive no antidepressant medications [48]. Depression is often missed altogether by neurologists, even when it is severe and accompanied by suicidal ideation [49,50]. We iteratively and extensively piloted and developed a closed-loop intervention designed to improve reporting, screening, and treatment of depression in a cohort of clinical patients with MS. The preliminary data presented here support our key premise underlying this closed-loop approach [11] that delivering reliable information about a patient’s mood in an interpretable, visual format to the clinician would increase the likelihood that information can be efficiently streamlined. In full clinical use, the patient-facing survey would be distributed once per month, and clinicians will not be reminded to launch BRIDGE. Studies have generally shown that integration between psychiatric and nonpsychiatric care in the EHR is often low,
MS include sequential blocks of medications [52] as well as combinations of behavioral and pharmacological interventions [53]. Extending beyond the usual screening and care components (such as asking about moods retrospectively), MS CATCH will comprehensively visualize the other functions contributing to depression, including other conditions (eg, sleep) and unmet social needs (eg, substance use counseling, neighborhood unsafe for walking exercise). These will support customized action prompts to help patients self-manage, and clinicians will tailor treatments, anticipate challenges, and make social and behavioral health referrals.

Some limitations were evident in the design and compromises had to be made. For example, the PHQ-9, which is widely adopted as a screening tool, may not be particularly specific. For example, in response to the “constant bother” question, one participant responded “MS is a constant bother.” However, this tool was selected because of its brevity, extensive validation across multiple conditions including MS, and because it comprised the 9 criteria that are identified in the diagnosis of depressive disorder per the DSM-IV [45]. Another limitation is the lack of information regarding insurance acceptance by mental health professionals. Unfortunately, this limits actionability in terms of referrals to mental health professionals in the United States. For the resources map, we chose to focus on mental health professionals near the patient who were considered to have expertise for individuals with MS, but we also included a link to a website that includes insurance information to allow cross-checking. A third challenge is scalability. Key technological and clinical features were intentionally selected to ensure that the tool’s modular infrastructure could be scaled to other symptoms, conditions, and clinical settings. Technological factors designed to support scalability include (1) the quality and content of static visualizations that can be disseminated broadly regardless of a clinic’s technology and (2) optimizing the industry technological standards used for the build so that the code can be shared by clinicians in other health settings (eg, other MS centers using Epic EHR). However, the integration of the build into other health systems ultimately depends on governance and motivation internal to that system.

MS CATCH is a comprehensive, low-burden, closed-loop platform designed to reduce depression severity and prevalence in people living with MS by supporting real-time communication and alerts, shared decision-making, and action prompts for comprehensive, personalized interventions. The research findings summarized here suggest that MS CATCH scores well on likeability and usefulness scales and that it improves attention to mood in individual clinic visits. In a complementary pilot study, we previously showed that remote monitoring of mood can lead to timely intervention [16]. Altogether, these findings support the results of a planned randomized single-center clinical trial evaluating its effect on behaviors that support depression reporting, ascertainment, and care. A similar model can be used to improve other clinical symptoms in MS and for managing other chronic medical conditions with high prevalence of depression.

Acknowledgments
This trial is funded by a Department of Defense US Army Medical Research Acquisition Activity Clinical Trials Award (project #W81XWH2210894; principal investigator: RB).

Authors' Contributions
KH drafted the manuscript. KK and JW collected preliminary data and revised the manuscript. JR was involved in trial design, conducted discovery interviews and interpreted results, and revised the manuscript. AF, CM, MD, AM, CYG, and LO contributed expertise from their respective fields through stakeholder feedback sessions and other avenues and revised the manuscript. NS and NM were involved in tool iterative development and revised the manuscript. RB was involved in trial design, obtained study funding, and drafted the manuscript. KPR and SS revised the manuscript.

Conflicts of Interest
The authors report no disclosures relevant to this clinical trial. KH, JR, KK, JW, NS, NM, MD, AM, JS, LO, and KPR had no conflicts of interest to disclose. CYG reports personal advisory board or consulting fees from Genentech and Horizon. AF received grant support from Multiple Sclerosis (MS) Society of Canada, Canadian Institutes of Health Research, book royalties from Johns Hopkins University Press, and speaker’s honoraria from Novartis. CM is supported by several grants from the National Institutes of Health (NIH; National Institute of Mental Health, National Institute on Minority Health and Health Disparities, National Institute of Allergy and Infectious Diseases, and National Institute on Drug Abuse), Health Resources and Services Administration, Doris Duke Charitable Foundation, California Health Care Foundation, Genentech, Gilead, and United Health Group. RB received research support from NIH, Department of Defense, National Multiple Sclerosis Harry Weaver Award, Biogen, Novartis, and Hoffman-La Roche. RB has received personal advisory board or consulting fees from EMD Serono, Horizon, Janssen, and TG Therapeutics. SS receives research funding from BioMarin Pharmaceutical.

Abstract

Background: Training in acute care, such as emergency medicine (EM), where exposure to critically ill and injured patients is high, impacts the well-being of trainees and contributes to burnout. Investigating how, and if, trainees prepare for these situations is necessary to ensure they are supported.

Objective: This study aimed to evaluate medical students’ perspectives and emotional preparedness for handling acute care and trauma.

Methods: We conducted a pilot investigation using a remote digital survey of medical students during their EM clerkship at a large, urban academic institution. The primary outcome of interest was student-reported preparedness and comfort in handling trauma and critical care patient encounters. Secondary outcomes included awareness of well-being resources and comfort in accessing digital well-being resources.

Results: A total of 57 medical students completed the voluntary digital survey, and half of the students (n=28, 49%) reported having witnessed the care of a critically ill or a penetrating trauma patient (eg, a victim of gun violence). A majority (n=40, 70%) had thought about how these events may impact them, and over half felt unprepared to identify the emotional impact these cases may have on them (n=31, 54%) or address the emotional or mental health impact (n=36, 63%). Less than a quarter (n=14, 25%) were aware of digital mental health resources, and 58% (n=33) did not feel fully comfortable connecting with resources if needed. Students who had previously witnessed critical care were significantly more likely to report feeling well prepared in identifying the emotional impact and addressing this impact.

Conclusions: In this cross-sectional survey, students did not feel fully prepared to identify or address the emotional impact of working in EM. Additionally, they lacked awareness of or comfort with accessing digital institutional resources meant to support their well-being, such as a large web-based platform. These findings can help inform and guide interventions by educational and academic leaders. The aim would be to create and promote environments that empower students with tools to identify their own emotions and connect to well-being resources.

Introduction

Health care–associated burnout persists in medicine and can be identified early in medical training [1-4]. This syndrome has negative impacts at the individual level, and it also affects patient care and the health care system by contributing to more medical errors, lower patient satisfaction, reduced productivity, poor clinical teaching and role modeling for trainees, increased cost, and increased physician attrition and ultimately contributes to physician suicide [5-8]. Physicians have a higher risk for suicide than the general population, and these mental health risks have been labeled as known “occupational hazards” [9,10]. Notably, the rate of US physicians annually completing suicide is estimated to be equivalent to the number of students in 3 graduating medical school classes [11,12].

Studies have demonstrated that the impact of burnout and mental health symptoms, such as depression and anxiety, begin early in medical education and are found in medical students, residents, and physicians in training [2,13-15]. Studies have also found that rates of depression are higher for medical students than other trainees, suggesting this group may be particularly in need of interventions to support well-being and prevent burnout [11,14]. The strain and emotional toll of working in health care emerges early in training. For students, investigating how one identifies, processes, and copes with feelings of anxiety, sadness, depression, or stress related to their clinical experiences within clerkships remains understudied [16]. Emergency medicine (EM) physicians consistently report some of the highest rates of burnout, with EM often being referred to as the “center” of burnout [6,17]. EM physicians are 3 times more likely to be burned out compared to non-EM physicians [4].

Investing in strategies to help trainees identify their own emotions related to providing care, how to cope, and how to sustain well-being is critical for the future of the workforce [18]. Rather than awaiting burnout to evolve, examining how prepared these students feel is necessary to ensure that health systems and medical schools adequately support and proactively maintain medical students’ well-being. This is especially important given the rise of mental health symptoms and burnout in health care within the backdrop of the COVID-19 pandemic and social unrest related to racial injustice and rising gun violence.

The goal of this study was to assess medical students’ preparation during their EM rotation to understand how students self-identify their capacity to deal with emotionally charged clinical settings (eg, critical care cases or trauma).

Methods

Ethical Considerations

This pilot investigation used an electronic voluntary survey administered to second- and third-year medical students at the University of Pennsylvania in Philadelphia during their EM clerkship at a large, urban academic institution. The study was approved by the University of Pennsylvania Institutional Review Board (849318). All research methods, consent, and activities were performed in accordance with the university guidelines and regulations.

Eligible Participants and Study Type

Inclusion criteria consisted of students in their second (preclerkship or M2) or third (clerkship or M3) year of medical school. This study was cross-sectional, and a voluntary response sample was used. There were no specific exclusion criteria, as other students were not invited to the survey.

Recruitment Procedures

Participants were invited via email, completed informed consent, and were not compensated for participating. Data were collected and aggregated for analysis. The students at this medical school are routinely surveyed, and questions from this study were incorporated into the preexisting and ongoing school surveying. In total, the survey was sent to 161 students in their preclerkship (M2) and 153 students in their clerkship (M3) during the final week of classes in December 2021.

Approach and Analysis

This cross-sectional pilot study was developed by the research team, with expertise in medical education (authors ST and DA), qualitative methods (AKA and RG), and clinician well-being (AKA). No previous instrument, to the knowledge of the study team, exists; thus, the instrument was developed and pilot-tested in this study. All answers were anonymous, and no demographic information was collected. The primary outcome of interest was student-reported preparedness and comfort in handling trauma and critical care patient encounters. Secondary outcomes included awareness of well-being resources available to them during their clerkship, feelings of preparedness, and comfort in accessing well-being resources. Comparisons were done using chi-square tests in Stata IC 16.1 (StataCorp), and a P<.05 was considered statistically significant.

Results

A total of 57 medical students completed the voluntary survey; 26 (46%) of them were M2 students, and 31 (54%) were M3 students. Almost half (n=28, 49%) of the students reported having witnessed the care of a critically ill or injured patient (defined as a victim of gun violence). Most (n=40, 70%) students had thought about how these events may impact them, but most did not feel fully prepared to identify the emotional impact these cases may have on them (n=31, 55%) or prepared to address this emotional or mental health impact (n=36, 63%). Although resources are widely available to support students’ well-being at this institution, only 25% (n=14) were aware of these institutional resources to help them cope with the emotions involved with care, and 58% (n=33) did not feel fully comfortable connecting with resources if needed (Table 1).

Differences were identified between those students who had witnessed the care of a critically ill or injured patient and those who had not (Table 2). Students who had witnessed such care were more likely to feel well prepared in identifying the emotional impact of these cases (n=7, 25% vs n=0, 0%; P=.007) and in addressing this impact (n=9, 32% vs n=0, 0%; P=.001). No significant differences were found in student awareness of...
resources and their comfort in connecting with these resources to cope with the emotions involved with care.

Discussion

Principal Findings

Given EM’s high rates of burnout and the vulnerable role medical students hold as trainees, medical students undergoing their EM clerkship are at high risk of emotional strain and stress [15]. The rising focus on physician mental health extends to those in training [8]. There is a gap in understanding how prepared medical students feel in identifying and addressing their emotional response and the impact experiences in EM may have upon them. This study assessed medical students’ preparation to better understand their needs and guide interventions toward key priority areas of focus.

This study found that, regardless of whether students had already witnessed the care of a critically ill patient, most students did not feel prepared to identify or address the emotional impact associated with these situations. This highlights the need to train students early and normalize the emotional impact of working in medicine [19,20]. The stigma associated with mental health in health care has pervaded the classroom and hospitals, and to build structures to prevent burnout, we must begin early to help trainees identify feelings of anxiety, depression, or stress as they experience them [13,21-23]. A proactive approach would provide students with the tools and resources they need to adequately identify their emotions and connect to appropriate resources when needed.

It is essential for institutions not only to have resources available to support students’ well-being and mental health but also to make these resources readily accessible and easy to navigate. Our findings reveal that even in an environment where resources are present, students may be unaware of these resources or may not be comfortable accessing them. The University of Pennsylvania School of Medicine has a robust infrastructure within the medical school, a separate web-based mental health...
and well-being platform, accessible to the entire health system community [24]. However, students in this study remained unaware of their availability or accessibility. Institutions must work to incorporate these resources into the clinical and teaching environments to reduce the stigma that may prevent students from accessing them.

Finally, the significant differences in feelings of preparedness between those students who had and those who had not witnessed the care of critical care patients suggest that students do not feel prepared to identify the emotional impact such experience may have until it has happened. It is important to act proactively to prepare students to experience the care of critical patients. EM provides an ideal environment to do so, as the likelihood that students will be placed in an emotionally charged setting is high [17,25]. Venues such as critical care, pediatrics, obstetrics and gynecology, as well as surgery provide other opportune areas for schools to think about deploying focused interventions to where students may need them most.

**Limitations**

This study has some limitations. First, to protect confidentiality and privacy, we did not collect demographic information. This prevented us from analyzing how these findings might differ by age, race, or ethnicity. Second, as medical students self-selected to participate, selection bias may play a role. The participants surveyed here may not accurately represent the experiences of all medical students in the clerkship program. Additionally, this study was performed at a single urban, academic program and may not be applicable to all medical students at other various institutions. We are also limited by a sample of 56 students, which may further limit our ability to generalize these findings.

**Conclusions**

Similar to other roles in health care, medical students do not feel fully prepared to identify or address the emotional impact of working in acute care. Additionally, they lack awareness of or comfort with accessing institutional resources designed to support their well-being. Medical students who have not witnessed the care of a critically ill or injured patient were more likely to feel unprepared in identifying or addressing the emotional impact such an event might have on them. These findings can help inform and guide interventions by educational and academic leaders. The aim would be to create and promote training environments that empower students with tools to identify their own emotions and connect to well-being resources. We need to normalize the conversation around mental health in the health care workforce and reduce stigma early in medicine, beginning with our medical students.

Abstract

Background: Parents of children with cleft lip with or without cleft palate (CL/P) often face stigmatization, which has a significant impact on their quality of life and mental health. However, to date, there is a lack of comprehensive, multicenter empirical research on parents of children with CL/P in China, particularly those with large-scale samples.

Objective: This study aimed to identify major factors that contribute to the perception of stigma experienced by parents of children with CL/P.

Methods: A cross-sectional survey was conducted. A total of 104 parents of children diagnosed with CL/P in 2 hospitals were selected by convenience sampling. Demographics and disease information, the Chinese Perception of Stigma Questionnaire, the Center for Epidemiological Studies Depression Scale, and the Social Anxiety Scale were used in this study. Descriptive statistics, t tests, and one-way ANOVA were used to compare the differences between participants’ demographic information and perception of stigma. Multivariable linear regression was performed to assess associations between demographic factors, social anxiety, depression, and perception of stigma.

Results: The mean scores for the dimensions of perception of stigma, depression, and social anxiety were 22.97 (SD 9.21), 38.34 (SD 8.25), and 22.86 (SD 6.69), respectively. Depression and social anxiety were positively associated with discrimination, while surgery status was a negatively associated variable. Parents with a college education or higher had significantly lower levels of perceived stigma compared to parents with a junior high school education (all P values <.05). These 4 factors explained 40.4% of the total model variance ($F_{8}=9.726; P<.001; R^2=0.450$; adjusted $R^2=0.404$).

Conclusions: Our findings highlight a concerning trend of diminished quality of life among parents of children with CL/P. Factors such as parents’ education level, surgery status, depression, and social anxiety are shown to influence the level of stigma experienced. Implementing comprehensive nursing care and providing presurgical support are effective strategies for alleviating parents’ social anxiety, reducing perceived stigma, and preventing depression.

KEYWORDS

stigma; social anxiety; depression; parents of children with cleft lip and palate; cleft lip; cleft palate; cross-sectional study
Cleft lip with or without palate (CL/P) is a common congenital developmental malformation affecting the oral and maxillofacial region [1], with a global prevalence of about 1.62%–1.82% [2], and the highest prevalence in Asian countries [3]. There are 35,000 babies born with CL/P in China each year [4]. Palate repair surgery is usually done when babies are 10 to 24 months old, while lip surgery is generally performed at the age of 6 months [3]. The management of CL/P is long-term, beginning from birth and continuing into the late teenage years. Children born with CL/P not only face a visible facial disfigurement but also have other challenges related to the cleft, such as feeding difficulties, speech impediments, hearing issues, and psychological problems, which may compromise their ability to communicate effectively [5].

Children with CL/P are vulnerable to external discrimination because of the malformation. A child with CL/P is subjected to bullying, rejection, and social isolation, sometimes even from their own family [6]. The discrimination can have devastating health and well-being impacts, not only on children affected but also on people associated with the discriminated person. Having a baby with CL/P has variable psychological impacts on the parents [7]. Parents are often concerned about whether their children will be accepted as they grow up, and parents’ psychological state directly affects their children’s perception of the condition [6,8,9]. Some studies [10,11] have indicated that the perception of stigma experienced by the mother and children is consistent. Numerous studies [2,12,13] have shown that children with CL/P experience significant stigma, and limited engagement in social activities suggests that the parents of these children may experience high levels of stigma. Furthermore, Parents are troubled by their children’s conditions from birth to adulthood, while children often experience discrimination after their cognitive development has matured. Therefore, exploring ways to prevent these patients and their parents from feeling stigmatized is urgently necessary.

Currently, research on the perception of stigma among parents of children with CL/P is predominantly qualitative, emphasizing the exploration of factors contributing to parental stigma. However, there is limited reporting on assessments regarding the level and variation in the perception of stigma. In particular, there is no research on the perception of stigma in children with CL/P in China. Previous studies [11,14] have shown that superstition is the main reason for parents’ perception of stigma, and only 40% of parents believe that genetic problems cause CL/P. One study [11] found that 72% of mothers felt ashamed of having children with CL/P, and some even abandoned their babies. Therefore, it is crucial to examine the perception of stigma among parents of children with CL/P, pinpoint those experiencing heightened stigma levels, implement tailored nursing interventions based on sensitive factors, and mitigate the likelihood of public incidents. This study aims to investigate experiences of stigma in parents of children with CL/P and analyze the contributing factors.

### Variables and Instruments

The demographic data were collected via a questionnaire. Three questionnaires with good reliability and validity were used to collect the data on stigma, social anxiety, and depression.

#### Demographics Questionnaire

The demographic information questionnaire was designed by researchers after consulting the literature and mainly included parents’ age, role (father or mother), education level, and working status as well as children’s age, sex, type of CL/P, surgery status, and number of surgeries.

#### Disability Discrimination Perception Scale

Stigma was assessed using the Disability Discrimination Scale (DDPS), initially developed by Liu and Shen [15]. The questionnaire comprises 10 items (eg, “When participating in activities, I feel that people around me would not talk to me and avoid me”), designed to explore the perception of stigma among individuals with disabilities in their daily lives. It is also suitable for children aged 10 to 16 years. Respondents rated each item on a 5-point scale, ranging from 1 (very inconsistent) to 5 (completely consistent). Higher total scores indicate a greater perception of stigma, with scores ranging from 10 to 50. The scale demonstrates good internal consistency, as evidenced by a Cronbach’s reliability of 0.89. The criterion validity was 0.47, indicating good validity [15].

#### The Center for Epidemiological Studies Depression Scale

The level of depression was measured by the Center for Epidemiological Studies Depression Scale (CES-D) [16]. CES-D
consists of 20 items (e.g., “I was bothered by things that usually don’t bother me”), and each item is scored from 0, indicating “rarely or none of the time (less than 1 day)” to 3, indicating “most or all of the time (5-7 days).” The total score of all items ranges from 12 to 60, with higher scores indicating a greater likelihood of depression; a total score of 15 points or less indicates no depression; 16 to 19 points indicate possible depression; and a score of 20 points or higher indicates definite depression [16]. The scale is suitable for screening people with depressive symptoms and can also be used to assess the severity of depressive symptoms. The Cronbach $\alpha$ of CES-D was 0.87, indicating good internal consistency. The split-half reliability was 0.85, the test-retest reliability was 0.70, and the criterion validity was 0.75. Therefore, CES-D had good reliability and validity.

**The Interaction Anxiousness Scale**

The Interaction Anxiousness Scale (IAS) was used to assess the subjective propensity to experience social anxiety independent of behavior [17]. The IAS contains 15 self-reported items (e.g., “I want to be confident in social situations more”), which are answered on a 5-point scale, ranging from 1 (very inconsistent) to 5 (completely consistent). Total scores range from 15 to 75, with higher scores indicating higher levels of social concern. The Cronbach $\alpha$ reliability of the scale was 0.87, the test-retest reliability was 0.80, and the criterion validity was 0.48. In this study, according to the actual situation, 7 items related to sexual life were deleted, and 8 items were selected for evaluation. The reliability of the scale was retested, and Cronbach $\alpha$ reliability was 0.68, indicating acceptable reliability.

**Statistical Analysis**

IBM SPSS Statistics (version 25.0; IBM Corp) for Windows, was used for statistical analysis. Standard descriptive statistical values (means and SDs) were calculated. The independent samples 2-tailed $t$ test and ANOVA were used for the intergroup comparisons of parameter changes. Pearson analysis was used to examine the relationship between perception of stigma, social anxiety, and depression. Multiple linear regression was performed to assess the association between demographic factors, anxiety, depression, and perception of stigma. The significance level was set at 5%.

**Ethical Considerations**

The study was approved by the Ethics Committee for Clinical Studies at Guangzhou Women and Children’s Medical Center, Guangzhou Medical University (NO.2022268A01). This study obtained informed consent from participants, who had the option to withdraw at any time. The research data were collected anonymously.

**Results**

In this study, a total of 110 questionnaires were distributed. Of the collected questionnaires, 104 were complete, resulting in a 94.6% response rate.

**Participant Characteristics**

Most participants were mothers aged 25-30 years and unemployed, with a high school diploma. Their children had CL/P, and surgery had not been performed. Unemployed parents constituted 71% (n=74) of the sample, with nearly half (n=14, 47%) of the employed parents being self-employed. Over half (n=61, 59%) of the respondents had completed high school. The children’s average age was 3.06 (SD 2.02) years. A total of 73 (72%) children had not undergone surgery, while most of those who had done the surgery (n=20, 65%) had undergone the procedure twice. A descriptive analysis of the general demographics, work-related characteristics, and disease-related information of the participants is shown in Table 1.
Table 1. Demographic characteristics of the participants (N=104).

### Prevalence of Stigma, Social Anxiety, and Depression

The mean scores for the dimensions of perception of stigma, depression, and social anxiety were 22.97 (SD 9.21), 38.34 (SD 8.25), and 22.86 (SD 6.69), respectively. Additionally, 38% (n=40) of the participants exhibited a perception of stigma level beyond the moderate level, and every participant experienced evident depression, with 72% (n=75) displaying average levels of social anxiety.

### Univariate Analyses of Factors Associated With Stigma

The demographic data, including parents’ age, role, education level, and working status as well as the children’s age, sex, CL/P type, surgery status, and the number of surgeries, were analyzed...
using a one-way ANOVA and $t$ tests. The results of the Kolmogorov-Smirnov test suggested that the continuous variables were reasonably and normally distributed. The $t$ tests revealed that the parents whose children had undergone surgery experienced lower stigma levels compared to those whose children had not undergone surgery ($P=.01$). The perception of stigma scores differed significantly among parents having different educational backgrounds ($P<.001$) and between those whose children underwent different numbers of surgeries ($P=.04$). The specific results are detailed in Table 2.

Correlation Analysis With Perception of Stigma, Social Anxiety, and Depression

The results showed that the perception of stigma was related to social anxiety ($r=0.54; P<.001$) and depression ($r=0.39; P<.001$); there was also a correlation between depression and social anxiety ($r=0.30; P=.002$). The specific results are shown in Table 3.

Table 3. Correlation (Pearson $r$) with stigma, social anxiety, and depression. At $P=.01$ (2-tailed), the correlation was significant.

Regression Analyses of Stigma

With the perception of stigma as the dependent variable, depression, social anxiety, and demographic data with differences between groups were included in the model as independent variables, and multiple linear regression analyses were performed. In the perception of stigma model, depression, social anxiety, educational background, and status of surgery were significant correlates explaining 40.4% of the total model variance ($F_{8}=9.726; P<.001; R^2=0.450; \text{adjusted } R^2=0.404$).

Discussion

This study found that parents of children with CL/P experienced a high level of perception of stigma and obvious social anxiety and depression. In addition, parents’ education level, children’s status of surgery, social anxiety, and depression affect parents’ levels of perceived stigma. This study complements the gap in the study of stigma perception in families of children with CL/P in China. Parents in our study exhibited a higher level of stigma perception. This could be attributed to the fact that most children underwent corrective surgery during infancy, making parents more attuned to discrimination, as they believe that visual impairments affect their children’s social lives. Thus, prevailing data suggest that Chinese clinical nurses should pay attention to the quality of life of parents of children with CL/P.

Our study showed that children’s sex and the type of CL/P could not affect parents’ discrimination perception. This is consistent with the findings of previous studies that reported no significant difference in the level of discrimination perception between patients of different sexes and CL/P types [10]. The results of our study showed no significant difference in the level of stigma perception between fathers and mothers. Fathers also had a high...
level of stigma perception. However, previous studies [14,18] suggested that mothers of children with CL/P experienced severe stigma or discrimination while ignoring the possibility that fathers also experienced high levels of discrimination. Two other studies [19,20] pointed out that the main sources of stress among fathers were the treatment process, feeding, and social stigma. Therefore, in the care process of children with CL/P, we should not only focus on the mother’s psychological state but also consider the psychological state of the father. The importance of family nursing should also be emphasized.

Parents of children with CL/P experience obvious depression and anxiety. It is consistent with the findings of previous studies reporting that parents of newborns with CL/P had significantly higher levels of anxiety compared to control parents [20]. The study findings are consistent with the current literature, as depression or depressed mood in parents of children with CL/P is a common phenomenon [21,22]. Kumar [23] reported the highest incidence of depressive episodes, with 42% of parents of children with CL/P aged >10 years showing a strongly or very strongly elevated depressive disorders screening index. Sommer [24] has pointed out that mothers of children with CL/P believe their children have a negative impact on them. Their negative views and emotions are mainly derived from the long treatment times, the difficulty of treatment, the uncertainty of the infant’s future condition, and the fear of rejection. Family members of infants with CL/P experience stigma, anxiety, and worry, which may lead to individual negative emotions and coping styles, produce adverse intergroup relations, reduce subjective well-being and life satisfaction, and ultimately affect the quality of family life. Relieving the stigma perceived by parents of children with CL/P is the first step to relieving negative emotions like anxiety and depression in these parents. Therefore, we should pay attention to the physical rehabilitation of children as well as the mental health of children and their parents.

In this study, parents with junior high school education showed a high level of stigma perception, and the perception of stigma was lower among parents with a college education or higher. So far, no study has investigated the relationship between the education level of parents who have children with CL/P and their stigma perception. A previous study [6] showed that caregivers of children with attention deficit hyperactivity disorder, who have higher education levels, experience higher levels of stigma. However, the results of this study were inconsistent with a previous study, possibly because parents with a junior high school education have less knowledge of the condition and are more likely to focus on the appearance of their children. The difference could potentially be attributed to the fact that parents with higher education levels are more likely to access relevant information about the condition and feel more confident about the later recovery process. Hence, health care professionals should focus on parents with a high school education or lower, monitor variations in their perceived stigma levels, comprehend their psychological well-being across different stages of their children’s lives, and offer tailored psychological support.

Cleft surgery provides hope to those children and their parents, offering the possibility of re-enrollment in schools, employment opportunities, social acceptance, and improved prospects for marriage [6]. Undergoing surgery directly affects the level of the stigma perceived by parents. Parents of children without surgery perceive a higher level of stigma, which is consistent with previous studies [14] suggesting that parents of children with CL/P show obvious negative emotions in the first 3 months after the birth of their children without surgery. Therefore, the initial 3 months emerge as a pivotal phase for health care professionals to alleviate parental anxiety and deliver emotional and educational assistance to parents of infants with CL/P. Through comprehensive nursing and presurgical support, mothers can enhance their early feeding capabilities, expedite the bonding process with their infants, and facilitate the infants’ swift recovery. Familiarity with CL/P beforehand serves to diminish maternal stress during initial interactions, mitigating anxiety and perceptions of discrimination. Consequently, encouraging mothers to engage with CL/P-related charitable organizations or fostering interaction among children with CL/P in shared spaces can effectively reduce anxiety and perception of stigma levels.

This study has several limitations. All the participants in this study were family members of children who were willing to undergo surgery, and no family members of children who were unwilling to undergo treatment were included, which may have led to selective bias. Parents filled out the scale based on recall, which may introduce information bias. The sample size of this study was small, as it was limited to hospitals only from 2 provinces with a large gap in economic levels between the 2 places, and fewer fathers were included in the study. Future studies should increase the sample size and broaden the scope of the investigation.

Our findings highlight a concerning trend of diminished quality of life among parents of children with CL/P. Factors such as parents’ education level, the status of surgery in children, depression, and social anxiety are shown to influence the level of stigma experienced by these parents. Implementing comprehensive nursing care and providing presurgical support are effective strategies for alleviating parents’ social anxiety, reducing perceived stigma, and preventing depression.

Acknowledgments

The authors are sincerely grateful to all the participants who responded to the questionnaires and all the nurses and doctors for supporting this investigation.

Abstract

Background: The incidence of major adverse cardiovascular events (MACEs) remains high in patients with acute myocardial infarction (AMI) who undergo percutaneous coronary intervention (PCI), and early prediction models to guide their clinical management are lacking.

Objective: This study aimed to develop machine learning–based early prediction models for MACEs in patients with newly diagnosed AMI who underwent PCI.

Methods: A total of 1531 patients with AMI who underwent PCI from January 2018 to December 2019 were enrolled in this consecutive cohort. The data comprised demographic characteristics, clinical investigations, laboratory tests, and disease-related events. Four machine learning models—artificial neural network (ANN), k-nearest neighbors, support vector machine, and random forest—were developed and compared with the logistic regression model. Our primary outcome was the model performance that predicted the MACEs, which was determined by accuracy, area under the receiver operating characteristic curve, and F1-score.

Results: In total, 1362 patients were successfully followed up. With a median follow-up of 25.9 months, the incidence of MACEs was 18.5% (252/1362). The area under the receiver operating characteristic curve of the ANN, random forest, k-nearest neighbors, support vector machine, and logistic regression models were 80.49%, 72.67%, 79.80%, 77.20%, and 71.77%, respectively. The top 5 predictors in the ANN model were left ventricular ejection fraction, the number of implanted stents, age, diabetes, and the number of vessels with coronary artery disease.

Conclusions: The ANN model showed good MACE prediction after PCI for patients with AMI. The use of machine learning–based prediction models may improve patient management and outcomes in clinical practice.

KEYWORDS
acute myocardial infarction; percutaneous coronary intervention; machine learning; early prediction; cardiovascular event
Introduction

Acute myocardial infarction (AMI) is a common clinical acute and severe disease with rapid onset, rapid progression, and high mortality [1-3]. In 2017, there were approximately 695,000 new cases of AMI in the United States, and it is estimated that 325,000 people will have recurrent events [4]. There are approximately 500,000 new cases of AMI in China every year, and 2.5 million patients have a history of myocardial infarction [5]. As technology has advanced, percutaneous coronary intervention (PCI) has become the primary approach for treating AMI. Although PCI can significantly reduce the fatality rate of AMI, the rate of major adverse cardiovascular events (MACEs) among patients after PCI is still very high, which seriously affects the clinical outcomes of patients [6-10]. A study by Copeland-Halperin et al [11] showed that the incidence of MACEs in patients with AMI one year after PCI was 17.8% [11].

Identifying patients with AMI undergoing PCI who are at high risk of MACEs may help clinical decision-making incorporate timely measures to improve clinical outcomes. Some studies, such as Global Registry of Acute Coronary Event [12], Thrombolysis in Myocardial Infarction Risk [13,14], and Acute Catheterization and Urgent Intervention Triage Strategy-PCI [15], as well as studies that generated the Mayo Clinic PCI Risk and the China Acute Myocardial Infarction scoring systems, have explored the risks after PCI [16]. Despite these advances, individualized prediction of MACEs remains challenging with low specificity and positive predictive accuracy, and most of the methods rely on traditional parameter models, such as logistic regression, to screen for variables and build a series of risk-scoring models.

In recent years, machine learning methods that rely on a strong self-learning capability, such as random forest (RF), k-nearest neighbors (KNN), support vector machine (SVM), and artificial neural network (ANN) have become increasingly prevalent in prognostic prediction [1,13,17,18]. By calling various functions, these models can extract and integrate information from all kinds of complex data to make better predictions. A study of a consecutive cohort of patients with hypertrophic cardiomyopathy (HCM) presented a machine learning–based model to identify individual patients with HCM at high risk of developing advanced heart failure symptoms. The results showed that the 5-year risk prediction of progressive heart failure in patients with HCM can be estimated [19].

We found that machine learning models, such as RF, ANN, SVM, and KNN, perform well in clinical prognosis prediction research. Thus, this study sought to develop a machine learning–based model, integrating clinical, anatomical, and laboratory features, to predict MACEs in patients who have recently been diagnosed with AMI after their first PCI and improve overall patient outcomes by implementing earlier management.

Methods

Study Design, Setting and Participant Selection

This retrospective cohort study was conducted at the Department of Cardiovascular Medicine, the Second Affiliated Hospital of Nanchang University (a teaching tertiary hospital), in Jiangxi Province, China. We collected electronic medical records of patients with AMI who underwent PCI for the first time from January 2018 to December 2019. These patients were followed up through December 2021.

The inclusion criteria of the participants were as follows:

- The patient was ≥18 years of age.
- This was the patient’s first clinically diagnosed AMI (clinical evidence of AMI as evident from the detection of a rise or fall of cardiac troponin values and at least one of the following symptoms of myocardial ischemia: symptoms of acute myocardial ischemia, new ischemic electrocardiogram (ECG) changes, and development of pathological Q waves.
- PCI was performed for the first time at this hospital.
- Among the left main artery, left circumflex branch, left anterior descending branch, and right coronary artery, at least one had stenosis ≥50%.
- Complete medical records and follow-up data were available.

The following exclusion criteria were applied:

- History of PCI and coronary artery bypass grafting treatment
- Complications from other heart diseases requiring surgical procedures, such as heart bypass
- Recent active bleeding
- An intracerebral mass or an aneurysm

We adopted the “Guidelines for Developing and Reporting Machine Learning Predictive Models in Biomedical Research” to guide the reporting of our study [20].

Data Collection, Definition of Outcomes, and Predictor Variables

Data were collected from electronic health records, including demographic characteristics, clinical investigations, the first laboratory tests, and disease-related events. MACEs were defined as cardiomyopathies (excluding infectious, familial, alcohol, and drug-related cardiomyopathies), hypertensive heart disease, recurrent myocardial infarction, heart failure, sudden cardiac death, revascularization, malignant arrhythmia, and stent thrombosis [21]. Abnormal Q waves were identified by the clinician based on ECG results. Left ventricular ejection fraction (LVEF) was defined as normal (more than 50%), mildly abnormal (40% to 50%), moderately abnormal (30% to 40%), and severely abnormal (less than 30%) [22]. According to the number of diseased coronary vessels and implanted stents, they were classified as I, II, III, and IV.

Ethics Approval
This study was reviewed and approved by the Second Affiliated Hospital of Nanchang University Medical Ethics Committee (No. Review 2017 No. (098)).

Data Preprocessing for Machine Learning Model Development
All analyses were performed with R software (version 4.0.1; R Core Team). The patients were randomly assigned to training (n=953, 70%) and testing (n=409, 30%) data sets by calling the createDataPartition function using the random number method, and chi-square tests showed that there was no statistical difference between them ($\chi^2=2.169; P=.14$). We developed machine learning models using the training data set. We analyzed the missing and out-of-range values with imputation methods. We used multiple imputation with chained equations to assign any missing predictor values [23]. The imputation processes were performed separately in the training and testing sets after the data were split. To improve the accuracy of the machine learning models and increase the speed of finding the optimal solution by gradient descent, we standardized and normalized all input variables before the model was built. To alleviate the problem of imbalanced classification samples, we adopted the random oversampling method. We used the ROSE package in R to generate new balanced training data. After random oversampling, the number of patients with MACE in the training data sets changed from 186 to 471.

Predictor Selection for Model Development
The model was built using demographic information (age and sex), personal comorbidities (diabetes and peripheral arterial disease), preoperative PCI (LVEF, the number of diseased vessels, and abnormal Q waves), serological examination (beta 2 microglobulin, B-type brain natriuretic peptide, glucose, serum creatinine clearance, and estimated glomerular filtration rate), and the characteristics of PCI (the number of implanted stents; n=65; Table S1 in Multimedia Appendix 1). A total of 12 variables with significant differences in the univariate analysis were included in the model development (Table 1).

Model Testing and Performance Evaluation

Based on a previous application of the model [24], the parameter range of the model was preset, and the GridSearchCV function was used to select the optimal parameters of each machine learning model.
the important predictors through importance analysis of the variables. Logistic regression analysis was used to compare the absolute value of the coefficients of variables; RF was used to measure the importance of features by calculating information gain through entropy; and the ANN method was used to calculate the relative importance of variables based on the generalized weight method.

**Statistical Analysis**

The following R packages for machine learning approaches were used: caret, randomForest, and neuralnet. Baseline characteristics were compared with the Wilcoxon rank sum test for continuous variables and the chi-square test for categorical variables. We considered $P<.05$ (2-sided) to be statistically significant.

**Results**

A total of 1531 patients were screened; 140 patients who did not undergo PCI for the first time were excluded; 19 patients were lost to follow-up; and 1362 patients who were successfully followed up were included in this analysis (Figure 1). The mean follow-up time was 28.0 (SD 11.0) months (median 29.9 months). A total of 252 MACEs were observed, including 128 cases of recurrent myocardial ischemia and 117 cases of myocardial infarction and reinfarction. The positive rates of MACEs were 4.63%, 11.38%, 14.54%, and 18.50% at 30 days, 6 months, 1 year, and 3 years after PCI, respectively. MACEs occurred in 203 (18.7%) male patients and 49 (17.8%) female patients. As shown in Figure 2, the survival rate of the sample population decreased rapidly in the first 3 months after PCI, especially 30 days after PCI, and there was no difference in the log-rank test of the survival curve between male and female patients.

Table 1 shows the baseline characteristics of the MACE group and the non-MACE group. Age, diabetes, peripheral and cerebrovascular history, LVEF, abnormal Q wave, the number of vessels with coronary artery disease, the number of implanted stents, brain natriuretic peptide, serum creatinine, estimated glomerular filtration rate, beta 2 microglobulin, and glucose were significantly different between the 2 groups ($P<.001$). The nonsignificant differences in variables between the 2 groups are shown in Table S1-S6 in Multimedia Appendix 1.

Table 2 shows the performance of the 3 models with 7-fold cross-validation. ANN, KNN, SVM, RF, and logistic regression exhibited the best to worst performance in terms of their AUC, accuracy, recall, and $F_1$-score. However, KNN performed best in terms of precision. The average accuracy, recall, precision, AUC, and $F_1$-score of the ANN model were 80.52%, 81.33%, 69.94%, 83.68%, and 79.47%, respectively.

In the testing data set, the ANN model showed a higher AUC than RF and logistic regression. Figure 3 shows that the AUCs of the ANN, RF, KNN, SVM, and logistic regression models were 0.805, 0.798, 0.772, 0.727, and 0.718, respectively; the average accuracy for the above 3 models was 0.821, 0.741, and 0.729, respectively, and the average $F_1$-scores were 0.804, 0.722, and 0.709, respectively.

The 10 most important predictors in the ANN model are shown in Table 3. These were LVEF (0.27), the number of implanted stents (0.14), age (0.13), diabetes (0.10), the number of vessels with coronary artery disease (0.09), vascular disease (0.08), brain natriuretic peptide (0.05), glucose (0.05), beta 2 microglobulin (0.04), and abnormal Q wave (0.02).

Discussion

Principal Findings

In this study, we developed a machine learning–based model integrating clinical, anatomical, and laboratory test features to predict MACEs in patients with newly diagnosed AMI after their first PCI. The major findings suggest that the ANN model had higher predictive accuracy (accuracy of 87.99%, AUC of 0.81, and F1-score of 0.71), compared to RF, KNN, SVM, and logistic regression.

Among the patients with AMI in this study, the rates of MACEs at 30 days, 6 months, 1 year, and 3 years after PCI were 4.63%, 11.38%, 14.54%, and 18.50%, respectively, and the incidence of MACEs at 30 days after PCI was slightly less than the 5.5% reported in the Harmonizing Outcomes with RevascularIZatiON and Stents in Acute Myocardial Infarction study (HORIZONS-AMI) [25]. The incidence of MACEs at half a year was higher than the 6.67% reported by Chow et al [26], consistent with the 2-year rate of MACEs reported by Sanmenxia City (18.06%). The survival condition of patients with AMI after PCI was slightly different from that in other studies. The participants in this study were all patients who were first diagnosed with AMI and underwent PCI for the first time, and their prognosis was better than that of patients with previous myocardial infarctions and multiple PCIs [27]. In addition, the progression of a patient’s disease is affected by not only individual differences but also access to medical resources and services. The HORIZONS-AMI trial was first reported in 2012. Although the treatment level in the HORIZONS-AMI trial was higher than that available in China at that time, with the development of China’s economy, the progress of science and technology, and the substantial improvement of medical care, the MACE rate obtained in our study was lower than that reported in the HORIZONS-AMI study.

One study found that machine learning demonstrated the highest performance for risk prediction in patients with extracardiac vascular disease for the prediction of both arrhythmogenic cardiomyopathy and MACEs [10]. McCord et al [28] proposed that machine learning can be used to assess AMI within 30 minutes and that the algorithm has high diagnostic and prognostic utility. In this study, 3 algorithms were used to predict MACE occurrence for patients with newly diagnosed AMI undergoing PCI treatment for the first time. The MACE prediction ability of the logistic regression model was lower than that of the ANN model and almost the same as that of the RF model. However, the positive predictive values of these 3 prediction models were not high. Kuang et al [29] also found that the ANN model had the best predictive value for the transition from mild cognitive impairment to Alzheimer disease with ideal stability [29]. The positive predictive values of the RF model and the logistic regression model were both approximately 50%, which means that their predictive ability for MACEs was poor. Their shortcomings may be associated with class imbalances [30], which can easily cause the predicted results to be biased toward a large number of classes (the positive type of fault can be placed into the negative class). ANNs, with their powerful self-adaptability, self-organization, fault tolerance, and “black box” operation of nonlinear mapping, are especially suitable for solving problems with complex internal mechanisms and have been widely used in various disciplines [31].

Our results indicated that the 3-year prognostic risk among patients with AMI undergoing their first PCI was mainly related to age, ECG characteristics, ventricular ejection ability, coronary artery lesions, stent implantation after PCI, and some serological variables. Yang et al [32] found that the risk ratio of hospital deaths after PCI was 3.723 (95% CI 2.86-4.84) for South Korean patients aged >65 years relative to those aged ≤65 years. A Korean multicenter AMI National Institutes of Health–registered project found that the MACE rate, 3 years after PCI, among patients with AMI with an LVEF <40% was 3.34 times that of the control group [33]. Fam et al [34] conducted a retrospective study on patients with clinical AMI in Asian multiethnic groups and found that the risk of MACEs among patients with diabetes, 2 years after PCI, was 1.84 times higher than that among patients without diabetes [34]. Diabetes is a chronic metabolic disease, and long-term diabetes is often accompanied by bleeding disorders, vascular endothelial dysfunction, small artery lesions, high blood sugar [35], hemostatic disorders [36], endothelial dysfunction, and a series of other changes [37]. These characteristics will accelerate the process of atherosclerotic disease deterioration. The number of coronary artery lesions

https://formative.jmir.org/2024/1/e48487

JMIR Form Res 2024 | vol. 8 | e48487 | p.1346
and the number of stents implanted in a patient are also positively correlated with the risk of postoperative MACEs to a certain extent. This may be because a higher number of vessels with coronary artery disease and the number of implanted stents tend to indicate a more serious condition, leading to a worse prognosis for the patients. Hongbo et al [38] found that the probability of a poor prognosis in patients with multiple coronary artery lesions was 20.0%, compared with 6.98% in patients with single coronary artery lesions [38].

The results of the machine learning model showed that predictors like LVEF, number of implanted stents, and age were more important to the model. LVEF is a common variable that reflects left ventricular function, and patients with a low LVEF have a significantly higher MACE rate [39]. An increase in age can lead to the aggravation of atherosclerosis [40]. The number of implanted stents may be related to the severity of the disease and the extent of the infarction [41]. This reminds us that we should pay special attention to the prognosis of patients with AMI who have a low LVEF value, older age, and more implanted stents in clinical practice.

Study Limitations
This study has some limitations. First, there may have been an issue of survival bias in the study, as patients with missing follow-up data were excluded. Second, the data have missing values. We have filled missing values with multiple imputation; however, imputation with these techniques could synthetically reduce the variance in these variables and may have affected the accuracy of the constructed model. Finally, although the models were internally validated with data from the same hospital, further work should include validation with external data from other hospitals or centers.

Conclusions
This study revealed that the ANN model showed good MACE prediction performance for patients with AMI after PCI, and it identified the most important predictors, which may aid in clinical decision-making and improve outcomes. This model needs to be externally validated in larger populations and multicenter settings.

Abstract

Background: Psychological inflexibility is a core concept of acceptance and commitment therapy (ACT), which is a comprehensive, transdiagnostic interpretation of mental health symptoms. Erectile dysfunction (ED) is a condition that affects male sexual performance, involving the inability to achieve and maintain a penile erection sufficient for satisfactory sexual activity. Psychosocial factors primarily influence ED in men younger than 40 years, whereas biological factors are more likely to be the underlying cause in older men.

Objective: This web-based cross-sectional study examined differences in depression, anxiety, and psychological inflexibility among men with ED younger and older than 40 years in a Japanese population.

Methods: We used a web-based survey to gather data from various community samples. ED was assessed by the International Index of Erectile Function - 5 (IIEF-5) questionnaire, while depression, anxiety, and psychological inflexibility were evaluated by the Patient Health Questionnaire-9 (PHQ-9), General Anxiety Disorder-7 (GAD-7), Acceptance and Action Questionnaire-II (AAQ-II), Cognitive Fusion Questionnaire (CFQ), and Valuing Questionnaire–Obstacle Subscale (VQ-OB) questionnaires. The chi-square test estimated the scores of PHQ-9 and GAD-7 among men with ED, comparing those younger than 40 years and those older than 40 years. Additionally, a two-way ANOVA was conducted with ED severity and age group as independent variables, assessing psychological inflexibility.

Results: Valid responses from 643 individuals (mean age 36.19, SD 7.54 years) were obtained. Of these, 422 were younger than 40 years (mean age 31.76, SD 5.00 years), and 221 were older than 40 years (mean age 44.67, SD 2.88 years). There was a statistical difference in the prevalence of depression as judged by PHQ≥10 between men with ED younger and older than 40 years (P<.001). On the other hand, there was no difference in the prevalence of anxiety as judged by GAD≥10 (P=.12). The two-way ANOVA revealed that the interactions for CFQ (P=.04) and VQ-OB (P=.01) were significant. The simple main effect was that men with ED younger than 40 years had significantly higher CFQ (P=.01; d=0.62) and VQ-OB (P<.001; d=0.87) scores compared to those older than 40 years in moderate ED and severe ED. Additionally, it was found that men younger than 40 years with moderate to severe ED had significantly higher CFQ (P=.01; d=0.42) and VQ-OB (P=.02; d=0.38) scores compared to men younger than 40 years without ED. On the other hand, no interaction was found for AAQ-II (P=.16) scores.

Conclusions: To the best of our knowledge, this web-based cross-sectional study is the first to examine the relationship between psychological inflexibility and ED. We conclude that men with moderate and severe ED younger than 40 years have higher psychological inflexibility and might be eligible for ACT.

Introduction

The efficacy of acceptance and commitment therapy (ACT) has been evaluated in numerous randomized controlled studies exploring various targeted conditions [1]. There is supporting evidence for ACT across various physical illnesses (eg, chronic pain [2], diabetes [3], epilepsy [4], cancer [5], and irritable bowel syndrome [6]). Many of these studies use a transdiagnostic method to analyze psychological issues within individual health conditions. Psychological inflexibility is a core concept of ACT, which is a comprehensive, transdiagnostic interpretation of mental health symptoms [7]. Psychological inflexibility highlights two interrelated processes: cognitive fusion and experiential avoidance. Cognitive fusion represents the phenomenon by which individuals are influenced by the literal meaning of their thoughts instead of viewing them as transient internal states [8]. Experiential avoidance represents an attempt or desire to suppress unwanted internal experiences, such as emotions, thoughts, memories, and bodily sensations [9]. These processes are obstacles to one’s valued living activities, decreasing well-being [10].

Erectile dysfunction (ED) is a condition that affects male sexual performance, involving the inability to achieve and maintain a penile erection sufficient for satisfactory sexual activity [11]. Several reviews and clinical guidelines are available for ED. However, many of these approaches to assessing and treating ED purely from a medical perspective seldom address the psychosocial components of ED [12]. Pharmacological treatment alone does not respond to all the concurrent factors of ED, including anxiety, loss of self-confidence, depressed mood, difficulties in a couple’s communication, relationship disputes, or a partner’s sexual problems [13]. Recent systematic reviews have shown that combining phosphodiesterase-5 inhibitors with psychological treatment exhibits significant potential for treating ED [14].

There is a widespread assumption that psychosocial factors primarily influence ED in men younger than 40 years, whereas biological factors are more likely to be the underlying cause of ED in older men. Moore et al [15] showed different symptom patterns among patients with ED according to age groups. They reported that younger men had comparatively more significant depressive symptoms, with lower relationship satisfaction, more negative reactions from partners, and lower job satisfaction. Given these findings, it is possible that people younger than 40 years are more psychologically inflexible than those older than 40 years and that ACT is more effective for them. However, studies on ACT for ED remain limited, with only a few identified. Therefore, this cross-sectional study used assessments to evaluate depression, anxiety, and psychological inflexibility in men younger and older than 40 years. However, it is well known that ED prevalence varies across geographical groups [16,17]; therefore, it is essential to research ED etiology according to different racial, cultural, religious, and socioeconomic backgrounds. There might be many potential patients with ED in Japan, so we conducted a web-based survey for this study.

Methods

Participants

To gather data from a wide range of community samples, we used a web-based survey, conducted with the assistance of a marketing research service provider (Rakuten Insight, Inc) in Japan. Based on the International Index of Erectile Function – 5 (IIEF-5) cutoff point [18], participants of all severities were recruited to include a certain percentage of patients of all ages. All enrolled participants followed the following criteria: (1) male; (2) aged 20 to 50 years; and (3) married or living with a fixed sexual partner for more than 6 months. The exclusion criteria were as follows: (1) sexual dysfunction caused by Peyronie disease or other organic lesions of the external genitalia; (2) prostate cancer, hypertensive disease, cardiac disease, cerebrovascular disease, chronic kidney disease, and diabetes; and (3) a history of sertraline or other medicines that may influence erection and psychological symptoms.

Participants were first instructed that this survey would be administered anonymously, and their responses were not compulsory. Then, those participants who agreed to participate in this research responded to the surveys. Participants were given points to exchange for items within the survey company’s system as a reward.

Ethical Considerations

This study was approved by the Waseda University Academic Research Ethical Review Committee (2019-363). The study protocol followed the guidelines for epidemiological studies in accordance with the Declaration of Helsinki.

Measurements

International Index of Erectile Function-5 (IIEF-5)

The Japanese version of IIEF-5 is a 5-item self-report questionnaire designed to measure erectile function [18]. Items are rated on a 5-point Likert-type scale, ranging from 1 to 5. The total score can range from 5 to 25, with high scores meaning high erectile function. Based on the original validation studies, the total score can then be interpreted as suggesting “no ED” (22-25), “mild ED” (17-21), “mild-to-moderate ED” (12-16), “moderate ED” (8-11), and “severe ED” (5-7).

Patient Health Questionnaire-9 (PHQ-9)

The Japanese version of the Patient Health Questionnaire-9 (PHQ-9) is a 9-item self-report questionnaire designed to measure depression [19]. Items are rated on a 4-point Likert-type scale, ranging from 0 to 3. The total score can range from 0 to 27, with high scores meaning high depression. Based on the original validation studies, the total score can then be interpreted as suggesting no depression (0-4), mild depression (5-9), moderate depression (10-14), moderately severe depression (15-19), and severe depression (20-27).
(15-19), or severe depression (20-27). A cutoff score of 10 is suggested as indicating a possible diagnosis of depressive disorder.

**Generalized Anxiety Disorder-7 (GAD-7)**

The Japanese version of the Generalized Anxiety Disorder-7 (GAD-7) questionnaire is a 7-item self-report questionnaire designed to measure generalized anxiety disorder [20]. Items are rated on a 4-point Likert-type scale, ranging from 0 to 3. The total score can range from 0 to 21, with high scores meaning high anxiety. Based on the original validation studies, the total score can then be interpreted as suggesting no anxiety (0-4), mild anxiety (5-9), moderate anxiety (10-14), or severe anxiety (14-21). A cutoff score of 10 is suggested as indicating a possible diagnosis of generalized anxiety disorder.

**Acceptance and Action Questionnaire-II (AAQ-II)**

The Japanese version of the Acceptance and Action Questionnaire-II (AAQ-II) is a 7-item self-report questionnaire designed to measure experiential avoidance [21]. Items are rated on a 7-point Likert-type scale, ranging from 1 to 7. The total score can range from 7 to 49, with high scores meaning high experiential avoidance.

**Cognitive Fusion Questionnaire (CFQ)**

The Japanese version of the Cognitive Fusion Questionnaire (CFQ) is a 7-item self-report questionnaire designed to measure cognitive fusion [22]. Items are rated on a 7-point Likert-type scale, ranging from 1 to 7. The total score can range from 7 to 49, with high scores meaning high cognitive fusion.

**Valuing Questionnaire–Obstacle Subscale (VQ-OB)**

The Japanese version of the Valuing Questionnaire–Obstacle Subscale (VQ-OB) is a 5-item self-report questionnaire designed to measure obstruction of valued living [23]. Items are rated on a 7-point Likert-type scale, ranging from 0 to 6. The total score can range from 0 to 30, with high scores meaning high obstruction of valued living.

**Statistical Analysis**

We used mean (SD) values to describe numerical data and counts and percentages to describe categorical data. The chi-square tests estimated categorical data, and numerical data were estimated by t tests. A two-way ANOVA test was used to assess the differences in men with ED aged younger and older than 40 years regarding psychological inflexibility and the interaction between them. Post hoc tests were conducted using the Holm method to control for type I errors. Cohen d index was calculated as effect sizes, serving as standardized indicators unaffected by sample sizes. All tests were 2-tailed, and a statistical difference was assumed when the P value was <.05. All statistical analyses were conducted through IBM SPSS Statistics (version 25.0; IBM Corp).

**Results**

We obtained valid responses from 643 individuals (mean age 36.19, SD 7.54 years). Of these, 422 were younger than 40 years (mean age 31.76, SD 5.00 years), and 221 were older than 40 years (mean age 44.67, SD 2.88 years). Table 1 shows the demographic characteristics of participants by age difference. No statistical difference was found in ED severity, phosphodiesterase-5 inhibitors use, and marriage status between men with ED younger and older than 40 years.

The prevalence of depression as judged by PHQ≥10 among men younger than 40 years was 39.81% (168/422), and it was 24.89% (55/221) among those older than 40 years. There was a statistical difference in the prevalence of depression between the two groups (P<.001). In addition, the prevalence of anxiety, as judged by GAD≥10, was 27.25% (115/422) among men
younger than 40 years, and it was 21.72% (48/221) among those older than 40 years. There was no difference in the prevalence of anxiety between men with ED in the two age groups ($P=.12$). Table 2 illustrates these results.

The two-way ANOVA was performed with ED severity and age (<40 or >40 years) as independent variables and the scores of AAQ, CFQ, and VQ-OB as dependent variables. The results showed no significant differences in AAQ-II ($P=.14$), CFQ ($P=.08$), and VQ-OB ($P=.30$) scores attributed to ED severity. Moreover, no difference in ED severity or psychological inflexibility depending on the duration of the marriage was found. On the other hand, there were significant differences in the scores of CFQ ($P=.04$) and VQ-OB ($P=.004$) attributed to age. As the interactions were significant for CFQ ($P=.04$) and VQ-OB ($P=.01$) scores, the simple main effect was examined. It was found that men with ED younger than 40 years had significantly higher CFQ ($P=.01; d=0.62$) and VQ-OB ($P<.001; d=0.87$) scores compared to those older than 40 years, in cases of moderate and severe ED. Additionally, it was found that men with moderate to severe ED younger than 40 years had significantly higher CFQ ($P=.01; d=0.42$) and VQ-OB ($P=.02; d=0.38$) scores compared to men with no ED younger than 40 years. These results are illustrated in Table 3 and Figures 1 and 2.

Discussion

Principal Findings

This cross-sectional study evaluated depression, anxiety, and psychological inflexibility in men younger and older than 40 years with ED. There was no statistical difference in demographic characteristics between the two groups. The average age of the participants was 31.76 (SD 5.00) years in men younger than 40 years; the population was assumed to have mainly mild-to-moderate psychogenic ED. On the other hand, the average age of the participants was 44.67 (SD 2.88) years in men older than 40 years; the population was assumed to have mostly mild-to-moderate organic ED.

Depression was found in both groups. The results of our study were consistent with a previous study [15], which found that younger men had comparatively greater depressive symptoms. In contrast, the prevalence of anxiety was not different between the two age groups. One possible reason is that the anxiety in men with ED is not general anxiety but specific anxiety about sexual situations. Masters and Johnson [24] highlighted the...
central role of sexual performance anxiety in couples presenting with sexual dysfunction [24]. In treating sexual dysfunctions, Kaplan [25] emphasizes the importance of addressing specific sources of sexual anxiety, such as fear of failure and not pleasing one’s partner [25]. Although a Japanese version does not exist now, it may be necessary to use a questionnaire like the Erectile Performance Anxiety Index [26].

Men with ED younger than 40 years had significantly higher CFQ and VQ-OB scores than those older than 40 years in cases of moderate and severe ED. Furthermore, men with moderate-to-severe ED younger than 40 years had significantly higher CFQ and VQ-OB scores compared to men without ED. These results partly support our hypothesis that men younger than 40 years are more psychologically inflexible than those older than 40 years. Cognitive fusion might be the critical component of ACT for ED. For example, the fusion with sexual performance anxiety, such as “I might fail again,” makes it impossible to pay attention to the sexual partner, which results in erectile failure. It is also consistent with Barlow’s theory [27]. Barlow [27] proposed a model for the interaction of anxiety and cognitive interference. This model examines how anxiety and cognitive interference interact, particularly in a sexual context, where a lack of control over one’s arousal diverts attention from erotic arousal to physical arousal and the negative consequences associated with failure to attain an erection.

On the other hand, there were no significant differences in the scores of the AAQ-II, which might be related to psychometric issues with AAQ-II. To date, the most used self-report measure of psychological inflexibility, especially experience avoidance, has been the AAQ-II. There was no significant difference in ED severity and psychological inflexibility depending on the duration of the marriage. However, various issues regarding the AAQ-II have emerged from the existing literature [28]. The authors found that the AAQ-II faced challenges in distinguishing distress (like negative affect and neuroticism) from experiential avoidance. For clinical application, researchers have expanded the range of measures for psychological inflexibility. They have developed specific versions of the AAQ-II tailored to different populations or disorders, with currently over 20 available versions (examples include those for the workplace, tinnitus, irritable bowel syndrome, exercise, and epilepsy). The disorder-specific AAQ-II variants indicate greater incremental validity in their targeted areas than the general AAQ-II [29]. Thus, developing a questionnaire on ED-related psychological inflexibility might be necessary.

There are some limitations to this study. First, this study used a cross-sectional approach, indicating merely “associations” rather than “causality” between psychological inflexibility and ED. Further controlled experimental and longitudinal studies are essential to delve deeper into the impact of psychological inflexibility on ED. Second, in this study, no responses were obtained from the partners of men with ED. Including the partners in the assessment and treatment of ED is recommended. It is desirable to obtain responses from partners in future studies. Finally, the specific racial or ethnic and socioeconomic profiles of the participants may restrict the broader applicability of the findings. The study was also conducted during the COVID-19 epidemic, which may have influenced the results.

Conclusions
To the best of our knowledge, this web-based cross-sectional study was the first to examine the relationship between psychological inflexibility and ED. We conclude that men with moderate and severe ED younger than 40 years have higher psychological inflexibility and might be eligible for the ACT. In addition, developing a Japanese version of the questionnaire is necessary to measure ED-related anxiety and psychological inflexibility.

Abstract

Background: Prior suicide attempts are a relatively strong risk factor for future suicide attempts. There is growing interest in using longitudinal electronic health record (EHR) data to derive statistical risk prediction models for future suicide attempts and other suicidal behavior outcomes. However, model performance may be inflated by a largely unrecognized form of “data leakage” during model training: diagnostic codes for suicide attempt outcomes may refer to prior attempts that are also included in the model as predictors.

Objective: We aimed to develop an automated rule for determining when documented suicide attempt diagnostic codes identify distinct suicide attempt events.

Methods: From a large health care system’s EHR, we randomly sampled suicide attempt codes for 300 patients with at least one pair of suicide attempt codes documented at least one but no more than 90 days apart. Supervised chart reviewers assigned the clinical settings (ie, emergency department [ED] versus non-ED), methods of suicide attempt, and intercode interval (number of days). The probability (or positive predictive value) that the second suicide attempt code in a given pair of codes referred to a distinct suicide attempt event from its preceding code was calculated by clinical setting, method, and intercode interval.

Results: Of 1015 code pairs reviewed, 835 (82.3%) were nonindependent (ie, the 2 codes referred to the same suicide attempt event). When the second code in a pair was documented in a clinical setting other than the ED, it represented a distinct suicide attempt 3.3% of the time. The more time elapsed between codes, the more likely the second code in a pair referred to a distinct suicide attempt event from its preceding code. Code pairs in which the second suicide attempt code was assigned in an ED at least 5 days after its preceding suicide attempt code had a positive predictive value of 0.90.

Conclusions: EHR-based suicide risk prediction models that include International Classification of Diseases codes for prior suicide attempts as a predictor may be highly susceptible to bias due to data leakage in model training. We derived a simple rule to distinguish codes that reflect new, independent suicide attempts: suicide attempt codes documented in an ED setting at least 5 days after a preceding suicide attempt code can be confidently treated as new events in EHR-based suicide risk prediction models. This rule has the potential to minimize upward bias in model performance when prior suicide attempts are included as predictors in EHR-based suicide risk prediction models.

Introduction

Suicide is the tenth leading cause of death in the United States, with more than 48,000 suicide deaths annually [1]. Over the past 20 years, the suicide rate has increased by over 35% [2]. Most people who die by suicide have recently interacted with the health care system, with over half having a health care visit in the month prior to death [3,4]. Health care systems thus offer a key opportunity to identify people at high risk for suicide. Unfortunately, clinicians are poor at predicting who will make a suicide attempt [5] and traditionally studied risk factors perform no better than chance at predicting future suicidal behavior [6].

Recent work has focused on developing and validating machine learning models that use routinely collected electronic health record (EHR) data to predict future suicidal behavior [7]. Such models have demonstrated high levels of accuracy, exceeding that seen with clinician prediction and usual clinical risk factors [6,8-10]. EHR-based suicide risk prediction models, however, face one significant challenge that to date has not been adequately addressed. Suicide attempt is generally the outcome of interest in these models and is typically defined by International Classification of Diseases (ICD) diagnostic codes [11,12]. Within a given patient’s EHR, a suicide attempt code may be given multiple times across distinct health care encounters, often over very short periods of time (eg, days and weeks). Such “recurrent” codes may represent either distinct, new events (ie, multiple suicide attempts) or refer to the same event (ie, a single suicide attempt). The latter may occur when, for example, after making a suicide attempt, a patient has an emergency department (ED) visit followed by an inpatient hospitalization or outpatient follow-up encounters, with one (or multiple) suicide attempt codes assigned at each. In the absence of manual reviews of the narrative notes within patients’ EHRs, which cannot be performed at scale, it can be challenging to determine whether such recurrent suicide attempt codes, especially when documented over short time periods, refer to independent, distinct suicide attempts. Failure to make this important distinction can result in a form of “data leakage” in which the outcome to be predicted is included among features used for the prediction. This can result in substantial inflation of model performance [13].

To address this issue, some researchers have restricted model development to predict only the first occurrence of a suicide attempt code in a patient’s EHR [14-16]. This approach has a major limitation, however, in that a past suicide attempt is among the strongest known predictors of future suicidal behavior [17]. Thus, models that predict only the first documented suicide attempt ignore the subset of patients who may be at highest risk and thus of greatest clinical concern: those with a prior suicide attempt. Another approach is to include any previous suicide attempt codes as predictors of a subsequent suicide attempt code [18-21] thus including potential “repeat attempters” in these models. This approach, however, poses a significant risk of artificially inflating model performance if subsequent codes do not in fact refer to new suicide attempts. In other words, if a suicide attempt code instance used as an outcome actually indexes an attempt that was included a predictor, model performance will be inflated.

To minimize the risk of data leakage while retaining the option of including prior attempts as predictors, we aimed to develop an automated rule for determining whether recurrent suicide attempt codes in the EHR refer to distinct events. Such a rule might be based on relevant variables including clinical setting (eg, a suicide attempt code documented in the ED may be more likely to refer to a new suicide attempt event than one given in a non-ED setting), method (eg, suicide attempt codes that specify different methods may be more likely to refer to distinct events than codes specifying the same method), and time (eg, the more time elapsed between 2 suicide attempt codes, the less likely it may be that the codes refer to the same event). Here, we conducted a comprehensive manual EHR chart review to derive an automated rule that could identify criteria for selecting distinct suicide attempts with high confidence.

Methods

Data Source

The data source for this study was the Mass General Brigham (MGB) Research Patient Data Registry [22]. This registry covers 6.7 million patients treated in MGB-affiliated hospitals including the Massachusetts General Hospital and Brigham and Women’s Hospital in Boston.

Ethics Approval

This research was approved by the MGB institutional review board, which granted a waiver of informed consent (protocol #2018P0001508).

Case Definition and Inclusion Criteria

Details of the development of our EHR-based case definitions for suicide attempt in the MGB health care system are reported elsewhere [14,15]. In brief, we first identified candidate ICD, Ninth Revision (ICD-9) and ICD, Tenth Revision (ICD-10) codes that are likely to capture suicide attempts. Next, expert clinicians conducted manual chart reviews of 670 patients (over 3000 narrative notes) to determine a final set of codes that capture suicide attempts with a positive predictive value (PPV) of >0.70: for ICD-9, E95*, 965*, 967*, 969*, and 881*, and for ICD-10, X71*-X83*, T14.91*, T36*-T50* where the sixth character is 2 (except for T36.9, T37.9, T41.4, T42.7, T43.9, T45.9, T47.9, and T49.9, where the fifth is 2) and T51*-T65* where the sixth character is 2 (except for T51.9, T52.9, T53.9, T54.9, T56.9, T57.9, T58.0, T58.1, T58.9, T59.9, T60.9, T61.0, T61.1,
T61.9, T62.9, T63.9, T64.0, T64.8, and T65.9, where the fifth is 2).

For this study, we randomly selected a sample of 300 patients with 2 suicide attempt codes documented at least one but no more than 90 days apart (the “narrow sample”). This interval was chosen to capture codes that were given within a narrow time frame and thus potentially enriched for being “leaked” codes. In a sensitivity analysis, we randomly selected a second, smaller sample of 100 patients with 2 suicide attempt codes documented at least 1 day apart but with no other restrictions on intercode interval (the “broad sample”). A total of 31 patients appeared in both narrow and broad samples. Patients for whom we were unable to confidently locate the narrative notes corresponding to documented suicide attempt codes (eg, no narrative notes available within 30 days of the suicide attempt code date, narrative notes recorded on paper and never migrated to the EHR) were excluded after the sampling process.

Procedure
Under the supervision of JWS (a senior clinician with expertise in the treatment of suicidal behavior), 2 study team members (EMM and ES) manually reviewed the EHR clinical encounter data (including narrative notes) relevant to each pair of suicide attempt codes (“code pair”) per sampled patient (1015 in the narrow sample and 300 in the broad sample; 1253 unique codes across the 2 samples). Each code pair comprised a given suicide attempt code and the immediately (temporally) preceding code in a patient’s EHR. All applicable code pairs per patient were examined (including other code pairs with >90-day intervals for patients in the narrow sample). Chart reviewers assigned the following variables to each code pair: (1) whether the code pair referred to 2 distinct suicide attempts (dichotomous variable indicating distinct or not distinct suicide attempts), (2) clinical setting in which each code in the pair was documented (dichotomous variable indicating ED or non-ED [eg, outpatient and inpatient] setting), (3) suicide attempt method of each code in the pair (categorical variable with 6 categories derived from previous literature: poisoning, cutting or piercing, hanging or strangulation, suffocation, jumping, firearm, and other [which included codes with no specified method]), and (4) time elapsed (in days) between codes in each pair [23]. When there were multiple encounters with suicide attempt codes on the same day, these variables were assigned to codes at the day level; see Table S1 in Multimedia Appendix 1 for an example of how we combined multiple same-day encounters.

Data Analysis
We defined PPV as the probability that the second code in a pair of codes identified a new suicide attempt independent of the first code in the pair. To mimic the approach that would likely be taken in building predictive models, each code pair was treated independently (ie, we did not account for the nested nature of code pairs within patients). First, for the narrow sample, we calculated (in Excel [Microsoft]) PPVs and 95% CIs by clinical setting, suicide attempt method, and intercode interval, respectively. For clinical setting, we calculated the PPVs for 4 possible code pair types: (1) both codes documented in the ED (ED/ED), (2) first code ED and second code non-ED (ED/non-ED), (3) first code non-ED and second code ED (non-ED/ED), and (4) neither code ED (non-ED/non-ED). For suicide attempt method, we calculated the PPVs of 2 possible code pair types: (1) same suicide attempt method for codes in a pair and (2) different suicide attempt methods for codes in a pair. For intercode interval, we first calculated PPVs for all 7-day intervals from 1 to 91 days, followed by collapsing across intervals from 92 days on. We then calculated the PPVs for time intervals within each of the 6 (4 clinical settings and 2 suicide attempt methods) code pair types. To derive our proposed rule, we set our benchmark PPV to 0.90. For each of the 6 code pair types, we determined the minimum time elapsed between codes (ie, interval floor) at which the PPV was at least 0.90. For a sensitivity analysis, we computed the same series of PPVs for the broad sample.

Results
Descriptive Statistics
The mean number of suicide attempt codes per patient in the narrow sample was 3.38 (SD 4.62; range 1–47). A total of 225 (75%) patients had <4 codes and 281 (93.7%) had <10 codes. A total of 210 (20.7%) code pairs had a second code reflecting a subsequent encounter for a condition for which the patient had received active treatment (indicated by a seventh “D” character).

Regarding how often the codes in a pair referred to distinct suicide attempts, of the 300 patients in the narrow sample, only 81 (27%) had more than one confirmed (by manual chart review) suicide attempt captured by the reviewed code pairs. Of the 1015 code pairs, only 180 (17.7%) referred to 2 distinct suicide attempt events. Table S1 in Multimedia Appendix 1 presents an example of sampled codes (and the variables assigned to each code and code pair) for a deidentified patient.

For clinical setting, the most common code pair types were non-ED/non-ED (n=542, 53.4%) followed by ED/ED (n=274, 27%). Regarding the 749 total non-ED codes, the most commonly represented clinical setting was inpatient (n=411, 54.9% of all non-ED codes), followed by other or unclear setting (n=149, 19.9% codes), intensive or critical care units (n=134, 17.9% codes), and outpatient (n=55, 7.3% codes). For suicide attempt method, the majority of code pairs (n=796, 75.5%) comprised 2 codes that referred to the same method. The median interval between codes in each code pair, across all codes, was 1 day. Among code pairs that referred to distinct suicide attempt events, the median interval was 35 days.

PPVs
Clinical Setting
Non-ED/ED code pairs (23 total code pairs) had the highest PPVs (0.96, 95% CI 0.87–1.04) for distinct suicide attempt events (Table 1). ED/ED pairs (274 total code pairs) had the second-highest PPVs (0.49, 95% CI 0.43–0.55). When the second code in a pair was assigned in a non-ED setting, PPVs were low (below 0.10).

In a sensitivity analysis, we excluded codes or encounters documented in inpatient settings with a prior code on the previous day from an inpatient or critical or intensive care setting.

https://formative.jmir.org/2024/1/e46364
setting. For example, if a patient was given suicide attempt codes on three consecutive days in an inpatient setting, we only used the day 1 code. This resulted in 792 (versus 1015) analyzed code pairs. The results were overall very similar to when we did not exclude contiguous inpatient codes (Multimedia Appendix 2).

### Intercode Interval

Table 3 presents PPVs for code pairs broken down by 7-day (week-long) intervals; the majority (n=797, 78.5%) of code pairs had an intercode interval of 7 days or less. The more days elapsed between 2 codes, the larger the PPV (and, fewer code pairs per strata). Table S7 in Multimedia Appendix 4 presents PPVs for code pairs broken down by interval and clinical setting (non-ED/non-ED, ED/non-ED, non-ED/ED, ED/ED), and Table S8 in Multimedia Appendix 5 presents PPVs for code pairs broken down by interval and suicide attempt method (same versus different). In another sensitivity analysis, given that ICD-9 is no longer used, we also computed all PPVs reported in Tables 1-3 when excluding code pairs with at least one ICD-9 coded event. The same pattern of findings held, with 95% CIs for all PPVs overlapping with those in Tables 1-3.

Table S6 in Multimedia Appendix 3 shows PPVs for each combination of the 6 aforementioned specific method categories derived from previous literature. All PPVs for strata containing more than 1 code pair were at or below 0.50.

*PPV: positive predictive value.

As shown in Figure 1, across all code pairs, pairs with an interval of at least 53 days had a PPV of 0.90 (range 0.88-0.93). The interval floor at which the PPV was at least 0.90 (or the maximum PPV) within each of the 6 code pair types are also labeled in Figure 1 (clinical setting) and Figure 2 (suicide attempt method). For non-ED/ED code pairs (23 code pairs), an interval floor of 1 day had a PPV of 0.96. When both codes were assigned in the ED (271 code pairs), PPV reached 0.90 when the intercode interval was at least 5 days. When the second code in a pair was documented in an ED (regardless of the setting in which the first code was documented), PPV was 0.91 when the intercode interval was 5 days (the PPV was 0.89 for 4 days). Thus, whenever the second code in a pair was documented in an ED at least 5 days after the previous code, the probability that the second code referred to an independent suicide attempt was at least 90%.

Figure 1. PPVs for interval floors by code pair types defined by clinical setting. The labeled data points indicate the interval floor at which the PPV was at least 0.90 (or the maximum PPV). Gray lines reflect PPVs for interval floors across all code pair types. Red lines refer to code pairs documented in ED (first code) and ED (second code) settings (ED/ED). Blue lines are non-ED/ED code pairs; purple lines ED/non-ED; and green lines non-ED/non-ED. ED: emergency department; PPV: positive predictive value.
Sensitivity Analysis: Broad Sample

Results from the same series of analyses in the broad sample are presented in Multimedia Appendix 6. Of the 100 patients, 45 (45%) had more than 1 confirmed suicide attempt. Of the 300 code pairs, 86 (28.7%) referred to 2 distinct suicide attempts. The median interval between codes in each pair was also 1 day. Among code pairs that referred to distinct suicide attempts, the median interval was 133 days. Overall, we found a similar pattern of PPVs (in almost all cases overlapping 95% CIs) to those from the narrow sample. Across all code pairs in the broad sample, those with an interval of at least 37 days had a PPV of 0.90 (range 0.87-0.93). When both codes were given in the ED (86 pairs), PPV reached 0.90 when the interval was at least 2 days.

Discussion

Primary Findings

Machine learning suicide risk prediction models that leverage routinely collected EHR data can outperform clinician assessment [8] and have the potential to improve how patients at risk for suicide are identified and treated. These models are typically trained using ICD codes to label suicide attempts. An under-appreciated challenge when building these models, however, is that ICD codes indexing a single suicide attempt are often used repeatedly across multiple encounters. This could create a substantial problem for models that incorporate prior suicide attempts, an established risk factor, in predicting subsequent attempts or suicidal behavior.

Some investigators side-step this issue by restricting model predictions to only the first occurrence of a suicide attempt code. This approach, however, limits the utility of prediction models by ignoring prior attempts, the best-known risk factor for suicidal behavior, and limiting their application to a subset of those at risk; prior studies indicate that nearly one-quarter of those who engage in deliberate self-harm have recurrent episodes within 3 years [24]. Here we aimed to develop a portable, automated rule for determining when recurrent suicide attempt codes refer to distinct suicide attempt events in a patient’s history. Based on chart review of clinical encounters corresponding to 1015 unique ICD code pairs, we found that, for patients with more than 1 documented suicide attempt code, repeat codes most often (>80% of the time) reflected nonindependent events, underscoring the high frequency of “leaked” suicide attempt codes. When collapsing across all clinical settings, repeat codes needed to be documented at least 53 days after the preceding code in order to refer (with probability >90%) to a new, distinct suicide attempt. However, repeat codes documented in an ED at least 5 days after the preceding suicide attempt code were likely (probability >90%) to refer to a new, distinct suicide attempt.

The most informative variables for determining whether recurrent suicide attempt codes referred to distinct suicide attempts were the clinical setting in which the codes were documented and the time elapsed between codes. First, regarding clinical setting, when a suicide attempt code was documented in an ED after the preceding code, it referred to a new suicide attempt more than half the time. Suicide attempt codes documented in non-ED settings, accounting for most of the second codes among all code pairs, however, were highly unlikely to refer to a new suicide attempt (probability <5%). This may be due to the fact that the vast majority (nearly three-quarters) of non-ED codes occurred in inpatient or intensive or critical care units, where patients may be treated over the course of several days or longer, potentially accumulating multiple suicide attempt codes that all refer to the same index event that may have prompted inpatient or intensive treatment. This pattern of findings, for one, highlights the considerable risk of treating all recurrent suicide attempt codes (especially those from non-ED settings) as distinct events, and the potential importance of using a simple rule, such as that proposed here, to identify probable distinct suicide attempt events.
Along these lines, the more time elapsed between 2 suicide attempt codes, the more likely it was the codes referred to distinct events. Combining these 2 variables—clinical setting and time elapsed—provided a simple rule for determining whether recurrent suicide attempt codes refer to distinct events with at least 90% probability. Although the accuracy of our proposed rule (at least 5 days elapsed between a code given in the ED and the preceding code) may differ in other health care systems, we recommend that others consider taking into account these 2 variables when incorporating recurrent suicide attempt codes in EHR-based suicide risk prediction models.

Perhaps surprisingly, whether the coded suicide attempt method for 2 codes in a pair was the same or different did not provide value in identifying distinct suicide attempt events. However, in the relatively small proportion of code pairs (24.5%) that referred to different methods, the most common “profile” was 1 code with a specific method (eg, poisoning and cutting or piercing) and the other code with method categorized as “other” (not a different specific method); notably, the “other” category included codes lacking any specified method. Thus, the fact that method did not help identify distinct events may largely reflect inconsistencies in how or whether the suicide attempt method is coded by providers. In contrast, neither of the other 2 variables examined (clinical setting nor intercode interval) should be impacted by irregular coding practices, and thus may also be more scalable and reliable for other health care systems planning to use this or a similar rule.

Our derived rule (at least 5 days elapsed between a code from the ED and the preceding code) may have more impact on certain suicide-related prediction tasks than others. For example, it may be especially relevant when estimating patients’ risk of repeat suicidal behavior, for example after an ED visit for suicidal behavior, which could influence clinical decision-making at the point of care (eg, about discharge home or to outpatient care versus hospitalization). This rule may have less impact for other related prediction tasks, such as estimating patients’ risk of suicidal behavior after nonsuicide-related outpatient visits or broader population-based prediction efforts [25]. These results may also be less relevant for models that solely predict fatal self-harm or suicide deaths [26,27]. Future work should systematically evaluate the performance and clinical utility of models that do and do not incorporate the proposed rule for incorporating recurrent suicide attempt codes across a range of prediction goals and clinical contexts.

Our results must be considered in the context of a few key limitations. First, some of the sampled patients may have presented to hospitals outside of the MGB system for suicide attempts. In these cases, the corresponding diagnostic codes and contextual information were either unavailable or only sporadically recorded in narrative notes at subsequent clinical encounters within MGB. We also excluded sampled patients for whom chart reviewers could not confidently match data pulled from the MGB Research Patient Data Registry to the narrative notes.

Conclusions
This analysis indicates that EHR-based suicide attempt prediction models that include ICD codes for prior attempts as a predictor may be highly susceptible to bias due to data leakage in model training. Our proposed rule for circumventing this issue should minimize this bias and its inflationary effect on model performance metrics. The key variables included in our rule (clinical setting and time elapsed between codes) are widely available in health system data warehouses and should be easily integrated into EHR-based models. It is also possible that the approach taken in this study may be relevant for developing and refining machine learning models aimed to predict other episodic events of interest that can be repeatedly documented in the health record, such as unintentional overdose, domestic abuse, or episodes of violence. If effectively implemented into existing and future suicide risk prediction models, this rule could increase the robustness and validity of machine-learning based approaches to identifying the individuals at highest risk for suicide, and ultimately advance suicide prevention efforts in health care contexts on a large scale.

Abstract

Background: There is a need for physical activity promotion interventions in adolescents and young adults with intellectual disabilities. Current interventions have shown limited effectiveness, which may be attributed to the absence of theory and a population-specific development. Combining a planning model (including theory) and cocreation with the target audience during intervention development could potentially address this gap.

Objective: This study aimed to report the systematic development of the Move it, Move ID! intervention by describing how the 8 different steps of the Behavior Change Wheel (BCW) were applied and present the results that emerged from those steps. In doing so, the (theoretical) content of the intervention is described in detail.

Methods: A total of 23 adolescents and young adults (aged 14-22 years) with mild to moderate intellectual disabilities were designated as cocreators of the intervention. Across 2 groups, 6 similar cocreation sessions were organized in each. The content and sequence of the sessions were structured to align with the 8 steps of the BCW. All sessions were recorded and transcribed verbatim. Both a deductive (ie, steps of the BCW) and inductive (ie, resonating the voice of the participants) analysis approach were applied specifically focusing on identifying and describing the findings within each of the BCW steps.

Results: After behavioral analysis (steps 1-4), 10 intervention goals were chosen and linked to Capability, Opportunity, and Motivation–Behavior components (theory within the BCW) that needed to be addressed. Psychological capability, social opportunity, and reflective motivation were emphasized as the first targets to focus on. A key finding was the urge for real-life social connectedness and social integration, which makes the social component as part of physical activity a central theme to focus on within intervention development. Judgments on the most suitable intervention functions (step 5) and behavior change techniques (step 7) were explained. When discussing the mode of delivery of the intervention (step 8), it was underscored that solely relying on a mobile health app would not fulfill participants’ social needs. Hence, the chosen intervention adopts a dyadic approach in which young individuals with intellectual disabilities are matched with peers without intellectual disabilities to engage in physical activities together, with a mobile app playing a supportive role in this partnership.

Conclusions: The transparent description of the development process highlights why certain intervention components and behavior change techniques were chosen and how they are intertwined by means of the selected intervention design. This paper provides a detailed blueprint for practitioners wanting to integrate the BCW and its associated behavior change techniques, in combination with actively involving the target group, into their intervention development for people with intellectual disabilities.

Introduction

Physical Activity for People With Intellectual Disabilities

People with intellectual disabilities (IDs), defined as limitations in intellectual functioning (IQ of <70) and adaptive behavior emerging in childhood (age of <22 years) [1], are at higher risk of chronic health problems, such as type 2 diabetes, obesity, osteoarthritis, thyroid disorders, and cardiovascular diseases, than people without IDs [2-7]. In addition, compared with their peers without disabilities, individuals with IDs have less access to health care services, face increased polypharmacy, have higher poverty rates, encounter social isolation, and engage more in behaviors that put their health at risk (eg, unhealthy nutrition and physical inactivity) [4].

Promoting physical activity (PA) may be one avenue to reduce increased health problems. PA has been shown to have beneficial effects on the physical and psychosocial health of people with IDs [8,9]. Nevertheless, they are less physically active than their peers without IDs [10-16]. The World Health Organization (WHO) recommends that adolescents engage in at least 60 minutes of moderate to vigorous PA (MVPA) per day and participate in muscle- and bone-strengthening activities 3 days per week. Adults are recommended to perform at least 150 minutes of moderate-intensity PA or 75 minutes of vigorous-intensity PA throughout the week or an equivalent combination of moderate- and vigorous-intensity activity supplemented by performing activities twice a week to strengthen muscles and bones [17]. Since 2020, these global PA guidelines include groups such as people living with IDs. It is a positive trend that, for the first time, there is attention to the specific target group in the WHO PA guidelines. However, it should be noted that the evidence is primarily based on individuals without IDs, and some argue that disability-specific guidelines are necessary [2].

A 2016 systematic review including 15 studies described that only 9% of adults with IDs achieved minimum PA guidelines (with a range of 0%-46%), measured using both objective and self-reported measurement tools [18]. Different PA guidelines were used as outcome measures in the included studies, such as 150 minutes of MVPA per week (in bouts of >10 minutes), 30 minutes of MVPA for at least 5 days per week, 20 minutes of mild exercise ≥4 times per week, 12 bouts of MVPA in 4 weeks (retrospectively), and >10,000 steps per day. A systematic review the year after (2017) reported that, in 5 out of 17 studies that assessed MVPA through accelerometry in participants with IDs (aged 6-72 years), none of the participants met the PA guidelines of 150 minutes of MVPA per week for adults and 60 minutes of MVPA per day for children and adolescents. In the remaining 12 studies, the percentage of participants with IDs who met the guidelines ranged from 6% to 66% (mostly because of the use of different protocols to measure PA) [19]. Both reviews concluded that only a small number of individuals with IDs meet the PA guidelines, indicating that they are less active than the general population [18,19].

Current PA Interventions and Their Effectiveness

Although PA research in people with IDs has been growing over the last decade, this field has been underresearched. A PA Series in The Lancet (2021) stated that, between 1999 and 2019, <5% of all articles in the 5 highest-impact medical journals focused on people with disabilities (not limited to IDs) and <7% of these addressed PA or health [2]. A systematic review from 2019 on the effectiveness of PA interventions among participants with IDs of all ages identified only three effective randomized controlled trials out of 9 [20]: (1) a 10-week progressive resistance training program in adolescents and young adults (aged 14-22 years) with Down syndrome in Australia [21], (2) a 12- to 16-month multicomponent diet and PA program in adults (aged 20-66 years) with mild to moderate IDs in Sweden [22], and (3) an 8-month PA and fitness program in “fast-walking” older adults with mild to moderate IDs (aged >40 years) in the Netherlands [23]. The success of these randomized controlled trials was mainly attributed to the following factors: (1) practical support from others (eg, a mentor) in guiding and helping participants with IDs through the intervention and for increasing motivation, (2) establishing a routine that involves regular PA as well as the adaptability of an intervention to the specific routines of both carers and participants, (3) the simplicity of an intervention by adapting interventions to the specific needs of the participants, and (4) familiarity with the intervention [20]. None of the 9 interventions in the systematic review by Hassan et al [20] included a technological component (ie, eHealth or mobile health [mHealth]). However, there seems to be no reason why digital interventions would not be feasible in this target group [24]. In the study by Ptomey et al [25], 95% of the participants, aged 14.9 (SD 2.2) years on average, reported that using a tablet computer was easy and enjoyable. It is then no surprise that, in recent years, there has been a growing interest in the development of digital interventions for individuals with IDs [26-30].

The number of effective PA interventions for people with IDs remains limited. A potential reason for the limited effectiveness is currently attributed to the lack of a theoretical framework for intervention development and the difficulty in concretizing behavior change techniques (BCTs) in an understandable way for this population [10,20,31,32]. A 2017 systematic review on the use of BCTs in lifestyle change interventions for people with IDs, for example, concluded that 73% of the studies aiming to improve PA in the target group did not use any theoretical framework [31]. Nevertheless, the use of a theoretical framework is an important prerequisite for intervention effectiveness [2,20,33-36]. Furthermore, when examining theory-based interventions for people with IDs, concerns have been raised regarding the suitability of the theories used (eg, social cognitive theory, theory of planned behavior, and self-determination theory) as a starting point for designing interventions for this specific target group. These theories may...
not sufficiently address the specific challenges faced by people with IDs. More specifically, these theories tend to be specific and detailed, yet they may not encompass the complete spectrum of potential influences on behavior within this particular target group and often concentrate on individual-level factors [20,31,32].

Applying the Behavior Change Wheel and a Cocreative Approach to Build Theory-Based PA Interventions

The Behavior Change Wheel (BCW) is a planning model aimed at guiding a scientific and systematic intervention development process [33,37]. The BCW contains a behavioral theory at its heart, the Capability, Opportunity, and Motivation–Behavior (COM-B) model, which encompasses the full range of influences contributing to the behavior of interest [33,38]. A total of 3 behavioral components are summarized in the COM-B model, which states that, for each behavior to occur, individuals need capability (physical and psychological), opportunity (physical and social), and motivation (reflective and automatic) [33,37,39]. The COM-B model is in turn linked to the Theoretical Domains Framework (TDF) [33,40], which subdivides the COM-B model into 14 domains. The BCW further formulates 9 intervention functions linked to 93 BCTs [41] and 7 policy types with the aim of modifying each of the 3 COM-B components and, thus, changing behavior. The COM-B model describes the minimal factors that behavioral scientists agree on to achieve behavior change and has been developed with interdisciplinary research in mind [37]. It is an open model and relatively easy to communicate, especially with vulnerable groups. In recent years, this model has demonstrated applicability in the context of PA among people with IDs and their carers [32,42]. This study chose the BCW as a planning model for intervention development because of its practical use and feasibility in combination with a cocreative approach. Current lifestyle modification approaches for this target group lack a robust foundation addressing their unique needs [10,32,43]. Therefore, deeply engaging with this group and customizing approaches to promote their PA is vital. Unfortunately, individuals with IDs are seldom heard in research, and interviews with caregivers often take precedence, potentially overshadowing their authentic experiences [43]. Neglecting the perspectives of individuals with IDs can undermine intervention acceptability, comprehensibility, and feasibility [10,44-48]. To clarify, previous intervention studies have reported that some BCTs may be too complex for the target group (eg, self-monitoring through the use of pedometers) [31,49]. The cocreative approach (in combination with the BCW planning model) in this study will aid in determining which BCTs might be most appropriate for people with IDs or adapting them if necessary through collaboration.

Aims

This paper aimed to (1) report the systematic development of the Move it, Move ID! intervention by describing how the different steps of the BCW were applied and (2) present the results that emerged from those steps. In doing so, we described the (theoretical) content of the Move it, Move ID! intervention in detail.

Methods

Participants and Recruitment

It was prioritized to focus on young people with IDs as cocreators rather than their parents or teachers because of the historical pattern of marginalization in previous research on intervention development [43]. Through purpose sampling, 2 class groups of adolescents or young adults with mild to moderate IDs aged between 13 and 22 years (ie, age of special needs secondary education in Flanders, Belgium) were recruited to participate in the cocreation sessions. In February 2021 and March 2021, a total of 2 physical education (PE) teachers from different special needs schools in Flanders were contacted to explain the purpose and design of the project via email and phone. They were asked whether they were interested in involving one of their classes in cocreating a PA promotion intervention. Each PE teacher subsequently suggested 1 class group to take part. All adolescents from the selected classes (classes A and B) were invited to participate during the first visit, in which written informed consent from all participants and passive consent from their parents were obtained (Table 1). Class A comprised 14 adolescents aged between 17 and 22 years with a mild to moderate level of ID (mean age 20.33, SD 1.94 years; 3/14, 21% female). Class B comprised 9 adolescents aged between 14 and 15 years with mild IDs (mean age 14.22, SD 0.44 years; 6/9, 67% girls). This aligned with cocreation guidelines, which recommend groups of 10 to 12 cocreators [45,50]. A detailed description of (the recruitment of) participants, as well as the ethical process (next subsection), can be found in the study by Maenhout et al [51].

| **Step 3:** specify the target behavior and formulate intervention goals | Specify the target behavior by:  
- Generating a nonexhaustive list of all potential barriers and facilitators that may be relevant to the target behavior  
- Describing these barriers and facilitators as what needs to be targeted in the intervention (who needs to do it, what do they need to do differently to achieve change, where and when do they need to do it, and how often and with whom do they need to do it)  
- Formulating 10 intervention goals based on the ranking by the cocreators | Cocreation session 1:  
- Introduction session (ie, explanation of the project and its purpose, process of informed consent, and getting to know each other)  
- Cocreation session 2:  
- Comapping barriers to and facilitators of PA  
- What PAs are they currently performing? What do they like or dislike?  
- Cocreation session 3:  
- Explore the most important barriers and facilitators on which the intervention should focus by voting and ranking them by importance  |  
| **Step 4:** link intervention goals to COM-B\(^d\) components and TDF\(^e\) domains | Select the components of the COM-B model and the theoretical domains of the TDF for each intervention goal | No input was gathered from the participants with IDs in this step as their input (from step 3) only needed to be linked to the theoretical components of the COM-B and TDF.  |  
| Stage 2: identify intervention options | | |  
| **Step 5:** select intervention functions | Select intervention functions using the APEASE\(^f\) criteria from the BCW guide \(\cite{33}\) | No input was gathered from the participants with IDs in this step as intervention functions were first considered to be feasible by the project team. However, an open-minded perspective was adopted in which only intervention functions that were deemed not feasible by the project team were removed.  |  
| **Step 6:** identify policy categories | Not applied as designers limited to a specific policy lever are directed immediately to step 7 \(\cite{33}\) | N/A\(^g\)  |  
| Stage 3: identify content and implementation options | | |  
| **Step 7:** identify BCTs\(^h\) | Choose the most appropriate BCT(s) based on the following:  
- The BCW guide \(\cite{33}\)  
- Input from participants with IDs  
- APEASE criteria (expert consultation) | Cocreation session 4:  
- Select BCTs and identify whether selected BCTs would suit the target group or how they can be redesigned to work for them  |  

\(^a\)IDs refer to participants with intellectual disabilities

Ethical Considerations

All participants and their parents or legal guardians received detailed and accessible information regarding the study design and purpose as well as data handling. To ensure privacy, the data were pseudonymized and only accessible to the researchers or their appointed representatives. Data confidentiality was always maintained. In consultation with the data protection officer of Ghent University (Belgium), the legal basis was changed from “active informed consent” of parents or legal guardians to “public interest,” although this did not exempt researchers from informing participants. This meant that parents or legal guardians needed to contact the researchers only if they disagreed with their child’s participation and, thus, researchers did not require active consent from parents or guardians to commence. The participants with IDs themselves were required to provide their active consent, which is why the first session involved a thorough, step-by-step review of the information and consent process with time for discussion. Young people with IDs participated voluntarily and could withdraw at any time. In appreciation of their participation, all participants received 2 cinema tickets, about which they were informed when they decided to participate. This study received approval from the Ethical Committee of the Faculty of Psychology and Educational Sciences at Ghent University, Belgium (2021/056 LM).

Combining the BCW Development Process and a Cocreational Approach

Overview

From April 2021 to June 2021, the 8 steps of the BCW were systematically followed for intervention development (Figure 1) [33]. In parallel, input was gathered from adolescents and young adults with IDs through 6 cocreation sessions (Table 1). The entire process was a mix of theoretical underpinnings (ie, COM-B), the domain expertise of the researcher, and the lived experiences of the target group (ie, cocreation sessions). The 6 sessions took place in their classrooms, each during 2 consecutive class hours. For a comprehensive explanation of the cocreation process, the methods used, and the participants’ experiences, we refer interested readers to our previously published paper [51].
**Stage 1: Understand the Behavior**

In *step 1*, the literature was reviewed by the principal investigator (PI; LM) to articulate the (health) problem in behavioral terms, this being “insufficient PA in people with IDs.” The next steps were then to select (*step 2*) and specify (*step 3*) the target behavior of the intervention, this being “increasing PA levels in adolescents and young adults with IDs,” by defining who needs to do it, what needs to be done differently to achieve change, where and when they need to do it, and how often and with whom they need to do it. This was done by generating a nonexhaustive list of possible barriers to and facilitators of PA for adolescents and young adults with IDs based on both the literature and information gathered in the second cocreation session (Table 1). Owing to the cocreative approach, insights from the literature (brought in by the PI) and input from the target group were intertwined (eg, visual cards of barriers and facilitators were developed by the PI inspired by the literature, which were brought up when the participants themselves could not come up with barriers and facilitators [anymore] [51]). In cocreation session 3, these barriers and facilitators were ranked according to importance by the target group. The most important barriers and facilitators were ranked accorded to importance by the target group. The most important barriers and facilitators were described as what needed to be targeted in the intervention and, consequently, formulated as the intervention goals. In *step 4*, these intervention goals were then assigned by the PI to the specific components of the COM-B model and theoretical domains of the TDF. No direct cocreation session was organized within this step as their input (from step 3) only needed to be linked to the theoretical components of the COM-B and TDF. However, this does not deviate from the essence of cocreation as the PI established these connections based on all the input provided by the participants.

**Stage 2: Identify Intervention Options**

In *step 5*, the BCW guide links COM-B components and TDF domains to 9 intervention functions [33]. Consequently, the broader research group of the PI (ie, the Physical Activity and Health research group) held expert meetings to decide which intervention functions were most suitable to work with based on the Affordability, Practicability, Effectiveness or Cost-Effectiveness, Acceptability, Side Effects or Safety, and Equity criteria [33]. These criteria are recommended by the BCW guide to make strategic judgments on the most appropriate intervention functions. No direct input from the cocreators was sought in this case, either. However, we approached this step with an open-minded perspective and only removed the intervention functions that were deemed not feasible by the project team. All other intervention functions were retained, allowing the cocreators to continue shaping the direction of development. The *sixth step* was to consider which policies would support the delivery of the intervention functions identified in step 5 [33]. However, as the researchers within this project did not have access to policy levers, step 6 was not applied. This is also described in the BCW guide by stating that “designers limited to a specific policy lever are directed to step 7 to identify BCTs” [33].

**Stage 3: Identify Content and Implementation Options**

In *step 7*, the BCW guide proposes the most appropriate BCTs for each intervention function (selected in step 5) [33]. In each of these, a distinction is made between “BCTs used most frequently and less frequently” [33]. For feasibility reasons, we focused primarily on the most frequently used BCTs during the development process. However, for the fourth cocreation session on BCTs, we also explored the less frequently used BCTs and selected relevant ones based on our expertise with the target group. The aim of this cocreation session was to find out which BCTs were understandable and feasible for adolescents and young adults with IDs and how BCTs could be adapted to meet these criteria. On the basis of the Affordability, Practicability, Effectiveness or Cost-Effectiveness, Acceptability, Side Effects or Safety, and Equity criteria and on input from the cocreators with IDs, a decision was made on which BCTs to include in the
Move it, Move ID! intervention. Finally, the *eighth step* was to identify the best way to deliver the intervention (ie, mode of delivery). As research has shown that the use of technology (ie, mHealth) is feasible and has high potential in adolescents and young adults with IDs [24,25,52], the target group was asked in the fifth cocreation session about their preferences and barriers to and facilitators of mHealth use.

**Analysis**

All the cocreation sessions were recorded and transcribed verbatim. A combination of a deductive (ie, 8 steps of the BCW) and inductive (ie, resonating the voice of the participants) analysis approach was applied specifically focusing on identifying and describing the findings from each of the steps of the BCW.

**Results**

**Stage 1: Understand the Behavior**

**Step 1: Define the Health Problem in Behavioral Terms**

Few people with IDs are sufficiently physically active [18,19].

**Step 2: Select the Target Behavior**

An increase in the total volume of PA should be targeted rather than aiming to meet the WHO guidelines regarding MVPA as even small positive changes in PA levels are associated with health benefits among people with IDs [53].

**Step 3: Specify the Target Behavior and Formulate Intervention Goals**

Multimedia Appendix 1 [32,54-63] provides an overview of 72 barriers to and 66 facilitators of PA for adolescents and young adults with IDs based on (1) a review of the literature by the PI in preparation for the cocreation sessions and (2) input from cocreators with IDs during these sessions. The appendix is divided into intrapersonal, interpersonal, and contextual factors, reflecting the multifaceted and complex nature of the influences on PA in this population. In the third cocreation session, participants ranked the barriers and facilitators according to their importance, providing guidance on which ones to address in the intervention. The 10 most important barriers (in the opposite direction, these would be facilitators) were identified: (1) the need for social connectedness, (2) the lack of practical support within the PA context, (3) the absence of a role model, (4) the need for others around them who also engage in PA, (5) the lack of confidence in their own abilities and body image, (6) the need for knowledge about the (health) benefits of PA, (7) the lack of knowledge about the different PA options available, (8) the low motivation to engage in PA, (9) the difficulty in setting goals, and (10) the need for help to incorporate PA into their existing schedules (ie, goal conflict) as they often depend on others for this. Evidently, this top list does not mean that the other barriers and facilitators were not relevant for some individuals at particular times, but in view of feasibility, it was decided to prioritize and primarily address those that were identified as the most important.

Previous studies have proposed schools as the ideal setting for PA promotion [8,32,64]. Participants with IDs in this study indicated that they are sufficiently encouraged at school to engage in PA via compulsory PE classes. However, they expressed difficulties in being physically active during leisure time. In the cocreation sessions, they expressed a preference for an intervention during their leisure time (ie, at home or in the community setting) rather than a school-based intervention:

*I think it’s best to go somewhere else. Then you have something separate from school. That you are really away. When you come back to school, that you can start again with a fresh head.* [Cocreator 1; cocreation session 3; group A]

* [... that you just keep your activities outside school and that you don’t keep it here between these four walls.]* [Cocreator 2; cocreation session 3; group A]

Textbox 1 summarizes the specifics of the target behavior gathered during the first 3 steps: who will perform the behavior; what needs to be done differently; and when, where, how often, and with whom it needs to be done.

Finally, the PI formulated 10 intervention goals targeting the most important barriers chosen by the cocreators (Table 2).
### Textbox 1. Specify the target behavior (step 3 of the Behavior Change Wheel).

</tr>
</tbody>
</table>

| Behavioral regulation                   | • Difficulty in setting up PA goals (mostly because of a lack of knowledge about PA options) | • Adolescents and young adults with IDs need to be facilitated/supported in formulating specific PA goals. |
|                                        | • Difficulty with planning PA (eg, mostly because of the dependency on others and goal conflict) | • Adolescents and young adults with IDs need to be facilitated/supported in planning PA. |

| Opportunity                              |                                        |                    |
| Social                                  |                                        |                    |
| Social influences                       | • Lack of social connectedness; having no one to do PA with (eg, friends or loved ones) | • Adolescents and young adults with IDs need to have the opportunity to engage in PA together with someone (ie, social connectedness). |
|                                        | • Not having a role model (ie, seeing other people engage in PA as well) | • Adolescents and young adults with IDs need a role model regarding PA. |
|                                        | • No guidance during PA or no practical support | • Adolescents and young adults with IDs need to have more (social and practical) support from others when engaging in PA. |

| Motivation                               |                                        |                    |
| Reflective                               |                                        |                    |
| Intentions                               | • No motivation to engage in PA        | • Adolescents and young adults with IDs need to be encouraged in feeling a sense of enjoyment when engaging in PA. |

| Beliefs about capabilities               | • Insecure about own capabilities and skills (eg, afraid of doing something wrong, afraid of the reaction of others, afraid of PA being too difficult, or afraid of being laughed at) | • Adolescents and young adults with IDs need to build self-confidence regarding PA (ie, increase self-image and confidence in their ability to perform certain activities). |

| Beliefs about consequences               | • Insecure or ashamed about weight or body shape |                    |
|                                        | • Lack of awareness about the health consequences of physical inactivity | • Adolescents and young adults with IDs need a better understanding of the benefits of PA. |

\(^a\)PA: physical activity.  
\(^b\)ID: intellectual disability.

**Step 4: Link Intervention Goals to COM-B Components and TDF Domains**

In step 4, the PI assigned the 10 intervention goals to the specific COM-B and TDF components of the BCW (Table 2). From this behavioral analysis, it can be inferred that psychological capability, social opportunity, and reflective motivation would be the first targets to focus on for increasing PA levels in adolescents and young adults with IDs.

**Stage 2: Identify Intervention Options and Steps 5 and 6 (Identify Intervention Functions and Policy Categories)**

Linking the selected COM-B components and TDF domains from step 4 to the intervention functions proposed by the BCW guide, all 9 intervention functions could be applied. In total, 7 intervention functions were chosen to further focus on: education, persuasion, incentivization, training, environmental restructuring, modeling, and enablement (see the detailed argumentation in Multimedia Appendix 2). The 2 other intervention functions were not selected as they were deemed (1) less practicable to apply as a research team (ie, restriction).
and (2) less acceptable or unlikely to have an impact on adolescents or young adults with IDs (ie, coercion).

Stage 3: Identify Content and Implementation Options

Step 7: Identify BCTs

Overview

A total of 12 BCTs were selected to proceed with. We have outlined our selection and reasoning for each selected BCT within the specific intervention function in the following sections. Multimedia Appendix 3 provides a detailed explanation of all the BCTs that were considered for the 7 intervention functions that came out of step 5, along with the accompanying rationale for why they were chosen and others were not.

Education

Participants with IDs expressed a lack of knowledge about PA options (eg, what is out there, what suits the person best, and where can it be done). For this reason, it was considered valuable to provide information on various PA options. However, the only BCTs formulated within the taxonomy by Michie et al [41] related to providing information are pertaining to consequences (ie, social, emotional, environmental, and health). Although participants mentioned the value of information about the health benefits of PA in previous stages, we collectively decided not to place a direct emphasis on information provision within our intervention. Participants do not desire an intervention centered on “learning” or “teaching” (see also their preference for an intervention outside the school context). According to them, the focus should be on enjoyment. Nonetheless, we anticipate that the target audience may indirectly experience positive effects through the intervention. In this regard, the BCT “salience of consequences” (under the persuasion intervention function) seemed more applicable as it focuses on using methods to specifically emphasize the consequences of performing a behavior, making them more memorable, which goes beyond mere information provision about these consequences. “Feedback on behavior” was also selected as participants indicated that they would like to receive feedback on how well they are performing the behavior.

Persuasion

The BCT “credible source” was valued by participants, but opinions varied on its presentation. Some preferred health professionals using fun visual communication, whereas others liked animated movies. In this target group, experts or influencers explaining PA benefits in an engaging way were considered more appealing than scientific videos. Furthermore, the significance of “verbal persuasion about capability” was strongly emphasized. Given the low self-efficacy within this population, offering verbal persuasion to counteract self-doubt was deemed highly valuable for adolescents/young adults with IDs.

Incentivization

Owing to the prominent role of social factors, we observed that the BCT “social reward” would be highly motivating for this target group.

Environmental Restructuring

Cocreators highlighted the importance of social connectedness and support in encouraging PA. As a result, we expect the greatest impact from recognizing and meeting their social needs, which entails a “restructuring of their social environment.”

Modeling

Participants expressed that it would be motivating to witness others engaging in PA around them, whether in person or indirectly through influencers such as on TikTok (serving as role models). The cocreators showed enthusiasm for involving influencers they admired to encourage PA. Considering budget limitations, it would not be feasible for us to incorporate a well-known influencer into the intervention. However, this does indicate that “demonstration of the behavior” might be an interesting BCT to include.

Enablement

The entire development process highlighted a strong emphasis on the importance of social support and social connections, whether from friends or individuals with expertise in PA (ie, social support BCT—practical, emotional, and unspecified). Participants expressed increased confidence when they could openly discuss their goals and challenges with friends, and their motivation to engage in PA was significantly higher when they could do it with others rather than exercising alone. Peer support was generally preferred, although younger adolescents with IDs (aged 14 years) also mentioned the potential for support from family members. Furthermore, participants agreed that having a list of goals to choose from would make it easier for them rather than having to come up with their own goals (ie, goal setting BCT). Most participants recognized the importance of “action planning” as a valuable BCT. However, insights from teachers revealed that adolescents and young adults with IDs often struggle with tasks such as maintaining a personal agenda or planner, which is typically managed by parents or carers. Therefore, it would be crucial to offer guidance during action planning. Creating a detailed action plan independently, including specifics such as what, when, where, and with whom, seemed challenging and burdensome for this group. Simplicity and minimizing cognitive effort were emphasized as essential factors. Similarly, the collaborative review and adjustment of the behavioral goal with individuals with IDs based on their progress was seen as advantageous. It was considered feasible to engage in close negotiation with them to either retain the same goal, make minor adjustments, or establish a new goal if necessary (referred to as “reviewing behavior goals”). The primary focus in this case is on shared decision-making and active involvement.

Training

The only BCT that we considered including under the “training” intervention function is “demonstration of the behavior.” However, we view this as more related to modeling behavior rather than as actual behavior demonstration within a training context. In the course of our intervention development, it became evident that the primary focus should be on addressing social needs and creating enjoyable experiences rather than on formal training in activities. Therefore, the “training” intervention function was omitted from this phase onward.
**Step 8: Identify Mode of Delivery**

On the basis of the literature, an mHealth app appeared to be a good and feasible approach for adolescents and young adults with IDs and, therefore, was verified during the fifth cocreation session. The cocreators indicated that they preferred an mHealth app with a straightforward design that clearly indicated its purpose and functionality (e.g., through an introductory video). They suggested that the app should be visually appealing, with minimal text, bright colors, and no foreign-language words. They also suggested that a game component or chat feature would be of added value. Cocreators would not use an app that they had to pay for, was childish, or looked rather old-fashioned. They mentioned preferring not to receive too many notifications (i.e., no more than 1 notification per day). Finally, this is a group that often faces negative comments and experiences of failure. When talking about mHealth, this also emerged as an aspect to be considered (e.g., by keeping the reactions that can be given to each other in an app controlled).

At the end of the fifth cocreation session, cocreators indicated that an app alone would not be sufficient to encourage them to engage in (more) PA. They suggested that an app could be integrated into a broader intervention but not be a stand-alone intervention. More specifically, the desire for social connection with peers and social integration in real life was found to be a more important theme in intervention development. Therefore, the decision was made to focus on a buddy system as many people with IDs reported a lack of friendships with peers outside school, resulting in decreased opportunities to engage in PA during leisure time. To facilitate this buddy partnership, we chose to work with a buddy without IDs who could offer practical support during the intervention period, which reduced the reliance on context alone (i.e., parents or carers) to guide the intervention implementation.

**Move It, Move ID! Intervention**

On the basis of the systematic steps of the BCW combined with a cocreational approach, the Move it, Move ID! intervention ultimately consists of a buddy partnership with a supporting app (i.e., dyadic intervention). Figure 2 illustrates the development process, showing how COM-B components, intervention functions, and behavior change techniques (BCTs) are intertwined with the selected intervention design. A more in-depth description can also be found in Multimedia Appendix 3.

![Figure 2](https://formative.jmir.org/2024/1/e51693)

---

**Figure 2.** Visualization of the development process showing how Capability, Opportunity, and Motivation–Behavior (COM-B) components; intervention functions; and behavior change techniques (BCTs) are intertwined with the selected intervention design. PA: physical activity; TDF: Theoretical Domains Framework.

During an intervention period of 3 months, adolescents and young adults with IDs will be paired with a buddy without IDs of the same age range and encouraged to try out weekly PAs in Ghent (Flanders, Belgium). Buddies without IDs will be students (aged 17-23 years) of the coauthors of this paper and will receive 3 short training sessions (i.e., maximum of 1 hour per session) on their role and responsibilities as a buddy.

Although the buddy partnership forms the core of the intervention, a supporting app will also be provided in which buddies and participants with IDs will be in direct contact with each other (an explanation of the scope and screenshots of the supporting app can be found in Multimedia Appendix 4). The app is considered a private space between participants with IDs and their buddies without adding parents or carers to the app. The PI will add a range of activities (e.g., walking a shelter dog, dancing, playing Kubb, and undertaking an altitude trail) to the app at the start of the intervention. Participants will have the autonomy to choose whether they want to try an activity by agreeing (swiping right) or disagreeing (swiping left) with a proposed activity. When both the participant with IDs and the
buddy agree with a certain proposed activity, they will receive a pop-up to a chat function to make arrangements and schedule this activity on their shared agenda. The buddy will take the lead in this process. During an activity, the buddy can provide feedback such as how well they perform the behavior or words of encouragement. On the app pinboard, pairs can share photos of the activity they performed together, give comments, and also rate the activity afterward. This allows them to keep track of successful activities and identify less enjoyable ones.

Discussion

Principal Findings

This paper describes the systematic, theory-driven development of a lifestyle intervention to promote PA in adolescents and young adults with IDs using the BCW planning model combined with cocreation sessions involving the target group. The purpose of this transparent and detailed description was 2-fold. First, it aimed to develop a PA promotion intervention by identifying intervention components and BCTs that address the specific needs of this target group. Second, it aimed to encourage future researchers and intervention developers interested in PA among adolescents and young adults with IDs to apply a theoretical planning model in combination with cocreation when designing similar interventions or take the insights described into account in their own intervention development. By transparently describing the theory and BCTs that underpin the intervention, researchers are facilitated in broader evaluations to explore their driving mechanisms. In doing so, we adhered to the Medical Research Council guidelines, which emphasize the importance of theorizing how an intervention works and what works in which setting and identifying its other impacts [65]. This discussion will first delve deeper into the key findings regarding the development of the Move it, Move ID! intervention followed by a reflection on the experience of the development process by combining the BCW and cocreation.

The development process underscored the essential importance of collaborating with the target group as the intervention looks different from what the research team had envisioned in the project proposal (ie, developing an mHealth app for young people with IDs targeted at promoting PA) with a thorough argument that adaptations are necessary from the perspective of the target group itself. In that regard, the combination of actively involving the target audience and applying a clear and scientific planning model was crucial. The most prominent planning models that are currently proposed to guide the development of effective interventions are Intervention Mapping [72] and the BCW [33]. Intervention Mapping includes 6 different steps to rigorously select determinants, performance, and change objectives using appropriate methods and strategies [72]. Although Intervention Mapping is comprehensive, its level of detail makes it more complex and, thus, less feasible, especially in combination with cocreation [73]. The BCW, in contrast, is more open, practical, and flexible as it was developed with interdisciplinary application in mind [37]. However, in applying the BCW within this project, it was noticed that its openness and flexibility could also lead to variable interpretations, with judgments from the researchers often required throughout the development process (eg, step 5). The variations in intervention development mainly depended on the resources available to the project team (eg, affordability and practicability). Moreover, even within this small research team of the Move it, Move ID! intervention, different steps within the BCW were sometimes interpreted differently. Some researchers saw the formulation of barriers to and facilitators of PA as belonging to steps 2 and 3 (as it was described in this paper), whereas others ascribed this to step 4 [74]. In our opinion, assigning these aspects to a certain step will not differ much from the behavioral diagnosis one will eventually arrive at. We consider it more important to discuss the different steps thoroughly within the research team so that the decisions made are well informed and can be argued for. By going through the different steps of the BCW, we learned that interventions can look different depending on the choices made without necessarily making one intervention better than the other. Further research should subsequently indicate which
interventions prove to be effective and why (ie, identifying driving mechanisms [65]). This could potentially lead to the formulation of guidelines outlining the best possible choices that could be made during intervention development within a specific target group and setting.

Nevertheless, by applying the theoretical planning model, the PI had a clear goal in mind in setting up the structure and flow of the cocreation sessions. In doing so, the BCW was instrumental in identifying an informed behavioral diagnosis and choosing which BCTs would be most applicable to have an impact on PA behavior change within this target group and setting. Although the literature suggests that the use of theory in intervention development is key [2,20,33-36], a 2019 meta-analysis formulated that the effectiveness of interventions would be less influenced by whether they are theoretically developed than by the specific BCTs used [75]. In contrast, we believe that both (ie, theory and choice of BCTs) are intertwined. A 2017 systematic review found that lifestyle change interventions for people with IDs aimed at improving PA levels typically used 5.9 BCTs, with “provide information on consequences of behavior in general,” “plan social support/social change,” “provide instruction on how to perform the behavior,” and “goal setting (behavior)” being the most frequently used BCTs [31]. However, 73% of the studies did not use any theoretical framework for intervention development [31]. After completing the full behavioral diagnosis based on the BCW, we included 12 BCTs in our intervention. This is not to say that the inclusion of more BCTs would be better but, rather, that the transparent description of the BCW steps made more evident why these specific BCTs were chosen and how they are intertwined by means of the intervention design. This demonstrates why we believe that the use of theory and the selection of BCTs are strongly connected.

Linking cocreation to the BCW, our goal was to create an intervention that starts with the experiences of the target group. This approach was intended to enhance the effectiveness and sustainability of the intervention by making it more suitable and acceptable for the target audience [10,44-48]. Cocreation with the target audience extended well beyond the described cocreation sessions for intervention development in this project. As the project progressed toward the effect study, ongoing collaboration continued with 2 coresearchers with IDs (ie, inclusive research [48]). These coresearchers maintained regular meetings (every 2 weeks) with the PI (LM) at the Department of Movement and Sports Sciences (Ghent University), actively engaging in various facets of the project. Their responsibilities included assessing prototypes of the app; offering feedback on the training of buddies; testing measurement instruments (comprising questionnaires, interviews, and accelerometers); providing insights into the recruitment strategy; contributing to the development of promotional materials such as flyers, information letters, and informed consent forms; and participating in efforts to enhance the project’s visibility among their peers, classmates, and other stakeholders. This ongoing collaboration with the coresearchers was purposefully designed to ensure the continued accessibility of the project even beyond the initial phase of intervention blueprinting. To conclude, the described intervention development addresses an important and often overlooked population that experiences health disparities and is at higher risk of physical inactivity and related health issues. This study highlights the importance of considering the unique requirements of people with IDs to develop tailored interventions that effectively meet their needs.

Limitations and Strengths

This study has some limitations. First, a wide age range of adolescents and young adults with IDs was included, which might make us question whether this intervention is applicable to both an individual aged 13 years and one aged 22 years. Indeed, younger adolescents with IDs (ie, aged 14 and 15 years) did indicate that they would be open to involving parents as buddies within an intervention, whereas this was not the case for young adults (ie, aged 17-22 years old). Choosing a tighter age limit (eg, ages of 13-16 years or 17-22 years) is recommended in future intervention development. Second, of the 23 coresearchers, 5 (22%) had a comorbidity with autism spectrum disorder, and 1 (4%) adolescent had attention-deficit/hyperactivity disorder. This is considered a limitation as previous research has found different effects on PA among youth who have IDs and youth who have other developmental disabilities in addition to IDs [8], suggesting that further comparison of PA experiences between these groups is warranted. Within the further intervention development, little weight was given to these comorbidities. In contrast, we can also conclude that their perspective was included from the start of intervention development as they also acted as cocreators and this was not an exclusion criterion. Third, following the prioritization of young people with IDs as cocreators in the initial stages of blueprinting an intervention idea, we were unable to gather input from buddies (peers intended to be matched with the participants with IDs) and consider the broader context of individuals with IDs in the actual development phase of the intervention. This constraint was due to the project’s timeline. In light of this constraint, we recommend that future intervention developers consider including these stakeholders in subsequent phases of intervention development. Their perspectives and insights are invaluable in creating interventions that are comprehensive, inclusive, and truly reflective of the needs and dynamics of the entire participant group. The greatest strength of this study was the fact that a theoretical planning model was used in combination with cocreation to develop a PA promotion intervention for this target group. In this way, it addressed the two main reasons why current interventions often prove to be ineffective: (1) a lack of use of theory and (2) a lack of population-specific research. To the best of our knowledge, this is the first study that describes the collaborative development of a PA promotion intervention for and with adolescents and young adults with IDs. Within the Move it, Move ID! project, the decision was made to work only with participants with mild to moderate IDs; consequently, the findings cannot be extended to the target group of severe or profound IDs. Although future research should focus on the representation of all people with IDs in health research, the fact that a specific group was chosen to truly tailor an intervention to their needs can also be seen as a strength.
Conclusions

The Move it, Move ID! intervention was developed based on the BCW in combination with cocreation. Going through this process was seen as an added value by the research team, which makes it highly recommended to allocate adequate time, budget, and experienced scientific staff for intervention development. By systematically identifying the needs of young people with IDs and linking them to theoretical concepts step by step, cocreators with IDs emphasized the importance of face-to-face interactions and social components in PA promotion interventions. They indicated that relying solely on an mHealth app would not fulfill their social needs. The intervention will consist of a dyadic approach in which young individuals with IDs are paired with a peer without IDs to engage in PAs together, with an app solely providing support within this partnership. The detailed and transparent development process described is a valuable blueprint for practitioners wanting to integrate the BCW and its associated BCTs, in combination with actively involving the target group, into their intervention development for people with IDs.

Acknowledgments

The authors wish to thank the adolescents or young adults and teachers who expressed their opinions during intervention development for this project. This work was supported by the Research Foundation–Flanders under grant 11F3621N (2020-2024).

Data Availability

The data sets generated and analyzed during this study are not publicly available to protect participants’ privacy and confidentiality because of the small number of participants but are available from the corresponding author upon reasonable request. In addition, the upcoming effect study has been preregistered at the Open Science Framework, where all other materials concerning this project can be found.

Authors’ Contributions

LM, SC, G Cardon, G Crombez, and GVH conceptualized the study. LM collected the data (ie, organized the cocreation sessions) and wrote the original draft. JL assisted in combining the Behavior Change Wheel planning model and a cocreational approach. SC, JL, G Cardon, G Crombez, and GVH edited the manuscript and provided feedback. All authors have read and approved the final manuscript.

Abstract

Background: Web-based surveys increase access to study participation and improve opportunities to reach diverse populations. However, web-based surveys are vulnerable to data quality threats, including fraudulent entries from automated bots and duplicative submissions. Widely used proprietary tools to identify fraud offer little transparency about the methods used, effectiveness, or representativeness of resulting data sets. Robust, reproducible, and context-specific methods of accurately detecting fraudulent responses are needed to ensure integrity and maximize the value of web-based survey research.

Objective: This study aims to describe a multilayered fraud detection system implemented in a large web-based survey about COVID-19 attitudes, beliefs, and behaviors; examine the agreement between this fraud detection system and a proprietary fraud detection system; and compare the resulting study samples from each of the 2 fraud detection methods.

Methods: The PhillyCEAL Common Survey is a cross-sectional web-based survey that remotely enrolled residents ages 13 years and older to assess how the COVID-19 pandemic impacted individuals, neighborhoods, and communities in Philadelphia, Pennsylvania. Two fraud detection methods are described and compared: (1) a multilayer fraud detection strategy developed by the research team that combined automated validation of response data and real-time verification of study entries by study personnel and (2) the proprietary fraud detection system used by the Qualtrics (Qualtrics) survey platform. Descriptive statistics were computed for the full sample and for responses classified as valid by 2 different fraud detection methods, and classification tables were created to assess agreement between the methods. The impact of fraud detection methods on the distribution of vaccine confidence by racial or ethnic group was assessed.

Results: Of 7950 completed surveys, our multilayer fraud detection system identified 3228 (40.60%) cases as valid, while the Qualtrics fraud detection system identified 4389 (55.21%) cases as valid. The 2 methods showed only “fair” or “minimal” agreement in their classifications (κ=0.25; 95% CI 0.23-0.27). The choice of fraud detection method impacted the distribution of vaccine confidence by racial or ethnic group.

Conclusions: The selection of a fraud detection method can affect the study’s sample composition. The findings of this study, while not conclusive, suggest that a multilayered approach to fraud detection that includes conservative use of automated fraud detection and integration of human review of entries tailored to the study’s specific context and its participants may be warranted for future survey research.

KEYWORDS
web-based survey; data quality; fraud; survey methodology; COVID-19; survey; fraud detection; Philadelphia; data privacy; data protection; privacy; security; data; information security; data validation; cross-sectional; web-based
Introduction

Web-based survey research has become increasingly common in recent years, particularly because of its ability to reach broad populations efficiently and economically [1]. Web-based surveys involve inviting potential respondents to complete questionnaires through digital platforms that manage how questions are presented and how data are collected and stored [2,3]. These research methods have been used in response to the difficulties faced in traditional survey methods (ie, recruiting participants using flyers, newspaper or radio or television advertisements or spreading by word of mouth and collecting data in person using computer-assisted survey instruments or over the phone), especially in reaching underrepresented populations [4,5].

The advantages of web-based surveys include eliminating the requirement for face-to-face interaction, offering flexible access to surveys, removing transportation and logistical barriers, and preserving anonymity. In recent years, COVID-19 pandemic restrictions limited opportunities for in-person research and provided additional justification for researchers to adopt web-based study designs while leveraging social media recruitment methods to reach diverse populations [6-9].

As web-based recruitment and survey methods in health research have become more ubiquitous and refined, so too have methods of web-based research fraud [10,11]. Fraud can manifest in multiple ways. For example, individuals may misrepresent themselves in order to appear eligible for a study or may submit duplicate surveys in order to receive multiple incentive payments. Additionally, fraudulent data may also come from automated operations enacting fraud at a large scale, often referred to as “bots” [11,12]. These methods are often used to target surveys offering participation compensation payments and can be lucrative when aimed at large web-based surveys, even those offering small payments [9,13]. Such fraud poses risks not only to research resources but also, importantly, to the integrity of research findings, as fraudulent data can distort results and undermine data quality. Specifically, fraudulent responses can introduce additional random noise or potentially add systematic bias to the data [14-16].

In response, researchers, companies operating in the digital research space (eg, Qualtrics) [17], and organizations interested in digital data integrity (eg, Google) [18] have developed methods to address fraudulent activity. The research community has crafted recommendations for fraudulent data identification and participant identity verification protocols [13,19,20]. Platforms specializing in web-based survey research such as Qualtrics [17] and Amazon Mechanical Turk [21] have also developed fraud detection features that accompany their services. While these proprietary systems for fraud detection offer a simple, automated approach to improving data quality, little information is available about the mechanisms they use [22]. Fraud detection systems often obscure details about how their validation process functions as an important strategy to protect the integrity of the fraud detection system, making it more difficult for fraudulent participants to circumvent protections. However, obfuscation also introduces questions about how fraud detection algorithms alter study samples and whether they introduce bias into analyses [20].

Little research has compared how fraud detection strategies impact study sample composition or examined their comparative effectiveness in correctly identifying fraud [22-25]. By accurately identifying and removing fraudulent responses to web-based surveys, research can improve data quality and strengthen the overall rigor of their methods. Robust, reproducible, and context-specific methods of accurately detecting fraudulent responses are needed to ensure integrity and maximize the value of web-based survey research. This paper aims to (1) describe the multilayer fraud detection techniques we developed and implemented in a large web-based survey collecting data about attitudes, beliefs, and behaviors related to COVID-19; (2) examine the degree of agreement between our multilayer fraud detection strategy and the proprietary fraud detection system used by Qualtrics; and (3) compare the study samples that resulted when using each of the 2 fraud detection methods.

Methods

Study Design

We collected data from November 2021 through February 2022 for the PhillyCEAL Common Survey, a cross-sectional study using a web-based survey to assess how the COVID-19 pandemic and response have impacted individuals, neighborhoods, and communities across the city of Philadelphia, Pennsylvania. The Checklist for Reporting Results on Internet E-Surveys was used to guide the reporting of our methods and results (Multimedia Appendix 1) [26]. The Qualtrics web-based survey platform was used to design the survey and automatically capture responses in a database. The usability and technical functionality of the survey were tested by the study team before launching the survey. Individuals were eligible to participate if they (1) resided within Philadelphia County (coterminous with the city limits) and (2) were at least 13 years of age. We recruited participants through advertisements on social media platforms (ie, Facebook, Instagram, Twitter, and Reddit) and referrals from community partners (including one partner that provided study recruitment materials to individuals via door-to-door canvassing). The recruitment process directed individuals to a voluntary, open web-based survey, where they completed a screener consent form and answered a series of questions to determine eligibility and record basic demographic information. We did not allow participants to change their answers through a back button feature.

Eligible participants were automatically directed to the full study consent form. Following consent, participants were asked to complete a 20-minute questionnaire about their experiences, behaviors, and beliefs about COVID-19, risk of infection, testing, vaccination, treatment, and knowledge and beliefs about COVID-19 clinical trials. Participants completed 1 of 3 slight variations of the survey (ie, the adult survey, the parent survey, and the youth survey), where additional questions or slight changes to wording were used on the parent and youth surveys. Participants completed only 1 of these 3 potential variations (ie, survey groups were mutually exclusive), with participants of any age who reported having minor children completing the parent survey (103 questions), participants ages 25 years or
younger and not having minor children completing the youth survey (126 questions), and all other participants completing the adult survey (92 questions). To reduce participant burden, we used adaptive questioning to reduce the number of questions displayed based on their answers. Participants saw an average of 6 questions per page.

Participants were excluded if they did not complete the entire survey (n=2930) or did not provide a residential zip code matching 1 of the 48 zip codes of Philadelphia County (n=647). Participants confirmed eligible and marked as complete by both Qualtrics automation and our manual review of the data were compensated with a US $15 electronic gift card. To protect participant data, the web survey data were downloaded to a secure university server, deidentified by replacing contact information with unique IDs, and stored in a restricted folder with password protection.

Ethical Considerations
All participants completed an informed consent process before proceeding to the survey. Ethics approval was obtained from the institutional review board at the University of Pennsylvania (protocol 848650).

Preliminary Fraud Protection
Given the prevalence of fraud and duplicate responses in web-based survey research, we used several strategies to prevent fraudulent participants from accessing and completing the survey, serving as a baseline level of fraud protection for both our multilayer and the Qualtrics detection methods. Our preliminary line of defense against fraud was targeted toward nonhuman interferences such as bots. To proceed with the survey, all respondents had to pass a built-in Turing test provided by Qualtrics using Google’s reCAPTCHA (version 2) antifraud technology [27]. Depending on the respondent’s on-device saved data such as browser cookies, they either had to click a checkbox or solve a simple image challenge to pass the reCAPTCHA (version 2) test.

Since sophisticated bots can trick the reCAPTCHA (version 2) test [28], we added a honeypot question as a second line of defense against bots. Honeypots are survey questions hidden from rendering on the screen using custom JavaScript code [11]. They are, therefore, invisible to human respondents but accessible to bots that do not rely on what is rendered on screen. Since the honeypot is not visible to human respondents, any responses to the honeypot would immediately disqualify the entire survey response and end the survey.

We also created unique URLs for each recruitment source and advertisement campaign for the study. The unique URLs enabled us to identify the origin (recruitment source and ad campaign) of each survey response. This allowed us to individually monitor and suspend links that became the target of fraudulent survey responses.

Multilayer Fraud Detection Methods

Real-Time Exclusion of Fraudulent Responses
We implemented a suite near real-time data verification procedures to assess the veracity of data as they were collected, including techniques based on recommendations from prior research as well as several manual checks that were developed specifically for this study. A research team member would individually inspect submitted responses and label responses as fraudulent using the following criteria: (1) participants were asked to provide their residential address and the colloquial name of their neighborhood. Responses were marked as fraud if the neighborhood name provided did not match a standard Philadelphia neighborhood name corresponding to the residential address provided or any adjacent neighborhood; (2) the residential address provided did not match an existing address in Philadelphia County [20,23,29]; (3) the survey had the same start times and stop times plus or minus 1 minute as 2 or more other submitted surveys (rapid survey submission) [11,29]; (4) the respondent’s email address matched a previously enrolled participant’s email address [11,20]; (5) the zip code provided as part of the residential address was nonstandard (ie, a post office box code or a unique code) [20,23]; (6) the residential address had already been reported by at least 2 other respondents [20,23]; or (7) the URL from which the response was referred did not match any of the URL links distributed by the study team during recruitment. Responses labeled as fraud during real-time validation were not eligible to receive survey compensation.

Automated Post Hoc Identification of Fraudulent Responses
We developed a set of automated post hoc techniques designed to detect fraud that our real-time procedures may not have captured. Three criteria were developed for this post hoc fraud identification based on recommendations from prior research [11,20,22,23,29-32]. Since these criteria only identify suspicious entries and do not definitively prove that an entry is fraudulent, responses were labeled as fraud only if they satisfied 2 or more criteria. We settled on using a threshold of 2 criteria (rather than 1 or 3) in order to balance concerns about the potential of each of our 3 criteria to incorrectly label a participant as fraud with the necessity to exclude causes that showed strong evidence of fraud. The criteria were as follows:

1. In response to a free text item at the end of the survey soliciting additional comments or questions from the participant, the submitted survey included text that was identical to text submitted by other respondents. We considered a free text response an identical match if it was among free text entries of 1 word or greater that were repeated 100 or more times, free text entries of 2 words or greater that were repeated 10 or more times, or free text entries of 3 words or greater that were repeated 3 or more times (see Table S1 in Multimedia Appendix 2 for list of unique text strings excluded and their frequency in the full set of responses).
2. The IP address of a response belonged to a virtual private network or data center or originated from outside the United States, as determined by using a security service for proxy virtual private network detection and IP location information [33]; and
3. Responses provided in the main survey were inconsistent with responses to the same items in the screener for one or more key items that would not be expected to be variable
(ie, age, zip code, number of adults living at home with the participant, number of minors living at home with the participant, Hispanic or Latinx ethnicity, “Have you ever been tested for COVID-19?,” and “Have you received at least 1 dose of the COVID-19 vaccine?”).

Qualtrics Fraud Detection Methods

Qualtrics is a widely used web-based survey platform that allows users to create surveys with complex flow logic and customizable visual design. Qualtrics surveys are easily optimized for use on mobile devices and can display a wide variety of question types on both computer and mobile phone interfaces. Another key strength of the Qualtrics platform is its integration of 1-click translation, allowing users to quickly switch between various languages. This was crucial for our study, which recruited participants from diverse populations across Philadelphia and was available in English, Spanish, and Mandarin. In addition to these valuable features, Qualtrics also offers tools for detecting fraudulent survey responses. This automated and user-friendly system for fraud detection has the potential to help researchers improve data quality in their web-based surveys. Given the lack of research exploring how these consumer tools compare to existing published protocols for fraud detection, we sought to compare our multilayer fraud detection methods to the system used by Qualtrics.

The Qualtrics fraud detection system relies on Google’s reCAPTCHA (version 3) and Imperium’s RelevantID antifraud technologies. Both tools rely on proprietary machine learning models that analyze passive and behavioral data, browser interactions, and respondent metadata to identify abuse and fraud [18,34,35]. Unlike the reCAPTCHA (version 2) test respondents had to solve at the start of the survey, bot detection using reCAPTCHA (version 3) does not present respondents with an image challenge nor block respondents and bots from proceeding with the survey. Instead, it returns a score (Q_RecaptchaScore) between 0.0 and 1.0 that Qualtrics records as part of the survey response. We used the recommended 0.5 score as the threshold for fraud, where a score under 0.5 is deemed likely to be a bot [17,18].

Like reCAPTCHA (version 3), RelevantID does not prevent bots from completing the survey. Instead, it attaches a score (Q_RelevantIDFraudScore) between 0 and 130 to each survey response. We followed Qualtrics’ recommendation in interpreting a score ≥30 as fraudulent and likely a bot [17]. In addition to bot detection, RelevantID identifies duplicate responses through digital fingerprinting and proprietary detection algorithms [34]. Qualtrics then attaches another score (Q_RelevantIDDuplicateScore) between 0 and 100 to the survey response. We followed the suggested score threshold where any score ≥25 is considered a duplicate [17].

Statistical Analysis

Agreement and Comparative Performance

The classification tables were created to display the degree of agreement between the 2 fraud detection methods for the full sample and for each of the 3 survey-type categories (ie, adult, parent, and youth).

Impact of Fraud Detection Method on Sample Characteristics

Descriptive statistics were computed for the full sample of responses, the subset classified as valid by our multilayer fraud detection method, and the subset classified as valid by the Qualtrics fraud detection method. As these 3 sets of responses are not mutually exclusive, we did not directly compare them statistically.

To test for differences between fraudulent and valid responses as classified by each fraud detection method, statistical comparisons were conducted for key study variables between the mutually exclusive sets of responses classified as fraudulent or valid within each method. Specifically, we used chi-square tests for categorical variables, 2-tailed t tests for normally distributed continuous variables, and Mann-Whitney U tests for continuous variables that were not normally distributed. The results of these analyses are presented in Table S2 in Multimedia Appendix 2 for the multilayer method and Table S3 in Multimedia Appendix 2 for Qualtrics.

To assess the degree to which the 2 fraud detection methods would impact the distribution of a key study variable, the point estimate and 95% CI were calculated for vaccine confidence by racial or ethnic group for each fraud detection method and for the entire sample without any fraud mitigation.

Variations in Survey Responses During Study Period

A time-series plot was created to show the cumulative responses to the study survey over time and their fraud classification by each of the 2 fraud detection methods. This plot highlights the periods in which social media recruitment campaigns are active and can also shed light on how the 2 fraud detection methods diverge in their classification of responses during different periods of high survey response. Additionally, we present a time-series plot showing the proportion of responses classified as fraud across the study period, including smooth locally weighted smoothing lines to visualize the trends over time. All analyses were performed with R (version 4.1.0; R Foundation for Statistical Computing).

Results

Multilayer Fraud Detection Methods

A total of 7950 completed survey responses were received. See Figures 1 and 2 for an overview of fraud detection results from our multilayer fraud detection methods. Using the real-time exclusion criteria of the multilayer fraud detection method, 4207 (52.92%) entries were classified as fraud. Of those classified as fraud, 1242 (29.52%) reported a neighborhood name that did not match their residential address, 648 (15.4%) provided an invalid residential address, 1397 (33.21%) displayed rapid reCAPTCHA response, 42 (1%) used a repeated email address, 77 (1.83%) reported a nonstandard zip code, 398 (9.46%) reported a residential address that was used more than twice, and 403 (9.58%) did not have a valid recruitment URL. After the real-time exclusion, 3743 (47.08%) cases remained classified as valid.
Our automated post hoc fraud detection criteria identified additional cases as fraud. Of the remaining 3743 initially valid cases, 1561 (41.70%) cases had a duplicate response in the free text entry item, 394 (10.53%) cases had an IP address from outside the United States or from a virtual private network, and 619 (16.54%) had inconsistencies between the screener and main survey on at least 1 key item. Using our “2-strike” rule, we classified an additional 515 (13.76%) responses as fraud for meeting at least 2 of the above criteria. Thus, our multilayer fraud detection strategy classified a total of 4722 (59.40%) entries as fraud and 3228 (40.60%) entries as valid.

**Qualtrics Fraud Detection Methods**

The Qualtrics fraud detection methods identified 498 (6.26%) cases as duplicates by the RelevantID DuplicateScore. The Qualtrics fraud detection strategy classified a total of 3561 (44.79%) entries as fraud (ie, meeting one or more of the 3 criteria above) and 4389 (55.21%) entries as valid.

**Agreement and Comparative Performance**

Table 1 presents confusion matrices showing the degree of agreement between our multilayer fraud detection method and the Qualtrics fraud detection method for the full sample and each survey-type category. The interrater reliability indicated “fair” or “minimal” agreement between the 2 methods for the full sample ($\kappa=0.25$; 95% CI 0.23-0.27), “moderate” or “weak” agreement for the adult ($\kappa=0.48$; 95% CI 0.43-0.53) and youth ($\kappa=0.50$; 95% CI 0.43-0.58) surveys, and “slight” or “none” agreement for the parent survey ($\kappa=0.13$; 95% CI 0.10-0.15) [36,37].
Table 1. Confusion matrix and interrater reliability ($\kappa$) between our multilayer fraud detection system and the Qualtrics fraud detection system for the full sample, only adult surveys, only parent surveys, and only youth surveys.

We conducted sensitivity analyses to assess the impact of choosing a “2-strike rule” for our post hoc fraud detection rather than a “1-strike rule” or a “3-strike rule.” Compared to the “2-strike rule,” which resulted in 515 additional cases being classified as fraud during the post hoc phase of fraud detection, the “1-strike rule” would have classified 2047 additional cases as fraud, and the “3-strike rule” would have classified 12 additional cases as fraud. In terms of agreement with Qualtrics’ fraud detection methods, the “1-strike rule” would have resulted in a $\kappa$ of 0.20 (95% CI 0.19-0.22) for the full sample, and the “3-strike rule” would have resulted in a $\kappa$ of 0.24 (95% CI 0.22-0.26) for the full sample.

Additionally, we explored how the 2 fraud detection strategies compared in their ability to classify cases with validated email addresses as valid entries. Validated email addresses were defined as email addresses ending in “.edu” or “.gov,” indicating an institutional affiliation. Of the 168 cases with validated emails, the multilayer fraud detection system correctly classified 166 (98.81%) as valid, while the Qualtrics fraud detection system correctly classified only 126 (75%) as valid.

**Impact of Fraud Detection Method on Sample Characteristics**

Decisions about which fraud detection strategies to use can impact the results of web-based survey research. Table 2 presents the descriptive statistics for sociodemographic variables, survey metric variables, and key study outcome variables on 3 versions of the data set: the full data set with no fraud detection (n=7950), the cases identified as valid by our multilayer fraud detection methods (n=3228), and the cases identified as valid by the Qualtrics fraud detection methods (n=4389). As these sets are not mutually exclusive, we cannot compare them directly; however, there are clear differences in the distributions of many study variables between the 3 sets. When comparing entries classified as fraud to those classified as valid for each of the 2 fraud detection methods (ie, mutually exclusive sets), all study variables, except for lifetime COVID-19 testing for the multilayer fraud detection, were found to be significantly different for both methods (Tables S2 and S3 in Multimedia Appendix 2).

Table 3 showcases in detail how a key variable of interest to researchers may be affected by using different fraud detection methods. In this data set, vaccine confidence among White respondents was greater when using our multilayer fraud detection ($\mu$=0.867; 95% CI 0.851-0.882) when compared to Qualtrics fraud detection ($\mu$=0.782; 95% CI 0.766-0.798). A similar pattern is seen for Hispanic or Latinx respondents and Black or African American respondents.

Variations in Survey Responses During Study Period The response rate varied throughout the study and was correlated to several social media advertising campaigns and an extended holiday break where no responses were accepted. Figure 3 shows the cumulative number of responses over time, differentiated by fraud detection method and fraud classification. Time periods when social media advertising campaigns were active are highlighted on these plots. Responses tend to increase during social media campaigns. Notably, between January 13 and February 7, 2022, no social media campaign was active, yet a significant number of responses were received (n=766). These responses were largely classified as fraud by our multilayer fraud detection method (n=716, 93.47% classified as fraud) but were often classified as valid by the Qualtrics fraud detection method (n=296, 38.64% classified as fraud). Figure 4 shows the proportion of responses classified as fraud across the study period. The comparative fraud detection between the 2 methods was similar during the first half of the study period (November to December 2021), while the multilayer fraud detection method consistently identified a higher proportion of responses as fraud during the later portion of the study period (January to February 2022).
**Figure 3.** Fraud detection by multilayer fraud detection system and Qualtrics fraud detection system during the study period (November 2021 to February 2022). Highlighted regions indicate periods when social media campaigns were active (November 3-18, 2021; November 29-December 22, 2021; and February 7-10, 2022). Data collection was paused during an extended winter break from December 23, 2021, until January 12, 2022. The dotted vertical line represents January 12, 2022, when data collection was resumed.

**Figure 4.** Proportion of responses classified as fraud by multilayer fraud detection system and Qualtrics fraud detection system during the study period (November 2021 to February 2022). Smooth locally weighted smoothing lines are included to help visualize the trends over time.

**Discussion**

**Principal Findings**

Our multilayer fraud detection methods identified a substantial number of fraudulent cases. However, when comparing our fraud detection methods to proprietary fraud detection systems provided by web-based survey software, we saw low levels of agreement between the 2 methods. Our results highlight how the choice of fraud detection method can alter the distribution of key study variables.

Both our multilayer fraud detection methods and the Qualtrics fraud detection system identified significant levels of fraud; however, the 2 methods differed in which cases they identified as fraudulent and in which they identified as valid. Notably, these differences were most pronounced for participants who administered the survey specifically for parents. It is possible that fraudulent participants made assumptions about eligibility or compensation (eg, parents are a more specific demographic that may be of interest to researchers, and thus, fraudulent entries that claim to be parents may be more likely to screen as eligible and receive compensation) and responded to eligibility questions in ways that guided them to the parent survey. With a greater
number, and perhaps a greater variety, of fraudulent participants, we then may have seen greater variability in the 2 methods’ ability to consistently identify the fraud.

The disagreement between our multilayer fraud detection and the Qualtrics fraud detection suggests that there are important differences in the methodologies being used by the 2 systems, which resulted in differences in classification. To fully understand and compare the relative performance of the 2 systems, detailed information is needed about the methods used by the Qualtrics fraud detection system. It is likely that the features of the RelevantID proprietary fraud detection method used by Qualtrics are intentionally obfuscated to prevent fraudulent participants from undermining its effectiveness. The trade-off for this black box tactic is that researchers who use the Qualtrics platform cannot ascertain how Qualtrics’ fraud detection algorithms function and how these methods compare to alternative fraud detection strategies. There is an inherent tension between transparency (ie, publishing the features of a fraud detection method improves scientific rigor) and defending against fraud (ie, making comprehensive information about a fraud detection method available may enable fraudulent participants to avoid detection) [22]. Additional research is needed to evaluate the effectiveness of proprietary fraud detection systems and compare them to published techniques used by researchers.

For both fraud detection methods, the cases identified as fraud differed in nonrandom ways from the cases classified as valid on key study variables. These differences could have implications for the interpretation of study results; if legitimate survey participants are classified as fraudulent, critical data are lost, and potential bias could be introduced. In addition, many automated fraud detection tools turn to proprietary machine learning data and predictive modeling for fraud detection [22,38]. This could disproportionately affect those with low literacy or barriers to internet access, as fraud detection tools may be more likely to flag them as fraudulent [19]. Given the existing digital divide across racial or ethnic groups [39,40], this may result in the further exclusion of racial or ethnic minorities in research if they are more likely to use older technologies and shared devices at home or in public spaces, such as computers at libraries or community centers (which may trigger the threshold for fraud due to user behavior that is atypical of a single-user device). One approach to overcoming this challenge is to integrate manual inspection of survey entries in place of or in addition to automatic processes that could result in bias [41,42]. However, human inspection of each survey entry can be time-consuming, more variable than automated processes, and could also result in bias. Future work should aim to better characterize subgroups that may be disproportionately flagged by fraud detection systems and develop ensemble approaches that integrate manual and automatic fraud detection while balancing fraud detection accuracy with protections against excluding valid participants.

While overly sensitive fraud detection could result in bias, fraud detection methods that are not sensitive enough to detect fraudulent entries could also add random noise or systematic bias to the data and threaten the integrity of the research [14-16]. It is important to note that we do not have insight into fraudulent participants’ techniques for responding to survey questions. Fraudulent participants may deliberately select specific demographic options (characteristics they believe will be more likely to result in their entry into the study), randomly select their responses, or use some combination of those techniques [9]. Additionally, rapid developments in machine learning and artificial intelligence have increasingly allowed bots to mimic human behavior [11,22], which could contribute to the seemingly human selection of responses on these surveys, including entries into free text fields [43]. Regardless, this analysis demonstrated the importance of developing study-specific fraud detection methods to supplant or supplement the proprietary fraud detection methods of web-based survey platforms.

Another point of note is the decreased effectiveness of fraud detection tools in determining user legitimacy, as major technology companies take increasing measures to protect user privacy. For example, it is common for fraud detection tools to rely on device fingerprinting and browser cookies to help determine the legitimacy of an individual [44]. While these 2 methods are regularly used by advertisers and marketers to track individuals and deliver targeted advertisements, they also provide a way for fraud detection tools to flag known bad actors and differentiate between legitimate and fraudulent responses. However, the invasive and comprehensive nature of device and browser fingerprinting has raised privacy concerns from users and privacy advocates alike [45,46]. Technology companies, such as Apple, Mozilla, and Brave, have in turn introduced measures to hide users’ identities and activity in a bid to protect user privacy. For instance, Apple’s Safari browser on the macOS desktop operating system now strips all unique identifiers from a user’s device profile, so they appear different from millions of other Safari users [47]. These privacy-protecting measures, while helpful in safeguarding an individual’s digital presence, make it more difficult for fraud detection tools to differentiate between a legitimate human and a bot. This could partially explain the discrepancy we found between the fraud detection by Qualtrics using reCAPTCHA and RelevantID and our multilayer fraud detection.

Without a method to make a conclusive determination regarding which entries are truly fraudulent and which entries are genuinely valid, it is difficult to compare the relative performance of our multilayer fraud detection methods with the Qualtrics fraud detection methods. However, several pieces of evidence suggest that our fraud detection methods have advantages over Qualtrics in this study context. First, we saw that for email addresses that had an institutional affiliation (ie, “.edu” or “.gov,” which require identity confirmation and cannot be generated en masse) and thus were presumed to be valid, our fraud detection methods correctly validated 98% (n=166) of cases. In comparison, Qualtrics only validated 75% (n=126) of cases. Second, we saw an unusually large discrepancy between the 2 fraud detection methods during a period when the survey link was open, but no advertising or recruitment had recently been active. During this time when we did not expect to receive responses, we received hundreds of responses that were largely classified as fraud by our fraud detection methods but were generally classified as valid by the Qualtrics system.
While it is possible that valid participants were still able to find and access this survey in the absence of active recruiting, we believe this pattern is evidence of noneligible actors using automated systems in an attempt to gain additional compensation payments from the survey. Taken together, these 2 observations are indirect evidence that our multilayer fraud detection method may have better specificity (ie, can correctly identify valid entries) as well as better sensitivity (ie, can accurately detect fraudulent entries) when compared to the Qualtrics system in this study. While we are unable to conclude that the approach we developed for this study is more or less accurate in identifying fraud when compared to the system used by Qualtrics, we believe these pieces of indirect evidence suggest that using an automated system, such as the one available through Qualtrics, alone may be suboptimal. A multilayered approach was recommended to fraud detection that includes conservative use of automated fraud detection and integration of human review of entries that is tailored to the study’s specific context and its participants.

Limitations

This study is subject to several limitations. First, our comparison of fraud detection methods is limited by the fact that we are unable to definitively determine which entries are valid and which are fraudulent. We selected fraud detection criteria specifically intended to identify repeat respondents (eg, multiple responses providing identical information), fraudulent submissions from outside the Philadelphia region (eg, location verification using IP addresses), and submissions from bots or bot-assisted fraudulent participants (eg, requiring responses that would be difficult to generate via algorithm such as local, colloquial neighborhood names). Applying these criteria may still have resulted in the inclusion of illegitimate responses and the exclusion of legitimate ones. Second, because we cannot know for certain the true fraud status of participants, we are unable to calculate metrics like precision and recall for the fraud detection methods. Future research should aim to establish gold-standard indicators for fraud that could then be used to directly compare the efficacy of the different methods for fraud detection. Third, without knowing how Qualtrics detects fraud, we are unable to determine which components of our strategy may overlap with the Qualtrics strategy. This limits the conclusions we can draw about the comparative effectiveness of these fraud detection methods. Fourth, while we choose to compare our fraud detection methods with the automated systems used by the Qualtrics platform, we believe that similar comparisons and research are also needed with other proprietary fraud detection systems.

Recommendations

The following recommendations are offered for improving data integrity in web-based survey research based on the findings from this study:

- Use a multilayered approach to fraud detection that combines different techniques like bot detection, location verification, consistency checks, and manual review. Relying solely on one method may miss certain types of fraud.
- Carefully evaluate proprietary fraud detection systems and request details on their methodology if possible. Black box methods make it difficult to fully assess their impact on sample composition.
- Avoid overly strict fraud detection rules that may disproportionately exclude valid respondents from vulnerable groups. Balance rigor with inclusion.
- Continuously monitor survey responses over time to identify changes in fraud patterns that may require adjustments to detection methods.

Conclusions

Web-based research and recruitment through social media platforms offer powerful flexibility for researchers to collect large, diverse samples. Web-based surveys, however, are vulnerable to low-quality data from fraud and duplicate entries. Researchers must actively design their web-based studies with this vulnerability in mind and adopt active and adaptable methods of detecting and responding to fraudulent survey responses. Automated, proprietary fraud detection systems offered by web-based survey software may be an important tool in combating fraud, but additional research is needed to evaluate their effectiveness. Human verification of survey entries, while time-consuming, can add another layer of protection and enhance the rigor of web-based survey research. We believe a multilayered strategy that includes a combination of automated fraud detection tools, data enrichment, and human intelligence is the best approach for combating fraud.

Acknowledgments

The authors would like to recognize the contributions of the community partners who helped to distribute the survey as well as the research participants who shared their experiences and insights as part of this research. The authors would also like to thank Gared Harbison for his contributions to validating survey responses and cleaning and managing the data. This work was supported by funding from the National Institutes of Health Agreement OT2HL16156 as part of the Community Engagement Alliance Against COVID-19 Disparities, PhillyCEAL.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.
Authors’ Contributions

SB, PST, JW, AD, AV, and JB conceptualized the research project; SB, PST, JW, and AD cleaned and managed the data; SB conducted formal statistical analysis of the data; AV and JB acquired financial support for the project; SB, PST, JW, JG, and JB developed the methodology for the analysis; SB, PST, and JW managed and coordinated day to day operations for the project; AV and JB provided oversight and leadership for the research; SB and WL created visualizations and data presentations; and SB, WL, PST, JW, and JG wrote the original draft of the paper. All authors reviewed and revised the paper and approved the final version.

Abstract

Background: Interprofessional education (IPE) facilitates interprofessional collaborative practice (IPCP) to encourage teamwork among dental care professionals and is increasingly becoming a part of training programs for dental and dental technology students. However, the focus of previous IPE and IPCP studies has largely been on subjective student and instructor perceptions without including objective assessments of collaborative practice as an outcome measure.

Objective: The purposes of this study were to develop the framework for a novel virtual and interprofessional objective structured clinical examination (viOSCE) applicable to dental and dental technology students, to assess the effectiveness of the framework as a tool for measuring the outcomes of IPE, and to promote IPCP among dental and dental technology students.

Methods: The framework of the proposed novel viOSCE was developed using the modified Delphi method and then piloted. The lead researcher and a group of experts determined the content and scoring system. Subjective data were collected using the Readiness for Interprofessional Learning Scale and a self-made scale, and objective data were collected using examiner ratings. Data were analyzed using nonparametric tests.

Results: We successfully developed a viOSCE framework applicable to dental and dental technology students. Of 50 students, 32 (64\%) participated in the pilot study and completed the questionnaires. On the basis of the Readiness for Interprofessional Learning Scale, the subjective evaluation indicated that teamwork skills were improved, and the only statistically significant difference in participant motivation between the 2 professional groups was in the mutual evaluation scale ($P=.004$). For the viOSCE evaluation scale, the difference between the professional groups in removable prosthodontics was statistically significant, and a trend for negative correlation between subjective and objective scores was noted, but it was not statistically significant.

Conclusions: The results confirm that viOSCE can be used as an objective evaluation tool to assess the outcomes of IPE and IPCP. This study also revealed an interesting relationship between mutual evaluation and IPCP results, further demonstrating that the IPE and IPCP results urgently need to be supplemented with objective evaluation tools. Therefore, the implementation of viOSCE as part of a large and more complete objective structured clinical examination to test the ability of students to meet undergraduate graduation requirements will be the focus of our future studies.

Introduction

Interprofessional Collaboration Between Dentists and Dental Technicians

Conflicts are part of the life of any organization, and the dental professions are not spared. Jurisdictional battles and supremacy struggles are not alien to dentistry [1]. Unfortunately, despite the obvious reported benefits of interprofessional education (IPE) for interprofessional collaborative practice (IPCP) [2], there is a paucity of data about IPE to promote IPCP among dental professionals. Dentists and dental technicians need to communicate effectively and contribute their professional skills to ensure that they make decisions that are in the best interests of their patients [3]. A clear understanding of the interactions of the dental care team can promote teamwork [4]; establish cooperative goals [5], encourage mutual respect [6], and promote IPCP between dental students and dental technology students [7].

IPE encourages teamwork among dental care professionals [8-11] and is increasingly becoming a part of the training programs for dental and dental technology students [12-17]; however, gaps still remain. Perhaps, the largest gaps are owing to the predominant focus of previous studies regarding IPE and IPCP on student and instructor perceptions and a lack of objective assessment of collaborative practice as an outcome measure [18,19]. This marked gap has necessitated the development of a conceptual framework to evaluate the impact of IPE on IPCP to strengthen the evidence for IPE as a tool to improve IPCP between dental and dental technology students [20].

The Objective Structured Clinical Examination

The objective structured clinical examination (OSCE) is an assessment tool based on the principles of objectivity and standardization, in which individual students move through a series of time-limited stations in a circuit for the purpose of assessment of professional performance in a simulated environment. At each station, the student is assessed and marked against standardized scoring rubrics by trained assessors [21]. OSCE has been widely adopted as a summative assessment in the medical undergraduate curriculum and is universally accepted as the gold standard for assessing clinical competence in dental education [22,23]; furthermore, its effectiveness has been confirmed by several studies [24-26]. On the basis of the extensive application of OSCE, the interprofessional OSCE (iOSCE) was initially developed to simulate IPCP [27]. Unlike conventional OSCE, iOSCE involves students from different professions, encourages students to work as a team, and requires the entire team to participate in all tasks [28]. This is performed to objectively evaluate the results of IPE. Within this framework, several variations of iOSCE have been developed to accommodate the training needs of health care teams built to address different disease categories (team OSCE [29,30], group OSCE [31,32], interprofessional team OSCE [28,33], etc). These iOSCE variants can be roughly divided into synchronous [33-36] and asynchronous [29,37] task-based variants. A team working in an operating room typically works synchronously, whereas health care teams of dentists and dental technicians typically work asynchronously. Although the use of iOSCE in medical education has been extensively reported [27-30,38-42], to the best of our knowledge, the use of iOSCE for asynchronous work, especially within dentistry and dental technology cross-professional education, has not been reported.

Although iOSCE may provide an ideal solution for dental and dental technology students to perform IPCP simulation based on real patient cases, the COVID-19 pandemic [43] highlighted the limitations of this traditional approach. For example, a plaster model generated from a clinical case and passed multiple times among students and examiners may pose a risk of infection. In addition, diagnostic stations are usually set up to facilitate OSCE. A station is typically equipped with a trained, standardized patient, and the students complete the diagnosis by asking questions and examining this standardized patient. The risk of infection at this type of station was heightened during the pandemic. Nevertheless, compared with the traditional OSCE, iOSCEs are more time consuming and resource intensive [44,45], especially in dental education; hence, a virtual approach, as developed and piloted in this study, is justified [46,47]. Notably, the conventional virtual OSCE (vOSCE) has been described as a method of performing OSCE using internet technology in medicine [47-49]. The major reason for this technological approach was the scattered nature of the locations of students requiring assessment. However, this approach does not fully leverage virtual technology in dentistry. The integration of digital dental technologies and cloud-based dental laboratory workflows could be practiced within the vOSCE framework [50], which now also forms a professional core course in dental technology education [51-53]. The development of iOSCE based on virtual technology could facilitate the inclusion of digital dental technology in the blueprint design of examination stations. This combination could simulate the critical needs of present-day dental laboratories and promote students’ improved perception about the current demands of the profession.

Objective

To address these research gaps, this study presented a new virtual iOSCE (viOSCE) to objectively assess the effectiveness of IPE as a tool to promote IPCP among dental and dental technology students. We have described the development and piloting of a viOSCE framework and its virtual techniques to validate the user-friendliness of IPE and document its effect on IPCP among dental and dental technology students. Data from both subjective and objective evaluations were collected, and their correlation was assessed.
Methods

Development of viOSCE

The principal investigator (PI) first limited the viOSCE knowledge to content related to the prosthodontics course. Content related to implantology and orthodontics was excluded because it is not part of the core undergraduate coursework for dental or dental technology students. On the basis of the Association for Medical Education in Europe guide [54], a modified Delphi method was used to generate content for viOSCE. The Delphi method is a decision-making process that uses expert opinion, gathered in the form of a survey, under the guidance and direction of the PI to reach group consensus through collaboration, independent analysis, and iteration [55]; this process is the most frequently used method to generate content for OSCEs [54]. The panel of experts in this study consisted of 9 instructors (including the PI) from the College of Stomatology, Chongqing Medical University. All 9 instructors had prosthodontics teaching experience and digital technology practical teaching experience with undergraduate dental and dental technology students. They had also participated in the design and examiner training for traditional OSCE, but only the PI had experience in IPE and vOSCE design.

In this study, there were 4 iterations (rounds) before the viOSCE station design was finalized. In the first round, the PI identified 10 potential topics for viOSCE based on the syllabus of the prosthodontics course for dentistry and dental technology students, gave initial suggestions for the station design, and created a manuscript that was emailed to the panel of experts. Each expert independently gave their opinion and selected 5 topics that they considered as the most important in the syllabus and the most suitable for assessment using viOSCE. In the second round, the PI identified 3 topics with the highest selection rate based on the expert feedback and designed draft blueprints for 20 stations based on the top 3 selected topics using existing virtual technology support. These were sent to the expert panel via email. The expert panel commented about the potential effectiveness of interprofessional collaboration at the stations, made necessary corrections, and returned the design drafts to the PI. In the third round, the PI summarized all the changes made by the expert panel and, finally, decided on 7 stations based on the availability of virtual technology and the time to be spent on the stations within the allotted time frame of the examination. Stations consuming a lot of time, requiring multiple devices for support, or requiring very large spaces were rejected. Next, the selected viOSCE station blueprint design was completed, the virtual technical support was finalized, and the PI sent the final viOSCE station blueprint to the expert panel via email. The expert panel created the scoring rubrics based on the final viOSCE station blueprint, and these were returned to the PI for finalization. In the final round, the PI compiled all the information and met with the group to get a consensus regarding the viOSCE station blueprint and scoring rubrics. Once all the experts approved the viOSCE test station blueprint and scoring rubrics, the PI declared the viOSCE design as complete and declared the panel of experts the viOSCE examiner panel (Figure 1).
The viOSCE development process based on the modified Delphi method. PI: principal investigator; viOSCE: virtual and interprofessional objective structured clinical examination.

The viOSCE Framework
The developed viOSCE framework consisted of 3 topics, namely, fixed prosthodontics, removable prosthodontics, and clinical diagnostics. There were 7 collaborative examination stations consisting of 4 asynchronous and 3 synchronous stations. All these stations were designed and developed using the Delphi method (Figure 2).
At the fixed prosthodontic stations, the dental student prepared tooth 8 (maxillary right central incisor) on the simulator (Nissan Dental Products) and then worked with the dental technology student to scan the preparations using an intraoral scanner (Panda P2; Freqty Technology). The dental and dental technology students at the intraoral scanning station worked collaboratively. The dental student performed an intraoral scan task, and the dental technology student observed the scan results to determine whether they could be used for the computer-aided design (CAD) wax pattern station. After obtaining a digital model, the dental technology student used a CAD system (Dental system; 3shape) to design a single crown on the digital model of the preparation. Individual scoring rubrics were designed for tooth preparation, intraoral scan, and CAD wax pattern. The 3 examiners scored each of the 3 stations (Figure 3 and Tables 1-3).
Figure 3. The fixed prosthodontics stations of the viOSCE. (A) A dental student prepared tooth 8 on the simulator. (B) Dental and dental technology students scanned the preparation using an intraoral scanner. (C) A dental technology student created a digital wax pattern using the computer-aided design system. • Correct contact relationship between adjacent teeth |
| Shape                              | 35     | • Tooth position: long axis is correctly aligned with the lip and tongue direction, correct proximal and distal orientation, tooth is correctly positioned in the dental arch, and ratio of the tooth length to width is coordinated with that of the adjacent teeth  
• Thickness: the thinnest thickness is not <0.5 mm, and the axial surface thickness is not <1 mm and not >1.5 mm  
• Gingival embrasures are correctly designed and coordinated with those of the adjacent teeth  
• Tooth length: the incisal position is in harmony with that of the adjacent teeth  
• Detailed structure of the surface, such as developmental grooves and ridges  
• Lingual morphology: lingual fossa and marginal ridge morphology |
| Cement space                       | 5      | • Acceptable cement space  
• Acceptable extra cement space |
| Restoration effect                 | 20     | • Acceptable functionality  
• Acceptable esthetics  
• Acceptable visual harmony |

At the removable prosthodontics station, real patient cases and intraoral digital models were selected and prepared by the PI, followed by approval by the expert panel. The intraoral digital model was a clinical plaster model scanned using Lab Scanner (E4; 3shape). Each dental student used our previously developed Objective Manipulative Skill Examination of Dental Technicians (OMEDT) system [56] to observe the intraoral digital model and to design a removable partial denture (RPD) framework. At the end of the design task, the dental student submitted the design and then discussed the design with the dental technology student; the dental student could make modifications if they wanted to. Next, each dental technology student used a CAD system (Dental system; 3shape) to design the framework of an RPD on the intraoral digital model based on the final design. A viOSCE examiner scored the first RPD design using the OMEDT system. Next, the viOSCE examiner scored the final RPD design and the digital framework of the RPD. The design discussion station was not scored by a separate examiner (Figure 4 and Tables 4 and 5).
Figure 4. The removable prosthodontics stations of the viOSCE. (A) A dental student designed the framework of a RPD using the Objective Manipulative Skill Examination of Dental Technicians system. (B) Dental and dental technology students discussed the RPD design. (C) A dental technology student created a digital framework of an RPD using the computer-aided design system. (D) A viOSCE examiner scored the first RPD design using the Objective Manipulative Skill Examination of Dental Technician system. (E) A viOSCE examiner scored the final RPD design and the digital framework of the RPD. RPD: removable partial denture; viOSCE: virtual and interprofessional objective structured clinical examination.

The clinical diagnostics station used a virtual standardized patient (VSP) with the haptic device (UniDental, Unidraw). The VSP hardware does not have an anthropomorphic shape, but it interacts through vocal, visual, and haptic devices. On the basis of the novel oral knowledge graph and the coupled, pretrained Bert models, the VSP can accurately interact with a dentist’s underlying intention and express the symptom characteristics in a natural style [57]. On the basis of this algorithm, the PI adjusted and entered the real patient case details, allowing the dental technology student to work with the dental student as a chairside dental technician to make a diagnosis based on the information obtained from the interactions with the VSP. In this study, the clinical case designed on the VSP was a patient who required root canal treatment and full crown restoration. At the end of the dental student’s diagnosis and simulation, the dental technology student was required to assist the dental student in designing the restoration plan and help the patient in choosing the materials for crown restoration (this often determines the price of the treatment). Thus, dental and dental technology students finalized the prosthodontic treatment plan collaboratively. The visual device built a virtual dental clinic environment and VSP model, allowing the students to view the VSP from global, extraoral, and intraoral perspectives. The haptic device allows dental students to perform intraoral and extraoral examinations using essential tools to explore the diagnostic evidence.

Owing to the complexity of collaborative diagnosis, the station was manually scored by 2 examiners independently based on the previously developed scoring rubrics, whereas the UniDental output machine provided an additional score according to the previously developed scoring rubrics. The average of the 3 scores formed the final score for the station. To ensure the relative independence and internal consistency of all scores, the examiners were not informed about the existence of the machine score. The PI exported the machine score data from the VSP at the end of the experiment (Figure 5 and Table 6).

Performance Evaluation of viOSCE

In this study, fourth-year undergraduate dental students and third-year undergraduate dental technology students participated in viOSCE because students at this stage of education had completed preclinical professional training. Overall, 50 students who met these requirements, including 25 (50%) dental students and 25 (50%) dental technology students, were recruited into the viOSCE user evaluation experiment and were divided into groups of 2 comprising 1 dental student and 1 dental technology student. The PI and examiner teams did not influence or determine the team-formation process. All participating students were informed that as this viOSCE was in the experimental phase, it was conducted as a small extracurricular skills competition, thus allowing for self-evaluation without a final examination situation, as previously reported [58]. This approach allowed for the simulation of an examination situation without affecting the final examination grade of the students. A month before commencing the experiment, the PI led an web meeting for students to explain the viOSCE, the relevant knowledge points, and the need to practice fully during the upcoming month. At the end of the meeting, the students completed the Readiness for Interprofessional Learning Scale (RIPLS) pretest questionnaire, which is a 19-item 5-point Likert-scale questionnaire; this type of questionnaire is the most frequently used method for the subjective evaluation of IPE and IPCP [18]. viOSCE was piloted after the 1-month preparation period. The panel of examiners marked points according to the previously prepared scoring rubrics, whereas some of the points were automatically scored by a machine. After this step, the participating students completed the posttest self-made questionnaire, to which a mutual evaluation scale and a viOSCE evaluation scale were added. The mutual evaluation scale asked the students to score the performance of their partner, whereas the viOSCE evaluation scale asked the students to score viOSCE. In total, 6 items were included in the mutual evaluation scale, and 7 items were included in the viOSCE evaluation scale (Textboxes 1 and 2). All items in both questionnaires were set to a maximum score of 100. Before issuing the questionnaire, the panel first reviewed all the questions, clarified ambiguities, and removed any double-barreled questions [59,60]. At the end of the experiment, one-on-one interviews were conducted with all the students to determine their perceptions about viOSCE.

The virtual and interprofessional objective structured clinical examination (viOSCE) evaluation scale administered to dental and dental technology student groups who participated in viOSCE.

### Items
- Evaluation of viOSCE effectiveness
- Evaluation of equipment, network operation and maintenance
- Evaluation of viOSCE examiners
- Evaluation of viOSCE staff
- Rationality of the clinical diagnostic design
- Rationality of the fixed prosthodontics design
- Rationality of the removable prosthodontics design

### Statistical Analysis
Data were tabulated in a Microsoft Excel spreadsheet and imported into IBM SPSS Statistics for Windows (version 26.0; IBM Corp) for descriptive analysis. GraphPad PRISM 8.0 software (GraphPad Software) was used to create the graphs. Responses were summarized, and comparisons were made. Output data were presented as percentages and in graphical format. The Shapiro-Wilk test was used to test for normal distribution. Specific data analysis tests performed included descriptive statistics, 2-tailed paired t tests, and correlation analyses.

### Ethical Considerations
The research ethics committee of the Affiliated Hospital of Stomatology, Chongqing Medical University, approved this study protocol (COHS-REC-2022; LS number: 096). All participants provided written informed consent before participation in the study.

### Results
Of the 50 students, 32 (64%) completed the experiment. Interviews were conducted with the students who dropped out of further participation in the study. The main reasons for dropping out included the students’ belief that they or their collaborating partners had not practiced sufficiently to perform well in the experiment. A group had a verbal confrontation approximately an hour before the experiment began. The main reason for the conflict was that the dental technology student accused the dental student of not practicing sufficiently before the experiment. According to the study protocol, at the end of the experiment, the conflict was resolved by the PI. Both parties were counseled, mediated by the PI, and the 2 parties reconciled.

Data from the RIPLS, mutual evaluation scale, and viOSCE evaluation scale were first analyzed to determine the impact of viOSCE on the subjective evaluation of IPCP. All students (32/32, 100%) who completed the experiment were administered the RIPLS questionnaire before and after the experiment. The Cronbach $\alpha$ values were .835 for the pretest data and .731 for the posttest data, suggesting that the reliability and internal consistency were acceptable. The results failed the Shapiro-Wilk test for normality; therefore, the data were analyzed using the Wilcoxon signed rank test. The teamwork and collaboration subscale scores were significantly increased after the experiment ($P=.004$). In addition, there was a nonsignificant decrease in the negative professional identity subscale scores ($P=.21$). There was also an insignificant increase in the scores on the positive identity subscale and on the roles and responsibilities subscale ($P=.13$ and $P=.96$, respectively). Figure 6 depicts the RIPLS data before and after the viOSCE pilot.
After the experiment, the mutual evaluation scale was administered to all participating students (32/32, 100%) who completed the experiment. The Cronbach α value was .873, suggesting good reliability and internal consistency. Comparison of the results of the dental and dental technology students revealed that only the mutual evaluation scores for competition motivation were significantly different between the 2 groups (P=.04). The dentistry and dental technology students evaluated each other’s motivation to participate in the competition (competition motivation), and the dental students had higher scores than the dental technology students. Figure 7 depicts the mutual evaluation scale scores of the dental and dental technology students.
Similarly, after the experiment, the viOSCE evaluation scale was administered to all students (32/32, 100%). The Cronbach $\alpha$ value was .706, suggesting acceptable reliability and internal consistency. Comparison of the viOSCE evaluation scale results of the dental and dental technology students with the Wilcoxon signed rank test results revealed that only the evaluation scores for the removable prosthodontics design were statistically significant ($P=.01$) among the 7 items. Figure 8 depicts the viOSCE evaluation scale scores of the dental and dental technology students.

Figure 8. viOSCE evaluation scale data for dental and dental technology students. viOSCE: virtual and interprofessional objective structured clinical examination.
To explore the validity of the examiner panel scores in viOSCE, correlation analysis was conducted on the scores of each station under the 3 topics. Using Spearman correlation coefficient, for the fixed prosthodontics topic, a strong positive correlation between the scores of the tooth preparation station and the CAD wax pattern station was noted, and it was statistically significant (r=0.67; P=.005). Positive correlations between the scores of the intraoral scan station and the CAD wax pattern station and between the intraoral scan station and the tooth preparation station were not statistically significant (r=0.179; P=.51 and r=0.387; P=.14, respectively). For the removable prosthodontics topic, 11 (69%) of the 16 student groups finally decided to modify the RPD design initially made by the dental students. A negative but statistically insignificant correlation between the scores of the RPD design station and the CAD wax pattern station was noted (r=−0.111; P=.68). For the clinical diagnostics topic, the correlation analysis was conducted primarily for the machine scores and the examiner scores to determine the usability of the VSP in viOSCE and the consistency of machine scoring and examiner scoring. The results revealed a significant positive correlation between the scores of the 2 examiners, and the positive correlation between the machine scores and the 2 examiners’ scores was also significant. The results are shown in Table 7 and Figure 9.

\(^b\)RPD: removable partial denture.
Figure 9. Spearman correlation analysis of the virtual and interprofessional objective structured clinical examination scores. (A) For the fixed prosthodontics topic, the positive correlations between the scores of the tooth preparation station and the CAD wax pattern station were significant. (B) For the clinical diagnostics topic, the positive correlations between the virtual standardized patient machine score and the examiners’ scores were significant. CAD: computer-aided design.

To explore the relationship between the objective and subjective evaluations, correlation analysis was conducted between the viOSCE scores and the RIPLS scores as well as between the viOSCE scores and the mutual evaluation scale scores. Insignificant negative correlations were noted between the subjective evaluation scores presented by RIPLS and viOSCE. Similarly, the correlation of the mutual evaluation scale score with the viOSCE scores was not significant. The SD of the scores on the mutual evaluation scale showed a decreasing trend among students with higher viOSCE scores and those with lower scores, but an increasing trend was observed among those with median scores (Table 8 and Figure 10).

\(^a\)viOSCE: virtual and interprofessional objective structured clinical examination.

Figure 10. Correlation analysis of the viOSCE scores and the mutual evaluation scale. (A) Correlation analysis of the viOSCE scores and the SD of the scores for each item on the mutual evaluation scale. (B) Correlation analysis of the viOSCE scores and the SD of the mean scores on the mutual evaluation scale. viOSCE: virtual and interprofessional objective structured clinical examination.

In the one-on-one interviews, 29 (91%) of the 32 students approved of the effectiveness of viOSCE and wanted to use it to assess their IPCP ability in the graduation examination. At the fixed prosthodontics station, 56% (9/16) of the dental technology students complained about the lack of lingual space prepared by their partners at the tooth preparation station, which made it difficult to design crown wax patterns, and the corresponding dental students reported not being aware of the condition before viOSCE. At the removable prosthodontics station, almost all the dental students (15/16, 94%) reported that the advice given by the dental technology students was effective in helping them complete the RPD design and considered their
design practice to be insufficient. In contrast, the dental technology students reported that helping the dental students complete the RPD design made them feel satisfied with their professional competence and felt that they were truly part of the team during the collaboration. At the clinical diagnosis station, the dental students felt that their clinical practice experience was not sufficient, especially when the dental technology students could provide a diagnostic plan faster than themselves.

In terms of positive feedback, the students believed that viOSCE promoted the friendship between themselves and their partners, helped them realize the continuity and relevance between their own work and the work of their partners, and enabled them to acquire a deep understanding of IPCP. The negative feedback mainly focused on their lack of clinical knowledge, inadequate preparation, and long waiting time at some stations.

**Discussion**

**Principal Findings**

The IPCP results of dentists and dental technicians reflect the quality of their IPE, skill training, and clinical experience. The results contribute to the much-needed IPE assessment literature and suggest that teamwork skills can be improved by IPCP and effectively assessed using this new evaluation scale. We used a modified Delphi process in this study. This is in accordance with Simmons et al [27], who found that the modified Delphi process is an effective tool to obtain consensus among professionals for the foundational work required. In addition, our study demonstrated the effectiveness of iOSCE in asynchronous and synchronous collaboration scenarios, while providing a methodological reference for developing a new iOSCE for dental health care professionals. As the collaboration scenario between the dentist and the dental technician may be both asynchronously applied through prescriptions and synchronously conducted in chairside discussions [61-63], it was deemed appropriate for the viOSCE framework to consider both synchronous and asynchronous scenarios.

The viOSCE scores in this study also reflect the effectiveness of the framework design. From the viOSCE examiner scores in the fixed prosthodontics section, a significant positive correlation between the scores of the tooth preparation station and the CAD wax pattern station was evident. This finding is consistent with the actual clinical asynchronous delivery scenario, where the dentist’s preparation largely determines the quality of the dental technician’s crown wax pattern. Qualitative evaluations extracted from the one-on-one interviews also supported this result. For the removable prosthodontics section, the negative correlation between the scores of the RPD design station and the CAD wax pattern station was statistically significant, which might be owing to the fact that more than half of the groups (15/16, 94%) worked collaboratively to modify the RPD design to possibly compensate for the lack of training, which is consistent with the findings about dentists’ inadequate competence in RPD design reported in other studies [64,65].

As OSCE is essentially a simulated scenario-based examination, the use of virtual technology to build simulated scenarios has become an important direction for OSCE-related studies, especially in the field of dental education [43]. The COVID-19 pandemic has further contributed to dental educators’ interest in this area, as dental clinical practice typically occurs in a virus-laden aerosolized environment [66]. Therefore, providing a safe and robust learning environment in the simulation clinic is also critical to help students compensate for lost educational time. The virtual technologies used to construct the simulated clinical environment in this study include VSP and CAD. Previously, Janda et al [67] developed a virtual patient as a supplement to standard instruction in the diagnosis and treatment planning of periodontal disease. However, it could not fully understand complex or ambiguous questions, and the students felt frustrated during the practice [67].

Tanzawa et al [68] developed a robot patient that could reproduce an authentic clinical situation and introduced it into OSCE. However, the dialogue recognition of the robot patients was prespecified; the robot was unable to identify subjective patient descriptions or the dentist’s interrogation intention and could not support intraoral or extraoral examinations to obtain diagnostic evidence [68]. To fill these gaps, our study used VSP with intention recognition and haptic feedback to construct virtual dental clinical practice and diagnosis scenarios more realistically. As the diagnostic evidence collected by students through interrogation, inspection, and palpation was automatically summarized for the final differential diagnosis, and omissions in the examination process eventually led to a misdiagnosis, the system simulated a high-fidelity clinical environment. In addition, the results showed that 1 (6%) of the 16 student groups misdiagnosed their VSP because of incomplete interrogation and palpation. The correlations between the scores of the 2 examiners and the machine scores were statistically significant, thus confirming the robustness of the high-fidelity simulation scenarios constructed by the VSP and the machine scores. On the basis of these results, the use of VSP should be expanded and integrated into daily teaching to give students more opportunities for clinical practice training.

Consistent with the results of previous OMEDT studies [56], the use of CAD technology in viOSCE significantly reduced the time spent at each station for the dental technology students. Some dental technology students complained about the slowness of the CAD program. Upon further investigation, it was found that they imported both impressions at the same time. In dental laboratory practice, dental technicians usually import the impressions separately to prevent computational issues. This finding exposes the lack of virtual dental laboratory practice skills in teaching, which needs to be addressed.

The results showed that the teamwork and collaboration subscale scores were significantly increased at the end of the study (F=.004), suggesting that viOSCE can improve students’ teamwork skills. The increase in the other 3 subscale scores, although not statistically significant, can be explained by the choice of timing of viOSCE. The optimal time to expose medical students to IPE is still subject to debate [18]. viOSCE, as a clinical IPCP intervention introduced during the clinical year, had no significant effect on the promotion of negative or positive
identity or roles and responsibilities. This finding may be due to the fact that the students’ professional cognition had been stereotyped at this time, making it difficult to effect significant changes through IPE or IPCP intervention. This conclusion is supported by a previous study [69].

The results of the mutual evaluation scale showed statistically significant difference in participant motivation between the 2 professional groups, which could be explained by the results of the roles and responsibilities subscale. Of the 16 dental technology students, 4 (25%) expressed that they would not practice as dental technicians in the future because they wanted to choose other careers. The differences in the scores of the other items were not statistically significant, thus showing the effectiveness of viOSCE in the development of teamwork spirit. This result confirms that the OSCE design is well suited as a final evaluation of IPE and IPCP. In addition, the average score of each item of viOSCE was >60, indicating that the students were satisfied with the design and operation of viOSCE. The differences in scores between the 2 types of professionals were not statistically significant, except at the removable prosthodontics station, which was probably caused by the dental technology students’ unfamiliarity with the CAD program.

Overall, the internal consistency of all subjective evaluations was acceptable, and the results met expectations. Interesting observations were also made regarding the correlation between the subjective and objective evaluations. The SD of the scores on the mutual evaluation scale showed a decreasing trend among the dental and dental technology students with higher viOSCE scores and those with lower scores, but an increasing trend in the median score was observed. Although this trend was not statistically significant due to sample size limitations, this early finding provides data support for a summary of clinical experience published previously by Preston [70], who reported that the intensity of the relationship between dentists and dental technicians is determined by the difference in their professional skills. If the professional skills of both parties are high, there will be few problems in their cooperative relationship. The more discriminating and demanding the technician or dentist becomes, the more the relationship is strained when either fails to perform up to the other’s standards. This result suggests that in the study of IPE and IPCP for dentists and dental technicians, it is not sufficient to explore the improvement of the traditional assessment dimensions such as team collaboration skills and identity. The final quality of the output must be included in the assessment dimension. This also reaffirms the effectiveness of viOSCE as an objective, quantitative evaluation tool for IPE and IPCP.

**Limitations and Future Studies**

The main limitation of our study is the small convenience sample of participating students, which could have led to self-selection bias. The sample size should be expanded in the future to obtain more data and to further verify the robustness of the viOSCE framework. In addition, whether viOSCE should be made a part of the large and more complete OSCE to test the ability of students to meet undergraduate graduation requirements will also be the focus of our next study. Moreover, the independent application of the novel VSP in the education of dental students is an interesting topic that will be explored in the next step of this study.

**Recommendations**

On the basis of our results, we provide the following recommendations:

1. All dental health professionals should be educated to deliver patient-centered care as members of an interdisciplinary team [16].
2. IPE intervention–related skills should be introduced as preclinical skills.
3. The cooperation of the dental care team is complex, and the training for improving the cooperation ability of the dental care team should include both subjective and objective assessments.
4. viOSCE and scale assessment should be introduced for the assessment of IPE and IPCP at the clinical stage of training.

**Conclusions**

In this study, a novel viOSCE framework was developed and piloted. Data based on subjective evaluation scales and objective examiner scores were collected and analyzed, confirming the effectiveness of viOSCE as an objective evaluation tool for IPE and IPCP. The experimental design should be expanded to include more randomly selected students with a scientifically determined sample size to further develop studies focused on IPE and IPCP in dentistry and dental technology, ultimately promoting quality in dental clinical practice.

**Acknowledgments**

This study was funded by a major project of Chongqing Higher Education and Teaching Reform of the People’s Republic of China (reference number 201019 to JS and reference number 193070 to MP) and the Teaching Reformation Fund of the College of Stomatology, Chongqing Medical University (KQJ202105 to YD and KQJ202003 to MP). Abstract

Background: From 2016 to 2021, the volume of peer-reviewed publications related to tobacco has experienced a significant increase. This presents a considerable challenge in efficiently summarizing, synthesizing, and disseminating research findings, especially when it comes to addressing specific target populations, such as the LGBTQ+ (lesbian, gay, bisexual, transgender, queer, intersex, asexual, Two Spirit, and other persons who identify as part of this community) populations.

Objective: In order to expedite evidence synthesis and research gap discoveries, this pilot study has the following three aims: (1) to compile a specialized semantic database for tobacco policy research to extract information from journal article abstracts, (2) to develop natural language processing (NLP) algorithms that comprehend the literature on nicotine and tobacco product use among sexual and gender diverse populations, and (3) to compare the discoveries of the NLP algorithms with an ongoing systematic review of tobacco policy research among LGBTQ+ populations.

Methods: We built a tobacco research domain–specific semantic database using data from 2993 paper abstracts from 4 leading tobacco-specific journals, with enrichment from other publicly available sources. We then trained an NLP model to extract named entities after learning patterns and relationships between words and their context in text, which further enriched the semantic database. Using this iterative process, we extracted and assessed studies relevant to LGBTQ+ tobacco control issues, further comparing our findings with an ongoing systematic review that also focuses on evidence synthesis for this demographic group.

Results: In total, 33 studies were identified as relevant to sexual and gender diverse individuals’ nicotine and tobacco product use. Consistent with the ongoing systematic review, the NLP results showed that there is a scarcity of studies assessing policy impact on this demographic using causal inference methods. In addition, the literature is dominated by US data. We found that the product drawing the most attention in the body of existing research is cigarettes or cigarette smoking and that the number of studies of various age groups is almost evenly distributed between youth or young adults and adults, consistent with the research needs identified by the US health agencies.

Conclusions: Our pilot study serves as a compelling demonstration of the capabilities of NLP tools in expediting the processes of evidence synthesis and the identification of research gaps. While future research is needed to statistically test the NLP tool’s performance, there is potential for NLP tools to fundamentally transform the approach to evidence synthesis.

Introduction
The use of nicotine or tobacco products is a leading preventable cause of cancer, heart diseases, and lung diseases in the United States [1], with cigarette smoking alone responsible for the death of half a million Americans each year [2]. Notably, sexual and gender diverse individuals, often referred to as the LGBTQ+ (lesbian, gay, bisexual, transgender, queer, intersex, asexual, Two Spirit, and other persons who identify as part of this community) populations, are particularly vulnerable to nicotine and tobacco product use [3]. Both the National Cancer Institute and the Centers for Disease Control and Prevention have recognized the LGBTQ+ populations as a critical target in their efforts to combat tobacco use disparities [4-10].

In response to the pressing need for tobacco control and the rapidly evolving landscape of the tobacco market, the National Institutes of Health (NIH) and other health foundations, including the American Cancer Society, have made substantial investments in tobacco control research and tobacco regulatory science [11,12]. According to our calculations using data from the NIH era reporter, funding for tobacco research has shown a remarkable increase, growing from US $7.7 billion in 2016 to US $11.2 billion in 2021 (Multimedia Appendix 1 [13]). Consequently, the volume of peer-reviewed publications related to tobacco has experienced a significant increase. This presents a considerable challenge in efficiently summarizing, synthesizing, and disseminating research findings, especially when it comes to addressing specific target populations, such as the LGBTQ+ populations.

One promising pathway to rapidly assessing the expanding body of literature is the use of natural language processing (NLP) models. NLP is dedicated to deciphering and comprehending how computers interpret human language, equipping them to analyze extensive data sets of natural language [14-16]. While NLP tools have garnered considerable recognition in biomedical research [4-10], aiding in tasks such as disease surveillance (eg, COVID-19) and diagnosing using medical records [17-23], their potential to expedite near real-time synthesis of evidence in tobacco control research remains untapped [24].

Another gap in existing NLP tools is the lack of applications in synthesizing social science research and modeling. A noteworthy example in the domain of tobacco research is the evaluation of the effectiveness of tobacco control policies, which are often assessed using complex statistical modelling and large-scale survey data. These methods demand a specialized semantic database for labelling studies and interpreting results. However, to the best of knowledge, such a semantic database has not been developed yet. Considering that policy interventions at federal, state, and local levels are designed to reach a large number of populations, the lack of a database to facilitate NLP applications may significantly undermine evidence synthesis and thereby the timely adoption of effective policies [25].

Furthermore, in light of the calls from entities such as the NIH and other health agencies to address tobacco use disparities within priority populations, including LGBTQ+ populations, the development NLP tools to aid in the discovery of effective policies tailored to these special populations remains uncharted territory [26-31]. There is an urgent demand for the development of NLP tools (eg, semantic database, NLP algorithms) in tobacco research that have the abilities to synthesize evidence in social science and assist in research gap discovery for priority populations.

In this pilot study, we aimed to achieve the following goals to address the identified research and application gaps: (1) compile a specialized semantic database for tobacco policy research to extract information from journal article abstracts, (2) develop NLP algorithms that comprehend the literature on nicotine and tobacco product use among sexual and gender diverse populations, and (3) compare the discoveries of the NLP algorithms with an ongoing systematic review of tobacco policy research among LGBTQ+ populations [32]. While this pilot study does not fully address the gaps by developing a comprehensive evidence synthesis or discovery tool for tobacco research, the outcomes may pave the road for future tools that can achieve this goal. Our vision is that NLP tools may be able to assist academic scholars and policy makers in prescribing public health policies, such as tobacco control policies, and addressing public health needs, such as reducing health disparities.

Methods
Development of a Tobacco Research Domain–Specific Semantic Database
Overview
To generate a tobacco research domain-specific semantic database, we used an iterative process that combines expert opinions and the reading of tobacco research papers in 4 leading tobacco journals (Tobacco Control, Nicotine and Tobacco Research, Tobacco Induced Diseases, and Tobacco Prevention and Cessation). The main categories of keywords were the follows: (1) tobacco use behaviors, prevalence, and outcomes; (2) population characteristics; (3) geographic locations; (4) method and inference; (5) policy; (6) tobacco products; (7) relation statement; and (8) tobacco characteristics. Under each main category, there were one or more subcategories, and each subcategory contained a list of named entities. Table 1 presents the categories of named entities in a domain-specific semantic database that were used for training and improving a language model for tobacco research on sexual and gender diverse populations. These categories are based on journal articles’ keywords, further guided by existing literature on how to use NLP methods to synthesize public health evidence [25,33]. These categories are important components of a study, encompassing measures, methods, results, conclusions, and hypothesis testing.

Journal Selection

We chose 4 peer-reviewed tobacco-specific multidisciplinary journals, namely, Tobacco Control, Nicotine and Tobacco Research, Tobacco Induced Diseases, and Tobacco Prevention and Cessation, to extract articles and compile keywords at the initial stage. The first 2 are among the journals that have the highest impact factors in addiction research; in 2022, Tobacco Control had an impact factor of 5.2 and a 5-year impact factor of 5.7 [34], and Nicotine and Tobacco Research had an impact factor of 4.7 and a 5-year impact factor of 4.2 [35]. Tobacco Induced Diseases [36] and Tobacco Prevention and Cessation [37] are 2 other peer-reviewed journals that specifically publish research on nicotine and tobacco products but are not as highly ranked as the other 2 journals. The textual data from the 4 peer-reviewed journal articles contained a total of 2993 abstracts from published papers from 2015 to early 2021.

While the 2993 articles extracted from these journals do not represent the full body of tobacco research, they cover a significant share of tobacco studies and integrate evidence across the 5 translational research stages: basic research, preclinical research, clinical research, clinical implementation, and public health. These journals also ask authors to specify how the research reported contributes to tobacco control objectives, which have policy implications. Alternatively, a random sampling from PubMed searches using tobacco related terms may not yield studies that are necessarily translational in nature. Therefore, we focused on the articles published in the 4 journals in our study.

Iterative Process to Expand Terms (Named Entities) in the Database

The general process included the following iterative steps: (1) to generate initial annotation data, we first compiled key terms from extracted articles and allocated key terms to categories using group discussions; (2) we enriched the database using various sources and group discussions (more specific descriptions below); (3) we fine-tuned the spaCy en_core_web_lg model with the initial annotation and following iterative versions of data (the en_core_web_lg model is a pretrained large language model that can extract multiple general named entities); (4) we expanded the list of named entities to include more keywords of similar meanings using SeedNER [38,39], that is, a small set of initial labeled examples or patterns that was used as a starting point for training a model; (5) we searched the occurrence of each keyword in the 2993 paper abstracts and kept those with high frequency; (6) during this process, named entities that were too generic to yield meaningful relations were removed from the database; and (7) we repeated steps 3 to 6 until the set of entities reached our satisfaction during group discussions.
Specific approaches were used for conducting step 2. For categories including “tobacco use behavioral outcomes,” “tobacco products,” and “tobacco characteristics,” the iterative process involved four steps: (1) discussions to determine whether to include newly identified key terms and how to allocate them into additional subcategories (Table 1); (2) using a named entity recognition (NER) model to extract named entities from 2993 paper abstracts from the 4 specific journals; (3) randomly sampling and reviewing the output of the NER model, correcting identified errors, and adding missed NERs; and 4) repeating steps 1 to 3 until we were satisfied with the model output.

The categories “population characteristics,” “geographic locations,” and “relation terms” are commonly used concepts in real life and not specific to tobacco control. We used Google searches, Wikipedia, and WordNet to enrich the key terms. In addition, for the “method and inference” category, we used the glossary of an econometrics methodology textbook by Cameron and Trivid to enrich the terms [40]. This textbook is widely used in economics and social science and its glossary should provide sufficient terms for this category.

For the “policy” category, we drew named entities from 2 sources that comprehensively summarize available tobacco control policies in the regulatory space. The first source was a peer-reviewed journal article by McDaniel et al [41] that conducted an intensive policy scan of all possible regulations that can contribute to tobacco endgame. The second source was the World Health Organization’s report on the global progress in implementing tobacco control policies, as recommended by the World Health Organization’s Framework Convention on Tobacco Control [42], which is the largest public health treaty signed by 182 countries and prescribes a comprehensive set of tobacco control policies. These policies are classified into 5 groups: M (monitor tobacco use and prevention policies), P (protect people from tobacco smoke), O (offer help to quit tobacco use), W (warn about the dangers of tobacco), E (enforce bans on tobacco advertising, promotion, and sponsorship), and R (raise taxes on tobacco) [42]. These sources cover policy key terms related to both national and international contexts and together create the most comprehensive policy terms to our knowledge.

Development of NLP Algorithms That Comprehend the Literature on Nicotine and Tobacco Product Use Among Sexual and Gender Diverse Populations

We used RoBERTa, an optimized BERT (bidirectional encoder representations from transformers)-based language model [43], to perform NER tasks. BERT is a state-of-the-art language model that excels at tasks such as sentiment analysis and text summarization. By learning patterns and relationships between words and their context in text, BERT can extract named entities that it has learned during training and potentially discover new ones.

We developed an NER model based on RoBERTa using the Python (Python Software Foundation) programming language and the spaCy library [44]. We began by defining 36 labels of categories (main and subcategories; Table 1) and extracting 1582 named entities using the existing NER model RoBERTa. Next, those named entities were used to tag abstracts and create a training set, using the annotation tool Prodigy [45]. A subset of the abstracts with labeled named entities was reviewed by 2 domain experts to identify key terms that were missing in our semantic database, which were added to the lists of named entities.

The RoBERTa model was then updated based on the richer database and further trained for a maximum of 20,000 steps, with early stopping implemented if no improvement was observed for 1600 consecutive steps. With a series of iterations, we used the updated RoBERTa model to assess the 2993 abstracts and labeled them with the categories.

When identifying studies related to LGBTQ+ populations, it is important to understand that this community is heterogeneous [46,47]. Given that LGBTQ+ key terms are included in the “population characteristics” categories, we were able to identify LGBTQ+ populations based on categorization. There were 111 LGBTQ+-related named entities in our database.

Comparison of the Discoveries of the NLP Algorithms With an Ongoing Systematic Review of Tobacco Policy Research Among LGBTQ+ Populations

Ideally, we would like to compare the results from our tools with those from systematic reviews and meta-analyses of studies related to tobacco control issues among LGBTQ+ populations. Systematic reviews and meta-analyses are state-of-the-art evidence synthesis methods that can provide the ground truth [48-50]. While we are currently conducting a separate systematic review of the effectiveness of tobacco control policies among LGBTQ+ populations, this review has not been finalized yet [32]. Nonetheless, the ongoing systematic review does provide some data points for comparisons, including the number of studies extracted from the 4 journals and presence of policy assessment. Therefore, we conducted comparisons of these 2 domains.

Ethical Considerations

This study does not involve human subjects, as it synthesizes data from research articles published at peer-reviewed journals. The Ohio State University Institutional Review Board has determined that it contains no human subjects and thus no further review is needed (study number: 2021E0776).

Results

In total, we identified 33 articles relevant to sexual and gender diverse populations from the 2993 abstracts. Our trained model successfully extracted 773 named entities (181 unique named entities) from the 33 paper abstracts to describe the themes of these articles. Among the 773 extracted named entities, 688 were already learned by the model during training, while 70 were new time- or age-related words (eg, 18 years, 2013), 9 were new statistical terms (eg, N=20), and 6 were newly discovered and labeled within other categories. We did not observe any newly discovered policy-related terms.

In Figures 1-3, we present the hierarchy of named entities extracted from abstracts in published papers that studied nicotine...
or tobacco product use among sexual and gender diverse individuals. Each number on the right is the frequency of the corresponding named entity by paper abstract. Named entities with the same color belong to the same main category.

**Figure 1.** Hierarchy and frequency counts of named entities extracted from published research in tobacco-specific journals from 2015 to early 2021 in 4 main categories: tobacco use, products, characteristics, and relation statement. Numbers represent the frequency of the corresponding named entity by paper abstract.
Figure 2. Hierarchy and frequency counts of named entities extracted from published research in tobacco-specific journals from 2015 to early 2021 in the main category of population characteristics. Numbers represent the frequency of the corresponding named entity by paper abstract.
According to our tool, among the 33 tobacco studies related to LGBTQ+ populations, the most frequent use outcomes were “cigarette smoking” (n=17), “substance use” (n=16), “prevalence” (n=16), and “risk” perception (n=14). Also, for these populations, “cigarettes” (n=15) were the most frequently mentioned combustible tobacco product and “e-cigarettes are” (n=8) was the most frequently mentioned noncombustible tobacco product. In addition, for tobacco characteristics, “alcohol” (n=7) and “nicotine” (n=5) were the most mentioned attributes among LGBTQ+ tobacco research papers.

The relation statement findings suggest that a majority of the studies examined “comparison” (n=26), “association” (n=23), and “correlation” (n=6). We found no studies that explicitly used the term “causal” or “causality” in the studies.
The population characteristics mentioned in the studies illustrated that among socioeconomic status terms, the most frequently included were “demographics” (n=8) and “SES factors” (n=8). Among sex and sexual and gender minority terms, the most frequent ones were “bisexual” (n=21), “lesbian” (n=19), and “gay” (n=19). Among racial and ethnicity minority group terms, the most frequent ones were “minority groups” (n=8) and “Race/ethnicity” (n=6). For age group terms, the terms included “adult” (n=14), “young adult” (n=11), “adolescent” (n=5), “students” (n=3), and “adolescents and young adults” (n=2).

The policy category showed that in these studies, the most mentioned term was “intervention” (n=16). In addition, while the general term “tobacco control” was mentioned in 6 studies, only 1 study contained any specific policy term (“smoke free air law”). As such, there was a significant gap in policy research among the published articles in the 4 leading tobacco journals between 2015 and early 2021, since only 1 study mentions specific policies when it comes to tobacco research among the LGBTQ+ populations. The statistics and methodology terms further indicated that the most used terms included “survey” (n=18) and “logistic regression” (n=10), and relatively fewer studies mentioned terms related to causal inferences, such as “experimental research” (n=4), “randomization” (n=3), and “clinical trial” (n=1). The studies mentioning “US” also dominated in the numbers, with 12 studies in total. Several studies that assessed countries with multilevel governing levels, such as Canada and the United States, also appeared to have mentioned “state,” “city,” and “province,” suggesting that attention was paid to these defined areas.

We next compared our results using the NLP tools with our ongoing systematic review. Similar to the conclusions of the ongoing systematic review, we found very few studies that yielded specific policy recommendations. This finding was further corroborated by the lack of causal inference methods labeled by the NLP tool. While our NLP tool cannot replace systematic reviews just yet, it does show potential to complement the existing methods and requires less human supervision (systematic reviews usually require at least 2 human coders).

**Discussion**

This pilot study builds a semantic database dedicated to tobacco research and developed NLP algorithms to automatically identify, extract, and summarize textual data from published tobacco studies. We further demonstrated a user case wherein we assessed LGBTQ+ tobacco research by labeling key components of a tobacco study: tobacco use outcomes, tobacco characteristics, population characteristics, geographic locations, method and inference, and policy relevance.

It is worth noting that the components we categorized, such as “method and inference,” align with the typical sections found in scientific articles in social science, including measures, methods, results, conclusions, and hypothesis testing. As a result, our tool extracts text segments that are frequently assessed in evidence synthesis, thereby showing the potential of using NLP tools to enhance systematic reviews and facilitate meta-analyses [25].

Additionally, we leveraged the NLP algorithms we created to identify gaps in tobacco research concerning the LGBTQ+ populations and concluded that there is a scarcity of studies assessing policy impacts on this demographic using causal inference methods. This finding is consistent with our ongoing systematic review [32], highlighting how NLPs have the capacity to aid in both evidence synthesis and research gap discoveries. This, in turn, has the potential to streamline research efforts, reduce labor costs, and influence the trajectories of future research directions [51,52].

Using the NLP tool, we further found some interesting patterns in tobacco research involving LGBTQ+ populations. It appears that the product drawing the most attention in the field is cigarettes or cigarette smoking and that the number of studies of various age groups is almost evenly distributed between youth or young adults and adults. Moreover, the existing evidence body is dominated by studies coming from the United States. These patterns are consistent with the research needs to reduce cigarette smoking among LGBTQ+ populations in the United States, where 16.1% of LGBTQ+ adults and 17.4% of LGBTQ+ high schooler students smoke cigarettes—this is 4% to 6% higher than their heterosexual counterparts [53,54]. Therefore, our findings align with the ongoing research needs and the financial investments made by the US health agencies like the NIH, thereby bolstering the confidence in the NLP tool that we developed.

Finally, while the semantic database and language model in this pilot study are designed to extract and summarize key components of tobacco research, many of the terms and labeling categories are broad and applicable to public health and social science research in general, such as “methods and inference” and “relation terms.” Therefore, our tool has the potential to transform the evidence synthesis paradigm in tobacco control and public health at large by enabling more efficient and effective analyses of large volumes of textual data. Future tool development may extend its reach to other public health domains, fostering the real-time translation of research findings into evidence-based policymaking, thereby contributing significantly to the advancement of public health initiatives.

Our study has several limitations. First, for the development of keywords and the application of the NLP, we focused on 4 peer-reviewed tobacco-specific research journals, which were not representative of the entire tobacco control literature. However, considering the prominence and extensive content covered by these journals, we believe that this selection is unlikely to introduce significant selection bias or result in the omission of crucial keywords. Second, although we used our ongoing systematic review as a benchmark for the qualitative assessment of the results obtained in this pilot study, we did not perform a quantitative comparison of our findings with the ground truth derived from the systematic review. This quantitative evaluation, which might include measures like Cohen kappa, was not conducted because the systematic review has not yet been finalized. Consequently, future research endeavors are required to undertake a thorough quantitative
comparison between the training data and the established ground truth using statistical testing for a more comprehensive assessment of the NLP tool’s performance.

Despite the limitations, our pilot study serves as a compelling demonstration of the capabilities of NLP tools in expediting the processes of evidence synthesis and the identification of research gaps. Expanding the scope of this pilot research to encompass other public health disciplines, extending beyond the realm of tobacco control, holds the promise of fundamentally transforming the approach to evidence synthesis. Such expansion has the potential to play a pivotal role in shaping policy development across a wide spectrum of public health domains.

Abstract

Background: e-Learning has rapidly become a popular alternative to in-person learning due to its flexibility, convenience, and wide reach. Using a systematic and partnered process to transfer in-person training to an e-learning platform helps to ensure the training will be effective and acceptable to learners.

Objective: This study aimed to develop an e-learning platform for Small Steps for Big Changes (SSBC) type 2 diabetes prevention program coaches to improve the viability of coach training.

Methods: An integrated knowledge translation approach was used in the first 3 stages of the technology-enhanced learning (TEL) evaluation framework to address the study objective. This included three steps: (1) conducting a needs analysis based on focus groups with previously trained SSBC coaches, meetings with the SSBC research team, and a review of research results on the effectiveness of the previous in-person version of the training; (2) documenting processes and decisions in the design and development of the e-learning training platform; and (3) performing usability testing. Previously trained SSBC coaches and the SSBC research team were included in all stages of this study.

Results: Step 1 identified components from the in-person training that should be maintained in the e-learning training (ie, a focus on motivational interviewing), additional components to be added to the e-learning training (ie, how to deliver culturally safe and inclusive care), and mode of delivery (videos and opportunities to synchronously practice skills). Step 2 documented the processes and decisions made in the design and development of the e-learning training, including the resources (ie, time and finances) used, the content of the training modules, and how coaches would flow through the training process. The design and development process consisted of creating a blueprint of the training. The training included 7 e-learning modules, the learning modalities of which included narrated demonstration videos and user-engaging activities, a mock session with feedback from the research team, and a final knowledge test. Step 3, usability testing, demonstrated high levels of learnability, efficiency, memorability, and satisfaction, with minor bugs documented and resolved.

Conclusions: Using an integrated knowledge translation approach to the technology-enhanced learning evaluation framework was successful in developing an e-learning training platform for SSBC coaches. Incorporating end users in this process can increase the chances that the e-learning training platform is usable, engaging, and acceptable. Future research will include examining the satisfaction of coaches using the SSBC coach e-learning training platform, assessing coach learning outcomes (ie, knowledge and behavior), and estimating the cost and viability of implementing this training.

Introduction

e-Learning has emerged as a popular alternative to traditional in-person education in recent years, particularly with the advancement of technology and widespread availability of internet connectivity. e-Learning has revolutionized the way people learn by providing flexible, wide-reaching, and convenient access to educational resources, as well as personalized learning experiences that cater to individual needs and preferences. e-Learning has been adopted across various fields, including health care, and is effective in enhancing learning outcomes and improving overall learner engagement [1-3].

There is a paucity of research on how e-learning platforms are designed and developed. Partnering with end users can help guide e-learning platform development. An integrated knowledge translation (IKT) approach meaningfully engages the right research users at the right time throughout the research process and can increase the chances that the e-learning platform is usable, engaging, and acceptable [4-7]. Such approaches require in-depth qualitative methods to understand the perspectives of end users throughout the entire research process.

Frameworks can help guide the process of platform conception, design, development, implementation, and evaluation. This study was guided by the technology-enhanced learning (TEL) evaluation framework [8]. The TEL evaluation framework was informed by commonly used learning models, including the Kirkpatrick model [9]. The seven TEL evaluation framework stages are (1) conduct needs analysis and environmental scan; (2) document processes, decisions, and final product; (3) test usability; (4) document key events during implementation and final product; (5) assess participant experience and satisfaction; (6) assess learning outcomes; and (7) estimate cost, reusability, and sustainability. The TEL lacks specific guidelines, which can be seen as both a strength and a limitation, as it permits flexibility for different users and contexts, but it can also be used haphazardly and may result in a product that has not considered end user needs.

This paper offers a guide for including an IKT approach to the needs analysis, design, development, and usability testing of an e-learning platform using the first 3 stages of the TEL evaluation framework. The proposed partnered stages of the TEL evaluation framework are described using the example of developing an e-learning platform for type 2 diabetes (T2D) prevention program coaches.

Methods

Context

Small Steps for Big Changes (SSBC) is a community-based T2D prevention program that aims to empower individuals with prediabetes to increase physical activity and improve their diet to reduce their risk of developing T2D. SSBC is delivered in and by staff and volunteers of the YMCA of Southern Interior British Columbia. Trained SSBC coaches (YMCA staff and volunteers) deliver 6 one-on-one sessions to clients over 4 weeks using a motivational interviewing (MI)-informed approach.

In-person 3-day workshops were previously used to train coaches to deliver SSBC. After completing the in-person training, coaches delivered the SSBC program with good levels of fidelity [10,11]. However, in-person coach training is not a viable format for future coach training due to difficulty in scheduling training time and the inability to revisit training components. Additionally, the in-person training was not developed using an IKT approach. To ensure usability and acceptability, the development of the SSBC coach e-learning platform used an IKT approach (ie, partnering with current SSBC coaches).

Needs Analysis

Overview

The information was gathered on the program needs and capacities (eg, the specific knowledge and skills required to become an SSBC coach) and individual needs of SSBC coaches (eg, preference for specific content and instructional approach). The various components of the needs analysis stage were assessed through meetings with the SSBC research team, focus groups with previously trained SSBC coaches, and analysis of previous research.

Previous Research

Dineen et al [10] evaluated the effectiveness of the SSBC in-person training. Data from this study helped determine coaches’ baseline levels of knowledge and skills prior to any training.

SSBC Research Team Meetings

The SSBC research team included the founder and director of SSBC (the last author) and the 2 in-person training facilitators (first and third author). The first meeting was held to determine whether the in-person training was a feasible and viable mode to continue to train SSBC coaches. The main reasons discussed for transitioning to e-learning were difficulties scheduling a 3-day in-person SSBC coach training for YMCA staff and volunteers, and concerns for practicality in the future expansion of SSBC to other Canadian and global facilities. Additional meetings with the research team were used to determine what knowledge and skills would be required of new SSBC coaches, what content from the in-person training would be included and excluded, and what new concepts could be added. Finally, SSBC research team meetings included discussions on measures to determine the effectiveness of the e-learning platform. In-depth meeting notes and minutes were recorded during meetings for later analysis.

Focus Groups With SSBC Coaches

Incorporating end users into the development of the e-learning platform (a main tenet of IKT) was done throughout the needs analysis, design, and development of the SSBC coach e-learning platform. Within the need analysis, focus groups with previously trained SSBC coaches were conducted. SSBC coaches who were trained through the in-person workshop were recruited via email to participate in a 2-hour focus group. Focus group questions centered on what content should or should not be included in the e-learning platform. Coaches also answered questions about motivation to learn, learning preferences (ie,
synchronicity, length of time, interactivity, and choice), and potential barriers for new coaches. Focus group data were analyzed using conventional content analysis [12].

Design and Development
To facilitate the design and development phase of this project, the research team hired a third-party digital health solutions company (3C Institute) that specializes in developing e-learning platforms. The first and last author had meetings with 3C Institute every 2 weeks to discuss project progress and make decisions. Throughout this time, the research team created a blueprint and storyboard of the detailed topics to be taught, discussed options for teaching formats (ie, a variety of didactic and user-engaging methods), and defined the learning objectives. The research team wrote the content for the module scripts, which were edited by 3C Institute to ensure they were clear and succinct. Modules were filmed by the research team, and 3C Institute developed graphics and compiled the modules.

SSBC coaches from the needs analysis phase were invited to participate in the design and development phase, specifically to review the overview of modules and methods of instruction and provide feedback.

All processes and decisions were documented in detailed meeting notes (eg, attendees, discussion points, and decisions). Calendar events and contracts captured the resources (eg, financial and time) required to develop the e-learning platform.

Test Usability
Usability evaluation helps to ensure that a product is usable, efficient, effective, and satisfying to its end users. Nielsen [13] identified five key components of usability: (1) learnability—how easily end users can accomplish basic tasks the first time they enter the e-learning platform; (2) efficiency—how well end users can perform tasks on the e-learning platform; (3) memorability—how easily end users can reestablish proficiency when they return to the e-learning platform after a period of not using it; (4) errors—how many errors the end users make, the severity of the errors, and their ease of recovery from the errors; and (5) satisfaction—how pleasant it is to use the e-learning platform.

Initial usability testing was conducted by the SSBC research team and the SSBC coaches involved in the e-learning platform design and development. Users were asked to navigate through the modules and learning activities and complete various tasks (eg, log in to the training platform, move through modules, and access the resource center). Written and verbal feedback on issues and errors were collected. A summary of concerns and usability issues was documented and sent to 3C Institute to be addressed. The level of usability was deemed acceptable by the first and last authors once all errors were resolved. In the true spirit of IKT, further usability testing will be examined through qualitative and quantitative methods upon release and implementation of the e-learning platform to ensure that the platform is usable by the end users.

Ethical Considerations
This study was approved by the behavioral research ethics board of the University of British Columbia (H21-01800). The participants provided informed consent for the focus groups and were involved in the further design and development of the e-learning platform. All data were deidentified upon data collection. Individuals were renumerated for their participation via e-transfer. Participants each received $50 CAD (US $36.83) for their participation in a focus group, and participants were given $25 CAD (US $18.42) for each module storyboard that they reviewed.

Results

Needs Analysis

Previous Research
Dineen et al [10] demonstrated that coaches had little knowledge about MI and SSBC program content prior to taking the in-person training. Coaches also reported high levels of satisfaction with the in-person training topics.

SSBC Research Team Meetings
The SSBC research team made the following decisions based on 3 meetings. SSBC coaches needed to have basic knowledge about T2D prevention, specific SSBC session content (ie, Canada’s physical activity guidelines, daily added sugar limits, carbohydrates, and the talk test), what MI is, the spirit of MI, MI skills (ie, open-ended questions, affirmations, reflections, summaries and ask-tell-ask), the 4 processes of MI, how to deliver SSBC content using MI, and how to deliver culturally safe and inclusive care. Coaches would need to demonstrate skills associated with delivering the SSBC program to clients, which includes appropriately delivering the correct information using an MI-informed approach.

Once a coach completed the e-learning modules, the coach would demonstrate their skills through a mock session, providing an opportunity for assessment and provision of feedback. Sufficient knowledge would be determined by scoring a minimum of 70% on a knowledge test on T2D prevention, SSBC-specific content, and MI at the end of the training. The research team would develop the knowledge tests, drawing from content directly covered in the SSBC coach e-learning training. Finally, the coaches’ skills would be monitored and assessed by coding a random selection of audio recordings from sessions with clients using session-content checklists and the Motivational Interviewing Competency Assessment tool [14].

Focus Groups With SSBC Coaches
Invitation emails were sent to 15 SSBC coaches to participate in a focus group, including information about the purpose of the focus group and remuneration of time. A total of 9 SSBC coaches volunteered to take part in a focus group, and they were split into 3 equal-numbered focus groups based on their availability. See Table 1 for focus group participants’ demographics and experience as a coach. On average, each focus group was 62 minutes.

The results from the conventional content analysis showed that coaches wanted more information on the evoking process of MI, on transitioning from sustain talk to change talk, and an understanding of the effectiveness of MI. The coaches spoke about the importance of knowledge checks throughout the
e-learning training, a collection of resources and commonly used documents (ie, a resource center), role-play videos demonstrating the skills being taught, and live sessions with a workshop facilitator to practice skills and receive feedback. The coaches suggested that modules be short in duration and for training to span over 2 weeks. The coaches’ recommendations also included the integration of a variety of learning methods through the use of didactic and user-engaging components. Additional resources suggested by coaches included video examples of delivering SSBC content using MI and various SSBC program delivery styles and scenarios. The participants desired a blended approach of asynchronous and synchronous learning, with an opportunity for practice and feedback.

**Design and Development**

The research team worked with 3C Institute and SSBC coaches over a series of 13 months (21 meetings) to design and develop the e-learning platform. Correspondence with the involved SSBC coaches to collect feedback was done over email. The flow of the entire design and development phases can be seen in Figure 1, showing each group’s contributions to development.

Information collected in the needs analysis stage was used to develop a blueprint for the e-learning platform, which was then reviewed by the 3C Institute. After consultations with 3C Institute and SSBC coaches, it was determined that the e-learning training would include seven modules—1 introducing SSBC and inclusivity, 1 covering SSBC-specific content, 4 covering MI, and 1 putting everything together. Additionally, 3C Institute provided suggestions for learning activities (eg, narrated videos, demonstration videos, and user-engaging activities) based on their expertise in developing e-learning platforms. All modules were designed to be asynchronous so coaches could move through them at their own pace, with user-engaging components and knowledge checks throughout the modules, and at the end of each module. The e-learning platform includes a resource center for coaches to access resources (eg, PDFs, video examples, and SSBC session paperwork).

The research team drafted 1 module script at a time. Scripts included what the narrator would say, and the content for the user-engaging activities and knowledge. The script for each module underwent numerous editing cycles between the 3C Institute and the research team before being sent to the 3C Institute multimedia artist. The multimedia artist developed storyboard proofs for each module. Storyboard proofs included still images representing what would be on the screen with the associated script. Feedback was collected from both the research team and SSBC coaches from the focus groups. For each module storyboard proof, 2 to 4 coaches provided feedback (dependent on their schedules and availability) and were remunerated for their time. After the storyboard proofs were approved by the SSBC research team and coaches, the narrators for the videos (first and last author) worked with a University of British Columbia Studios Okanagan producer and the 3C Institute editor to film the 7 modules. Talent was hired to act as coaches and clients in the role-play videos for the modules and the resource center. After each module was filmed, the 3C Institute
multimedia artist and video director worked to edit and finalize the modules. An overview of the SSBC e-learning training platform is provided in Table 2 and a selection of screenshots from the online training platform are provided in Multimedia Appendix 1.

Based on decisions made following the needs analysis, the entire training process for new SSBC coaches includes 3 stages. First, the coaches must complete the 7 modules. Next, the coaches are required to schedule a 1-hour mock session with an SSBC research team member and are then provided with written feedback within 2 weeks of completing the mock session. Following the mock session, coaches are given access to the final knowledge test. After passing the final knowledge check, coaches are certified to take on SSBC clients independently.

Overall, the authors spent a total of 192 hours on this project (eg, preparing for and leading SSBC research team meetings and focus groups, analyzing data from needs analysis, designing blueprints, writing and editing scripts, developing knowledge check questions, emails, correspondence with SSBC coaches and talent, meetings with 3C Institute, filming, and usability testing). The final cost of developing the SSBC coach e-learning platform was ~US $80,000 (cost to hire 3C Institute and professional talent for filming).

<th>Module</th>
<th>Topics covered</th>
<th>Learning objectives</th>
<th>Module features</th>
</tr>
</thead>
</table>
| Module 1 | Introduction to SSBC, prediabetes and T2D\textsuperscript{b}, cultural safety, and inclusivity | • Broadly describe T2D and prediabetes  
• Explain how diet and exercise changes can help prevent T2D  
• Describe what the SSBC program includes  
• Understand why having an inclusive mindset is integral to being a SSBC coach  
• Understand the need to learn and act with empathy when working with clients, regardless of their background and life experiences | Narrated video, role-play videos, and knowledge check questions |
| Module 2 | SSBC session content, taking client measurements, tools associated with the program (eg, health tracking mobile app), and exercise protocols | • Describe the content that comprises each of the 6 SSBC counseling sessions  
• Understand the program tools and session documentation requirements  
• Know the difference between SSBC’s moderate-intensity continuous training and high-intensity interval training exercise sessions and the weekly progressions for each  
• Know which measurements to perform on your clients and when to take them | Narrated videos, demonstration videos, and knowledge check questions |
| Module 3 | Introduction to MI, definition of MI, and spirit of MI | • Define MI and identify where it falls on the spectrum of counseling styles  
• Describe each of the 4 elements of the spirit of MI  
• Understand how to implement the spirit of MI in SSBC sessions | Narrated videos, role-play videos, and knowledge check questions |
| Module 4 | MI skills: open-ended questions, affirmations, reflections, summaries (OARS\textsuperscript{d}), and ask-tell-ask | • Define and use the OARS skills  
• Describe and use the method “ask-tell-ask” to provide information or advice to your clients | Narrated videos, role-play videos, and knowledge check questions |
| Module 5 | Listening and responding to change talk, sustain talk, and ambivalence | • Define change talk and sustain talk  
• Define ambivalence  
• Describe preparatory change talk and mobilizing change talk  
• Understand which OARS skill will work best when a client engages in change talk, sustain talk, or ambivalence | Narrated videos, role-play videos, and knowledge check questions |
| Module 6 | 4 processes of MI: engaging, focusing, evoking, and planning | • Describe the 4 processes of MI  
• Understand how to use them in sessions with your clients | Narrated videos, role-play videos, and knowledge check questions |
| Module 7 | Putting it all together: how to deliver the SSBC content using MI | • Describe the elements of an SSBC session  
• Understand how to provide SSBC content in a way that embodies the spirit and skills of MI | Narrated videos, role-play videos, and knowledge check questions |
| Resource Centre | Additional information on topics covered in modules, sessions scripts, session checklists, and video role-plays | • N/A\textsuperscript{e} | PDFs and role-play videos |

**Test Usability**

Results from the initial usability tests conducted by the research team and the SSBC coach partners showed high levels of learnability, efficiency, memorability, and satisfaction within the provided feedback. Some errors were recorded including technical bugs, which were corrected by 3C Institute.
Discussion

Principal Results

This paper provides a clear and transparent outline for the needs analysis, design, development, and initial usability testing of the SSBC coach training e-learning platform. Importantly, this process demonstrates how an IKT approach can be used with the TEL evaluation framework. To our knowledge, this is one of the first e-learning platforms that has been developed using an IKT approach. Engaging end users through this process increases the chances that they will find the e-learning platform useful, acceptable, and appropriate [15,16].

The development and use of e-learning platforms for SSBC coaches will improve the viability of the program as new coaches will be able to take the training from any location and at a time that is convenient for them. This process can be used to inform other T2D prevention and health programs currently training coaches in person. e-Learning has become a popular education tool; however, there is still a lack of meaningful engagement with end users and research outlining the development process.

A preliminary study demonstrated high levels of satisfaction and gain in coach knowledge after completing this SSBC e-learning platform [17]. The next steps include implementing and evaluating the SSBC coach e-learning platform to examine the real-world applicability and effects of the platform using the TEL evaluation framework phases 4-7. This will include documenting key events during implementation, assessing new coaches’ experience and satisfaction with the e-learning platform (ie, user-friendliness and appropriateness of the platform), assessing learning outcomes (Kirkpatrick levels 2-4) through changes in knowledge, behavior, SSBC client outcomes, and finally, estimating the total costs to develop and implement the e-learning platform, as well as determining viability.

Beyond the use of SSBC, other programs should consider an IKT approach in developing e-learning platforms and transparently report the process. Once training programs have been developed and implemented, it is crucial that research teams monitor coaches’ knowledge, skills, and behaviors and report on the fidelity of their coaches [18].

Limitations

Only a small number of previous SSBC coaches were involved in the design and development of this e-learning platform, and their preferences for content and delivery style might not be reflective of that of all coaches who will take this e-learning training. However, working with 3C Institute allowed us to incorporate their expertise in e-learning platforms, content, and learning styles. This study does not examine the effectiveness of this training, and at this point, we cannot be certain that this training will improve coaches’ knowledge, skills, and behaviors. Future research will look at these learning outcomes.

Conclusions

This is the first paper to outline the needs assessment, design, and development of an e-learning platform for a T2D prevention program. One of the main limitations of the current T2D prevention programs is the limited reporting of coach training modes and training fidelity. This paper demonstrates how an e-learning platform can be designed and developed for T2D prevention program coaches using an IKT approach combined with the TEL evaluation framework. It is expected that this training will be acceptable and effective because of the methods and approaches used in this study.

Acknowledgments

The authors would like to acknowledge the Small Steps for Big Changes coaches for their important input on this project and the 3C Institute as the software developer and host of the e-learning training platform. This work was supported by a Canadian Institute for Health Research Grant (018647). This work was also supported by a Social Sciences and Humanities Research Council of Canada doctoral fellowship and the WorkSafe BC Doctoral Research Training Award.

Data Availability

The data sets generated and analyzed during this study are not publicly available to protect the intellectual property of SSBC but are available from the corresponding author on reasonable request.

Authors’ Contributions

KDC conceived the study, conducted the focus groups, led analysis, and wrote the paper. NJG assisted with the focus groups, data analysis, development, and usability testing. TED assisted in study conception and development. MEJ assisted with study conception and oversaw the project. All authors reviewed and approved the final paper.

Conflicts of Interest

None declared.

Abstract

Background: Clinical trials (CTs) are crucial for medical research; however, they frequently fall short of the requisite number of participants who meet all eligibility criteria (EC). A clinical trial recruitment support system (CTRSS) is developed to help identify potential participants by performing a search on a specific data pool. The accuracy of the search results is directly related to the quality of the data used for comparison. Data accessibility can present challenges, making it crucial to identify the necessary data for a CTRSS to query. Prior research has examined the data elements frequently used in CT EC but has not evaluated which criteria are actually used to search for participants. Although all EC must be met to enroll a person in a CT, not all criteria have the same importance when searching for potential participants in an existing data pool, such as an electronic health record, because some of the criteria are only relevant at the time of enrollment.

Objective: In this study, we investigated which groups of data elements are relevant in practice for finding suitable participants and whether there are typical elements that are not relevant and can therefore be omitted.

Methods: We asked trial experts and CTRSS developers to first categorize the EC of their CTs according to data element groups and then to classify them into 1 of 3 categories: necessary, complementary, and irrelevant. In addition, the experts assessed whether a criterion was documented (on paper or digitally) or whether it was information known only to the treating physicians or patients.

Results: We reviewed 82 CTs with 1132 unique EC. Of these 1132 EC, 350 (30.9%) were considered necessary, 224 (19.8%) complementary, and 341 (30.1%) total irrelevant. To identify the most relevant data elements, we introduced the data element relevance index (DERI). This describes the percentage of studies in which the corresponding data element occurs and is also classified as necessary or supplementary. We found that the query of “diagnosis” was relevant for finding participants in 79 (96.3%) of the CTs. This group was followed by “date of birth/age” with a DERI of 85.4% (n=70) and “procedure” with a DERI of 35.4% (n=29).

Conclusions: The distribution of data element groups in CTs has been heterogeneously described in previous works. Therefore, we recommend identifying the percentage of CTs in which data element groups can be found as a more reliable way to determine the relevance of EC. Only necessary and complementary criteria should be included in this DERI.

Introduction

Background

Clinical trials (CTs) are key to medical progress as they are used to implement a new therapy, a medical device, a diagnostic procedure, or a preventive measure [1,2]. CTs thus form an essential component of “translation,” the transfer of findings from basic medical research to clinical application [3].

An important part of planning a CT is to define criteria that all participants must meet. The main goal of these inclusion—and exclusion—or eligibility criteria (EC) is to specify the CT’s target population (ie, patients who have specific conditions and might benefit from the studied therapy). EC are also used to minimize disruptive factors that are under suspicion to interfere with the CT objectives. Additionally, EC consider individuals for whom a CT could pose a health risk, such as pregnant women. Finally, some EC are necessary for legal or organizational reasons [4,5].

The successful implementation of CTs depends on the recruitment of a suitable number of participants who fulfill all EC. Insufficient participant recruitment is the foremost reason for the premature discontinuation of CTs, which raises ethical concerns because participants are exposed to risk, without potential benefits. Furthermore, the extension of the recruitment period is also associated with significant financial costs and is consequently inefficient [6-10].

Clinical Trial Recruitment Support Systems

Identifying individuals who fulfill all the EC of an study and are willing to enroll is challenging and time-consuming. In many cases, trial personnel manually search for suitable candidates in electronic health records (EHRs) [9,11]. A clinical trial recruitment support system (CTRSS), also called a patient recruitment system (PRS), can assist in increasing participant numbers [12-14]. These systems simplify study participant identification with secondary use of data already collected for care and billing purposes in clinics [15] and work by comparing EHR data with the specified EC of CTs. Most CTRSSs described in the recent literature are implemented for only 1 specific trial, medical department, or clinic, but there are also some approaches to develop a CTRSS that can be used for a wide range of CTs [14,16-22].

Several key considerations are necessary for the successful deployment of a CTRSS. First, to implement a CTRSS, it is necessary to have patient records as well as EC in machine-readable format to perform a comparison of both and create a list of potential participants [23,24]. The formatting of EC in machine-readable form depends on the underlying technology used. For instance, in a database-oriented system, the criteria can be developed using Structured Query Language (SQL). Previous research efforts have used ATLAS software (Observational Health Data Sciences and Informatics [OHDSI]) for this purpose. Artificial intelligence (AI)–based methods exist for translating ethical considerations from study protocols into ATLAS software, which can partially automate the process [25].

As previously stated, medical data from hospitals or medical centers are used to compare a CTRSS with the EC and shortlist individuals from the data pool who meet the EC for the study [26]. Consequently, a CTRSS can only specify search criteria that correspond to the existing data pool. Hence, to ensure efficient prefiltering of the data pool, the CTRSS must contain the maximum number of desired search criteria.

The consolidation of medical data in a centralized format remains a significant challenge in many systems due to limited data availability [27]. Additionally, many hospitals lack a retrievable centralized system for all accumulating medical data. Despite ongoing efforts to harmonize data, these approaches are not yet widely accessible. Therefore, establishing a connection to a comprehensive data repository that facilitates all the necessary search criteria is crucial in implementing a CTRSS, and a predetermined list of search criteria is essential.

Eligibility Criteria

To characterize the necessary data for CTRSS implementation, multiple studies have examined the prevalence of data element groups in the EC of CTs. Even though the results of these examinations are heterogeneous, it is evident that diagnosis is the most frequent data element used in official study protocols, followed by data about therapies, medications, and diagnostic results [25,28-30].

When searching for potential study participants, there is often a need to manually search through a large number of patient files. Study personnel typically start by making a preselection. Initially, they check the EC that they consider most important, as this helps narrow down the pool of potential CT participants effectively. Some EC can only be assessed right before including participants in the study or necessitate a personal evaluation by the trial staff. One such criterion is the consent form that participants are required to sign during the inclusion process. Not all the EC specified in the study protocol are likely used for preselection in the context of a CTRSS [11]. When implementing a CTRSS, it is sufficient that only relevant data element groups be queried to obtain appropriate suggestions [30].

Objectives

In previous work, we identified which data element groups are most commonly used in CT EC [30]. In this study, we investigated which of the data element groups identified in the previous studies, mentioned in the Eligibility Criteria section, are relevant in practice [25,28-30].

Another objective was to categorize these EC according to their underlying data element in order to identify the element groups, such as diagnosis, laboratory values, or demographics, that are most commonly used for patient recruitment, as well as those
that are mostly irrelevant to a CTRSS. Since the use of different data elements and search algorithms is strongly influenced by the availability of this information in EHRs, we also investigated when a data element needs to be checked but is not available in the patient’s EHR.

The overall goal was to determine the relevance of data element groups for use in a CTRSS. Therefore, we wanted to find out how often different data element groups occur in CTs and how often the groups are considered relevant. We also wanted to determine how many studies these data element groups occur in.

Methods

Participants

Two groups of participants were enrolled in the study. The first group included 1 or more project participants (PPs) at each site who were responsible for data collection. These individuals had deep knowledge of medical informatics in general and were also involved in the development of a CTRSS.

The second group of participants were trial staff actively working in the field of study recruitment. They were referred to as trial professionals.

Data Collection Sheet

To assess the relevance of data element groups, we first developed a data collection sheet to capture relevant information from the trial professionals. We wanted to capture all EC of the selected CTs in their original format, the underlying data element, and the assessment of study personnel in terms of relevance to patient recruitment. The development of the data collection sheet was an iterative process in which the categories were first discussed in a group of 10 CTRSS developers and then tested by 2 persons of this group on 3 randomly selected studies. In the next step, the group discussed any issues that arose. After 3 iterations, we achieved full agreement among all testers and developers.

For simple but unambiguous categorization, we used the 40 most common data element groups of EC from our previous work [30] and combined some rarely used groups into broader categories (e.g., special laboratory information into a category laboratory value). If none of the given data element groups were appropriate, it was also possible to select a broader category, such as other procedural information, and provide a more specific description as a comment. These categories are then strongly linked to the data in EHRs and can therefore provide more insight into the possibilities of accessing elements of EC in clinical systems. For a complete list of all data element groups and other information composed on the data collection sheet, see Multimedia Appendix 1.

EC were classified into 3 CTRSS relevance categories: necessary, complementary, and irrelevant. Necessary items are those that determine the main selection of the desired cohort, complementary criteria in a manual process are mostly used in a second step to obtain more precise results, and irrelevant criteria are not used at all. Because there are criteria that may be important for participant selection but are not regularly documented in the EHRs and therefore must either be known by the treating physician or verified by direct questioning of the patient, we added the categories “necessary, not documented” and “complementary, not documented.” In addition, there are various reasons criteria may be irrelevant. Therefore, we decided to add the categories “irrelevant, redundant” and “irrelevant, recorded at the time of enrollment.” The category descriptions are summarized in Table 1.

Table 1. Tabular view of EC\textsuperscript{a} relevance categories with descriptions.

\textsuperscript{a}EC: eligibility criteria.

In addition, we had a field to note surrogate data element groups that could be used if a criterion was not documented in the EHR system. For example, if a particular condition is not documented in a timely manner and there is a lab result that is indicative of that condition, that lab result can potentially be used as an alternative data element.

Taking an example CT on diabetes with the inclusion criteria of a diagnosis of diabetes, an elevated laboratory value, and consent to participate in the CT, as well as the exclusion of drug abuse, this can be classified as shown in Table 2. In this example, the presence of diabetes is the main inclusion criterion, so it is classified as “necessary” and the laboratory value is classified as “supplementary,” since this criterion usually applies to all patients with diabetes. Alcohol abuse can be diagnosed in the medical history but is usually not documented in the patient’s record, and therefore, it is an additional filter criterion but cannot be verified by inspection of the file. Alternatively,
it is possible to find notes about possible alcohol abuse in the records of the patient’s medical history.

Selection of Trials

We collected CT information from 8 university hospitals in Germany between December 2021 and March 2022 using the data collection sheet described in the Data Collection Sheet section.

The participating centers conducted the CT selection, including only CTs that recruited participants prospectively. This means that the CTs actively searched for individuals and asked them to participate. Animal, biomaterial, and case-control CTs were excluded. Psychiatric and oncological CTs were also excluded due to organizational reasons. There were no further restrictions on the selection of medical specialties.

Trial centers were contacted by the PPs to inquire about participation in the study. If a positive response was received, the CTs recommended by the trial personnel were incorporated into the analysis. The trial professionals were also asked to participate in this study to obtain a real-world view of the CT recruitment process. The PPs had either face-to-face or video meetings with the trial professionals to discuss the process of identifying potential participants and to categorize each individual criterion based on both parties’ experiences. If a positive response was received, the CTs recommended by the trial professionals were discussed and incorporated into the analysis.

Data Validation and Analysis

All PPs were trained in a common training session where the data collection sheet was presented and tested. To ensure the correct use of the data element groups and the CTRSS relevance categories, we performed an additional step to validate the collected data: 2 authors went through all records and checked for consistency and face validity. If the entries were not fully understandable, they contacted the responsible PPs and discussed the case until agreement was reached. Despite the validation step, the distribution of relevance categories remained unchanged. However, the distribution of data element groups changed. All steps are shown in Figure 1.

Figure 1. Sequence of data collection, with a mention of the groups of persons involved: contacting local CT centers (PPs), grouping and categorizing all EC of the given CTs (PPs and trial professionals), checking the face validity of data element groups and relevance categories (authors), discussing all ambiguities (authors and PPs), new grouping, if necessary (authors and PPs). CT: clinical trial; EC: eligibility criteria; PP: project participant.

Statistical Analysis

Statistical analysis and graphing were performed using R (R Core Team and the R Foundation for Statistical Computing) [31]. Due to a high number of items in the collection categories such as “Other” or “Other medical history,” we decided to group the corresponding items into new categories. This work was performed by 2 authors to avoid errors.

Ethical Considerations

Data capture and analysis only included individuals associated with the project. No Institutional Review Board approval was requested, as this would only be appropriate for studies including direct contact with patients [32], but we did not capture or process any patient-related data, so informed consent was not required.

Results

Studies Investigated

Figure 2 shows the departments to which the reviewed studies belong. Although no prior decision was made as to which departments to select, there was an overrepresentation of neurological studies.
Figure 2. Distribution of the medical specialties among the analyzed studies, sorted in descending order: neurology (n=30, 36.6%), cardiology (n=8, 9.8%), urology (n=7, 8.5%), general surgery (n=7, 8.5%), dermatology (n=6, 7.3%), gastroenterology (n=5, 6.1%), orthopedics (n=3, 3.7%), hematology (n=3, 3.7%), pulmonology (n=2, 2.4%), neurosurgery (n=2, 2.4%), gynecology (n=2, 2.4%), diabetics (n=2, 2.4%), anesthesiology (n=2, 2.4%), trauma surgery (n=1, 1.2%), rheumatology (n=1, 1.2%), and other (n=1, 1.2%).

Data Element Groups

In total, we included 82 CTs from 8 different university hospitals, and at each site, 3-25 (4%-30%) CTs were processed. In total, we identified 1157 EC, of which 1132 (97.8%) unique criteria remained after the removal of duplicates, which were classified as “irrelevant, redundant.”

Figure 3 shows the frequency of data element groups in all examined EC. With 28.4% (321/1132) of all EC, diagnosis was, by far, the most common data element, followed by informed consent and date of birth/age in second and third places, respectively.

Figure 3. Frequency of data element groups in all EC, in descending order: most frequent were diagnosis (n=321, 28.4%), followed by informed consent (n=97, with 8.6%) and date of birth/age (n=78, 6.9%). EC: eligibility criteria.
**Relevance Categories**

In terms of EC relevance, 350 (30.9%) of the 1132 EC were categorized as “necessary,” 224 (19.8%) as “complementary,” 217 (19.2%) as “not documented,” 52 (4.6%) as “irrelevant,” and 289 (25.5%) as “irrelevant, recorded at the time of enrollment.” The overall percentages are shown in Figure 4.

**Figure 4.** Distribution of relevance categories of all EC: 350 (30.9%) “necessary” criteria, 109 (9.6%) “necessary, not documented,” 224 (19.8%) “complementary,” 108 (9.5%) “complementary, not documented,” 52 (4.6%) “irrelevant,” and 289 (25.5%) “irrelevant, recorded at the time of enrollment.”

**Total Irrelevant Criteria**

In total, 341 (30.1%) EC were categorized as “irrelevant” and “irrelevant, recorded at the time of enrollment.” These were mainly patient consent information (n=90, 26.4%). In addition, the EC “other” (n=42, 12.3%) and “other medical history” (n=26, 7.6%) were often marked as not relevant for patient screening. Diagnosis was only a small part (n=24, 7%) of all irrelevant EC, which is low compared to the general data element distribution shown in Figure 3, where this category makes up the largest part. A visualization of the complete list and frequencies can be found in Multimedia Appendix 2.

**Nondocumented Criteria**

In total, 217 (19.2%) necessary and complementary EC were categorized as not documented and were most commonly the data element groups diagnosis (n=121, 55.8%), examination results (n=36, 16.6%), and procedures (n=28, 12.9%). As noted in the example in Table 2, it is possible that data element groups such as diagnosis were sometimes categorized as documented and sometimes with other categories, which is valid because it may depend on the medical context of what information is documented. All data element groups and their frequencies can be found in Multimedia Appendix 3.

**All Relevant Criteria**

As defined before, both complementary and necessary EC were relevant for an automated search of potential participants, which were 574 in number (Multimedia Appendix 4). The most frequently used data element groups were diagnosis code, which accounted for 44.4% (n=255) of all necessary EC, followed by date of birth (n=74, 12.9%) and procedure codes (n=48, 8.4%).

**Relevance Distribution by Data Element Group**

Since each criterion was individually classified into a data element group and a relevance category, it is possible that common data element groups play a role in several of the categories. For this reason, the categorization between data element groups was heterogeneous. For example, the data element group diagnosis was mostly categorized as necessary or complementary (n=255, 79.4%), while the data element group informed consent was mostly categorized as “irrelevant, recorded at the time of enrollment” (n=90, 92.8%). In addition, the data element groups pregnancy, contraception, and lactation were mostly either not documented or documented at the time of enrollment. Figure 5 shows the relevance distribution for all data element groups.
Figure 5. Distribution of relevance categories in percentage by data element group; the groups were recorded at least 5 times in our data set, ordered by the proportion of necessary EC: date of birth/age, other details of encounter, diagnosis, and diagnosis date showed the highest proportion of necessary EC. EC: eligibility criteria.

Data Element Relevance Index

More important than the absolute frequency of a data element is the question of how many CTs the element is used for in patient screening and not how often a group is represented in a CT. This parameter, the data element relevance index (DERI), can be calculated without considering the frequency of data element groups in CTs.

For the calculation, we determined the number of CTs in which the data element was used at least once and removed all entries marked as undocumented or irrelevant. The results showed that the data element groups diagnosis and date of birth/age were present in more than 50% of the CTs: diagnosis, n=79 (96.3%); date of birth/age (85.4%). All other DERI values are shown in Figure 6.
Surrogate Parameters

For the case of unavailability of an original data element, 92 (8.1%) of the EC were documented surrogate parameters to use. Surrogate parameters were often used for the grouping categories “Other medical history” (n=14, 15.2%) and “Other diagnosis information” (n=13, 14.1%). Diagnosis had the highest frequency in both original elements (n=20, 20.7%) and surrogates (n=52, 56.5%). As a surrogate data element for diagnosis, procedures (n=5, 25%) and laboratory results (n=5, 25%) were most often used.

Discussion

Principal Findings

EC have been analyzed and categorized repeatedly in recent years to measure their prevalence in CTs. These studies have mostly categorized EC into semantic categories [33]. Comparing the studies, we saw that the frequency of semantic categories shows some overlap but also varies to some extent [28]. This could be due to the selection process of the studies or a different way of categorization by the diverse researchers.

Data Element Groups

Although the categorization by Luo et al [33] focuses on the semantic categories of EC rather than individual data elements, as in this paper, parallel categories exist that we used to find similarities and differences. Previous studies have measured the prevalence of data element groups as a percentage of all EC examined [25,28-30,33].

Our measured prevalence of similar data element groups differed by no more than 0.5 from the minimum and maximum of the measured frequency percentages of comparable studies. This comparison using the semantic categories described by Luo et al [33] is provided in Multimedia Appendix 5. An exception is the consent category, which we used more often. In our review, consent was often used more than once for a CT, not only to describe consent to the CT itself, but also when a participant was asked to consent to specific procedures or circumstances of the CT. This included, for example, consent to use adequate contraception for the duration of the CT. The high deviation from other studies may be due to the fact that other studies have only used this data category for specific CT consent [25,28,29].

Relevance Categories

The results show that about 70% of the examined EC are relevant for the selection of potential CT participants. About 19% are not usually documented in EHRs and therefore cannot be used for filtering, even if the trial professional searches all patient records. Whether a criterion is classified as undocumented depends, in part, on the capabilities of hospital information systems and therefore varies from hospital to hospital. In addition, certain information may only be collected depending on the context of care and the severity of illness.

About 51% of all EC are relevant for the electronic prefiltering of patients. Since the implementation of EC is one of the obstacles in the development of a CTRSS, the realization that only about half of the EC are relevant can mean a simplification in the implementation of EC in the systems.

Figure 5 shows that it is not possible to link data element groups only to 1 relevance category. Instead, depending on the context of the CT, different relevance categories were assigned to the data element groups. In some cases, the same group was sometimes categorized as documented and sometimes as undocumented. This can be explained by the fact that whether information is documented depends not only on the data element group but also on several other factors. For example, often, only diagnoses that are considered important and investigated in the context of therapy are documented. In these cases, the trial
professionals may be able to make an assessment because they are either part of the patient care or are in close contact with the treatment physicians and are therefore aware of these details for documentation purposes. Figure 5 can provide some guidance as to which data element groups are typically not needed, but an assessment should always be made directly by the trial professionals.

In previously published studies on the prevalence of EC, this was usually also referred to as their relevance. Our results show that a significant proportion of EC is not used to search for participants. Since the classification according to relevance categories varies between the data element groups, as shown in Figure 5, it is apparent that filtering according to relevance criteria affects not only the number of EC but also the frequency distribution of the data element groups.

For this reason, we compared the general frequency of data element groups (Figure 3) with those categorized as necessary or complementary (Multimedia Appendix 4). From this comparison, we saw that the percentage prevalence of all data element groups is sometimes different from the prevalence of the relevant data element groups. Diagnosis and date of birth/age as well as procedures show a particularly strong increase in frequency. However, consent, other medical history, and pregnancy are significantly less frequent among the data elements classified as relevant.

**Data Element Relevance Index**

The frequency order of data element groups depends on how they are viewed. If the EC criteria are filtered based on their relevance in prefiltering possible participants, the frequency order changes.

The introduction of a new DERI measurement value changes the perspective. The occurrence frequency of data element groups, such as various laboratory values, in a study is no longer relevant. The consideration now lies only in the frequency of the respective group’s use in studies. Studies with a significant number of exceptional cases exert less influence on the general outcome.

Furthermore, by using the DERI value, it is possible to determine the number of studies reliant on a specific data element group. Consequently, a direct inference can be made about its impact within a CTRSS, which is unachievable through pure frequency data.

**Data Completeness**

In 2018, Vass et al [34] examined the data quality of data element groups commonly used in CT EC in 10 university hospitals in Germany. They found that the data completeness is partly heterogeneous and that elements are rarely collected in a structured way in daily clinical practice, which hinders automated retrieval [34].

Comparing the DERI values of the data element groups and the completeness of data in the EHRs (Figure 7), we saw that more than 80% of the information is available for the 3 most relevant data element groups (diagnoses, demographics, and procedures). The less relevant categories of laboratory results and other diagnostic information are still available in more than 65% of cases. However, medication information (medication history and current medication) is problematic, with availability ranging from 13% to 61%. Nevertheless, medication history and current medication are relevant groups, with DERI values of 13% and 26%, respectively. Scores are also poorly documented, with a data completeness of 18%.

**Figure 7.** Data completeness measured by Vass et al [34] in comparison with DERI. It can be seen that although diagnosis and date of birth/age both have a high data completeness rate and DERI, problems arise with scores, medication anamnesis, and current medication, which have a low data completeness rate. OPS: Operationen- und Prozedurenschlüssel.
To reliably use these data in a CTRSS, a higher level of completeness should be present for DERI values higher than 10%. Poor data quality of data from EHRs, when matched with EC from CTs, can lead to high false-negative rates for inclusion criteria and high false-positive rates for exclusion criteria. The former, in particular, is fatal to the use of a CTRSS, as matching individuals are thus overlooked. High false-negative rates, in turn, lead to increased workload for trial personnel.

The study by Vass et al [34] showed that some data element groups are well captured in EHRs but other elements are problematic. This generates a data gap between EC and EHRs, which was analyzed by Butler et al [35]. They found that about 40% of all EC are not captured in EHRs. Since a structured collection of clinical patient-related information is important not only for the implementation of a CTRSS but also for billing purposes and patient safety, hospitals as well as governments are pushing the digitalization of patient records. In recent years, many initiatives and laws have been implemented to make data from EHRs available for research purposes [36,37]. Therefore, it is likely that the accessibility of medical information has recently improved or will improve in the future.

The timeliness of data element accessibility was not considered here but should be in future studies to assess not only whether a data element is documented in EHRs but also whether this data element is accessible in time. We should also examine whether the results of Butler et al [35] are reproducible when only relevant criteria are examined.

Implementation of Patient Recruitment Systems

In previous publications, the relevance of data element groups has been described as the frequency of a group relative to the number of all data elements found in all EC, which depends only on the distribution of data element groups. Since the prevalence of EC is defined heterogeneously in the literature, it is not useful to assess the relevance of data element groups based on the frequency distribution alone.

Especially for the implementation of a CTRSS, it is useful to evaluate how many CTs use a data element group. Using the DERI to determine the relevance of data element groups can be helpful here, as it additionally includes only groups that are used to search for participants.

The core functionality of a CTRSS is to compare EC with clinical data to identify potential participants. For the system to be useful to trial staff, the suggestions must be as accurate as possible, with minimal false-positive or false-negative rates. Since the comparison between the clinical database and EC is the critical factor at this point, it is particularly important that as many EC as possible be checked automatically. When implementing a CTRSS for different types of CTs, it is recommended to first identify important data element groups by determining a local DERI for all data element groups.

Therefore, a set of CTs should be analyzed in cooperation with the trial sites, and all data element groups with a high DERI should be accessible to the CTRSS. For this purpose, it is useful to set a threshold value for the DERI determined and to make available all data element groups that exceed this value. For this purpose, we could start with a value of 10, since this means that a data element group is used in at least 10% of the CTs, and gradually increase this value. Further studies are needed to determine the quantitative relationship of the DERI to the results of a CTRSS.

In contrast to the determination of local DERI values, there is the additional task of determining the data quality of the available data sources to be used for matching with the EC of CTs. Again, data completeness and timeliness should be determined locally to ensure that the necessary data element groups identified are available in the highest-possible data quality.

Limitations

Since the PP s at the study sites were allowed to select participants themselves, the selection of participants was through the convenience sampling method. Randomization was not possible; instead, all participants who were currently supervising at least 1 CT and who were willing to participate in the study were included. Additionally, we could see an overrepresentation of neurological CTs in our sample and had to exclude oncological and psychiatric CTs.

The categorization of EC was performed with the cooperation of CTRSS experts and trial professionals at each site. To minimize the bias of different categorization methods, all the categorization of data element groups was validated by 2 experts.

The results presented here are dependent on the study sites selected. The clusters we identified may be prone to local variation, and their applicability to other sites is unclear.

Conclusion

In this study, we demonstrated that automated recruitment support of CT personnel requires only roughly 50% of the EC indicated in the CT protocols. Since the frequency of EC in CTs is described differently in the literature, exclusively focusing on the frequency of EC is misleading. Instead, we propose to define the relevance of EC as the proportion of CTs in which a criterion occurs. In addition, only EC considered relevant (necessary or complementary) for patient recruitment should be included for this determination. This DERI can be used to quantify the relevance of EC data element groups.

Further examination is necessary to find out whether the relevant data element groups are documented in EHRs in a structured way and accessible in time for the implementation of a CTRSS.

Acknowledgments

This study was conducted in the Medical Informatics in Research and Care in University Medicine (MIRACUM) Consortium. MIRACUM is funded by the German Ministry for Education and Research (funding number FKZ 01ZZ1801A/B/C/D/G/L/M).
We greatly appreciate the work of Ines Reinecke, Susanne Zabka, Phillip Macho, Alexandra Stein, and Frederike Elisabeth Euchner for their support in the development of data extraction sheets and in data collection. We also thank Fabian Wäldchen for his help with writing and proofreading.

**Data Availability**

We added the parameters of our data collection sheet, as well as all analysis and results, either in this paper or in the appendices. Additionally, all data our analysis is based on can be found in Multimedia Appendix 6. We only had to remove original trial descriptions, as they would allow a conclusion on concrete clinical trials and locations.

Abstract

Background: The prevalence of childhood obesity and comorbidities is rising alarmingly, and diet is an important modifiable determinant. Numerous dietary interventions in children have been developed to reduce childhood obesity and overweight rates, but their long-term effects are unsatisfactory. Stakeholders call for more personalized approaches, which require detailed dietary intake data. In the case of primary school children, caregivers are key to providing such dietary information. However, as school-aged children are not under the full supervision of one specific caregiver anymore, data are likely to be biased. Recent technological advancements provide opportunities for the role of children themselves, which would serve the overall quality of the obtained dietary data.

Objective: This study aims to conduct a child-centered exploratory sequential mixed methods study to identify user requirements for a dietary assessment tool for children aged 5 to 6 years.

Methods: Formative, nonsystematic narrative literature research was undertaken to delineate initial user requirements and inform prototype ideation in an expert panel workshop (n=11). This yielded 3 prototype dietary assessment tools: FoodBear (tangible piggy bank), myBear (smartphone or tablet app), and FoodCam (physical camera). All 3 prototypes were tested for usability by means of a usability task (video analyses) and user experience (This or That method) among 14 Dutch children aged 5 to 6 years (n=8, 57% boys and n=6, 43% girls).

Results: Most children were able to complete FoodBear’s (11/14, 79%), myBear’s (10/14, 71%), and FoodCam’s (9/14, 64%) usability tasks, but all children required assistance (14/14, 100%) and most of the children encountered usability problems (13/14, 93%). Usability issues were related to food group categorization and recognition, frustrations owing to unsatisfactory functioning of (parts) of the prototypes, recall of food products, and the distinction between eating moments. No short-term differences in product preference between the 3 prototypes were observed, but autonomy, challenge, gaming elements, being tablet based, appearance, social elements, and time frame were identified as determinants of liking the product.

Conclusions: Our results suggest that children can play a complementary role in dietary data collection to enhance the data collected by their parents. Incorporation of a training program, auditory or visual prompts, reminders and feedback, a user-friendly and intuitive interaction design, child-friendly food groups or icons, and room for children’s autonomy were identified as requirements for the future development of a novel and usable dietary assessment tool for children aged 5 to 6 years. Our findings can serve as valuable guidance for ongoing innovations in the field of children’s dietary assessment and the provision of personalized dietary support.

Introduction

In the Netherlands, childhood overweight and obesity have reached an alarming prevalence of 15% in 2021, indicating a pressing public health concern [1]. Childhood obesity has a major impact on psychological health and later-life risks of developing noncommunicable diseases, mortality, and morbidity [2,3]. As a healthy diet is known to play a vital role in the prevention of obesity [4], interventions encouraging children toward healthier food choices receive high priority globally. However, the long-lasting effects of past and ongoing dietary interventions are rather limited, mainly related to their “one-size-fits-all” approach, which calls for more personalized interventions [5].

Personalized dietary interventions require accurate individual-level dietary assessment and monitoring [6] to facilitate realistic personalized dietary feedback. However, dietary assessment methods in young children are extremely challenging owing to their limited literacy, writing skills, food knowledge, and interest [7]. Consequently, caregivers currently serve as the primary sources of (surrogate) dietary information for their children. However, as primary school children gain independence in their food choices, the likelihood of misreporting increases [8]. Recent technological advancements now provide opportunities for a role for children themselves in the dietary assessment, which may serve the overall obtained dietary data quality.

Accordingly, there is growing interest in the development of innovative tools to assess dietary intake in children, with a particular emphasis on more effective and engaging technology-based solutions [9,10]. However, most of the developed tools thus far lack proper validation and are not tailored to the Dutch context, including Dutch food databases [11,12]. Country-specific dietary assessment tools are essential to accurately capture dietary information while considering cultural, regional, and nutritional differences. Moreover, given children’s rapid cognitive development, there is also a need for dietary assessment tools that align with their age-specific developmental stages. Current research has mostly focused on tools for children aged ≥8 years [11], as children tend to be better at independently reporting their food intake from this age onward [7]. However, considering the high level of technology readiness in today’s generation of children and the continuously changing technological possibilities, it is worth exploring the development of dietary assessment tools for younger children.

A “child-centered approach,” which places the user in the center of the design and development process, can effectively address young children’s age-specific cognitive needs for innovative dietary assessment. This approach enables researchers to understand the context, needs, and preferences of the tool’s intended end users [13,14] by engaging children in identifying challenges and finding solutions [15]. As a result, a child-centered approach can enhance design outcomes, improve user experience [16], and potentially improve data collection procedures and accuracy. In the decades marked by an increasing prevalence of childhood health issues, understanding the dietary behaviors and needs of young children is vital for informing effective interventions.

Therefore, as a first step, this study aimed to reveal user requirements for a novel child-friendly food intake registration tool designed for Dutch children aged 5 to 6 years. In pursuit of this goal, we developed and evaluated 3 distinct prototypes specifically created for children aged 5 to 6 years while considering age-specific cognitive and developmental characteristics to serve as valuable guidance for advancing the field of dietary assessment tools for children across a broader age range.

Methods

This study applied an exploratory sequential mixed methods study design, combining qualitative and quantitative measures [17]. Phases included a formative research phase (qualitative), a developmental phase (qualitative), and an evaluation phase (mixed methods, but with qualitative emphasis; Figure 1).

Figure 1. Flowchart illustrating the design process of the dietary assessment tool prototypes FoodBear, myBear, and FoodCam.

Formative Research

We performed a nonsystematic narrative literature research to identify existing dietary intake assessment tools for young children, their validity, and age-specific developmental considerations. This information was then used in an expert workshop to probe prototype idea generation. This nonsystematic search followed an abductive approach [18], focusing on extracting valuable insights to inform the design process effectively (eg, formulation of a list of user requirements and wishes for designing a dietary assessment tool for children aged 5-6 years; Textbox 1), rather than aiming for an exhaustive review of the available literature. The search query included a combination of the following Medical Subject Headings terms: dietary assessment, food intake, nutritional assessment, child centered design, child*, kid*, preschool*, child computer interaction, and eHealth. To our knowledge, this study is the first to focus on self-reported tool development among children.
aged 5 to 6 years. Therefore, our requirements are based on heterogeneous literature, including studies related to design for children [19-21], dietary assessment tools for older children outside the Netherlands [22-27], or child development [7,28]. In the context of this study, requirements were defined as being vital for usability and wishes as being desirable for enhancing usability and motivation among children. Our requirements were assessed in terms of perceived importance (ranging from 1 to 5) based on close consultation and consensus within our research team (Textbox 1). In the weighted decision matrix (WDM), decisions were rated on a scale of 1 to 5, with 1 indicating low importance and 5 signifying high importance for successful use.

**Textbox 1.** List of user requirements for a novel dietary assessment tool for children resulting from formative research and their importance (score ranging from 1 to 5). The list includes aspects that the dietary assessment tool should have (ie, requirements) or could have (ie, wishes).

- Incorporate gamification [21,26]
- Include a storyline [21,25,26]
- Include rewards [21]
- Incorporate learning and/or repetitive elements [19]

### Development

#### Idea Generation

Concepts for dietary assessment tools were developed through a 1-hour web-based expert panel workshop hosting nutrition (n=4), design (n=4), behavior (n=1), and technology researchers (n=2). Experts were carefully selected from various universities in the Netherlands and came together on the web-based Miro whiteboard platform. The workshop unfolded in 3 key stages. First, the experts immersed themselves in the world of our target audience by engaging with emotional image prompts. Next, experts were presented with our comprehensive list of requirements, as detailed in Textbox 1, and tasked with generating prototype ideas that could address these requirements. In the third and final phase of the workshop, the experts collaborated in pairs to refine these ideas and transform them into feasible prototypes. The results of this collaborative effort produced a wide range of innovative concepts, including a food piggy bank, food camera, digital plate, Tamagotchi, smartwatch, and a food diary.

#### Prototype Development

The results of the expert panel workshop were scored and evaluated against the list of requirements and subsequently multiplied by their importance (ranging from 1 to 5) in a WDM [18] (Multimedia Appendix 1), a decision-making tool that can be used to evaluate a set of options against critical factors and compare design concepts based on the overall value of each design concept. Three researchers from Wageningen University and Research (WUR) completed the WDM individually to ensure objectivity. The 3 concepts were considered to align most closely with the requirements and subsequently further advanced, which resulted in the 3 functional prototypes, FoodBear (average WDM score: 144.1), myBear (average WDM score: 148.4), and FoodCam (average WDM score: 144.7; Figure 2; Multimedia Appendix 2).
FoodBear can be used as a food recall or food record [9] and serves as a physical eating buddy in the shape of a bear. FoodBear can be fed with coins that match the foods consumed by the child (Table 1). A coin represents 1 item of the food group eaten (eg, 1 slice of bread) and children are challenged to put the number of coins corresponding to the number of items eaten in the bear’s belly as an estimate of portion size. This allows the assessment of food group diversity and provides a rough estimate of dietary intake.

Table 1. Included food groups in myBear and FoodBear and their contribution to the lunch of Dutch children aged 5 to 6 years [24].

myBear can be used as a food recall or food record [9] but in the form of a tablet-based app. The user interface design was developed with Adobe XD software, and the prototype app can be displayed on a smartphone or tablet. Children feed the bear with the same foods as they ate themselves. On the home screen of the app, children select the food groups they consumed, which then appear in the belly of myBear. The child uses plus and minus buttons to indicate the quantities of items from the food group they have consumed. Children receive a sticker on a digital sticker sheet after completing all entries. Similar to FoodBear, myBear can be used to provide a rough estimate of dietary intake and to track food group diversity.

FoodCam is based on the food record methodology [9] and consists of a camera and a “cookbook template.” The camera is specifically designed for children, and for this specific purpose, it was used to take pictures of food items. As the camera immediately prints the captured photo, it also provides immediate feedback to the child. Subsequently, the printed photos can be used by children to create their own cookbook, which offers the opportunity for children to draw and express their creativity. FoodCam can be used to assess daily food intake. FoodCam is accompanied by a cookbook stencil (in Dutch) on which children can put a picture of their lunch, draw it, indicate how full they feel [29], and how much they enjoyed it [30].

Prototype Content

The first prototypes were developed to assess lunchtime and focused on the most frequently consumed foods during lunchtime by young Dutch children according to the Dutch Food Consumption Survey [31] (Table 1). Only food groups that contributed for >10% to children’s lunch were included.

Recruitment

Overview

We recruited 14 Dutch (n=6, 43% girls and n=8, 57% boys) children aged 5 to 6 years through purposive sampling, as 10 (±2) participants were considered sufficient for usability evaluation [32]. Data saturation was assumed to be acquired within 6 to 12 sessions [33], which in this study was reached after 11 sessions. Children were recruited via colleagues within the Division of Human Nutrition and Health at WUR and through personal networks.

Figure 2. From left to right, FoodBear, myBear, and FoodCam. myBear (in Dutch) shows the entry screen for lunch, where children can report their intake during lunch based on the food groups depicted in Textbox 1.
User Testing

The functional prototypes were evaluated on usability and user experience by combining qualitative and quantitative measures [17]. To make the child feel comfortable, the researcher visited the child at home in the presence of a parent or caregiver. Before the start of the session, the parent or caregiver was instructed to introduce the researcher as a toy inventor and that their child would act as an assistant inventor. Moreover, parents were instructed to interfere as little as possible during the user tests. The entire procedure took approximately 30 minutes and took place after lunch, between 1:30 PM and 3:00 PM. The 30-minute time frame was selected to align with the attention span of young children. We conducted 3 streamlined usability tasks (lasting a maximum of 140 seconds) and a user experience task and interview within this time frame to minimize any potential loss of interest or fatigue among participating children. To ensure that all tasks would fit within our proposed time frame, the procedures were piloted twice. All parents completed a demographic questionnaire on the child’s age (y), gender (boys or girls), number of siblings, siblings’ age (y), interactive screen time (h/d), foods and portion sizes eaten during lunch, and time of lunch. Parental lunch dietary intake data gathered in the questionnaire were used as the criterion to assess successful recall by the children, instead of more objective direct lunch observation, to be able to create a study environment that is comfortable and engaging for children. Testing order for FoodBear and myBear was alternated across participants. To assess the usability of FoodCam, parents were instructed to prepare a duplicate (i.e., an “identical meal to what their child had eaten for lunch on the day of testing”) of the children’s previously consumed lunch during the test. This prototype was always tested last because FoodCam is the only prototype that does not rely on children memorizing their lunch.

The procedure consisted of 3 usability tests (steps 3, 5, and 6; Textbox 2) and a user experience test (steps 7-9; Textbox 2). To assess usability, children performed a task with every prototype while measuring the completion rate and task completion time. Completion rate was defined as the proportion of children that successfully completed the usability tasks, and completion time was defined as the time needed to complete the task. The time required for the researcher to explain or draw attention to the task was subtracted and the number of interruptions required to complete the tasks were registered. Behavioral observations and field notes were evaluated to identify the usability issues. A detailed description of the study procedures is provided in Textbox 2.
Step 1: Introduction

- The researcher engaged in a small talk with the child to build trust. Study procedures were explained in a child-friendly manner, and it was emphasized that the child could say anything.

Step 2: Lunch recall

- As the usability task of myBear and FoodBear required recall of the lunch, the child was asked to do this before starting these tasks. Lunch was considered as being correctly recalled when it resembled the lunch written down in the questionnaire by caregivers, in terms of food items and numbers. If the child was unable to recall his or her lunch independently, standardized help questions were asked: (1) “Did you eat bread?” (2) “How much bread did you eat?” (3) “What kind of topping did you eat? Cheese, meat or something sweet?” (4) “How much bread did you eat with this topping?” If the child answered a question with “no,” the following questions were prepared: (5) “Did you eat a salad, pasta or rice for lunch?” (6) “Did you drink something with your lunch? Milk, tea, or water?” (7) “Did you eat anything else, such as candy, fruit or soup?” The number of questions required was noted.

Step 3: Usability task: myBear

- The child was asked to provide myBear with the same foods as recalled in step 2 or 4. The session started by clicking the “lunch” button (ie, as one of 5 different eating moments), which started the time measurement. The time measurement ended once the last food item was entered in myBear. The assignment was completed when all food groups and amounts were correctly entered.

Step 4: Lunch recall

- To mitigate potential effects arising from the passage of time between recalling the lunch and subsequent assessment of prototype’s usability, the child was asked to recall the lunch again.

Step 5: Usability task: FoodBear

- The child was asked to give the same lunch to FoodBear as recalled in step 2 or 4. The time measurement started once the researcher asked the child to start feeding FoodBear and ended when the child put the last coin into its belly. The assignment was completed when all food groups and amounts were correctly entered.

Step 6: Usability task: FoodCam

- The child was asked to take a picture of his or her (duplicate) lunch with FoodCam. Time measurement started once the researcher handed over the camera to the child and ended when the child took the picture. The assignment was completed when the (1) photo was sharp and (2) included all consumed foods in a recognizable way. To assure objectivity, photos were assessed by 3 researchers.

Step 7: This or That method

- As a response to 5 “This or That” questions, children indicated which prototype they liked best [34]. The original This or That method uses pairwise comparison, but this study compared 3 prototypes. One of the original questions was considered irrelevant and excluded: “Which of these three would you most like to take home?” The following This or That questions were included: “Which of these three was most fun?” “Which of these three was a bit stupid?” “Which of these three was a little boring?” “Show me which of these three you would like to play again?” “Show me which of these three you would like to receive as a gift?” Children could indicate more than 1 prototype but were not told beforehand to facilitate decision-making.

Step 8: Reward

- The child received a biscuit and a stamp set to express gratitude for time investment and participation in the study.

Step 9: Behavioral choice selection

- The researcher told the child “that there was some time left,” and that he or she could select a prototype to play with again. The researcher ensured that the child ate the biscuit first to prevent the child from automatically choosing the prototype they played with last.

Data Analysis

Usability

All sessions were audio- and video-recorded and transcribed verbatim. The researcher watched the videos and documented the examples of interest. Using the qualitative data analysis software ATLAS.ti (ATLAS.ti Scientific Software Development GmbH), examples of interest were grouped into themes to identify the most important usability issues, by means of using a reflexive and inductive approach, allowing for the emergence of unexpected insights, and understanding of prototype usability. Specific attention was paid to behaviors that hindered the completion of the usability tasks. As this study was exploratory in nature, our goal was to generate a foundation for further research. Therefore, data were coded by a single coder to gain a deeper understanding of the research objectives and context. To determine usability task effectiveness and efficiency for each prototype, average time and corresponding SDs were calculated for the usability tasks. By integrating qualitative and quantitative usability in the discussion and interpreting our results, we aimed to provide a more comprehensive assessment of the prototypes’ usability among the target group.
**User Experience**

The quantitative results for This or That method were coded dichotomously for each of the 5 questions. A preference was scored 1 in case of the 3 positive questions. In contrast, a preference was scored −1 in case of the 2 negative questions. Consequently, the total score for the 3 prototypes ranged from a minimum of −2 to a maximum of 3, for which a mean score and corresponding SD were calculated. One-way ANOVA was performed to test for significant differences using SPSS Statistics (version 25; IBM Corp). A P value of ≤0.05 was considered statistically significant. Furthermore, qualitative data were analyzed by using a combination of deductive and inductive thematic coding in ATLAS.ti. Qualitative and quantitative data were integrated to gain a deeper understanding of prototype user experience.

**Ethical Considerations**

All parents provided written informed consent and children gave their verbal consent. When the child did not fully understand the study procedures, these were explained again. Participation was voluntary and participants could withdraw from the study at any time, without stating a reason. The study protocol was reviewed and deemed not subject to the Medical Research Involving Human Subjects Act (2021-13199). Subsequently, the protocol was reviewed and approved by the Social Sciences Ethics Committee of the WUR. The organization conducting this study established procedures for data management and data protection. Participants were not financially compensated for participating in this study, but children received a small gift as a thank you (a cookie and a stamp set).

**Results**

**Sample Characteristics**

Table 2 presents the descriptive characteristics of the study sample. A total of 14 children participated in the study and evaluated the 3 prototypes. Most children had at least 1 highly educated parent (12/14, 86%) and actively used technology for ≤1 hour per day (11/14, 79%). Moreover, most of the children had no older siblings (11/14, 79%).

*a*Interactive screen time use is defined as the time a child spends actively interacting with a device (eg, tablet, PC, or smartphone).

*b*“Highly educated” is defined as having completed a degree at a university or a university of applied sciences.

**Usability Testing**

**Quantitative Results**

Of 14 children, 10 (71%) correctly recalled their lunch; half of the boys (4/8, 50%) and all the girls (6/6, 100%) succeeded in recalling their lunch. None of the successful children were able to do so without the assistance of standardized recall questions. Overall, 1 (7%) child needed the maximum number of 5 recall questions and 4 (40%) children needed one recall question; successful children needed an average of 2.2 (SD 1.4) recall questions. FoodBear’s usability task had the highest completion rate (n=11, 79%), followed by myBear (n=10, 71%) and FoodCam (n=19, 64%). The mean completion time (s) was faster and the number of interruptions (n) was lower for FoodCam (mean 9, SD 6; n=0.9) followed by myBear (mean 51, SD 17; n=3.3), and FoodBear (mean 65, SD 43; n=3.9; Table
Children who failed to complete either FoodBear’s (n=3, 21%) or myBear’s usability task (n=4, 29%) were all boys, but 1 (20%) girl failed to complete FoodCam’s usability task (n=5, 36%). Among these children, approximately all children had no highly educated parents (100%) or one highly educated parent (50%). When visually inspecting our data, no differences in age, interactive screen time (≤1 hour per day), or having older siblings (no) were observed across the children who did not complete their tasks. Finally, the order in which FoodBear and myBear were tested alternated. Children who successfully completed both FoodBear’s and myBear’s usability task (n=10, 71%) performed their second task on average 26.1 (SD 27.1) seconds faster.

Observational Results

Thematic analysis of the video and field notes obtained during usability testing revealed several key usability issues that were mainly related to 4 themes: food groups, frustrations related to unsatisfactory functioning of (parts of) the prototype, recall of food products, and distinction between eating moments (Figure 3).

Figure 3. Thematic map of usability issues revealed by user testing of the dietary assessment tool prototypes FoodBear, myBear, and FoodCam.

Theme 1: Food Groups

In terms of food group–related usability issues, 93% (13/14) of the children reported problems related to the recognition of icon/images and classification of food products into food groups. When using FoodBear and myBear, approximately all children (13/14, 93%) experienced usability problems related to the depicted icons or images, which were mainly related to recognizing the food group represented by the icon, resulting in incorrect food group reporting. To illustrate, most children (n=10, 71%) became confused when the consumed product did not exactly resemble the depicted icon: “Cheese spread and jam. Which one is the jam?” (Participant 11). Some children (n=8, 57%) solved the problem by choosing the icon that they thought most resembled the product they ate. In some cases (n=5, 36%),
the children eventually classified food products into the correct food group: “I don’t see baguette, but I do see bread, so I press the bread” (Participant 10), but other participants failed to do so: “Which one is gingerbread? This one? [points to icon for fish]” (Participant 14). Moreover, 21% (3/14) of the children ate >1 product of the same food group during their lunch and reported problems with categorizing these different food products into the same food group. One participant asked the researcher for help and the other 2 chose different icons for different products. Finally, it was also observed that some icons were not chosen at all even though the icon was applicable for several of the children, for example, the icon for “something else.”

**Theme 2: Frustrations Related to Unsatisfactory Functioning of (Parts of) the Prototypes**

Overall, 93% (13/14) of the children encountered ≥1 usability problem related to unsatisfactory functioning of (parts of) the prototypes, that is, prototype-specific issues. For FoodBear, several children encountered problems with where and how to put coins in FoodBear’s belly (n=4, 29%) and that coins did not fit properly through the intended opening (n=6, 43%). The latter led to visible frustrations among participants: “Stupid bear!” (Participant 6). When using myBear, the main usability issues were caused by interaction design. Most children (n=9, 64%) struggled with the plus and minus button to indicate the amount of the product eaten; children either pressed the button again, causing the product to disappear from myBear’s belly or asked the researcher for help. FoodCam’s usability issues were mainly related to finding the photo button (n=5, 36%) and quality of the printed photos (n=6, 43%): “It’s annoying that you cannot choose colors when you print it, so you can see the right colors” (Participant 6).

**Theme 3: Distinction Between Eating Moments**

More than half of the participants (n=8, 57%) had difficulties with distinguishing eating moments throughout the day. Some children (n=4, 29%) pointed out that they did not fully understand the concept of lunch. Other children (n=2, 14%) tended to also name products they consumed earlier that day: “But I had also yogurt today!” (Participant 6).

**Theme 4: Recall**

In the category of recall-related usability issues, the subcategories forgetfulness, portion size, and fantasy issues were distinguished. Overall, 57% (8/14) of the children reported usability issues related to ≥1 of these subcategories. For FoodBear and myBear, 29% (4/14) of the children failed to perform the usability tasks because of forgetfulness. For example, children forgot to feed certain products to myBear or FoodBear: “O, I just completely forgot about that one!” (Participant 6). Moreover, 36% (5/14) of the children had problems indicating consumed quantities, which resulted in underreporting by all 5 children, that is, an insufficient number of icons or coins for a specific food group in FoodBear’s or myBear’s belly. Finally, 21% (3/14) of the children were unable to complete the usability tasks because of their fantasy, that is, children fed FoodBear or myBear products that were not consumed (n=2, 14%) or expressed unrealistic amounts (n=1, 7%). To illustrate the latter, one participant reported: “I think ten breads. In every lunchbox” (Participant 2).

**User Experience**

**Quantitative Results**

No significant difference in mean preference scores for FoodBear, myBear, and FoodCam was observed based on the This or That method, that is, 0.57 (SD 1.94), 0.50 (SD 1.45), and 0.86 (SD 1.65; F=0.18; P=.80), respectively (Table 4).

**Table 4.** Results after applying This or That method. The first choice is defined as the prototype that children selected as their top preference (ie, most points). Conversely, the last choice defined is defined as the prototype they ranked as the least preferred option (ie, the least points).

aPercentages are calculated based on the number of times participants selected each prototype. As children were allowed to choose more than one prototype, the sum of percentages may exceed 100%.

**Observational Results**

During the behavioral choice selection (Textbox 2; step 9), all children (14/14, 100%) chose (one of) the prototypes they scored best during This or That.

**Qualitative Results**

Although some children (n=5, 36%) experienced difficulties with answering the “why-questions” that followed the 5 This or That questions, several determinants for product liking could be identified. First, an important reason for children to choose one prototype over the others was autonomy, because they liked being able to do it “themselves” (n=5, 36%): “Because I can put the coins in there myself!” (Participant 13). Moreover, children (n=5, 36%) referred to the reward, such as the printed photo, as being a determinant for product liking: “I like that one because you can print your taken picture and keep it as a memory!” (Participant 6). In addition, 29% (4/14) of the children indicated that they liked the prototype being challenging: “I like that one because you can do a lot with that one. The camera is a bit stupid because you can only take a picture with it” (Participant 4). Such a challenge could be presented in the form of a game; the gaming element was emphasized by some children (n=4, 29%) as a fun element of one of the prototypes: “I like myBear because you can play games on it” (Participant 9). The shape of the prototype was also mentioned by several
children; 29% (4/14) of the children indicated that they liked the prototype because it was tablet based or because they liked its appearance (n=2, 14%). Other determinants of preference included its social aspect (n=2, 14%) and the time frame (n=2, 14%): “I didn’t like this one very much because this one took too long and that one took too short” (Participant 13).

Discussion

Principal Findings

This study provided several insights related to usability and user experience that can be used to inform the development of dietary assessment tools for use by children. At the first encounter, most children were able to use FoodBear, myBear, and FoodCam and fulfill the accompanying usability tasks. However, all children required assistance from the researcher to succeed, and most of the children encountered several usability problems. The most important usability issues included problems related to food groups, frustrations related to the unsatisfactory functioning of (parts of) the prototypes, recall of food products, and distinction between eating moments. These issues, along with the queries needed to accomplish usability tasks, may suggest that dietary assessment tools may not be independently usable by children aged 5 to 6 years. However, the completion rates suggest that children can play a complementary role in dietary data collection to enhance data collected by their parents. No differences in product liking were observed when comparing the 3 prototypes. However, it is notable that all children selected one of the prototypes they scored best with This or That for the behavioral choice selection to play with again. The qualitative part of This or That revealed several determinants for liking a product, including autonomy, challenge, gaming elements, being tablet based, appearance, social elements, and time frame.

Usability

Overview

The 3 prototypes differed in terms of usability rate, time needed to complete the assessment, and required number of interruptions by the researcher, which may be partly explained by the fact that prototypes are based on different dietary assessment methodologies, that is, food recall (FoodBear and myBear) and food record (FoodCam) [9]. As a recall requires additional memory-based cognitive capacities compared with a food record, FoodCam was expected to yield the best results in this population. However, a lower number of children successfully completed FoodCam’s (9/14, 64%) usability task compared with FoodBear’s (11/14, 79%) and myBear’s (10/14, 71%) tasks, meaning that a lower number of children were able to take a sharp photo on which all consumed products were recognizable. On the other hand, if completed, the time and help needed with FoodCam’s usability task was substantially less than the other 2 tools. Aflague et al [27] showed that using the Mobile Food Record for capturing eating occasions could be a feasible method for use by children aged ≥3 years. In contrast to our study, participants in the study by Aflague et al [27] were allowed to practice and use a tablet or smartphone, whereas FoodCam is based on a more old-fashioned camera. Additional research is required to determine whether there is a difference in usability between traditional cameras and the cameras on smartphones or tablets. However, this research should also address the current challenges related to automatically extracting dietary information from real-world, user-generated images. As our prototypes were tested at the first encounter, it is likely that usability will increase with practice or a training module, but further studies are required to test this. Moreover, this study primarily evaluated the usability of 3 prototypes designed for independent use, thereby revealing some inherent challenges. Nonetheless, adopting an approach that combines children’s data with those collected by parents can potentially enrich the comprehensiveness of a child’s daily dietary intake assessment. Such a combined method would offer the possibility of gaining more detailed insights into foods consumed outside the home, ultimately enhancing the reliability of the dietary intake data. Further research is needed to investigate the potential bias of this approach. Moreover, consistent with previous findings [23,35], girls performed better than boys for all 3 usability and lunch recall tasks in terms of completion rate. This difference may be explained by girls’ higher attentional and memory performance compared with boys and emphasizes the need to consider sex differences in further development of the tools [36].

Strategies to Increase Usability

To address these usability issues, we identified several strategies for further improvement. To increase usability, the tools might benefit from a training module providing practice runs on estimating quantities and portion sizes, recognizing food categories, handling FoodCam, or the interaction design of myBear. Practical effects were already observed in this study, that is, all children who successfully completed myBear’s or FoodBear’s usability task performed their second usability task at a faster pace. Similar training effects have been observed in other studies [27,37]. Auditory or visual prompts, reminders, and feedback may also improve the usability of updated versions of the prototypes, that is, to remind participants to report their dietary intake throughout the day, or help with the correct use of the tool, for example, by checking whether all products have been reported in the correct amount, or send reminders when photos are incomplete or unsharp. Reminders and help with the tasks were now verbally performed by the researcher (eg, with recall questions), but should be automated in the next versions of the prototypes to facilitate independent use by the target group. Integrating multiple reminders is commonly used in other methods as well, for example, in Compl-eat [38], and is used to trigger the report of often forgotten products, such as cooking fats or drinks. In addition, myBear could particularly benefit from a more user-friendly and intuitive interaction design. Improvements in the interaction design should among others focus on simplifying consumed portion sizes. For example, using a slider to indicate portion size or pressing the button twice for the specific product may be more intuitive than using a plus or minus button. The use of age-appropriate interactions and images could also contribute to a better understanding of the different eating moments, for example, by using a clock model to capture mealtimes throughout the day. The direct effect of improving the interaction design has proven to be effective.

(page number not for citation purposes)
in another study on the adolescent dietary assessment tool myfood24, where they compared the usability and acceptability of myfood24 among adolescents before and after making amendments [39]. Finally, the usability tasks of FoodBear and myBear illustrated that children experienced difficulties in understanding or interpreting the food group icons and categorizing their consumed products into food groups, asking for a more child-friendly approach. Therefore, further research is needed to identify child-friendly food groups and icons [25].

User Experience

No preferences were observed for one prototype over the others when using This or That method. However, it is notable that all children selected one of the prototypes they scored best with This or That to play again. This consistency suggests that the reported This or That choice is a good predictor for short-term preference in this sample. However, as the children only used the prototypes for a short time, it should be emphasized that This or That may not reflect the long-term preference. To gain insight into long-term engagement, more research is needed where children use the prototypes for a longer period in a home-use setting handling different mealtimes throughout the day.

As This or That determines preference relatively, it does not offer the opportunity to determine the magnitude of preference [34]. Although the This or That scores revealed no differences between the prototypes, it is important to consider this relativity when interpreting the qualitative results. What stands out is that most of the determinants for product liking pointed out by the children were in line with our list of requirements (Textbox 1), except for the determinant autonomy. Children in the preoperational phase, including our target group, have a strong curiosity and are interested in learning [40]. Therefore, the finding of autonomy being a determinant for product liking by children is not unexpected and should be included in the updated version of the program of requirements. Strategies to increase this feeling of autonomy within young children’s dietary assessment could include, for example, making the design accessible for children’s independent navigation (eg, by using navigation without text and making it real-time responsive), focus on children’s decision-making (eg, by including options for personalization and customization in the design), or encouraging their initiatives (eg, by including a reward system) [41].

Strengths and Limitations

Although this exploratory study contributes to the body of knowledge in several areas, it has some limitations. First, our first list of user requirements (Textbox 1) is based on literature only, which ideally would have included expert interviews as well, as conducted by de Gooijer et al [42]. As this study is the first to explore self-reported dietary assessment among children aged 5 to 6 years, this first list may have been insufficient. Second, as the usability tasks in this study were performed under favorable circumstances, the usability for FoodBear and myBear may have been overestimated. More specifically, the dietary assessment tasks took place shortly after lunch (a maximum of 3 hours after lunch). As other studies showed that meals with shorter retention intervals are in general easier to accurately recall and report compared with meals with longer retention intervals, results may become less accurate when measurements were performed after a longer period [43,44]. Moreover, prototypes were only evaluated for lunch and longer interaction (eg, over the course of a day) with the prototypes is needed to evaluate the accuracy of dietary intake data collected through our prototypes. In addition, it is worth noting that Dutch children typically have bread with spreads or toppings for lunch [45]. This was also reflected in our study sample, where all participating children ate bread for lunch. As previous studies showed that children struggle with identifying components within mixed meals [46], it is important to consider the relative simplicity of the Dutch lunch when interpreting our results. Considering these favorable conditions in this study, it raises questions about the ability of children aged 5 to 6 years to accurately use FoodBear and myBear without parental assistance for more complex meals consumed over an extended time frame in future research. Therefore, FoodBear and myBear might have more potential for use with caregivers. Another important limitation that should be considered when interpreting our findings is related to our sample. The sample size of this study was small and not representative of the Dutch population, primarily owing to the high proportion of highly educated parents among the participants. This demographic bias limits our ability to generalize our findings to a more diverse population. To gain a better understanding of the application of such tools in populations of lower socioeconomic status, future studies are necessary. Moreover, considering the qualitative focus of our research, the small sample size of our study underscores the necessity for caution when interpreting our quantitative results. This is particularly relevant in terms of statistical power and generalizability. Future research efforts could focus on studying the quantitative aspects of our study in more detail by recruiting a larger sample size.

Conclusions

This exploratory study identified essential user requirements for a novel dietary assessment tool designed for children aged 5 to 6 years, including (1) a comprehensive training program, (2) incorporation of auditory or visual prompts, (3) implementing reminders and feedback mechanisms, (4) a focus on a user-friendly and intuitive interaction design, (5) use of child-friendly food groups or icons, and (6) allowing room for children to exercise autonomy. By addressing these identified user requirements in the development of new dietary assessment tools, we can significantly enhance the quality of dietary intake data collected among children. Furthermore, these findings can serve as valuable guidance for ongoing innovations in the field of children’s dietary assessment and the provision of personalized dietary support. This, in turn, can inform strategies aimed at guiding children toward healthier food choices.

Abstract

Background: Qualitative health services research often relies on semistructured or in-depth interviews to develop a deeper understanding of patient experiences, motivations, and perspectives. The quality of data gathered is contingent upon a patient’s recall capacity; yet, studies have shown that recall of medical information is low. Threats to generating rich and detailed interview data may be more prevalent when interviewing older adults.

Objective: We developed and studied the feasibility of using a tool, Remembering Healthcare Encounters Visually and Interactively (REVISIT), which has been created to aid the recall of a specific telemedicine encounter to provide health services research teams with a visual tool, to improve qualitative interviews with older adults.

Methods: The REVISIT visual appointment summary was developed to facilitate web-based interviews with our participants as part of an evaluation of a geriatric telemedicine program. Our primary aims were to aid participant recall, maintain focus on the index visit, and establish a shared understanding of the visit between participants and interviewers. The authors’ experiences and observations developing REVISIT and using it during videoconference interviews (N=16) were systematically documented and synthesized. We discuss these experiences with REVISIT and suggest considerations for broader implementation and future research to expand upon this preliminary work.

Results: REVISIT enhanced the interview process by providing a focus and catalyst for discussion and supporting rapport-building with participants. REVISIT appeared to support older patients’ and caregivers’ recollection of a clinical visit, helping them to
share additional details about their experience. REVISIT was difficult to read for some participants, however, and could not be used for phone interviews.

**Conclusions:** REVISIT is a promising tool to enhance the quality of data collected during interviews with older, rural adults and caregivers about a health care encounter. This novel tool may aid recall of health care experiences for those groups for whom it may be more challenging to collect accurate, rich qualitative data (eg, those with cognitive impairment or complex medical care), allowing health services research to include more diverse patient experiences.

**Introduction**

Qualitative health services research often relies on semistructured or in-depth interviews to develop a deeper understanding of patient experiences, motivations, and perspectives. The quality of data gathered is contingent upon a patient’s recall capacity. Studies consistently show recall of medical information is low. Patients remember between 20% and 60% of the information provided by health care practitioners immediately after an encounter [1], dropping to 12.8% a month later [2]. In a seminal study of patient recall in a routine clinical setting by Anderson et al [3], of the 40% of medical information recalled by patients, 48% of it was misconstrued. Various practitioner- and patient-related factors pose threats to recall: practitioner-related factors include the use of complicated medical terminology, high volume of information relayed, and mode of information presentation (eg, verbal vs visual), while patient-related factors include low education level and emotional state during the visit [1,4].

Threats to generating rich and detailed interview data may be more prevalent when interviewing older adults. Aging is associated with a decline in sensory and cognitive function, making it difficult to understand and remember medical information [5]. Compared to younger individuals, older adults have more difficulty recalling details of health care experiences that researchers may be interested in exploring, including medication regimens [6], treatment recommendations [7], and appointment reminder telephone messages [8]. Routine recurring visits are also more poorly recalled than nonrecurring ones—patients tend to collapse recurring visits into a single, generic memory instead of separate, specific occurrences [9]. Older adults may be especially prone to do so as they are estimated to have an average of 7 medical visits per year [10].

To ensure qualitative data are accurate, researchers must carefully consider how to plan and conduct qualitative interviews with older adults. Visual methodologies have been used to mitigate the threats to validity resulting from recall bias in qualitative health services research [11-13]. These methods invite participants to tap into memories through nonverbal ways of thinking, improving participant recall and allowing researchers to access participant perspectives that can be difficult to articulate through conversation alone. Commonly used strategies include viewing and discussing photographs, video elicitiation, drawing, chart-stimulated recall, and mapping and timelines exercises [11,14,15]. In our review of the literature, we found no documented cases of using visual recall aids with older adults, a group for whom such tools may be particularly useful, given known challenges with medical information recall [1].

In this paper, we explore the development and use of a new visual tool, Remembering Healthcare Encounters Visually and Interactively (REVISIT), created to aid recall of a specific telemedicine encounter among older adult interview participants. In spring 2021, a team of Veterans Health Administration (VA) qualitative researchers interviewed 30 rural, older (65 years of age and older) veterans and their caregivers remotely as part of an evaluation of GRECC Connect, a program that uses telemedicine to connect rural veterans with complex care needs to geriatric specialty care at 15 urban VA medical center hub sites. GRECC Connect hub teams are comprised of interprofessional care teams affiliated with Geriatric Research, Education, and Clinical Centers, VA centers of excellence focused on aging. Given the focus of many GRECC Connect sites on treating cognitive impairment, we anticipated that interviewees might experience challenges recalling details of their most recent GRECC Connect appointment (the “index visit”), posing a risk to the completeness and validity of interview data. We also anticipated challenges isolating information about their most recent GRECC Connect appointment from other appointments due to the increase in telemedicine visits during the COVID-19 pandemic. The REVISIT visual appointment summary was developed to better facilitate interviews conducted remotely with our participants. Our primary aims were to aid participant recall, maintain focus on the index visit, and establish a shared understanding of the visit between participants and interviewers. In this paper, we describe the development of REVISIT and interviewer experiences with the tool and suggest considerations for broader implementation and future research to expand upon this preliminary work.

**Methods**

**Evaluation Team**

A multidisciplinary VA project team contributed to the evaluation. Team members included physicians with expertise...
in primary care, geriatrics, and dementia; a veteran consultant; GRECC Connect leadership; and researchers with expertise in qualitative methods and project coordination.

Developing REVISIT

REVISIT was designed as a template to be populated with data from the veteran’s electronic health record (EHR). A member of the team with a background in media design drafted template options on Canva (Canva), a free web-based graphic design platform. REVISIT’s design drew upon VA’s Patient Experience Journey Map, a visual representation of commonly experienced moments before, during, and after a veteran’s health care visit [16]. Draft REVISIT templates were presented to the full multidisciplinary team for review, resulting in 3 iterative rounds of feedback and refinement.

The information included in the final iteration of REVISIT focused on aspects of the index visit we sought to confirm and explore, which were separated into three groupings: (1) the referral, including the reason and referring provider; (2) the index visit, including individuals present and main topics discussed; and (3) changes in the veteran’s health and health care resulting from the visit, including changes in diagnoses, medications, and referrals.

The overall structure of the first iteration of REVISIT (Figure 1) contained 3 columns, with each column representing a step in the GRECC Connect visit (before, during, and after the visit). For the first iteration, initial refinements suggested by the team focused on simplifying the template to include only information pertinent to the interview. Team members also felt REVISIT should focus more on the “Post-Visit” section to better aid participants’ recall of what worked well about the visit and what health needs remained unmet.

Figure 1. First iteration: the first iteration of REVISIT included elements subsequently omitted, such as the sections containing questions at the bottom of each column. REVISIT: Remembering Healthcare Encounters Visually and Interactively.

The second iteration (Figure 2) incorporated the aforementioned feedback for simplification. For example, the “Pre-Visit” section was changed completely to include only GRECC Connect referral information, and the heading for this section was edited to “Referral” to reflect this change. The “GRECC Connect Visit” section still included persons present during the index visit, but the other sections were collapsed into one summary of the visit details. The “Post-Visit” section was expanded to take up more of the page, emphasizing this section as the focus of the interview.
Figure 2. Second iteration: the second iteration of REVISIT includes an expanded “Post-Visit” section and simplification of the other 2 sections. REVISIT: Remembering Healthcare Encounters Visually and Interactively.

After reviewing the second iteration, the team encouraged further simplification of the template’s design to reflect REVISIT’s primary goal of helping participants recall details about their experience of the telemedicine visit. Team review of the second iteration also focused on possible modifications to the included language. EHRs contain medical jargon that is likely unfamiliar to interview participants. Team members suggested translation of these terms into more lay language for the last iteration, a process that relied heavily on input from the physician team members.

Design considerations for the final REVISIT iteration (Figure 3) included using boxes with rounded edges, as the team felt this connoted friendliness compared to the sharp edges shown in Figure 1. Icons were included alongside text descriptions wherever possible to increase ease of understanding. Arrows showed flow from one section to the next, green “+” symbols signified newly prescribed medications, and red “x” symbols signified deprescribed medications. Calibri font was used in accordance with VA’s graphic design standards.
Figure 3. Final iteration: the final iteration of REVISIT includes edits to language used, such as “memory changes” instead of specific diagnoses, and “Moving Forward” instead of a “Post-Visit” heading. This version also reflects the omission of interview probe questions in the “Moving Forward” section. This sample REVISIT includes only fictional participant information. REVISIT: Remembering Healthcare Encounters Visually and Interactively.

The colors of each section were specifically chosen based on color-in-context theory [17], which posits color meanings are grounded in learned associations that develop from repeated pairings of colors with particular messages, concepts, or experiences. The color motif was loosely based on the 3 phases of a traffic light—the initial referral to GRECC Connect was yellow (to symbolize a transition) and the postvisit was green (to symbolize moving forward). Blue, as opposed to red, was chosen to represent the index visit because of its generally accepted calming effects [18]. The team felt this was a more suitable color choice, given the potentially sensitive topics that may surface during discussion of the index visit during interviews. The team also opted for colors with lighter versus darker hues, as these were felt to be easier on the eyes.

Language edits were incorporated into the final iteration. Potentially sensitive medical issues such as dementia diagnoses or cognitive decline were instead referred to as “memory changes.” We deemed this step necessary as it was sometimes unclear, based on the medical notes, what was explicitly discussed with the participant versus only documented in the clinic note. The inclusion of more neutral language helped ensure that REVISIT would avoid distressing a participant with potentially new information about their health.

Participants

REVISIT was used in the context of a health care evaluation with a sample of 30 rural veterans attending specialty geriatric telemedicine visits at 6 geographically diverse GRECC Connect hub sites. We defined “telemedicine” as medical appointments conducted through one of three modalities: (1) video appointments from a veteran’s home or other location to a remote specialist using VA Video Connect (VVC), (2) video appointments from a VA outpatient clinic near the veteran’s home to a remote specialist using Clinical Video Telehealth (CVT), or (3) telephone. An option to participate as a veteran-caregiver dyad was offered in cases where veteran participants had some degree of cognitive impairment or where caregivers were substantially involved in care. Due to the impact of dementia, some dyads were primarily represented by the caregiver.

Prior to initial contact, 3 team members briefly reviewed each veteran’s EHR to confirm the most recent telemedicine visit date and modality (VVC, CVT, or phone), veteran location, initial reason for referral, the presence of a caregiver, and any cognitive or other health concerns that would preclude study participation (eg, a veteran in hospice or deceased). Veterans were considered eligible for participation if they were 65 years and older of age, resided in a rural area (rural-urban commuting
area [RUCA] > 1), participated in a telemedicine GRECC Connect appointment between December 2020 and March 2021, and spoke English as their primary language. Verbal permission was obtained from each veteran and caregiver to participate in the evaluation.

**Interview Preparation**

Once participants agreed to participate in an interview, a team member performed a detailed chart abstraction of the veteran’s EHR 6 months prior to the index appointment using a structured data abstraction template (Multimedia Appendix 1). This data abstraction template helped team members extract only information relevant to the GRECC Connect visit from the participant’s EHR, which can contain many notes from numerous clinicians. GRECC physicians on the multidisciplinary team helped to develop the data abstraction template and interpret EHR data when questions arose. These data were then used to populate REVISIT to create an individualized visual appointment summary and tailored interview guide for each participant. To protect participants’ health information, each populated REVISIT was saved in a password-protected participant-specific folder on a secure server. On average, team members spent 2 to 4 hours abstracting data and creating the visual summary. Time varied depending on the extensiveness and clarity of the participant’s medical chart.

**Data Collection**

Four experienced qualitative researchers conducted semistructured qualitative interviews with veterans and their caregivers who agreed to participate in the evaluation. We asked participants about their GRECC Connect telemedicine visit, including support received, what worked and did not work well, preferred modality for medical care, impact of visit, satisfaction, and recommendations. Interviews took place approximately a month after the index visit and were conducted via VVC or by phone depending on participant preference and ability. In total, 16 interviews were conducted via VVC on various devices (eg, smartphone, tablet, and laptop), and 14 were conducted by phone.

REVISIT was shared with participants who were interviewed via VVC using its screen-sharing feature. The use of REVISIT was incorporated into the GRECC Connect interview guide. The interviewer shared REVISIT when beginning to discuss the index visit following initial rapport-building questions. In at least one case, REVISIT was shown earlier in the interview because the participant needed more recall support.

Following the data collection process, team members who conducted interviews debriefed their experience using REVISIT, sharing the benefits and challenges of using the tool. Elements of the debrief were recorded on digital sticky notes, which were then grouped together by theme along the project timeline. Team members’ perspectives were informed by observations of participants when REVISIT was shared onscreen. We reviewed participant interview transcripts to find relevant excerpts to illustrate our observations.

**Ethical Considerations**

The VA Bedford Healthcare System Institutional Review Board determined this work was undertaken to inform VA operations as part of program evaluation and quality improvement activities and was not human subjects research.

**Results**

Use of REVISIT was limited to the 16 participants with whom interviews were conducted via VVC. Given the focus on our development of and initial experience with REVISIT, patient perspectives are only included insofar as their observed reactions influenced the team’s experiences and perspectives.

Interviewers used REVISIT to familiarize themselves with relevant details of the index visit prior to conducting interviews. This was particularly helpful when the interviewer did not complete the detailed chart review and was therefore less immersed in the details of each participant’s case or care. REVISIT provided the most salient information at a glance, so interviewers felt it was easier to review than the longer summary extracted from the chart review. With REVISIT, team members also felt better prepared to tailor interview questions to each participant. Additionally, the process of creating or reviewing each participant’s REVISIT visual encouraged the team to consider appropriate language to use during the interviews, such as using “changes in memory” versus “cognitive impairment.”

During the interview, team members used REVISIT as a shared reference point with participants, providing a focus and catalyst for discussion and prompt for further questioning. In one example, REVISIT allowed an interviewer to probe about other aspects of the index visit that were not brought up by the participant organically:

**Interviewer:** So this [REVISIT] is what we saw as sort of the summary of the visit that you and Mr. XXXX had. We’ve talked about a lot of this. We’ve talked about the changes in diagnoses, the memory changes. It did look like … they referred you to Audiology to check his hearing. Do you remember that referral at all?

In this way, REVISIT allowed interviewers to bring up contextual details about the visit, which helped to confirm that participants were discussing the index visit. This was particularly important for those who had numerous health care encounters.

Using REVISIT also helped interviewers cross-reference EHR data with participant accounts in real time, confirming congruence or revealing discrepancies between participant recollection and EHR data:

**Interviewer:** So you mentioned that there were some suggestions for medication changes in the future if anything progresses. We also noticed that there was a recommendation to consider using B12 supplements.

**Participant:** I don’t recall hearing the recommendation of the B12 supplements.

**Interviewer:** Okay.
Caregiver: So I didn’t have that in my notes. He has previously been given B12 but it has been quite some time since he’s been given B12 so I don’t remember her mentioning that.

In several cases, interviewers felt that REVISIT seemed to help both veterans and caregivers remember details about the index visit that they otherwise did not bring up:

Caregiver: So, I remember now those conversations and that I had requested – his [the veteran’s] mood was so angry, rage-y – that I had requested Dr. XXXX to increase his quetiapine, get to add one more during the morning and one at noon in addition to the three at night and so your visual helps me remember that.

This contributed to rapport-building by alleviating participants from the onus of remembering every detail of their visit. REVISIT was appreciated by participants, at least one of whom expressed challenges with information recall:

Caregiver: ... it was hard for me to remember what all we talked about that day and that [REVISIT] was very helpful.

However, the use of the tool was not without challenges. Interviewers noted that several participants expressed difficulty seeing REVISIT when shared over the videoconference platform. At least one participant felt that the visual was too light, while several others noted it was too small to read. Most participants who had difficulties with the size of REVISIT viewed it through their cell phone, so the issue of size may partially have to do with the device used:

Participant: I think I can say, for me, it was too small a screen, and you could probably mention, you know, it’s better if you’ve got a tablet or a laptop.

However, one participant on a larger tablet still had issues with font size and readability. It is thus unclear whether these challenges can be attributed to the visual alone or other computer-related factors (eg, whether the VVC window was maximized on the screen and the device’s brightness display). Researchers could not assess or control participants’ computer settings during interviews.

See Table 1 for further organization of interviewer experiences with REVISIT into relevant benefits and challenges.

**Discussion**

**Principal Results**

REVISIT is a promising visual tool for enhancing the quality of data collected during interviews with older, rural veterans and caregivers. REVISIT enhanced the interview process by providing a focus and catalyst for discussion and supporting rapport-building with participants. Interviewers felt that the tool supported participants’ recollection of the clinical visit, as many participants noted this while sharing additional details about their experience. Our findings demonstrate that the novel use of visual methodologies during videoconference interviews with older adults is feasible and may be useful in supporting the overall success of qualitative evaluations.

**Comparison With Prior Work**

Visual methods, combined with in-depth interviews, have been shown to increase data quality, relevance, and trustworthiness [11,13]. Using REVISIT in our evaluation of GRECC Connect appeared to lead to similar enhancements in data quality by aiding participant recall during interviews, resulting in additional disclosure from participants. This finding is consistent with neuroscience principles that demonstrate how visual stimuli evoke brain regions involved in nonverbal information processing and memory [19].

Our experience is also consistent with other studies that demonstrate visual methods support interviewers in facilitating discussions with participants by prompting further questioning by interviewers, providing direction for discussion, streamlining topic transitions, and promoting increased attention [20-24]. Maintaining participant focus on relevant topics during an interview is essential to generating valid data [25]. Yet, researchers have argued that inhibition, or the ability to direct attention away from irrelevant information, declines with age [5]. Using a simplified visual aid such as REVISIT, which we found to provide a focus for discussion, may be particularly useful when interviewing older adults.

Using REVISIT highlighted, for interviewers, difficulties participants experienced recalling details of their index visit. A real-world implication of this insight is that patients may not remember the health and health care information shared by clinicians to properly care for themselves after the visit. For
some evaluation participants, viewing REVISIT was the first time they saw any written information about their visit from a practitioner. There are a number of provider-focused information-giving interventions that have been shown to positively influence patient recall [26,27], including intentional specific structuring of written postdischarge information [28]. At the very least, then, as our experience also suggests, older telemedicine patients may benefit from an after-visit summary outlining pertinent details about their health and health care discussed during the visit.

Consistent with previous studies [23], interviewers felt that using a visual memory aid contributed to rapport-building by providing a shared focus with which to interact and reflect upon. Rapport building is an important dimension of interviewing older adults with communication or cognitive barriers, as these challenges may lead them to view interviewers as threatening and increase feelings of powerlessness or a desire to withdraw from study participation [25,29]. Kirkevold and Bergland [30] suggest allocating more time over the course of a project to establish rapport with older interviewees, which can be challenging for research and evaluation projects with strict time constraints. REVISIT addresses this challenge by providing an accelerated rapport-building option for use directly within participant interviews.

The main challenge of using REVISIT as expressed by participants was the inability of some to see the visual due to its light color and font size. Age-related changes in visual acuity and contrast sensitivity can make it more difficult for older adults to read [5]. Therefore, images should have a high degree of contrast and use a large font. Further, participants in this study noted they or others might benefit from viewing images from a larger screen (eg, a tablet or laptop vs a cell phone). Additionally, although our evaluation of GRECC Connect showed it is possible to use visual tools during video interviews with older adults, it does not address potential barriers to the use of technology among this population; limited knowledge, comfort, or experience with technology, challenges with internet access, and existing cognitive and sensory impairments may hinder participants in studies conducted over videoconferencing platforms [31].

Additional Considerations

Future users of REVISIT and other similar recall aids should be mindful of how to introduce such tools and integrate them into the interview process. REVISIT may diminish rapport if interviewers share the visual at the wrong time; doing so may inadvertently disrupt the flow of the conversation, distracting participants from the interview as they try to make sense of the visual tool. Using REVISIT also reduces the capacity for nonverbal communication when shared on screen, since this action usually minimizes the window of the participant and researcher across videoconferencing platforms. Additionally, if a participant disagrees with the information presented on the visual, it may create confusion, discomfort, or distrust. Another consideration is the substantial amount of time it takes to prepare the visit summaries and subsequent REVISIT visuals for each interviewee. While the preparation time reduced as the team members gained experience with the methodology, given the time investment needed, this method may not be practical for studies with considerably larger sample sizes.

More research is needed to optimize REVISIT’s usability and understand its acceptability among older adults with cognitive impairments. Future research should also explore the extent to which the visual tool affects recall by systematically comparing appointment recall using REVISIT with interview discussion alone. REVISIT may be useful for understanding the experiences of other patient populations with cognitive impairment (eg, traumatic brain injury and posttraumatic stress disorder) or complex medical care (eg, cancer treatment) and adaptable to in-person use (eg, on an iPad or paper). Further research and evaluation are needed to ensure the efficacy of REVISIT with different populations and settings.

Limitations

This is a preliminary study. Observations were limited to our sample of 16 veterans and veteran-caregiver dyads, most of whom had some degree of cognitive impairment and were interviewed over VVC, as REVISIT use was only possible through its screen-sharing feature. Further, participants were not systematically asked about their experience of viewing and using REVISIT during the interview. Because of this, we only included patient experiences that directly influenced team members’ own experience with and perceptions of the tool. Additionally, though REVISIT appeared to support recall in this study, it does not guarantee that a participant will truly recall relevant details as opposed to simply agreeing with what they are seeing.

Conclusions

REVISIT is a novel visual tool that aids the recall of health care encounters by tapping into memories through nonverbal ways of thinking. The use of REVISIT, a carefully curated visual representation of one particular health care encounter, helps to address a number of threats to generating rich, detailed interview data that may be more prevalent when interviewing older adults. As health services research seeks to understand more diverse patient experiences within health care, a tool such as REVISIT may aid recall of health care experiences for those groups for whom it may be more challenging to collect accurate, rich qualitative data. Further research is needed to understand its usefulness with different populations and settings.

Acknowledgments

The authors wish to acknowledge Mr Robert Bruno, a veteran consultant on our project team, for providing valuable input and feedback on our work. Abstract

Background: Social media is rapidly becoming the primary source to disseminate invitations to the public to consider taking part in research studies. There is, however, little information on how the contents of the advertisement can be communicated to facilitate engagement and subsequently promote intentions to participate in research.

Objective: This paper describes an experimental study that tested different behavioral messages for recruiting study participants for a real-life observational case-control study.

Methods: We included 1060 women in a web-based experiment and randomized them to 1 of 3 experimental conditions: standard advertisement (n=360), patient endorsement advertisement (n=345), and social norms advertisement (n=355). After seeing 1 of the 3 advertisements, participants were asked to state (1) their intention to take part in the advertised case-control study, (2) the ease of understanding the message and study aims, and (3) their willingness to be redirected to the website of the case-control study after completing the survey. Individuals were further asked to suggest ways to improve the messages. Intentions were compared between groups using ordinal logistic regression, reported in percentages, adjusted odds ratio (aOR), and 95% CIs.

Results: Those who were in the patient endorsement and social norms–based advertisement groups had significantly lower intentions to take part in the advertised study compared with those in the standard advertisement group (aOR 0.73, 95% CI 0.55-0.97; P=.03 and aOR 0.69, 95% CI 0.52-0.92; P=.009, respectively). The patient endorsement advertisement was perceived to be more difficult to understand (aOR 0.65, 95% CI 0.48-0.87; P=.004) and to communicate the study aims less clearly (aOR 0.72, 95% CI 0.55-0.95; P=.01). While the patient endorsement advertisement had no impact on intention to visit the main study website, the social norms advertisement decreased willingness compared with the standard advertisement group (157/355, 44.2% vs 191/360, 53.1%; aOR 0.74, 95% CI 0.54-0.99; P=.02). The majority of participants (395/609, 64.8%) stated that the messages did not require changes, but some preferred clearer (75/609, 12.3%) and shorter (59/609, 9.7%) messages.

Conclusions: The results of this study indicate that adding normative behavioral messages to simulated tweets decreased participant intention to take part in our web-based case-control study, as this made the tweet harder to understand. This suggests that simple messages should be used for participant recruitment through Twitter (subsequently rebranded X).

Introduction
For researchers, increasing use of the internet has opened up new ways to investigate society and behavior at lower costs [1], producing higher data quality (Kongsved et al [2]), faster return rates, and lower data entry times [3]. Web-based participant recruitment (eg, websites and apps, such as social media) has also been applied in the social and behavioral sciences.

The new internet, or social media, also known as Web 2.0, enables people to connect with friends, family, companies, and other entities to produce and share content on the web [4,5]. The benefits of using social media for participant recruitment, and over and above Internet 1.0, have been increasingly demonstrated [6,7]. For example, at the height of the COVID-19 pandemic in 2020, social media allowed many social scientists to connect with thousands of people and include populations with unmet needs in their research [8-10]. In addition, compared to paid panels, using paid social media advertisements to recruit research participants has been shown to cost less [11,12] and be more time-efficient [13,14]. Furthermore, it is also suggested that social media can reach larger pools of participants and access hard-to-reach populations [15]. Social media allow researchers to recruit participants quickly and cost-effectively, as they are accessible through various devices at any time and allow the creation of specific digital content to target specific populations, increasing the likelihood of achieving the required sample size [15,16].

Facebook, Twitter (subsequently rebranded X), and Instagram are some of the most popular social media platforms for health research [13,17-20]. In 2022, more than 70% of internet users in the United Kingdom reported using Facebook and 42.8% Twitter [21]. Social media has become so deeply embedded in our daily lives that people rely on them for every need, such as entertainment, information, purchases, social connections, and work [22]. As new social media platforms enter the market, it is expected that the number of social media users will continue to grow [22].

So far, only a few studies have investigated the effectiveness of social media for health research. Most studies have investigated their effectiveness concerning recruitment in offline studies [13,16,17,23], with only a few making comparisons between different web-based recruitment methods for web-based studies [24]. While there is some guidance for the ethical use of social media for recruiting participants for health research [25], little is known about optimizing the use of platforms such as Twitter and Facebook for health-related research recruitment [19,26], such as the contents of the message to be used for targeting eligible individuals.

However, we can infer potential key components of a social media message from other areas using behavioral sciences. For example, marketing research has shown that credibility and trust in the source are important factors for clicking on advertisements [17,27-30]. In relation to this, studies have suggested that web-based health information from an expert source is viewed as more experienced and credible [31,32]. These findings demonstrate that aspects of endorsement and credibility when creating and disseminating messages are important. Similarly, several studies have shown that messages containing descriptive and normative social norms can be effective methods of engaging with the public [33-35]. In these studies, individuals receive information about socially desired (normative norms) or most frequently observed behavior (descriptive norms). Social norm messages provide individuals with a standard against which they can compare their intentions [36]. To our knowledge, no previous studies have tested whether social norms or patient endorsement messages on social media posts increase engagement with target audiences. The primary aim of this web-based experimental study, therefore, was to design and test the use of tailored Twitter posts, which integrate elements of patient endorsement and social norms, for the recruitment of participants into an observational case-control study.

Methods
Setting and Context
In 2020, a simulated randomized web-based experiment was programed on SurveyMonkey (SurveyMonkey Inc). The experiment was designed to test the effectiveness of targeted social media messages to increase intentions to participate in a real-world observational case-control study called the Cancer Loyalty Card Study (CLOCS) [37]. CLOCS is an observational case-control study that aims to investigate the self-care behaviors of patients with ovarian cancer before their cancer diagnosis. It seeks to do this by investigating differences in transactional data (such as medication purchasing) between women with and without ovarian cancer (the transactional data are collected through the loyalty cards of 2 UK-based high street retailers). Cases (ie, women with ovarian cancer) were recruited through participating National Health Service sites, while controls were recruited through the study website. Thus, those who were eligible to take part as control participants were recruited through social media and other internet-based sources.

Study Eligibility and Recruitment
The study sample comprised women aged between 18 and 70 years living in the United Kingdom without an ovarian cancer diagnosis who were potentially eligible for the real-world observational case-control study. Study participants were recruited through a web-based survey vendor, Dynata (Dynata Global UK Ltd).

https://formative.jmir.org/2024/1/e48538

XSL•FO RenderX
Procedure

At the beginning of the experiment, those who were interested in taking part in the web-based experiment were presented with information about the study, including a brief description of CLOCS as well as a consent form. If participants consented and were eligible, they were randomized (in a 1:1:1 ratio) to receive 1 of 3 simulated Twitter posts: a standard advertisement (control condition), an advertisement with patient endorsement (patient endorsement condition), or an advertisement with a descriptive social norms message (social norms condition; Table 1). To generate authentic Twitter messages, real tweets were posted on a dummy Twitter account, alongside an infographic detailing information about CLOCS. Screenshots were taken of these posts for use in the experiment (the messages were immediately deleted after each one was posted; Figures S1, S2, and S3 in Multimedia Appendix 1 contain screenshots of the messages).

### Table 1. Messages used in the experimental study with readability scores and character count. The Flesch-Kincaid readability score ranges from 0 (“extremely difficult to read, best understood by university graduates”) to 100 (“very easy to read, easily understood by an average 11-year-old student”).

</tbody>
</table>

The content of the messages is presented in Table 1, along with a Flesch-Kincaid readability score calculated using the web-based software Grammarly (Max Lytvyn, Dmytro Lider, and Alex Shevchenko). This was done to ensure that the message was understandable to the target audience [38]. The standard and patient endorsement messages had the lowest readability scores (15 and 7.9, respectively) and were the easiest to understand (Table 1).

After being presented with the Twitter messages, participants were asked 2 comprehension questions on whether CLOCS only recruits women with ovarian cancer and what kind of data CLOCS are analyzing. Participants could only continue in the survey if they answered the questions correctly [35,39,40]. The primary outcome was participants’ intention to take part in CLOCS, and we asked individuals whether they would participate in the advertised study, adapted from previous literature [34,35,39,41,42]. It featured a fully labeled 4-point response scale (“definitely not,” “probably not,” “yes probably,” and “yes definitely”).

To explore how the messages were perceived by the participants, we included 2 questions on how easy the message was to understand (“very difficult,” “fairly difficult,” “fairly easy,” or “very easy”) and how clearly the aims of the study were communicated (“not at all,” “a little,” “very,” or “extremely”).

In the next step, participants were asked about their past participation in health care research (“yes” or “no”) and whether they had loyalty cards from UK-based high-street retailers. Sociodemographic questions covered age (“18-24,” “25-34,” “35-44,” “45-54,” or “55-70”), education (“no college degree” or “college degree, equivalent, or higher”), employment status (“yes” or “no”), marital status (“single”, “married or living with a partner”, “divorced or separated or widowed”), self-reported health (“poor,” “fair,” “good,” or “excellent”), and history of cancer in themselves, family, or close friends (“yes” or “no”).

Individuals were then given the opportunity to state their thoughts on improving social media messages for the recruitment of study participants in an open-ended question.

The survey concluded with an active interest question on whether participants would be interested in being redirected to the CLOCS website for more information on how to participate [34,40-42]. Those who responded yes were provided with a link to the CLOCS website on the final page of the survey. The website opened in a new tab for participants who clicked on the link. No further data associated with their direct participation in CLOCS were collected in this experiment. The web-based experiment took, on average, 5 minutes to complete.

**Ethical Considerations**

Ethics approval for this study was obtained from the University College London Research Ethics Committee (17813/001). All participants provided consent to take part in the study. All the data collected as part of the study were anonymized, meaning no identifiable information were collected. Eligible participants who completed the questionnaire received a small financial incentive from Dynata, as per their panelist agreements.
Data Analysis

A pilot study was conducted beforehand for sample size calculations. Based on the findings from the initial sample of 359 participants, with a 10 percentage point difference in the intention to take part (“yes, definitely” or “yes, probably” versus “definitely no” or “probably no”), we determined that the number of participants needed to achieve 95% CI and 80% power was 350 per trial arm. Data from participants in both the pilot and final samples were combined for analysis.

Sample characteristics were assessed using descriptive statistics (Table 2). Differences in participants’ intention to take part in CLOCS and perception of the messages were assessed using univariate and multivariate ordinal logistic regression. Willingness to visit the actual website was assessed between groups using univariate and multivariate binary logistic regressions. Adjusted odds ratios (aORs), 95% CIs, and *P* values are presented in the results, with *P* values below .05 regarded as statistically significant.

The responses to the open-ended feedback question were categorized into main themes through content analysis [43].

Study Sample

Figure 1 demonstrates the flow of participants through the study. In total, 2500 invitations were sent out on behalf of University College London researchers to women registered on a survey panel (Dynata), and 47.8% (1195/2500) responded to the invitation. Out of these potential participants, 92.6% (1107/1195) were eligible for the study.

Eligible participants were randomized to the experimental conditions: 376 to the control condition, 358 to the patient endorsement condition, and 373 to the social norms condition. Across conditions, 4.2% (47/1107) did not finish the survey after randomization, leaving a final sample of 1060, who were all included in the analysis: 34% (360/1060) in the control condition, 32.5% (345/1060) in the patient endorsement condition, and 33.5% (355/1060) in the social norms condition. Most women in the analytical sample were in paid employment (705/1060, 66.5%), married or cohabiting (605/1060, 57.1%), did not have a college degree (549/1060, 51.2%), owned at least 1 loyalty card from a pharmacy (783/1060, 73.9%), experienced cancer closely (ie, either themselves or with family or close friends) (772/1060, 72.8%), and reported good or excellent health (701/1060, 66.1%). Post hoc comparisons revealed that sociodemographic variables did not vary significantly across the experimental conditions (Table 2).

Figure 1. Flow through the study.

Intention to Take Part in CLOCS

Overall, the intention to take part in CLOCS was high, with 60% (636/1060) of women stating that they would probably or definitely participate. Table 3 shows the distribution of intentions after reading the Twitter messages. The ordered logistic regressions in Table S1 in Multimedia Appendix 1 show that the behavioral messages, both patient endorsement (odds ratio [OR] 0.74, 95% CI 0.56-0.98; *P*=.03 and aOR 0.73, 95% CI 0.55-0.97; *P*=.03) and social norms (OR 0.74, 95% CI 0.54-0.93; *P*=.015 and aOR 0.69, 95% CI 0.52-0.92; *P*=.009), decreased intention to take part in CLOCS. None of the sociodemographic variables were significantly associated with the intention to participate in CLOCS.

Perception of the Messages

Table 4 shows that most study participants stated that the messages were fairly or very easy to understand (796/1060, 75.1%) and that the aims of the study were very or extremely clearly communicated (594/1060, 56%). However, the ordered logistic regression results in Table S2 in Multimedia Appendix 1 show that individuals in the patient endorsement condition perceived the message as more difficult to understand (OR 0.63, 95% CI 0.47-0.84; *P*=.002 and aOR 0.65, 95% CI 0.48-0.87; *P*=.004) and the study aims as less clear (OR 0.70, 95% CI 0.53-0.92; *P*=.01 and aOR 0.72, 95% CI 0.55-0.95; *P*=.02) than those in the control condition. There were no statistically significant differences in the perceptions of those in the social norms condition and those in the control condition.

**Active Interest in CLOCS**

Almost half of the study participants (526/1060, 49.6%) indicated that they would like to be redirected to the CLOCS website after the survey. The binary logistic regression in Table S1 in Multimedia Appendix 1 shows that participants who were presented with the social norms message were less interested in being redirected than those in the control condition (157/355, 44.2% vs 191/360, 53.1%; OR 0.70, 95% CI 0.52-0.94; P=.02 and aOR 0.74, 95% CI 0.54-0.99; P=.05). While there were no significant differences between the patient endorsement and control conditions (178/345, 51.6% vs 191/360, 53.1%; OR 0.94, 95% CI 0.70-1.27; P=.70 and aOR 0.96, 95% CI 0.71-1.30; P=.78), women with a loyalty card (117/205, 57.1% vs 58/144, 40.3%; aOR 1.47, 95% CI 1.10-1.95; P=.008), excellent health (70/135, 51.8% vs 22/57, 38.6%; aOR 1.94, 95% CI 1.00-3.76; P=.05), aged between 55 and 70 years (117/205, 57.1% vs n/N, 40.3%; aOR 1.89, 95% CI 1.19-3.00; P=.007) and those who had experienced cancer closely (404/772, 52.3% vs 122/288, 42.4%; aOR 1.37, 95% CI 1.03-1.83; P=.03) were more interested in visiting the study website. Those who had previously participated in health research were less likely to want to be redirected (348/734, 47.4% vs 178/326, 54.6%; aOR 0.75, 95% CI 0.58-0.99; P=.04).

**Feedback Question**

Table 5 shows the main themes of the content analysis per message. While 57.5% (609/1060) of the study participants were willing to provide some feedback, the majority (395/609, 64.8%) stated that the messages did not require changes. Another common theme was clarity (75/609, 12.3%), where participants thought there was too much jargon, that the message should be shorter, adding the hashtags at the end would make it more readable, and message format (59/609, 9.7%), where participants recommended using brighter colors or adding more infographics or a video instead of text.

Moreover, some participants (237/609, 3.8%) stated that the messages were unclear on how the advertised study uses loyalty cards to help with an ovarian cancer diagnosis. To increase the credibility of the message, 3.3% (20/609) of participants suggested including the university’s or sponsor’s logo at the beginning of the message. Some participants also suggested posting the messages on several social media platforms (16/609, 2.6%), as well as using patient or celebrity endorsement (9/609, 1.5%) or advertising an incentive (7/609, 1.1%).

Discussion

Overview
This randomized web-based experiment examined the effectiveness of adding behavioral messages to Twitter advertisements for participant recruitment in a real-world case-control study (CLOCS). The results show that the standard messages yielded the highest intentions compared to the 2 normative behavioral messages. Furthermore, the social norms message decreased the willingness to visit the real study website after the survey. The vast majority of participants stated that the messages did not require changes, but some preferred clearer and shorter advertisements.

Comparison With Previous Literature
Our findings contrast with previous research, which has shown that using behavioral messages, such as social norms [34,35] and patient endorsement [31,32] can be effective methods to engage with the public on the web. The negative effect we found can partially be explained by the reduced readability of the messages, as individuals in the social norms condition perceived the message to be more difficult to understand—and the aims of the study were less clear than those in the standard advertisement.

Individuals who have had experience with a cancer diagnosis, either themselves, with family, or with close friends, were found to be more interested in CLOCS. This is in line with research reporting that familial history of cancer is associated with increased breast and ovarian cancer screenings due to individuals’ increased awareness of cancer-related complications [44]. In this study, participants’ awareness of ovarian cancer and its risks—partially informed by their close experiences with cancer—may explain their increased interest in CLOCS. Therefore, having a personal awareness of or connection to the proposed project can increase individuals’ interest in health-related research. We also found that women aged between 55 and 70 years had increased interest in visiting the CLOCS website. Ovarian cancer is rare in women younger than 30 years, but the risk increases with age, drastically spiking after 50 years—with the average age of diagnosis being between the ages of 50 and 70 years [45]. Thus, the saliency of the risk for ovarian cancer in these age groups may, in part, explain their interest. Final, while individuals recommended including a video in the message, a recent experimental study did not find any effect of adding animated decision aids to a website with the intention to participate in a case-control study [42].

Strengths and Limitations
One strength of this study was the use of a randomized experimental design to evaluate the effectiveness of adding behavioral messages to Twitter messages. Additionally, the study used validated questions on intentions and active interest. A final strength of this study is that the statistical analysis included a large number of covariates known to influence participation in health research.

This study has some important limitations, which call for follow-up research. First, the 2 messages were grounded in social norms and patient endorsement, which have mixed and limited evidence supporting the efficacy of these messages in influencing participation in clinical research [46] and may not have been the right theoretical basis for the content of the recruitment messages. This limitation is further exacerbated by the paucity of experimental research testing and reporting different messages on digital and social media platforms and their effectiveness on research recruitment. More theory-based formative research using social media marketing techniques, field experiments, and co-design approaches is needed to improve our understanding of the evidence-based application of social influence on research participation for recruiting participants to health research using social media.

Second, throughout the design and testing of both the social norms and patient endorsement messages, the authors considered whether the messages were suboptimally designed despite having contributions from patient representatives who reviewed the messages, and these have undergone various iterations. This is due to 2 reasons. While previous studies have shown that proximal social norms are more effective in different contexts [30-36], it was not possible to use them in our experiment due to the lack of data supporting the claim at the time of the CLOCS recruitment [37] and the novelty of this case-control study. Additionally, the social norm message had to use a vague verbal quantifier, “many women,” and focus on satisfaction with participation rather than the participation rate to ensure messages were ethical and not coercive. Similarly, the patient endorsement message may not have highlighted the link between motivation and action because the message only referred to the patient representative buying medication for symptoms from retailers before a cancer diagnosis. It is possible that future studies focusing on barriers and facilitators of health research participation in the design of the recruitment messages rather than normative behaviors may demonstrate different outcomes.

The authors aimed to address the aforementioned issues with feedback from the participants. However, this exercise did not lead to clear future recommendations other than the use of the factual message used in the control condition. Nevertheless, the outcomes of this experiment informed the recruitment of the CLOCS participants. The authors gained further understanding of the potential limitations of recruiting participants to CLOCS and successfully recruited 249 participants using Facebook advertisements with the control message [47]. The cost per participant recruited was between US $12 and $19, which is comparable to and less than other health-related studies with a targeted population [48]. This hypothetical experimental study demonstrates the importance of testing messages to be used in internet-based recruitment strategies, the potential limitations, and biases, and not relying only on consensus methods. Embedding process evaluations and pre- and postresearch data collection could have a significant impact on the resources allocated to recruitment as well as whether they reach their intended outcomes. Based on the outcomes of the CLOCS study [37], future studies could emphasize how the participation of women without ovarian cancer in the case-control study can help better early diagnosis of ovarian cancer, use their response rates, and further explore why the existing participants took part in this research to develop effective messages.
Furthermore, in line with previous literature, we measured attitudes toward the simulated Twitter message and CLOCS to capture individuals’ potential reactions to the website [42], which has its limitations, as several studies have reported on the intention-behavior gap [49]. As such, motivational interventions are necessary but often not sufficient to change behavior. It is possible that the hypothetical nature of the web-based experiment may have introduced a potential response bias. Similarly, there might have been a social desirability or agreement bias, where study participants tended to overestimate their intentions.

Last, we did not account for participants’ familiarity with Twitter. Our sample may have contained women who were not used to reading messages containing hashtags (Twitter use was not verified). Moreover, while we tried to include a behavioral outcome by including an option for participants to visit the CLOCS website, our experiment did not formally assess the analytics of the website or investigate how the messages influenced click behavior. Final, this study may have been affected by selection bias, as factors shaping computer use (age, gender, socio-economic status, etc.) tend to influence the demographics of the sample in web-based studies [50]. For instance, there are usually similar demographic patterns across social media platforms, where users are primarily made up of young, female, and urban individuals [51,52].

Implications for Policy and Future Research

Our findings suggest that researchers conducting health-related studies should focus on using simple messages for participant recruitment through Twitter. To increase engagement with potential participants through social media, recruitment messages should be easy to read, transparent, and appropriately targeted to an audience that could have experience related to or an interest in the proposed study. Future research could test messages involving social proofing, such as sharing the experiences of study participants. Additionally, messages could be tested in field experiments by controlling the date, time, hashtags, and images used.

Conclusion

In conclusion, our results indicate that adding behavioral messages containing patient endorsement or social norms to simulated recruitment messages on Twitter decreased participants’ intention to take part in a real-world case-control study. The social norms message also decreased participant interest in visiting the actual study website. These results can be partially explained by difficulties in reading and understanding the message content, with the addition of normative behavioral components. Future research should continue exploring and optimizing methods that can effectively leverage social media platforms for the engagement of potential participants in health-related research.

Acknowledgments

This study was funded by Cancer Research UK’s Early Detection and Diagnosis Project (grant C38463/A26726 to YH and HRB) with support from the Peter Sowerby Foundation. The authors would like to acknowledge Emily Kuipers, MSc, who worked on this project as part of her MSc health psychology dissertation project at University College London. We did not use generative artificial intelligence for this project or for its write-up.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors’ Contributions

STS, RK, and YH developed the study concept and design. YH, HRB, and JMF designed and developed the Twitter messages for the Cancer Loyalty Card Study. STS and YH performed the data analysis and interpretation. STS and YH drafted the manuscript, and all authors provided critical revisions. All authors approved the final version of the manuscript for submission.

Conflicts of Interest

None declared.

Abstract

Background: Although intended to support improvement, the rapid adoption and evolution of technologies in health care can also bring about unintended consequences related to safety. In this project, an embedded researcher with expertise in patient safety and clinical education worked with a clinical informatics team to examine safety and harm related to health information technologies (HITs) in primary and community care settings. The clinical informatics team participated in learning activities around relevant topics (eg, human factors, high reliability organizations, and sociotechnical systems) and cocreated a process to address safety events related to technology (ie, safety huddles and sociotechnical analysis of safety events).

Objective: This study aimed to explore clinical informaticians’ experiences of incorporating safety practices into their work.

Methods: We used a qualitative descriptive design and conducted web-based focus groups with clinical informaticians. Thematic analysis was used to analyze the data.

Results: A total of 10 informants participated. Barriers to addressing safety and harm in their context included limited prior knowledge of HIT safety, previous assumptions and perspectives, competing priorities and organizational barriers, difficulty with the reporting system and processes, and a limited number of reports for learning. Enablers to promoting safety and mitigating harm included participating in learning sessions, gaining experience analyzing reported events, participating in safety huddles, and role modeling and leadership from the embedded researcher. Individual outcomes included increased ownership and interest in HIT safety, the development of a sociotechnical systems perspective, thinking differently about safety, and increased consideration for user perspectives. Team outcomes included enhanced communication within the team, using safety events to inform future work and strategic planning, and an overall promotion of a culture of safety.

Conclusions: As HITs are integrated into care delivery, it is important for clinical informaticians to recognize the risks related to safety. Experiential learning activities, including reviewing safety event reports and participating in safety huddles, were identified as particularly impactful. An HIT safety learning initiative is a feasible approach for clinical informaticians to become more knowledgeable and engaged in HIT safety issues in their work.

Introduction

Background

Health care delivery is increasingly dependent on technology, and health care organizations are heavily investing in technological infrastructure [1]. Health information technologies (HITs), such as electronic health records (EHRs), computerized provider order entry, and mobile devices, play an ever-increasing role in clinical practice, and it is largely thought that these technologies have the potential to promote safe care and contribute to better patient outcomes [2,3]. However, a growing body of research [4-7] has also identified the potential for HITs to contribute to harm, where harm is defined as something “that should not have happened and that you don’t want to happen again” [8]. In this study, the acronym HIT refers to technologies used in the health care system for health information management. This study focused on HIT safety concerns, more specifically, unintended harm or potential harm that involved an HIT-based system.

An example of harm related to HIT is an overdose event that occurred when a patient aged 16 years received 39 antibiotic pills when they should have received only 1 pill [9]. The overdose event occurred after a series of computer and human failures, including a confusing computer interface design that forced weight-based dosing for pediatrics, an automated “robot” system in the pharmacy that performed a “double check” rather than human verification, a hidden curriculum for prescribing doctors to “ignore all computer alerts,” and a novice nurse who trusted the computer recommendations because “the computer had been right” in the past [9]. The design of technology and overreliance on the accuracy of the information presented can lead to unintended consequences, and there is increasing recognition that events such as this are occurring alongside the increasing uptake of technologies in health care [4-6,10-13]. There is also a growing identification that well-designed and well-deployed systems may help to mitigate some of these issues [14,15]. Clinical informatics teams, with expertise in the effective use of HITs, are ideally positioned to recognize and respond to HIT-related harms and contribute toward enhanced quality and safety in health care delivery. In this study, we explored clinical informaticians’ experiences in incorporating safety practices into their work.

Defining HIT Safety and Harm

The field of patient safety has conventionally focused on hospital and inpatient settings, with the measurement and monitoring of adverse events (including near misses) well established as a widespread practice designed to reduce harm from activities in the acute care setting (eg, medications, surgical procedures, falls, and diagnostcs) [16-19]. For this study, focused on primary and community care settings, a broader view of safety was taken up, with consideration for all 6 interconnected dimensions of quality health care (safety, effectiveness, patient centeredness, timeliness, efficiency, and equity) [20]. Using the broad definition of harm as “something happened that you did not want to happen,” harm is not simply the opposite of safety; instead, the definition makes space for recognizing the potential for harm related to other circumstances, such as inequity, inaccessibility, and poor patient experiences. Recognizing the interconnectedness of the 6 dimensions of quality, an expansive definition of harm is useful because it places a greater emphasis on the complex nature of the health care system and can thus help identify latent problems. A focus on latent problems that contribute to harm (as opposed to a focus on human error) has the potential to yield more systems-focused solutions to mitigate against recurrence and thereby improve the quality of care. This is particularly relevant with HIT, where latent errors may impact people who are several degrees away from an HIT origin of error, such as the numerous clinicians involved in the overdose example described in the preceding section.

Embedded Research Context

This study was conducted as part of an embedded researcher project supported by an innovative program and funding model designed to maximize the impact of research by supporting formal partnerships between emerging academics and health system leaders to address pressing challenges in health service delivery [21]. The funding program provided support for a doctoral student researcher to conduct their dissertation research while holding a position within the health service organization. The program is designed to help researchers develop professional skills to support evidence-informed improvement within the health system alongside conventional research outputs [22]. The embedded researcher, the researcher’s supporting academic committee, and leaders from the organization collaborated to design an applied research project that met usual academic requirements and simultaneously was relevant and useful to the organization. In project conceptualization, the health care organization prioritized patient safety and a focus on HIT in primary and community care settings. Upon funding, the researcher was embedded within the organization’s community clinical informatics team for a 2-year period (2019 to 2021). The embedded researcher was experienced in clinical education and had experience in the areas of clinical nursing, clinical education, informatics, patient safety, and quality improvement. Having a role within the organization allowed the researcher extraordinary insights into the role of the team within the organization, the team’s learning needs related to HIT safety, and opportunities to address learning needs. Fostering daily working relationships was an intentional aspect of the project to support engagement and build capacity in the team, apply learning to existing processes, and promote sustainable practices [23]. The organization’s quality and safety leaders were also key contributors to the project, collaborating closely with the embedded researcher to guide the course of the project.

Codevelopment of the HIT Safety Process

In the early stages of the project, the embedded researcher worked with a clinical informatics leader to conduct a retrospective sociotechnical analysis of reported HIT safety concerns [24]. This part of the project was possible because the organization had added a question (“Was a computer involved in the incident?”) to their web-based voluntary incident reporting system in 2016. The findings from the incident analysis study [25] provided the foundation for the clinical informatics team and the embedded researcher to cocrate a new process that
uses sociotechnical systems analysis for identifying, analyzing, and responding to HIT safety events. The new process used safety huddles [26,27] and was aligned with the concept of a learning health system in which theoretical frameworks and scientific evidence are integrated with internal data to inform continuous improvements [28,29]. Throughout the project, the researcher was positioned within the clinical informatics team with a constant focus on facilitating learning using adult learning principles [30-32], drawing on a variety of fields such as patient safety [17,18,20,33,34], quality improvement [35-37], and learning health systems [38-40] as well as HIT safety and harm specifically [5,41-45]. The aim of this study was to examine the clinical informaticians’ experiences in learning about HIT safety and to understand their experiences in codeveloping the new process to address HIT safety concerns in their work.

Methods

Setting

The study was carried out in a large health care organization in western Canada that provides acute, primary, and community care for >1.25 million people and includes both densely populated urban areas as well as rural and remote communities. The study focused on members of a clinical informatics team assigned to support services delivered in non–acute care settings (ie, primary care, home care, population and public health, long-term care, mental health, and substance use services). The clinical informatics team comprised 15 to 20 multidisciplinary staff members as part of the organization’s efforts to strengthen primary and community care delivery. The team was established at the beginning of the research project, which proved to be serendipitous for the research project because the embedded researcher was able to enter a newly formed group. The team was responsible for the clinical integration and operation of all HIT systems in primary and community care settings. There were different roles and responsibilities among the members of the team. For example, the educators were responsible for supporting clinical staff in using the clinical software systems. The specialists were responsible for working with the HIT software development team to communicate the changes that might be required for the HIT system (eg, practice policy changes). In addition, team members were dedicated to specific clinical service areas, such as mental health or home care. The clinical informatics team did not include any prescribing clinicians, pharmacists, or medical office assistants; however, the embedded researcher did consult and obtain input from members of these groups to inform them of the learning experiences and codevelopment of the HIT safety process. An organizational chart of the team is available in Figure 1.

Study Design

This study used qualitative description methods to explore the clinical informaticians’ perspectives and reflections on their experiences of learning about HIT safety and the codevelopment of the process to manage HIT safety events. Qualitative description is useful for capturing the meanings and interpretations that informants ascribe to their experiences [46,47]. Aligned with a constructivist paradigm, which posits that human knowledge is subjective and socially constructed, the study aimed to capture both the participants’ perspectives and acknowledge the subjectivity and involvement of the embedded researcher in constructing interpretations of the data [48]. In this study, having been embedded within the team for an extended period, the researcher was able to glean an in-depth understanding of the context surrounding the participants’ accounts.

Figure 1. Team chart and research participation.
During data collection and analysis, the embedded researcher engaged in ongoing reflexivity by attending to their unique positioning, the circumstances surrounding the study, and the potential influences on knowledge construction [48]. From a postpositivist perspective, the close relationship between the researcher and participant is conventionally thought to perpetuate bias and prevent the attainment of rigor in research [49,50]. However, we contend that it was the strength of the relationship between the embedded researcher and the clinical informatics team that allowed the researcher to fully explore how HIT safety was in alignment (or not) with the work of the team. The intention of situating an embedded researcher with the team was to encourage relationships between the researcher and the clinical informatics team members to support the meaningful, effective, and sustainable integration of knowledge into practice [51-54]. Indeed, as team members began to apply their learning in their work (ie, using the sociotechnical framework to analyze a problem), the researcher was available for guidance and consultation as needed, and as the team’s capabilities developed, less support from the researcher was required.

Ethical Considerations

Before conducting this study, ethics approval was obtained from the University of British Columbia Research Ethics Board (H18-02677), and all participants signed a consent form. The conduct and reporting of the study followed the Consolidated Criteria for Reporting Qualitative Studies guidelines for qualitative research reporting.

Data Collection

We used purposive sampling, targeting clinical informatics team members who supported primary and community care and who had participated in the HIT safety initiatives over the previous 12 to 24 months. The embedded researcher emailed all team members (N=16), inviting them to participate in 1 of 3 web-based focus groups, with a clear statement that participation was optional and in no way related to their job. The study was carried out during the COVID-19 pandemic when face-to-face meetings were discouraged; thus, the embedded researcher facilitated focus groups over Zoom (Zoom Video Communications, Inc) [55]. A semistructured interview guide was used (Multimedia Appendix 1), and the focus group sessions were recorded using Zoom video capture, downloaded onto the private secure computer of the researcher, and manually transcribed verbatim by the researcher. The informants reviewed the transcript of their comments, and all participants approved the transcripts with no revisions.

Data Analysis

Thematic analysis was conducted [46,56,57] using NVivo (version 12; Lumivero). Thematic analysis is well suited to address broad research questions and provides a flexible approach to remain “data-near” [47], searching across the data for patterns and allowing for both inductive and deductive approaches to the analysis. An overarching framework of 3 categories—barriers, enablers, and outcomes (Textbox 1)—was used to provide an initial structure for the analysis.

After completing the deductive coding to classify the data as barriers, enablers, or outcomes, the data were re-examined to inductively generate subcategories. Subcategories were developed and refined over several iterations (between CR and LMC), and a member-checking session was conducted with the clinical informatics team to support the descriptive and interpretive validity of the findings [46,48].

Textbox 1. Operational definitions of high-level analytic categories.

- Barriers to understanding and applying methods to address health information technology (HIT) safety: Activities or conditions that may have impeded learning
- Enablers to learning about safety and mobilizing their knowledge: Activities or experiences that facilitated or promoted learning
- Outcomes of the HIT safety project: A product or result from engaging in learning activities

Results

Overview

Three 1-hour web-based focus groups were held with 10 informants. Of the 10 informants, half were in clinical informatics educator roles, and the other half held roles such as clinical informatics team leader or clinical informatics project manager. A total of 50% (5/10) of the informants had been in their current role for <2 years, 40% (4/10) for 2 to 5 years, and 10% (1/10) for >10 years. In total, 90% (9/10) of the informants had a clinical background, including 6 nurses, 1 physiotherapist, 1 occupational therapist, and 1 social worker. The team member, who did not have a clinical background, had been working in the health care sector for >10 years. The informants’ previous work experience in their respective clinical roles before taking on an informatics-focused role ranged from 0 to 24 years, with an average of 9.7 years.

The informants shared several barriers and enablers related to their experiences of learning about and developing strategies to address safety. They also described outcomes such as new learning and capabilities. Figure 2 displays the categories and subcategories. A description of each item follows, including excerpts from the data. Characteristics of the individual informants are limited to preserve their anonymity.
Barriers to Understanding and Applying Methods to Address HIT Safety

The informants identified several barriers to understanding and applying methods to address HIT safety, including a lack of knowledge, previously held perspectives, organizational pressures, and challenges related to event reporting before the project began.

Limited Prior Knowledge of HIT Safety

A common barrier described by the informants was initially having little or no foundational knowledge related to safety principles and their application to HIT. As an informant reported, “My experience with technology safety was pretty limited prior to all of this.... I didn’t really know much at all.” More specifically, informants shared that they had a limited understanding of any negative impact HIT systems could have on patient care. For example, one of the most experienced informants stated, “I had no idea what was going on for people at the front-line level with whatever they consider a computer incident.” This limited initial understanding exemplifies the learning needs within the team that needed to be addressed to begin to incorporate HIT safety practices into their work.

Previous Assumptions and Perspectives

The informants also shared different assumptions and perspectives about safety and harm in health care that they had previously held. Some were unaware that HIT could introduce risks to safety, were under the impression that safety concerns were beyond the scope of their role, or attributed safety concerns to user mistakes. An informant stated:

Technology was always supposed to be something that would make things safer, right? You streamline some processes, you make some things maybe, more automatic, take out some of the human element—that should be safer.

Others expressed that they were initially uncertain whether this topic was relevant. For example, an informant who had been with the team for 2 years stated, “I felt like it wasn’t really my role or responsibility to be identifying them [safety concerns].” Another shared that they had previously assumed another department of “internal auditors” was responsible for addressing problems related to HIT and now they saw the value in having a clinical perspective, “focusing on solutions, rather than, it’s just a number.”

Some informants described their initial attitudes toward reported HIT safety events as “narrow,” “judgey,” or “blaming,” articulating that they previously dismissed these events as user error. An educator described this shift away from a perspective of blame as, “not just dismissing it as ok, this one person screwed up this one thing, but more than likely, that person isn’t the only one who’s maybe made that same mistake.” Another educator explained how their perspectives moved from blaming toward curiosity:

I came from a narrow point of view, you [the end user] did something wrong, the [HIT] system didn’t work for you, what was that about? And now it’s more about, more curious—what else happened? How could we support you? What would’ve filled the gaps to make this less of an incident?

Competing Priorities and Organizational Barriers

The informants indicated that their capacity and capabilities to address HIT-related safety concerns were challenged by competing priorities and organizational barriers. An informant who had worked within the organization for 4 years perceived this as a systems issue: “The whole organization gets caught up in all these new initiatives, all these new projects, all these things
you know to make things better, but learning from the past and all these safety incidents, I feel like they get brushed aside.” Another team member described recognizing that there was a need for a focus on HIT safety but struggled with knowing how to proceed: “It just seemed too big to wrap our hands around without some support.”

Safety Culture and Reporting

A further challenge was related to the internal patient safety reporting system and processes, including concerns that it is onerous to use and, therefore, underutilized. A person who had extensive clinical experience questioned the usefulness of the reporting system, “Coming from the mindset of a clinician, you’re busy you know, am I going to take the time to do a [report], what’s the value there?”

On a broader scale, there were also knowledge gaps related to using the existing reporting system. As 1 person commented, “There’s still a lot to do in developing the reporting culture around technology needs in community.” More specifically, an informant noted the point-of-care staff’s lack of understanding of what constituted a computer-related safety event, “People don’t really understand what [an HIT] system-related error really is, and so a lot gets put into that [reporting] system that may not be appropriate for our eyes.”

The informants were also concerned that underuse of the patient safety reporting system meant that issues reported in the event reports were just the tip of the iceberg: “There’s so many safety issues that we don’t know about, things that are actually happening that aren’t being reported.” The challenges with the reporting system impeded their ability to address HIT issues because fewer reports meant that they had fewer opportunities for learning by analyzing events. Another informant made an analogy to the concurrent COVID-19 pandemic:

> It’s just like the COVID out there right now, there’s probably more cases than there actually are, we just don’t know about them...what we don’t know, is how to actually properly capture that all, and encourage people to come forward when they have an issue.

Enablers to Learning About HIT Safety and Mobilizing Their Knowledge

The informants reported some key enablers to learning about HIT safety and mobilizing their knowledge, including making space to participate in learning sessions and safety huddles, the hands-on experience of analyzing reports, and their observations of the embedded researcher as a role model.

Participating in Learning Sessions

Team members identified short education sessions led by the embedded researcher as supportive of their learning, having “collapsed all the salient points into a quick, easy-to-understand, salient presentation.” The evidence and resources referenced in the learning sessions were also identified as helpful: “I don’t know that there’s often opportunity to bring in scientific literature into our day-to-day jobs so I think that was a great opportunity, to hear and to see what’s happening in the academic realm and consider its application to practice.”

The informants specifically highlighted the case study about the antibiotic overdose (described earlier in this paper) [9] from the learning sessions as an effective tool to understand complexity and sociotechnical systems. A clinical informatics educator who had been with the organization for 3.5 years stated: “That [case study] was very, very engaging and very interesting, and you could see how like, just to see the breakdown like that...and it again, made me aware of all these little things that can go wrong or have to go wrong to lead to something like this, and how the [HIT] system played into it at each step.”

Gaining Experience Analyzing Reported Events

The informants also shared that the experience of analyzing safety events was valuable in learning how to apply what was gleaned from the analyses to make improvements. An informant who was newer to the team explained, “Actually receiving the [reports] and actually doing the investigative work teaches you a lot about the [HIT] systems... I enjoyed doing that and then thinking about how it could be better in the long run.” They went on to explain how this experience provided an opportunity to consider how different sociotechnical dimensions may be related to safety concerns: “You’re not just thinking about the actual documentation system, but you’re thinking about all the systems around that, like whether it be a workflow, or chaos, or whatever it is that contributed to that scenario.”

Participating in Safety Huddles

The informants also explained that the experience of sharing the event analyses with other members of the team and participating in the safety huddles was supportive of their learning around HIT safety in that this activity provided a peer learning experience. One of the educators stated, “I found [safety huddles] really informative, especially having other people there that use other [HIT] systems, and again, it’s someone else’s perspective and how they’re reading the situation and what I can learn from that other person that I’m working with.”

Another team member expressed an appreciation for safety huddles as a venue for communication among the team members and found them worth the time and effort for the team:

> I found that making space for us, like dedicated time and focus, to talk about these concerns that we have, or the patient safety events that have occurred... I’d never had that experience before, and I found it was so helpful talking as a group about what we found or what those problems that were being reported were about.... I found that it was easy to actually make the time and spend the effort to do that. You know we are all busy, but I think in the long run it’s all going to do us well as an organization and as a team to continue that [the safety huddles]

Role Modeling and Leadership From the Embedded Researcher

The informants also indicated that the role of the embedded researcher supported their learning and facilitated changes within the team’s practices. An informant who had been with the team for 2 years described the key function of the embedded researcher as initiating a focus on HIT safety: “I think we needed...”
someone to come in and really help to set the tone and set that framework...and so it’s been learning. I think the last year has been learning across the board.” Building on this, the informants also recognized the embedded researcher as an expert and champion for HIT safety, as a different informant explained: “It’s helped really mobilize the team in that direction and create more of a team sort of focus on working with these teams committed to safety-related issues.” An educator from the team described the embedded researcher as a role model for how to approach analyzing safety events, having “instilled curiosity” in the team. Finally, there was also a recognition of how to integrate HIT safety into the work of the informatics team; a long-standing member of the team noted, “what I didn’t realize before is really how well this conversation fits within an organizational structure and within a team structure.”

Outcomes

A variety of outcomes from the HIT safety project surfaced in the focus group discussions, some of which were individual outcomes and some of which were team outcomes. Individual outcomes included increased ownership and interest in HIT safety, the development of a sociotechnical systems perspective, and increased consideration of end-user perspectives. Team outcomes included increased team communication and the ability to use the processes to guide strategic planning.

Individual Outcomes

Expanding Ownership and Interest in HIT Safety

Several informants shared an increased sense of personal interest in the topic of HIT safety. A team member explained, “It’s given me an appreciation and actual interest in safety and how that pertains to design of [HIT] systems and how we interact with the [HIT] systems.” Furthermore, an informant with 8 years at the organization described having an increased sense of both personal and team ownership in relation to HIT safety: “Not only is it my role and responsibility, but we’re really well positioned to identify and sort of bridge between practice and workflows.” The informants recognized the role their team plays within the organization in supporting the delivery of care, as one person with extensive clinical and informatics experience noted, “Having a good understanding of why we exist as informatics...it’s not just for the users, although that’s important, it’s also for the patients and reducing risk...so it all ties together...that kind of holistic view.”

Developing a Sociotechnical Systems Perspective

The informants shared new insights into their work based on learning about sociotechnical systems theory as it applies to informatics. They expressed an increased appreciation for the relationships among the technology, the users, and the context in which these are situated. An educator with 24 years of experience explained:

I sort of think that technology doesn’t take into account the human being. It’s just, technology is a set of algorithms, it’s a set of stuff that’s written by a developer who tries to take in all the considerations possible. But you can’t take in all the considerations of a human being, and how a human being will respond to certain situations, or certain pieces of technology.

This was echoed by another educator with 3.5 years of experience, who stated, “Our technology is only as good as how people understand it, and so the education piece around it and you know, understanding the workflow and how to actually apply it and use our [HIT] systems is so important...because the [HIT] system could be working as designed, but if people don’t know how to use it properly, then it just leads to a lot of problems.”

Related to this, the notion of human factors as it applies to safe HIT use was also a new concept for many team members. An informant explained, “I never knew this existed, human factors—and now I am seeing that there is a whole theory behind it, there’s a lot to learn about, there’s best practices in design, there’s all these things that I had no idea even existed.”

Thinking Differently About Safety

Building on their knowledge of the sociotechnical perspective, the informants demonstrated an increased awareness of the factors and circumstances that may increase the risks of harm. As one educator highlighted, they previously “had just kind of considered the obvious errors, like with a malfunction or with a bug or something like that.” However, this educator went on to explain how their awareness of safety risks had grown beyond the technical aspects of HIT, noting, “Technology’s not infallible. There’s so many factors, and it’s quite complex, and it’s given me kind of an appreciation for...the whole topic, and it makes me think about problems in a different way.” Similarly, another educator described how their view of safety had expanded beyond just focusing on the HIT end user:

It’s not simply, one person did something wrong. There [are] so many different things—there’s the workflow, the human factor, was it the actual user interface—all those different subcategories.

Developing the Ability to Identify and Analyze Reported Events

The informants shared how they applied what they learned to their work and developed the ability to identify and analyze HIT-related safety events. First, among the informants, there was a greater awareness of “just what is a safety event,” as one of the more experienced members of the team put it. Several people described adopting the practice of systematically analyzing reported events. For example, how they learned to “think of [HIT safety events] in those different dimensions that we learnt about with the sociotechnical model, just being able to, like, think of it in a framework like that, in sort of a structured way, to help break it down.” Another informant shared how taking a systematic approach had changed their thinking:

It does help us see sort of where perhaps a gap was with a reported [event]. So, before we just knew there was an issue, but...I wasn’t looking at it as all these different sort of levels.

Similarly, another informant explained:

What I’ve learned is how to break it up. Was it the [HIT] system?... Was it the workflow? The process?
Applying Learning to Mitigate Against Harm

Going a step further, informants also articulated how they learned to be more proactive and tried to prevent harm from occurring in the future. An educator explained that they have observed patterns over time from the analyses of events, and this has increased their awareness of the potential for future risks:

I'm actually already starting to see some patterns and starting to think about the complexities of some of these [HIT] systems. Just this one tiny little move can make a big change, can put someone at risk, and it shouldn’t be that easy to put a client [patient] at risk.

Another educator described having an increased awareness of patterns as well, and how this informed their thinking around mitigating future issues: “I think being aware of the patterns and being aware of the common sort of issues is really helpful in terms of thinking about future solutions and making sure that those problems can’t be easily replicated.” Furthermore, the informants described how they had been able to communicate concerns about HIT safety in the context of their work. One of the more experienced team members explained, “I didn’t always have the language to describe why something in the [HIT] system was a problem, but that information with systems thinking really helped me frame those conversations.” Another informant described how the clinical informatics team has begun to take a more proactive approach to safety:

I think it’s also changed the conversation around; just when we’re discussing [HIT] system changes or potential projects that we may undertake, it’s just the safety risks factors. Having more general dialogue around that...just being more proactive.

Growing Consideration for User Perspectives

Consideration for clinicians and HIT users was a commonly expressed sentiment. Team members reflected on their previous experiences as clinical care providers and reflected on this when considering the functions and dysfunctions of HIT in a clinical context. An educator commented:

When we get these reports now, I’m trying to think like the clinician. I’m not working as a clinician anymore, but I am trying to put myself in their shoes—what are all these other surrounding factors, what led them to report about this?

Another informant in the role of educator elaborated on this idea:

But it’s probably easier if you have the open mind to actually really understand, again the empathy factor of it, understanding what had happened in terms of if it’s a system error or whatever, and yeah, it’s just having that understanding that it’s not always the person at fault, it’s not always the system at fault, it could be a combination of everything. And again, what do we do next? It’s how do we learn from this.

Pairing this consideration with their knowledge of HIT safety, another informant demonstrated new insight into the users’ experiences with HIT:

And so they think it’s one way, and then an error happens because they misread something or they didn’t know to check somewhere, and...I just felt like I never clued into how much the design can really impact that front end user experience.

Furthermore, another informant contextualized the challenges clinicians and HIT users may face in using HIT:

I’m just thinking about, really, the environment that people are working in and the complexity of that...the environment might be...very chaotic, and then we’re asking them to do something very complex in the [HIT] system. I think that is a safety concern.... I think that’s where it would be very easy to have errors, obviously.

Team-Level Outcomes

Enhanced Communication Within the Team

The informants described how sharing their experiences about HIT safety worked to enhance communication within the team and further expand their awareness of potential HIT safety concerns. As described earlier, there were separate groups within the team that focused on different HIT systems and clinical areas in primary and community care, which could sometimes create siloed communication. Team members expressed that participating in the HIT safety activities opened up new communication channels and supported an exchange of learning across the different teams. An educator, whose work was focused on a particular clinical area, shared the following:

It was great awareness to hear what was happening in other places...kind of raising that awareness so that if we see something similar in our clinical area, it just kind of alerts you to look out for things that you maybe would’ve never considered...and all of a sudden, your level of awareness is there.

Another informant highlighted how increasing communication across the smaller teams within the larger clinical informatics team helps provide better support to the clinicians or HIT users: “Clinicians are interacting with many systems, and many applications, and many types of technologies, that in fact, we need those opportunities to speak with our colleagues who lead or support other [HIT] programs so that we really get a sense of what those safety events meant.”

Informed Future Teamwork and Strategic Planning

On a broader scale, the informants also gleaned new insights into the role of their team within the organization. One of the more senior team members asserted:

I think that our team is perfectly positioned to handle, be handlers of technology related [safety] reports, and make sure we close the loop. I think it needs to be part of our work and just have it as a regular ongoing piece of work that we do and...service that we provide to the organization.
In addition, the informants shared insights into how their knowledge of HIT safety relates to organizational decision-making and strategic planning. An informant in an educator role considered how their team can contribute to future decisions about HIT: “Whether it be just the organization, or operationally within a clinic, and they make a request for a change in a [HIT] system, or it’s a bigger change, like made at a higher level, even at the [executive] level, maybe they’re not making the best decision because we’re not providing them with the best information about our clinical [HIT] systems.”

**Promoted a Culture of Safety**

From a patient safety perspective, the informants shared an increased emphasis on a culture of safety and leveraged learning from their analyses to mitigate future concerns and make improvements. An informant explained:

> I think as a team member in clinical informatics, instead of focusing on the mistakes...thinking of the next time. What can be done better? How can it be resolved much better? It’s always the next time, it’s always learning, and it’s always a different situation. But it’s probably easier if you have the open mind to actually really understand...it’s just having that understanding that it’s not always the person at fault, it’s not always the system at fault, it could be a combination of everything. And again, what do we do next? How do we learn from this?

**Discussion**

**Principal Findings**

**Overview**

This study examined clinical informaticians’ perspectives on learning about HIT safety and the co-creation of a process to manage HIT-related safety reports. To our knowledge, this is a novel examination of the topic. The findings from this study provide valuable new insights into the barriers and facilitators to developing HIT safety within clinical informaticians’ practices, as well as the potential outcomes that a robust, evidence-based approach to knowledge mobilization can have.

**Barriers to the Uptake of HIT Safety**

From the clinical informaticians’ perspectives, some of the barriers that were initially challenging included the lack of knowledge about HIT safety and previous assumptions they carried at the outset of the project. For patient safety in general, a lack of knowledge about incident reporting and assumptions about the value or repercussions of event reporting are known barriers to initiating reports [58]. The embedded researcher was able to spend time at the beginning of the project to build relationships and assess the team’s gaps in knowledge. Recognizing the team’s initial limited understanding of HIT safety, learning activities were focused on fundamental topics in HIT safety and contextualizing learning within their existing work. Another identified barrier was competing priorities and organizational barriers, a challenge echoed in the literature about evidence-based practice [51,59]. While competing priorities may be a perennial challenge in health care, strategically aligning and incorporating learning activities into the current priorities of the clinical informatics team was crucial because mutual learning and appreciation of others’ perspectives and contributions may lead to better processes and outcomes by generating more relevant and applicable knowledge [60].

The findings surfaced challenges with the internal safety reporting systems, the processes, and the underuse of the safety system. The informants expressed concern over the value of reporting if there is not a proper follow-up, stressing the value of “closing the loop” to ensure that the person who reported the event is aware of the implications of their report from an informatics perspective. The costs and benefits of safety reporting are debated in the literature. Insufficient action following a safety report is thought to negatively affect clinicians’ commitment to the reporting process [61]. Macrae [62] argues that “we collect too much and do too little” [63], explaining that although the technical infrastructure for safety reporting has been established in many health care organizations, the requisite processes of investigation and improvement have been underemphasized. Other research suggests that low rates of safety reporting derive from clinicians being prone to applying quick fixes or workarounds to system failures rather than reporting issues to trigger more in-depth analysis and sustainable solutions [64,65]. In any case, it seems that safety reporting is yet to achieve its full potential [61], and the latency of safety issues related to HIT may pose further challenges, with near misses and errors being dismissed or going undetected [66]. However, the findings of this study suggest a way to establish practices to identify and mitigate latent errors.

**Supportive Learning Environment and Openness to New Ideas**

The enabling elements identified by the clinical informaticians focused primarily on participatory and experiential activities. Facilitating informal, locally owned processes for clinical informaticians’ learning around safety has been shown to enable the staff to raise concerns and actively contribute to improvement [58]. Although there is a growing collection of research studies that have applied the Sittig and Singh [24] sociotechnical model in analyzing safety concerns [27,67-69], no literature was identified where this framework was incorporated into experiential learning activities or embedded into clinical informatics work processes in real time. Safety huddles are thought to be transformational in shifting attitudes and practices related to safety, providing a “reliable framework for interdisciplinary communication and action” [26]; however, the evidence to support this is largely anecdotal [70]. Menon et al [27] used safety huddles to address EHR safety concerns in a hospital setting, and although the format differed from this project, the huddles promoted a culture of safety for clinical informaticians, providing a venue for open communication about safety concerns and facilitating learning and improvement, which was also found in this study.

The informants also noted the role the embedded researcher played on the team to “set the tone,” “mobilize the team,” and “instill curiosity,” which supported their learning in the project. A concerted effort was made in the initial stages of the project to develop strong, collaborative partnerships at all levels of the
organization [52,60]. At the end of the project, efforts were made to promote the sustainability of the cocreated sociotechnical analysis of HIT safety events by integrating new practices into existing team workflows, and the researcher intentionally stepped back to allow the clinical informatics team to carry out new practices with minimal support [71].

The findings indicated that the clinical informatics team exhibited the knowledge, skills, and attitudes of an effective team [72], which in turn support the notion of a high reliability team [73]. For example, the participants found the safety huddles a “good use of their time.” Furthermore, formal financial and organizational support for the embedded researcher throughout the duration of the project created a fertile environment for learning, with dedicated resources, endorsement and collaboration from leaders, and multiple opportunities for interactions between researchers and knowledge users [51,60].

**Effective Knowledge Mobilization**

The findings of this study include positive outcomes in terms of moving knowledge into action. The focused approach to supporting HIT safety seemed to support a group-level identity transformation, incorporating different professional perspectives, adding value, and acting as a lever for system-wide, evidence-informed sustainable change [74]. The informants described being more knowledgeable and engaged in HIT safety issues in their work. They developed their knowledge base in clinical informatics, with an increased recognition of some perennial problems related to HIT [60,75], and the contextual issues that surround the use of HIT in health care settings [76,77]. The informants also expressed greater ownership regarding safety. This is echoed in the literature in which EHR safety is ascribed as being a shared responsibility among key stakeholders including EHR developers, health care organizations and users, and government regulators [42]. Clinical informatics, with its emphasis on bridging technical and clinical perspectives, can play a central role in facilitating efforts to improve safety [78,79].

The cocreated sociotechnical analysis process for addressing HIT safety events produced immediate and ongoing insights to inform operational decision-making within the organization. The current findings provide additional evidence that a clinically focused informatics team is well positioned to take on this work of “closing the loop” with the end user using the system to report an event. Similarly, by leveraging voluntary safety reporting for quality assurance, Williams et al [54] identified 242 EHR-related safety events analyzed by nurse informaticians, 30 of which led to specific system changes to improve usability.

In this study, informants expressed an appreciation for the structure that the Sittig and Singh [24] analytic framework brought to conducting an analysis and that they learned to look for patterns in reviewing reported events. The process developed by the team was an adaptive approach based on experiential cycles of learning, from which they gradually developed new insights and expanded their collective expertise on HIT safety [80]. Demonstrating a thoughtful approach to safety, the findings indicate that informants’ perspectives moved beyond a reactive “find and fix” approach and instead they were embracing complexity to “enable things to go right more often” [81].

The findings of our study also indicate that enhanced communication helped team members develop a more empathetic approach to supporting clinicians using HIT. Specifically, safety huddles were thought to have improved communication within the team as well as informed their perspectives on all aspects of their work, including planning for future HIT-related needs of the organization [27,82]. Although safety event reporting is not without its limitations [83], reporting can effectively contribute to participatory learning, improve practice, and promote safer care [84].

**Limitations**

A possible limitation of this study is that the embedded researcher functioned as both the lead of the initiative and the interviewer for this project. It is possible that the informants’ responses were influenced by social desirability [48]. However, the participants’ responses also showed vulnerability. For example, several respondents indicated that they had been judgmental about end users’ errors in the past. This level of candor suggests that social response bias may have been minimal and possibly was overcome by prolonged engagement, given the long duration that the embedded researcher participated with the team. This study also assessed only the experiences of the clinical informaticians in retrospect. It did not account for the impact on the knowledge users in the same way that a longitudinal design may have. Tracking the knowledge user’s experiences over the course of the project may have offered a more precise account of the impact of the various approaches to supporting HIT safety and the progression of the partnerships within the research [52]. Future research should focus on assessing the mechanisms by which the impact is achieved to articulate an optimal, replicable approach to knowledge mobilization. In addition, this study was situated in a nonacute setting, and therefore, the applicability of our findings is limited as such. However, given the adaptable and codeveloped nature of the processes for learning, it is possible that other health care settings may benefit from using similar approaches [45,85].

**Conclusions**

Overall, the findings of this study indicate that the evidence-based, experiential learning model used in this instance was an impactful approach to supporting HIT safety in the context of clinical informatics. Furthermore, the intensive focus on HIT safety resulted in increased knowledge and some evidence of group-level identity transformation related to clinical informaticians’ management of HIT safety events. An embedded researcher model can be an effective mechanism to support clinical informaticians in learning and applying HIT safety practices in their work.

Abstract

Background: There are disparities in the prevalence of physical activity (PA) with women engaging in less PA than men, a gap which widens during midlife. Walking is a generally accepted form of PA among women and should be encouraged. Motivations, barriers, and attitudes to engaging in walking change with age, but the influencing factors are not well understood nor are the features of mobile apps that facilitate daily walking.

Objective: This study explores the relationship between age and women’s self-reported motivations, barriers, attitudes, and beliefs toward daily walking. It further assesses attitudes toward features of a mobile app designed to sync with a wearable step tracker to increase and maintain levels of daily walking among women.

Methods: A web-based anonymous survey was completed by 400 women, aged 21-75 years. The 31-item survey captured women’s perceived barriers and motivators toward daily walking and attitudes toward mobile apps to support and maintain daily walking. For analysis, responses to the survey were grouped into 2 categories of women: ages 21-49 years and ages 50-75 years. Bivariate analyses were conducted through SPSS (IBM Corp) for each of the survey questions using chi-square for dichotomous variables and 1-tailed t tests for scales and continuous variables to identify significant differences between the groups. One-tailed t tests were run for scaled variables to identify significant differences between the 10-year age increments.

Results: Significant barriers to daily walking were observed in the 21-49-year group for personal and work responsibilities, motivational and psychosocial factors, and physical and environmental factors. Motivators to walk daily in the 21-49-year group were significantly higher to reduce stress and anxiety, and motivators to walk daily in the 50-75-year group were significantly higher to help manage or lose weight and to reduce the risk of chronic illness. Women’s walking preferences, beliefs around their walking behaviors, and their perceived importance of the features of a future mobile app for walking designed specifically for women showed significant variation according to age. When asked about the importance of features for a mobile app, women aged 21-49 years indicated a significantly higher number of positive responses for the following features: digital community support, rewards or point system, and seeing a daily or weekly or monthly progress chart.

Conclusions: Our findings indicate that barriers, motivators, and beliefs around daily walking and the importance of preferred features of a mobile app vary according to women’s ages. Messaging and app features should be tailored to different age groups of women. These study results can be viewed as a foundation for future research and development of mobile health interventions to effectively increase daily walking among women of all ages.

Introduction

Physical activity (PA) has established benefits of preventing and treating many adverse health conditions in women, such as heart disease, type 2 diabetes [1], osteoporosis [2], depression [3], and anxiety [4]. Current guidelines recommend that adults engage in at least 150 minutes of weekly moderate-intensity aerobic PA, such as walking, and suggest that health benefits can be achieved in bouts as short as 10 minutes [5]. However, despite the overwhelmingly positive evidence for performing regular PA, older adults continue to be underactive, with older women in particular being the most inactive segment of the population [6]. This gender difference, which is observed across the life span, widens during midlife (ages 40-60 years) [7,8]. Regular exercise declines for many women just when menopause-related physiological changes increase their risk of weight gain and chronic diseases [7,9-11].

The percentage of all adults in the United States, aged 18 years and older, who met the Centers for Disease Control and Prevention’s Physical Activity Guidelines for Americans for aerobic PA in 2020 was 22.7% [12]. Percentages by gender of all age groups who met both aerobic activity and muscle strengthening guidelines in 2020 show males at 28.3% and females at 20.4%. The prevalence of PA among females declines with age from 28.7% for ages 18-34 years to 22.7% for ages 35-49 years [12]. Prevalence continues to further decline to 17.6% for ages 50-64 years ending with 10.8% for those aged 65 years and older. The decline in males moves from 41.3% (ages 18-34 years) to 15.3% (65 years and older) [12]. Men are more likely than women to meet both PA guidelines across all age groups [12].

Walking is one of the most effective interventions for reducing rates of chronic disease as well as one of the best, low-cost, easily implemented, widely accessible, moderate-intensity forms of PA [10,13-16]. Furthermore, the low risk of injury can allow individuals to remain active in older age [10]. The effectiveness of walking programs relies on initiatives aligning with women’s key barriers and motivators [7]. Previous research on walking levels in midlife women shows a lack of time as the primary barrier [7,10,14]. This combined with professional obligations and family care responsibilities relegates walking to a low daily priority for many women [7,17]. Health issues, poor motivation, and absence of social support are other barriers noted [7]. Women are more likely than men to a cite lack of social support and other social influences (eg, embarrassment due to being overweight) as obstacles to PA engagement [18,19]. Furthermore, the effectiveness of the role of social support for PA may be influenced by cultural norms, which should be considered when creating groups and matching walking partners [18]. Environmental factors, such as poor weather, lack of walking paths, and safety concerns [10], can inhibit daily walking as well [7,19].

Motivators of daily walking for midlife women include the associated health benefits, greater well-being, reduced stress, enjoyment, social support, and accountability to others [20]. Walking for transport was an important facilitator for some. Midlife women are motivated by immediate enjoyment versus long-term benefits [7]. The social aspect of making friends was a primary motivation for participating in health walks [7,21]. A study involving low-income urban mothers identified social connection as their most powerful facilitator alongside “me time” and the opportunity to gain a brief respite from their responsibilities [22].

Encouraging inactive populations, particularly women, to increase walking is an important public health consideration and remains a challenge [23]. The first step to increasing walking is to accurately measure it [24]. The use of technology, including wearable fitness trackers and smartphones, shows a great deal of promise for measuring and encouraging walking among women [25]. Results of a 2015 feasibility study by Arigo [17] showed that a large proportion of midlife women had purchased or intended to purchase a wearable tracking device for personal use after returning the program device used in the study (16/20, 80%). This continued interest in tracking highlights the potential for longer-term behavior change, particularly with novice users, with commercially available wearable technology [18].

Increasing health issues among youths due to a sedentary lifestyle as well as the growing demand for fitness apps for women are key factors propelling the market growth into a multibillion-dollar business [26]. Fitness apps are designed to motivate and persuade behavior change to help their users achieve health and wellness goals. While the industry of fitness apps for women is rapidly evolving, there is a lack of research on the impact of gender-centered design on users’ adoption, usage, perceptions, retention, and outcomes. This study explores the relationship between age and women’s self-reported motivations, barriers, attitudes, and beliefs toward daily walking. It further assesses attitudes toward features of a mobile app designed to sync with a wearable step tracker to increase and maintain levels of daily walking among women.

Methods

Research Design and Participant Recruitment

Our study design involved a web-based anonymous survey hosted on SurveyMonkey only in English. The inclusion criteria were to be female as sex assigned at birth, or intersex identifying as female, and to be 21–75 years of age living in the United States. Exclusion criteria were to be male as sex assigned at birth and to be younger than 21 years or older than 75 years of age. Proof of gender and age was not required. Recruitment for the survey was carried out using a URL link or QR code, which was distributed on the following digital platforms: email listservs, Facebook, LinkedIn, and Reddit. The survey remained open for approximately 4 months, from February to June 2022, until 400 participants consented to take it.

Ethical Considerations

The “Research on Daily Walking Habits Among Women Ages 21 to 75” was approved by The George Washington University Institutional Review Board on February 3, 2021 (NCR224026). All participants were recruited via digital outreach. Privacy and confidentiality protections included anonymous and deidentified data collection. All questions on the survey were broad enough.
to avoid any chance of identification of individuals. To ensure informed consent, immediately upon opening the survey, as the first question, participants were greeted and given information about the research to decide whether to complete it or not. The paragraph concluded with the question, “Would you like to continue?” Answering yes opened the survey. Participants could skip questions or opt out of the survey at any time. There was no time limit to complete it. Completion rate by the 400 respondents was 100%. Average completion time was 5 minutes. There was no compensation, and no physical risks were associated with the survey.

**Data Collection**

The survey was comprised of 31 questions (Multimedia Appendix 1). The first question was focused on consent to participate, and the next 5 questions were designed to capture sociodemographic information including sex assigned at birth, age, current relationship status, race, Hispanic, Latinx, or Spanish origin, and employment or student status. Questions 7 to 13 covered dog ownership, employment status, chronic disease diagnosis, advice from a doctor on walking, and the use of mobile apps and devices to track steps. Question 14 asked participants if their walking rates changed since the start of the COVID-19 pandemic. Question 15 asked approximately how many steps a participant walks each day. Questions 16 to 21 were designed to glean information on possible barriers and motivators for daily walking. Questions 22 to 30 were aimed at capturing data on the acceptability of features of a mobile app designed for women to increase daily walking. The last question, question 31, asked participants if they would be willing to use a walking app designed for women and to wear an activity-tracking device, such as a Fitbit, to increase daily walking.

**Data Analysis**

When the survey results were downloaded, a codebook was created and uploaded to SPSS software (version 28.0.0.0-142; IBM Corp). We analyzed our independent variable, ages of women, and two dependent variables: (1) barriers and motivators toward daily walking and (2) attitudes toward features of a mobile app to increase walking. Data analysis included descriptive statistics to describe respondents’ demographics (eg, age, relationship status, employment status, and diagnosis of chronic illness). All data were analyzed with stratification by age. The first type of stratification was based on dividing the population into 2 groups of ages: 21-49 years (21- to 49-year group) and 50-75 years (50- to 75-year group), respectively. The second type of stratification was based on dividing the population into groups with 10-year age increments. Bivariate analyses were conducted through SPSS for each survey question using chi-square for dichotomous variables and 1-tailed t tests for scales and continuous variables to identify significant differences between the 2 groups. One-tailed t tests were run for scaled variables to identify significant differences divided by decades.

**Results**

**Descriptive Statistics of Demographics**

Sociodemographic questions captured in the survey and displayed in Table 1 included information on sex assigned at birth, age, relationship status, race and ethnicity, employment or student status, chronic disease status, doctor’s advice regarding walking, and having a dog that you walk daily. Results showed that all 400 respondents self-identified as female for sex at birth. Most women were in their 20s (n=123, 29.6%), followed by 30s (n=101, 25.4%), 50s (n=78, 19.3%), then 40s (n=52, 13%), 60s (n=32, 8%), and 70s (n=14, 3.5%).

</table>
In the 21- to 49-year group, most women were single, while in the 50- to 75-year group, most were married. The majority of the 400 women were White (n=297, 74.3%), followed by Black (n=54, 13.5%), and small percentages were Asian, American Indian or Alaska Native, and others. Only 7.5% (n=30) of the women identified as Hispanic, Latinx, or Spanish origin. In both groups, the majority of women were full-time employed. The 50- to 75-year group had significantly more part-time employment and significantly less students. Women who self-reported chronic disease were 20% (55/276) in the 21- to 49-year group and 29% (36/124) in the 50- to 75-year group. More women owned a dog that they walked daily in the 50- to 75-year group. Almost no women were told by their doctor not to walk 2.3% (n=9), and 39.9% (n=159) of all women were advised by their doctor to increase their daily walking.

Women’s Current Walking Behaviors

Results of current walking behaviors show that approximately the same percentage of women in both groups use a step-tracking device (n=144, 52% in the 21- to 49-year group vs n=57, 45.9% in the 50- to 75-year group) and a mobile app to track steps (n=90, 32.7% and n=39, 31.7%). The number of approximate daily steps self-reported by women showed that the 21- to 49-year group had significantly higher percentages for less than 2000 steps (n=28, 10.1% vs n=4, 3.2%; P=.03). Other differences in step counts were not as significant between the 2 groups: 2000 to 3000 steps (n=42, 15.2% vs n=16, 13%), 3001 to 5000 steps (n=72, 26% vs n=29, 23.2%), and 5001 to 8000 steps (n=80, 28.9% vs n=28, 22.7%). The 50- to 75-year group had significantly higher percentages in the 8001 steps or more (n=83, 30% vs n=22, 17.4%; P=.001) category.

This survey was conducted from February to June 2022 during the COVID-19 pandemic. Women were asked one question on the survey about COVID-19 to give some context to possible changes in their daily walking habits during the time of the pandemic. Their responses showed that a significantly higher percentage of women in the 21- to 49-year group reportedly reduced their daily walking than the 50- to 75-year group (n=77, 27.9% vs n=15, 12.1%; P=.001), while a higher percentage of women in the 50- to 75-year group maintained their amount of daily walking (n=40, 32.2% vs n=55, 19.9%; P=.001) or increased it (n=67, 54% vs n=142, 51.4%) during the time period of the survey. Specific groups of women, delineated by age decade, who increased daily step counts during COVID-19 showed that women in their 70s (n=13) self-reported the highest change in walking, and those in their 30s (n=96) self-reported the lowest. Figure 1 illustrates these findings.

Figure 1. Survey results of step tracking with a wearable device and mobile app for walking.

Women’s Barriers to Walk Daily

Regarding barriers to daily walking displayed in Table 2, the 21- to 49-year group had significantly higher percentages than the 50- to 75-year group for the following reasons: personal and work responsibilities (including lack of time, lack of child or older adult care, and work or other scheduling barriers), motivational and psychosocial factors (including lack of motivation to exercise in general, lack of motivation to engage in self-care, lack of support from partner or family, lack of support from work environment, not being able to find a walking group or community to support walking, not enjoying walking or would rather do another form of exercise), and physical or environmental factors (including lack of safe spaces to walk, lack of proper clothing, fear of falling or getting injured, doctor advised not to walk, and difficult or uncomfortable to walk). The most cited barriers with significant differences between the 2 groups, with the 21- to 49-year group higher in all categories, were lack of time (n=172, 62.3% vs n=43, 34.6%; P<.001), lack of motivation to exercise (n=119, 43.1% vs n=38, 30.6%);
In Table 2, the category “Most cited barriers” illustrates the top 5 barriers to walking by women’s age groups.

**Table 2.** Survey results of women’s barriers to walking daily according to age.

**Most cited barriers**

- Lack of time: 215 (53.8) vs 172 (62.3) vs 43 (34.7)
- Lack of motivation to exercise: 157 (39.3) vs 119 (43.1) vs 38 (30.7)
- Work or scheduling barriers: 143 (35.8) vs 115 (41.7) vs 28 (22.6)
- Lack of safe spaces to walk: 64 (16) vs 57 (20.7) vs 7 (5.7)
- Lack of motivation to engage in self-care: 61 (15.3) vs 49 (17.8) vs 12 (9.7)

**Motivators for Women to Walk Daily**

Motivators to walking daily displayed in Table 3 included the following options: physical factors (feels good physically, gives me more energy, reduces my risk for chronic disease or improves my overall health, burns calories or helps with weight management, and builds strength) and mental or emotional factors (reduces depression, reduces anxiety, reduces stress levels, boosts self-esteem, and allows me to work through issues). Both groups had approximately the same percentage of responses in the categories of feels good physically, gives me more energy, and reduces depression. The 21- to 49-year group had significantly higher percentages than the 50- to 75-year group for the motivator category reduces anxiety (n=181, 65.6% vs n=62, 50%; P=.003). While the 50- to 75-year group had significantly higher percentages for walking to burn calories or help with weight management (n=100, 81% vs n=186, 67.4%; P=.004) and reduce risk of chronic disease or improve overall health (n=95, 76.6% vs n=168, 61%; P=.002). The top 5 motivators to walking by women’s age groups were feels good physically, reduces stress levels, helps with weight management, gives me more energy, and reduces risk for chronic illness or improves overall health as illustrated in the category “Most cited motivators” of Table 3.

Daily Current Walking Routines and Preferences

Results on current and preferred daily walking routines showed that the 21- to 49-year group had higher percentages than the 50- to 75-year group in the categories of taking child or children on walks (n=39, 14.1% vs n=3, 2.4%; \( P<.001 \)), walking for work or use of public transit (n=92, 33.3% vs n=14, 11.3%; \( P<.001 \)), and walking on campus (n=84, 30.4% vs n=7, 5.7%; \( P<.001 \)). The 50- to 75-year group scored highest in the categories of walking the dog (n=48, 39% vs n=69, 25%; \( P=.005 \)) and none of the above, referring to all of the options as motivators to walk (n=59, 48% vs n=35, 28.2%; \( P<.001 \)). Findings in Table 4 show that more women in the 21- to 49-year group prefer to walk alone than in the 50- to 75-year group (n=193, 70% vs n=62, 50%; \( P<.001 \)), while more women in the 50- to 75-year group prefer to walk with a friend (n=66, 53.2% vs n=105, 38%; \( P<.001 \)), or walk with their partner (n=44, 35.1% vs n=76, 27.4%), or with their dog (n=45, 36.2% vs n=72, 26.1%; \( P=.04 \)).

Women’s Beliefs Around Increasing Walking Behavior

The results of survey questions about beliefs around walking behaviors showed one significant value in the 50- to 75-year group associated with the survey statement: “I would walk more often if people around me walked more often” (scale: 1=strongly disagree to 5=strongly agree). Overall, respondents scored 3.67, while respondents aged 21-49 years scored 3.78, and respondents aged 50-75 years scored 3.41 (\( P<.001 \)). Other survey statements using the same response scale did not show significance: “I would walk more if I had an app with reminders,” all respondents scored 2.83, ages 21-49 years scored 2.84, and ages 50-75 years scored 2.80; and “I believe I can walk up to 8000 steps on most days with proper support,” all respondents scored 4.04, ages 21-49 years scored 4.00, and ages 50-75 years scored 4.12 (Figure 2).
Women’s Attitudes Toward the Importance of Mobile App Features

Results for survey questions concerning the importance of features for a mobile app showed a significantly higher number of positive responses in the 21- to 49-year group for the following features (scale: 1=low, 2=medium, and 3=high): digital community support ($P=.03$), rewards or point system ($P<.001$), and seeing a daily or weekly or monthly chart of progress ($P<.001$). No significant differences were found for tracking of steps, reminders to walk daily, reminders to wear a step-tracking device, daily in-app motivational messaging, and daily in-app educational messaging.

In Table 5, a deeper analysis of the importance of features on a mobile app was examined by age categories delineated by age decades. The results showed that the youngest age group of women, aged 20-29 years, placed the highest importance on the following features: reminders to walk daily, reminders to wear a step-tracking device, digital community for support ($P<.05$), daily in-app motivational messaging, daily in-app educational messaging, in-app reward or point system ($P<.001$), and daily or weekly or monthly progress reports ($P<.001$). The 50- to 75-year group only placed higher importance on step tracking.

Figures 3-5 map out mobile app features grouped into different categories: the importance of step tracking and reminders, importance of community support and daily messaging, importance of in-app rewards, progress charts (daily, monthly, and weekly), and willingness to use an app designed for women and to wear a step-tracking device. Our results show that approximately the same percentage of women in both groups use a step-tracking device (n=64, 52% in the younger group and n=127, 46% in the older group), and the same applies to using a mobile app to track daily steps (n=91, 33% and n=40, 32%). Responses to the survey question, “I would be willing to use a walking app designed for women and to wear an activity-tracking device to increase daily walking,” showed overwhelmingly positive responses among all women: yes (n=240, 60%), no (n=55, 13.8%), and not sure (n=105, 26.3%).

Discussion

Principal Findings
This study explores the relationship between age and women’s self-reported motivations, barriers, attitudes, and beliefs toward daily walking. It further assesses attitudes toward features of a mobile app designed to sync with a wearable step tracker to increase and maintain levels of daily walking among women. Findings indicate that barriers, motivators, and beliefs around daily walking and the importance of preferred features of a mobile app vary according to women’s ages. Therefore, messaging and app features should be tailored to different age groups of women.

Explanations for Women’s Walking Behaviors
Not surprisingly, women in the 21- to 49-year group, comprised primarily of students, women of childbearing age, young mothers, and women with careers, tended to walk more with children, walk to work or use public transit, or walk on campus.
The majority prefer to walk alone, which may be attributed to the need for alone time in their hectic lives, similar to the results of Jones et al’s [21] study in which women wanted “me time” and a respite from their responsibilities. Women in the 50- to 75-year group also preferred to walk alone, but they were more accepting of walking with a friend. One reason might be that more women in the older group have leisure time to walk with friends. In this study, older women were more inclined to walk more if people around them walked more often, which is an important data point to be considered in any walking intervention for older women. These age-focused findings demonstrate the need for more research on gender-tailored fitness apps that satisfy the specific needs of women’s lifestyles at different stages. Catering to women engaged in childcare, for instance, requires communication reminding them to make time for themselves without feeling guilty, while older women might respond well to messaging about walking with a friend to help keep them motivated. There is a dearth of research that systematically examines the acceptability, user experiences, and outcomes of tailored messaging in walking apps for women and the potential impacts they deliver.

**Barriers to Women Walking**

The main barriers to walking in the 21- to 49-year group included lack of time, lack of motivation, and work scheduling. This is understandable as many women might be advancing their careers, while also juggling families and other pressures. For the 50- to 75-year group, these same barriers existed but were not as significant and became less significant as age increased. Previous studies have shown lack of time as a primary barrier to PA, as well as professional obligations, family care responsibilities, health issues, poor motivation, and absent social support, which are consistent with our results [7,19]. Addressing these barriers has generated meaningful insights in previous research but has not yet led to a large increase in PA that is sustained over time [25].

This study did not find environmental and safety concerns as common barriers, but these may be related to our sample demographic of mostly White women in either their 20s or 50s. Other studies have shown that in the presence of individual characteristics, such as low self-efficacy and functional limitations, the effects of a prohibitive neighborhood environment on walking behavior in older women were further magnified [6]. More work is desperately needed to address the barriers of environmental concerns, particularly among older women in underserved or unsafe neighborhoods.

**Motivators for Women to Walk**

Both age groups of women in this study were motivated to walk because it makes them feel good physically, gives them more energy, and reduces depression, suggesting the powerful physical and mental health benefits of walking. The younger group was more focused on reducing anxiety, while the older group noted walking for burning calories, weight management, reducing the risk of chronic disease, and improving overall health. However, given our concurrent findings of relatively high rates of self-reported chronic disease in the 21- to 49-year group, messaging on chronic disease prevention and management in a walking app should be equally targeted to both groups but in different contexts with tailored nuances.

Menopause increases the risk of weight gain and chronic diseases, happening simultaneously as women’s PA levels tend to decline [27]. Research by Sydora et al [10] found that women experiencing menopause were not averse to regular exercise, especially those seeking to avoid the perceived increased health risks of hormonal therapy, and that walking is the preferred type of exercise among menopausal women. In this study, walking to reduce stress and anxiety was less important for the older group, which supports the results of the Hedgeman et al [28] study on perceived stress across midlife, which found self-reported stress decreased for most women as they transitioned across midlife.

The social aspect of walking, whether to make friends or for social support, has been well received in previous studies, particularly in midlife women [7]. Interestingly, our results showed that social- and family-based walking was not as popular as walking with a friend or walking alone in both age groups of women. A study by Cho et al [29] offers insights into how walking with a partner might motivate walking due to social support; however, it often results in reduced speed that may unintentionally reduce health benefits, a trade-off that needs more research. A feature to build a digital community of support was more favored in the younger group. This is admittedly contradictory, as our data for the 21- to 49-year group showed a preference to walk alone. Furthermore, while the younger group may not want to walk in person with others or they cannot fit it into their schedules, they placed importance on a digital community of support through a mobile app. A study by Hollander et al [20] found that a mobile app for walking (not limited to women) created a digital connection among walking group members, and participants felt that walking improved their mental health, helped to relieve stress, and made them feel more connected with friends or family members. More research should be aimed at determining the effects of sociodemographic variables of women (eg, income, location, age, race, and ethnicity) and their preferences for a digital or in-person community to support walking.

**Acceptance of Technology**

The use of smartphones, mobile apps for fitness, and wearable devices to track steps, such as Fitbit, are accepted by women of all ages, and adoption of these devices and exercise apps increases every year [30]. The Pew Research Center concluded that about 1 in 5 Americans use a smartwatch or fitness tracker, with more women than men wearing one (25% vs 18%), and among age groups, more adults aged 18-49 years (25%) wearing one than people aged 50 years and older (17%) [30,31]. In Tong et al’s [32] study, the use of mobile apps and fitness trackers during the COVID-19 pandemic was associated with higher levels of PA in a sample of educated and likely health-conscious individuals among males and females [32]. Our survey responses showed that while an equal percentage of both groups of women wore fitness trackers in general, during COVID-19, higher percentages of women in the younger group reduced their daily walking, as opposed to the older group who maintained or increased steps. More research is needed to ensure walking is
maintained among all women during adverse events, such as a pandemic.

Successful interventions to increase women’s daily walking should ideally combine a wearable tracking device with support from mobile app features, such as goal setting, self-monitoring, positive feedback, and social support [9,24,25]. In 2022, findings from a systematic literature review on assessing the acceptability and effectiveness of mobile-based PA interventions for midlife women during menopause concluded that mobile apps and wearable activity trackers showed a small to moderate increase in moderate to vigorous PA among midlife women [27]. The most acceptable features of mobile apps were manual goal setting and step tracking plus the attractiveness and comfort of wearable activity trackers [27].

In this study, younger women placed importance on app features for community support, rewards or a point system, and progress charts, and they are more inclined to use technology for lifestyle interventions, from gaining and redeeming points for coffee and grocery purchases to using apps to track sleep and menstrual cycles. Women in the 21- to 49-year group placed high importance on reminders to walk daily, reminders to wear a step-tracking device, motivational messaging, and educational messaging. The 50- to 75-year group placed the highest importance on step tracking, though they did not place significant importance on progress charts. This may be a technology-based generational difference as more younger women engage with progress charts for academics, digital banking, and other platforms and therefore are more inclined to accept them and to possess the digital literacy to use them with confidence. Daily motivational and educational messaging was more accepted in the younger group perhaps because mini modules of communication, such as text messages and direct messaging on social media platforms, are widely used.

Insufficient exercise among women of all ages is a global public health issue [33]. Walking should be encouraged as much as possible using evidence-based tools to obtain sustainable results. Integrating fitness into health care on a large scale continues to be a challenge, but this is changing as the US health care system is moving more toward a value-based model of care with a focus on prevention and population health versus one that does not normally inhibit walking, such as diabetes.

Understanding how and why women are motivated to walk will lead to increasingly effective interventions to manage physical and mental health issues at all ages. As the US population aged 65 years and older is projected to nearly double over the next 3 decades, from 48 million to 88 million by 2050 [37], promoting PA among older adults is an important public health, clinical, and economic issue deserving greater attention [27,31,38]. Ideally, future mHealth walking interventions that are uniquely designed for women will combine a wearable tracking device and mobile app with evidence-based behavioral approaches to promote daily walking [39]. This study is among the few focused on women’s walking habits from ages 21 to 75 years old, providing insights into walking behaviors and the motivations and barriers behind them. Our results provide a foundation on which to guide future research and development in this space.

**Strength and Limitations**

The major strength of this study was the number of respondents (N=400), all of whom completed the survey 100%. This study had several limitations. First, the survey included self-selected participants who might already be walking enough or would be willing to increase their daily steps. Second, survey question 15 asked approximately how many steps a participant walks each day. Limitations to answering this question include the inherent difficulty to recall and estimate accurately the number of steps one walks daily without using a tracker, which may lead to a lack of reliable data. Inflating daily step counts may also reflect an element of social desirability. Third, the uneven number of participants in each group causes concern as well as the lack of diversity in the sample. Fourth, we did not specifically define chronic disease in the survey. Reporting might be different among women with a chronic disease that significantly reduces mobility, such as rheumatoid arthritis, versus one that does not normally inhibit walking, such as diabetes.

**Conclusions**

Insufficient PA is a leading risk factor for noncommunicable diseases and can also negatively affect mental health and quality of life for women of all ages. Findings indicate that barriers, motivators, and beliefs around daily walking and the importance of preferred features of a mobile app vary according to women’s ages. Messaging and app features should be tailored to different age groups of women. These study results can be viewed as a foundation for future research and development of mHealth interventions to effectively increase daily walking among women of all ages.

Abstract

Background: Z-hypnotics or z-drugs are commonly prescribed for insomnia and sleep difficulties in older adults. These drugs are associated with adverse events and dependence and are not recommended for long-term use. Despite evidence of older adults being more sensitive to a wide array of adverse events and clinical guidelines advocating limiting use, inappropriate use in this population is still prevalent. Previous intervention studies have focused mainly on prescriber information. Simple, individually focused intervention designs are less studied. Brief intervention (BI) is a simple, easily transferable method mainly used to treat patients at risk of alcohol overuse.

Objective: Our objective was to design and test the feasibility and acceptability of a BI intervention adapted to address individual, inappropriate use of z-hypnotics among older adults. This preparatory study aimed to optimize the intervention in advance of a quantitative randomized controlled trial investigating the treatment effect in a larger population.

Methods: This feasibility case series was conducted at Akershus University Hospital, Norway, in autumn 2021. We included 5 adults aged ≥65 years with long-term (≥4 weeks) use of z-hypnotics and 2 intervening physicians. Additionally, 2 study investigators contributed with process evaluation notes. The BI consists of information on the risk of inappropriate use and individualized advice on how to reduce use. The focus of the intervention is behavioral and aims, in cooperation with the patient and based on shared decision-making, to change patient behavior regarding sleep medication rather than physician-based detoxification and termination of z-hypnotic prescriptions. Qualitative and descriptive quantitative data were collected from intervening physicians, study investigators, and participants at baseline, immediately after the intervention, and at the 6-week follow-up.

Results: Data were obtained from 2 physicians, 2 study investigators, and 5 participants (4 women) with a median age of 84 years. The average time spent on the BI consultation was 15 minutes. All 5 participants completed the intervention without problems. The participants and 2 intervening physicians reported the intervention as acceptable and were satisfied with the delivery of the intervention. After the intervention, 2 participants stopped their use of z-hypnotics completely and participated in the follow-up interview. Study investigators identified logistical challenges regarding location and time requirements. Identified aspects that may improve the intervention and reduce dropouts included revising the intervention content, focusing on rebound insomnia, adding an information leaflet, and supporting the patient in the period between the intervention and follow-up.
notion that the intervention should best be located and conducted by the patient’s own general practitioner was supported by the participants.

Conclusions: We identified important aspects to improve the designed intervention and found that the BI is feasible and acceptable for incorporation into a larger randomized trial investigating the treatment effect of BI for reducing z-hypnotic use by older adults.

Introduction

Sleep difficulties and symptoms of insomnia are common, experienced by up to 50% of older adults [1]. Prevalence is higher in the older population than the younger population, and not staying asleep is the most common complaint, followed by initiating sleep and nonrestorative sleep [1-4]. Sleep difficulties in older adults are often associated with comorbid conditions including obstructive sleep apnea, cardiovascular disease, restless legs, nocturia, depression, and neurological conditions, as well as side effects from medication use [3,5].

Z-hypnotics or z-drugs (zolpidem, zopiclone, and zaleplon) are commonly used in the treatment of insomnia and sleep difficulties in older adults. These drugs have been suggested to be milder and safer options than benzodiazepines with a shorter half-life and selective gamma-aminobutyric acid (GABA)–binding qualities [6]. They are now the dominant prescribed sleeping medication in many countries [7,8]. Even so, these drugs are associated with adverse events and dependence [9,10]. A meta-analysis concluded that 13 patients need to be treated for 1 patient to experience improved sleep, while the number needed to harm (any adverse event) is 6 patients [11]. Z-hypnotics are not recommended for more than 2 weeks to 4 weeks of continuous use [12,13], as such use has been associated with reduced sleep quality, reduced cognitive function, and reduced psychomotor skills, including increased risk of falls [11,14]. In our work investigating hospitalized older Norwegian adults, we found a substantial proportion using z-hypnotics on a regular basis with a further considerable share having addictive behavior related to their use [15]. Reducing the use of these drugs by older adults is associated with improved muscle strength, better sleep quality, improved quality of life, and reduced daytime fatigue [16,17]. Despite the risks associated with z-hypnotics, reducing their use seems difficult for patients, with initial rebound insomnia as a common withdrawal symptom [9].

Evidence supports brief interventions (BIs) for reducing z-hypnotic and benzodiazepine use [18]. A BI is a specific structured intervention method that aims to facilitate and encourage a behavioral change in the patient. We developed a BI based on the framework suggested by Babor and Higgins-Biddle [19]. This framework has previously been used as an early intervention for patients at risk of substance abuse and is effective in treating patients at risk of alcohol overuse. Our research team has demonstrated that the BI method is effective for reducing pain medication use in patients with medication-overuse headache [20,21]. Based on this, we suggest that an adapted BI may also be beneficial for reducing the use of z-hypnotics. The BI scheme is a short one-time intervention based on individual behavioral adaptation and shared decision-making. It offers possibilities for the intervening physician to provide individualized support for the participant. The focus is to reduce the use of potentially addictive medications, in this case z-hypnotics, and not as an intervention to specifically treat insomnia. Cognitive behavioral therapy for insomnia is the recommended first-line treatment for insomnia [22] and includes a range of different components including sleep hygiene. With the risk of experiencing rebound insomnia as a side effect of reducing the use of z-hypnotics, the individualized BI scheme is open to provide advice on sleep hygiene, although this is not the main focus of the BI itself. Our aim was to investigate the logistics, feasibility, and acceptability of using the BI with older adults who have inappropriate use of z-hypnotics, in order to optimize the intervention itself in preparation for a later full-scale randomized controlled trial (RCT).

Methods

This feasibility study investigated the logistics, feasibility, and acceptability of our BI design for reducing the use of z-hypnotics by older adults. The study was conducted at Akershus University Hospital, Norway, during September 2021 to November 2021.

Main Outcomes

The main outcomes for this study were the feasibility and acceptability of the intervention. Acceptability was tested based on indicated parameters [23-26] with an emphasis on the following: logistics including the costs and practicalities, burden and the perceived effort for participation, affective attitude and self-efficacy toward the intervention, and intervention coherence and perceived effectiveness. This was investigated using the following research questions:

- How do the logistics work out from the participating patient point of view?
- How do the logistics and administration work out from an organizing point of view?
- Are the instruments for data collection acceptable?
• Is the BI framework acceptable to perform from a physician point of view?
• Is the BI understandable and acceptable for the patients?
• How do the patients experience the attempt to reduce use of z-hypnotics?

The collected data consisted of qualitative measures and descriptive data collected at baseline and a 6-week follow-up.

Participants
Adults aged 65 years and older with long-term (≥4 weeks) use of z-hypnotics were invited to participate. Prescription of z-hypnotics in Norway is exclusively approved for the purpose of sleep difficulties, with or without fulfilling the diagnostic criteria for insomnia [27,28]. Participants were recruited from eligible z-hypnotic users in an in-hospital observational study of 246 older adults originally conducted in 2017 and 2018 [15] as well as directly through the geriatric department at the hospital. The participation flowchart is presented in Figure 1.

We included 5 participants aged ≥65 years with previously reported inappropriate use of z-hypnotics. Inappropriate use was defined as using z-hypnotics for ≥5 days per week for ≥4 weeks based on clinical guidelines [12,13]. A score ≥5 on the 15-point Severity of Dependence Scale (SDS) indicated a risk of dependence [29]. Participants were not excluded if there was a discrepancy between previously reported inappropriate use and their current self-reported use during the BI intervention. As part of the individualized intervention, self-reported use as well as the SDS score were incorporated in the discussion as basis for the individual plan (see the description of the BI in Figure 2). Exclusion criteria consisted of having a Mini-Mental State Examination (MMSE) score ≤21, a serious visual or hearing impairment, insufficient Norwegian language skills, and the following pre-existing diagnoses: moderate to severe depression, stroke, dementia, or psychiatric disorders.

Study Logistics

The intervention consisted of a baseline consultation and follow-up 6 weeks later. The baseline data collection was conducted in a hospital setting either in a consultation room or at the bedside by the study investigators (MTB and TBS). Subsequently, the BI consultation was conducted separately by 1 of 2 participating physicians (CL and SH). After the intervention session, both physicians and participating patients completed a short, written questionnaire with open-text responses regarding their experiences with the BI. The follow-up 6 weeks later involved a home visit by the study investigators (MTB and TBS) and consisted of questionnaires and a qualitative semistructured interview. This study was conducted during the COVID-19 pandemic, and care was taken with regards to safety measures and infection control.

Brief Intervention

The developed BI scheme was based on the BI framework as described by Babor and Higgins-Biddle [19]. Based on studies previously conducted by our research group, we adapted the BI scheme for older adults using z-hypnotics [30,31]. Application of the BI was conducted in 2 steps. The first step consisted of providing training, information, and communication advice for the intervening physicians. The second step consisted of the physicians performing the BI scheme with the participants included in the study.

The BI conversation with the participant consisted of the following (full procedure outlined in Figure 2): identifying the risk of the participant’s dependency on z-hypnotics using the SDS questionnaire (Table 1), informing participants of their risk of inappropriate use and dependence, providing structured information using fact sheets about difficulties associated with...
reducing medication and possible withdrawal symptoms such as rebound insomnia [32,33], and adjusting individualized information to the participant’s own experience and inviting the participants to make a decision toward reducing or stopping use and to make a plan on how to proceed. The plan could include strategies on how to handle withdrawal symptoms including rebound insomnia and strategies for contact and support from a physician if needed.

aEach is scored on a 4-point scale (0-3), and the total maximum score is 15 points. In older adults using z-hypnotics, the cutoff score was ≥5 [26].

Data Collection and Instruments

The main focus was to test the experience with, acceptability of, and logistics of the entire BI including the incorporation of quantitative assessment instruments that would be needed in a full-scale RCT. In this study, however, the demographic information and instruments were only used as descriptive information. The data collected included demographic information; the MMSE [34]; health-related quality of life measured with the EuroQol Group’s EQ-5D-3L [35]; the 6-item De Jong Gierveld Loneliness Scale [36]; the Hospital Anxiety and Depression Scale [37]; visual analogue scale (VAS) [38] scores for intensity of pain, anxiety, and depression; questions on experiences with pain; questions on experiences with sleep difficulties; the Bergen Insomnia Scale (BIS) [39]; the PROMIS-57 Profile v2.1 for sleep quality [40]; the clock test [41]; Cognistat [42]; the SDS [29]; the Cumulative Illness Rating Score-Geriatrics [43]; the Barthel Index for Activity of Daily Living [44]; the single leg balance test [45]; a record of medications and dosage; the degree of expectations and beliefs in the intervention and outcome measured using a VAS at baseline; and a written plan with individual goals for reducing z-hypnotics. A questionnaire on the experience delivering the BI was collected from physicians after each session. Process evaluation notes were obtained from study investigators.

At the 6-week follow-up, we also collected the experiences with the intervention and outcome using a VAS and a medication diary (z-hypnotics) for the past 6 weeks. We also conducted a semistructured qualitative interview (interview guide in Multimedia Appendix 1) evaluating the participants’ experiences with the BI conversation and their experiences during the 6-week follow-up period. The qualitative interview was tape-recorded and subsequently transcribed verbatim and analyzed.

Analysis

The qualitative data were analyzed by investigators MTB and TBS using the text condensation method [46], and findings are reported as quotations. ELAN computer software (version 6.3; Max Planck Institute for Psycholinguistics) was used to transcribe the interviews. SPSS for Windows (version 26.0; IBM Corp) was used to record quantitative data. Quantitative data are reported descriptively.

Ethical Considerations

This study was approved by the Regional Committee for Medical and Health Research Ethics (REK) (2016/2289) and the Akershus University Hospital data protection officer (PVO; 17-054). All participation was by written informed consent. Collected data were analyzed and stored de-identified as required by the REK and PVO. Data were stored on a protected server approved by the Akershus University Hospital PVO. Participants received no financial nor other compensation for their participation.

Patient and Public Involvement

The Health Services Research Unit User Advisory Board at Akershus University Hospital reviewed and provided advice about the study. The board includes both patient representatives and representatives of the health services as well as other public representatives.

Results

Participants

We recruited 5 older adults (4 women) with a median age of 84 years and ≥4 weeks of z-hypnotic use. We recruited 3 of the 5 participants from eligible participants in our previous hospital-based observational study [15,29,47-50], and 2 participants were recruited directly through the geriatric department. The study population flowchart is presented in Figure 1.

Of the 5 participants, 4 reported using z-hypnotics ≥6 days per week, and 1 participant reported using z-hypnotics 1 day per week at baseline. The median number of days per week using z-hypnotics was 7 days. The median SDS score was 5. The median BIS score was 27 (max score 42), and 3 participants reported that they believed that they would have greater sleep disturbance. The main reasons for sleep disturbance included extensive daytime napping, nocturia, pain, and lying in bed thinking. Demographic and clinical characteristics of the...
participants are presented in Table 2. At baseline, 3 participants reported that their current experience with not regularly taking their z-hypnotics resulted in greater sleep disturbance, and 3 patients reported that they believed they would have greater sleep disturbance if they did not take their sleeping medication (Table 2).

**Intervention Logistics, Physicians’ Experience, and Feasibility**

The median duration of the BI consultation was 15 minutes. The 2 intervening physicians reported that the BI framework for a potentially sensitive subject made the doctor-patient consultation easier to conduct (Textbox 1, quotes 1 and 2). They also reported that performing the BI in a consultation room was preferred over a bedside setting. They further reported that all 5 participants were open and positive toward the BI conversation (Textbox 1, quotes 2 and 3), as demonstrated by the participants listening actively and asking questions. The tools for patient communication that were received during training for the BI were beneficial during the consultation. The most beneficial tools for communication included asking open questions, letting the participants talk about their own experiences, having the participant repeat information, and writing down information together with the participant. The study investigators identified that the number of instruments used and the travel to participants were time consuming and advised making adjustments toward limiting time consumption.
Individual quotations from physicians immediately after the brief intervention (BI) consultation and individual quotations from the participating patients at the 6-week follow-up.

**Quotations from the intervening physicians immediately after the BI consultation:**

1. “Overall positive atmosphere. Patient understood the content and stated that effect on cognitive function made an impression. Patient stated little belief in health advantages of changing medication use and stated that, at her age, it did not matter.”

2. “The BI was overall received with a positive attitude. Patient stated that she found quitting difficult as she was living alone and was afraid of not falling asleep.”

3. “Patient was open-minded, interested, and motivated to try to change medication use. Was aware of possibilities of medication misuse in general.”

**Quotations from the participants at the 6-week follow-up:**

4. “I stopped the sleeping pills that same night and have not touched them since. [...] I thought, that pill I will manage without, and that has gone very well. And after that, I have realized that I do not need to take them. [...] It does not take me any longer to fall asleep, and when I sleep, I sleep well. [...] It has been a relief not having to remember to take that pill.”

5. “Trying to stop the sleeping medication has been very hard. [...] I have not slept more than half of what I should have. Normally, I am up for the toilet 1 to 2 times a night, but throughout this period, I have been up 3 to 5 times each night, and that leads to poor sleeping. [...] So, therefore, I had decided to tell you that I cannot have it like this in the future. I am so old, maybe I will live 2 more years. It does not matter. I rather have good nights than to become a hundred years.”

6. “It [the BI] was a mild form of advice. I believe in that type of approach. Doctors have tried to scare me about things before, for example, when they wanted me to quit smoking.”

7. “I experience that what they said at the hospital [the BI] and what my general practitioner has said earlier; that information corresponds. That is good for me to hear.”

**Participants’ Experiences and Feasibility at Baseline**

All 5 participants attending the BI consultation were positive overall toward participating and interested in the BI conversation. Expectations and beliefs measured by the VAS immediately after the intervention found median expectations of reducing medication use of 35 (min;max 3;100), median beliefs about improved health with reducing z-hypnotic use of 33 (min;max 2;100), median beliefs about the importance of reducing the medication of 27 (min;max 2;100), and beliefs in one’s own ability to reduce z-hypnotic use of 42 (min;max 1;100). Expectations and beliefs are presented in Table 3.

The participants’ intentions and goals on how to proceed after the BI were recorded, and 2 participants decided to quit z-hypnotics completely and immediately. Of the remaining 3 participants, 1 wanted to reduce dosage but continue regular use, 1 wanted to discuss a change to the type of z-hypnotic used with her general practitioner (GP), and 1 aimed to continue use as before and reported that this was about once a month.

The greatest challenge for reducing or stopping z-hypnotic use was reported by 3 participants as a worry that they would not sleep. One stated that she was not sure if changing medication mattered, as she was old and was soon going to die. One participant reported a need for support from the physician to stay motivated to stop z-hypnotic use, and 4 participants did not set up a direct plan for what they would do if they encountered difficulties.

Logistics and Participants’ Experiences With Reducing Z-Hypnotics

At the 6-week follow-up, 2 participants completed the questionnaire and qualitative interview. Both managed to completely stop their use of z-hypnotics. Although 1 participant reported that stopping was easy and did not notice any difference (Textbox 1, quote 4), the other participant reported that trying to reduce medication had been very hard and aimed to start the medication again in the hope of getting more sleep (Textbox 1, quote 5). Of the 3 participants who decided to not participate in the follow-up interview, 1 stated a preference to engage in conversation about these types of medications with her GP, 1 reported having too much going on at home with disease in the family, and 1 participant was lost to follow-up. Experiences at the 6-week follow-up are presented in Table 3.

Participant Feedback During Interviews at the 6-Week Follow-Up

Regarding the practicalities of participating, the 2 participants stated that it had been very easy, with no burden regarding cost or time requirements. They added that there would have been difficulties with participating at the follow-up if it had not been arranged as a home visit, as travelling to the hospital was difficult. Both stated that the BI conversation itself had been a good experience and that the information conveyed had been understandable (Textbox 1, quotes 6 and 7).

Discussion

Principal Findings

In this study investigating the feasibility of a BI for older adults with inappropriate use of z-hypnotics, we identified important aspects to improve before we proceed with the intervention. The focus for this study was to test the method, logistics, and intervention coherence, identifying strengths and weaknesses to improve the protocol for a larger study investigating the treatment effect. We tested the logistics and found that it is advantageous for the intervention to be delivered in primary care as opposed to secondary care; we need to reduce the number of data collection instruments; the designed BI communication framework was acceptable overall for both physicians and participants; and the participants found it challenging to participate further and reduce their medication, which in turn calls for further support during the intervention period.

Previous research has concluded that long-term use of z-hypnotics by older adults is to be avoided [12,13] and that the...
treatment effect of z-hypnotics is questionable [8]. It is suggested that attention should be directed at educational interventions [8], and such interventions have been found beneficial [51-53]. The BI method has been proven effective at handling substance overuse and dependence [19,20]. Adjusting the BI to benefit older adults with inappropriate use of z-hypnotics is probably appropriate and valuable for both individual patients and health care professionals and systems.

**Evaluation of Study Logistics**

Female gender and being ≥75 years of age are associated with a greater risk of inappropriate use [15], hence we believe we tested our intervention in a relevant population. Recruiting and intervention were linked to a previous observational study [15] and conducted in a hospital setting, which we decided was the most cost-effective and practical solution to test both the study logistics and intervention under the current circumstances. The hospital setting is a good opportunity for revising patients’ medications according to START/STOP criteria [54]. Conducting the intervention in a specialist environment at the secondary health care level was theorized to carry some impact for adherence. We did, however, experience that this type of intervention may be better suited to the primary care setting where it can occur as a conversation between patients and their GPs. Prescriptions for z-hypnotics, although often initiated during a hospital stay, are commonly continued by the GP. Training GPs to perform the BI may increase awareness of prescription habits regarding z-hypnotics. One study participant reported her preference for discussing issues regarding her use of z-hypnotics directly with her GP as the reason for withdrawing from the follow-up interview. Although the participants reported no burden and low perceived effort with participating in the study, they noted not having to travel to the hospital was important for participation. GPs’ proximity to their patients’ locale and their everyday involvement in their patients’ health issues may provide a more effective and suitable setting for this intervention.

The average duration of the BI was 15 minutes, which is longer than anticipated. During the design, we aimed for a 10-minute intervention, as we have previously experienced this duration to be acceptable [20,30]. We believe that limiting time spent on the intervention could increase feasibility in a busy daily practice for both patients and GPs, and it may be advantageous to revise the BI scheme accordingly. However, the increase in expected duration could be manageable for GPs during a conversation with older patients.

Both at baseline and follow-up, the participants completed a series of questionnaires, patient-reported outcomes forms, and tests. As these were in addition to the BI itself, participating in the study was both time-consuming and demanding. In a future study investigating the treatment effect, limiting data collection would be advantageous for both reducing load and possibly increasing adherence at follow-up.

**Evaluation of Patient Intervention Coherence**

Core to this study was investigating the participants’ own understanding of the intervention and their thoughts and beliefs regarding it. To get an understanding of how the intervention would affect the participants, we also investigated their thoughts and beliefs regarding sleep disturbance and z-hypnotics.

In our study, reported reasons for not sleeping included extensive daytime napping (poor sleep hygiene), nocturia, and pain. Once awake, lying in bed thinking was reported as the most common reason for not sleeping. When adjusting for comorbidities, pain, depression, and medication use, which are all factors associated with sleep disturbance, the prevalence of insomnia, as defined by the International Classification of Sleep Disorders (3rd edition) [27,28,55] criteria, decreases in older adults [3,56]. This calls into question the appropriateness of pharmacological treatment for sleep disturbance in older adults and underlines the importance of identifying all issues regarding sleep disturbance during diagnosis and treatment. Reasons for sleep disturbance may have an impact on the measured effect of an intervention study, indicating a benefit for adjusting for this in the study design.

When reporting on their pre-intervention experience with the use of z-hypnotics, the participants stated that, during nights when they had not taken their z-hypnotics, they would have a worse night. Further, they reported anticipating having a worse night if they did not take their z-hypnotics. Rebound insomnia is a known symptom of z-hypnotic withdrawal [32]. It is most prevalent during the first days of withdrawal, and the patient may interpret this as confirmation that they cannot sleep without their medication. In addition, research has shown that there is a large placebo effect with z-hypnotics. The difference in sleep latency between active treatment and placebo is only 22 minutes of objectively measured effect in favor of active treatment [8], demonstrating a very low clinical gain of active treatment compared with placebo and underlining anticipation as a considerable portion of the experienced effect. Further, only 50% of patients are aware that long-term use of z-hypnotics can reduce sleep quality, and up to 84% of patients are aware of dependence, interaction with alcohol use, and dizziness. Regardless of the awareness of side effects, only 26% of patients report an interest in reducing their use of z-hypnotics [57]. Not being aware of possible side effects and placebo effects in addition to experiencing rebound insomnia with withdrawal are factors that will affect intervention compliance and patients’ interest in making changes to their z-hypnotics.

At the follow-up interviews, the participants reported that they could not recall information shared during the BI consultation regarding use of z-hypnotics, risk of adverse events, and benefits from reducing use. They stated that they did not learn anything new about z-hypnotics during the consultation but that the BI consultation had confirmed some previous knowledge. This underlines the importance of investigating the patients’ knowledge about the substance in question. Awareness about patients’ knowledge is important on an individual level. It emphasizes the importance of revising the content and delivery of the information about z-hypnotics presented in the BI. It also prompts exploring more aspects of the BI technique such as providing a short information leaflet [19] that summarizes and repeats the core information given at the consultation. In this study, we chose not to use such additions, as we wanted to explore the feasibility of using just a single consultation.
Another aspect of the BI technique we chose not to pursue in this study was to contact participants to offer support during the follow-up period. We regarded 6 weeks to be a relatively short follow-up period and therefore did not actively seek contact. As part of the BI, the participants were invited to make a plan about what to do in case they had challenges reducing their medication. They were given a phone number to contact if they had questions, needed support, or encountered difficulties. One participant reported needing support from the physicians during the follow-up, but 4 did not make a plan for what to do if they met with challenges. Prompting patients to create a plan about what to do if they meet with difficulties and contacting the patients during the weeks after the intervention may improve participation and adherence.

Strengths and Weaknesses
This feasibility case series was performed as part of our development of a complex intervention [58], as suggested by the UK Medical Research Council, in which a central component is conducting a feasibility study [58,60]. It provided useful information regarding the feasibility, acceptability, and logistics. Naturally, such a small feasibility series does not contribute quantitative data nor solve the central question about whether the BI is an effective intervention. It was a valuable opportunity for an in-depth investigation of the BI scheme with older adults using z-hypnotics. It also provided information about older adults’ thoughts and beliefs about sleep disturbance and their medication use. The main weakness was the small sample as well as the attrition of participants: 3 of 5 participants declined the follow-up interview. We found, however, that both the participants who completed and those who withdrew provided valuable information to further design and optimize the BI scheme for older adults using z-hypnotics.

Conclusion
This study assessing the feasibility of the BI design for older adults with inappropriate use of z-hypnotics identified some important aspects with regards to improving the design before proceeding to a larger study investigating the treatment effect. Conducting the BI in primary care, limiting the duration of the BI while emphasizing core information, providing patients with an information leaflet, and contacting patients for support may improve the effect of the intervention.

Acknowledgments
We are grateful for the support during data collection from the geriatric department at Akershus University Hospital. We also recognize the extraordinary commitment of the patients who participated in this study.

This work was funded by ELIB (Stiftelsen Et Liv I Bevegelse) and the Health Services Research Unit of the Akershus University Hospital. CL also received funding from the South Eastern Norway Regional health authority. No grant numbers were provided by the funders. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Data Availability
The raw data are closed for public access due to data protection regulations by the Akershus University Hospital data protection officer and the Regional Committees for Medical and Health Research Ethics. However, summarized data may be available upon reasonable request to the corresponding author MTB.

Conflicts of Interest
CL has participated on an advisory board and received payment for lectures arranged by AbbVie Pharma AS, Novartis AS, Lundbeck AS, Teva AS, and Roche AS, Norway. He has also received research sponsorship from AbbVie Pharma and Lundbeck AS. The other authors declare no conflict of interest.

Abstract

Background: The accumulation of vast electronic medical records (EMRs) through medical informatization creates significant research value, particularly in obstetrics. Diagnostic standardization across different health care institutions and regions is vital for medical data analysis. Large language models (LLMs) have been extensively used for various medical tasks. Prompt engineering is key to use LLMs effectively.

Objective: This study aims to evaluate and compare the performance of LLMs with various prompt engineering techniques on the task of standardizing obstetric diagnostic terminology using real-world obstetric data.

Methods: The paper describes a 4-step approach used for mapping diagnoses in electronic medical records to the International Classification of Diseases, 10th revision, observation domain. First, similarity measures were used for mapping the diagnoses. Second, candidate mapping terms were collected based on similarity scores above a threshold, to be used as the training data set. For generating optimal mapping terms, we used two LLMs (ChatGLM2 and Qwen-14B-Chat [QWEN]) for zero-shot learning in step 3. Finally, a performance comparison was conducted by using 3 pretrained bidirectional encoder representations from transformers (BERTs), including BERT, whole word masking BERT, and momentum contrastive learning with BERT (MC-BERT), for unsupervised optimal mapping term generation in the fourth step.

Results: LLMs and BERT demonstrated comparable performance at their respective optimal levels. LLMs showed clear advantages in terms of performance and efficiency in unsupervised settings. Interestingly, the performance of the LLMs varied significantly across different prompt engineering setups. For instance, when applying the self-consistency approach in QWEN, the $F_1$-score improved by 5%, with precision increasing by 7.9%, outperforming the zero-shot method. Likewise, ChatGLM2 delivered similar rates of accurately generated responses. During the analysis, the BERT series served as a comparative model with comparable results. Among the 3 models, MC-BERT demonstrated the highest level of performance. However, the differences among the versions of BERT in this study were relatively insignificant.

Conclusions: After applying LLMs to standardize diagnoses and designing 4 different prompts, we compared the results to those generated by the BERT model. Our findings indicate that QWEN prompts largely outperformed the other prompts, with precision comparable to that of the BERT model. These results demonstrate the potential of unsupervised approaches in improving the efficiency of aligning diagnostic terms in daily research and uncovering hidden information values in patient data.

KEYWORDS
obstetric data; similarity embedding; term standardization; large language models; LLMs
Introduction

The advancement of medical informatization has resulted in the accumulation of vast amounts of electronic medical records (EMRs) in hospitals, giving rise to medical big data [1]. These data hold significant research value. Using obstetrics as an example, the implementation of China’s “three-child” policy in 2021 has led to an increasing proportion of women with advanced maternal age and multiparity. Studies indicate that as maternal age and parity increase, the occurrence of pregnancy complications and adverse pregnancy outcomes also tends to rise, posing new challenges for obstetrics across health care institutions at all levels [2]. Extracting valuable information from obstetric EMRs could significantly benefit clinical research aimed at improving pregnancy success rates.

However, due to varying writing habits among doctors, diagnostic descriptions in medical records lack standardization, which hinders the analysis and use of medical data. Consequently, mapping clinical diagnostic descriptions to a standard terminology database is vital for medical data analysis. This process enables the standardization of medical terms across different health care institutions and regions, preventing misunderstandings and confusion caused by varying terminologies. It positively impacts health care quality, reduces medical costs, enhances doctor-patient relationships, and promotes the development of medical science.

The emergence of large language models (LLMs), represented by ChatGPT, has caused a surge in interest in their application across various fields of research. In the medical domain, LLMs have been extensively used for tasks such as intelligent medical history collection and preliminary diagnosis, personalized treatment and drug recommendations, medical record documentation and report generation, literature retrieval and analysis, and medical education and training [3-6]. Kanjee et al [7] assessed ChatGPT’s ability to accurately diagnose challenging medical cases and suggested that generative artificial intelligence (AI) models hold promise as potential aids to human diagnostic cognition. Research by Agbavor and Liang [8] demonstrated that GPT-3–generated text embeddings can reliably distinguish Alzheimer disease patients from healthy controls and infer cognitive test scores of patients, potentially enhancing early dementia diagnosis. Palanica et al [9] explored ChatGPT’s potential applications in psychological counseling, emotional support, and mental illness screening while discussing related challenges and future research directions.

LLMs have also played a crucial role in medical research. Clinical research often involves large amounts of unlabeled natural language data, and LLMs’ zero-shot learning ability allows them to effectively process such data. Agrawal et al [10] showed that ChatGPT excels in extracting zero-shot and few-shot information from clinical texts. Hu et al [11] revealed ChatGPT’s potential in zero-shot clinical entity recognition tasks. Furthermore, Lamichhane's [12] 3 text-based experiments on mental health classification demonstrated ChatGPT’s potential in zero-shot text classification tasks.

LLMs are chatbot technologies based on natural language processing and deep learning; they learn language patterns and knowledge from a large amount of text data to realize natural conversations with humans. The key to effectively using LLMs is to set an optimal prompt [13].

In few-shot learning, designing appropriate prompts can help LLMs learn better from a small number of training samples and improve performance [13]. Even in zero-shot learning scenarios, appropriate prompts can guide LLMs to use contextual information to output correct results [14]. Prompt engineering has been widely used in various fields of natural language processing, such as question answering, text generation, and sentiment classification, as well as other tasks. By carefully designing prompts, LLMs can better understand the task requirements and context and generate more accurate and useful outputs [13,15,16]. In addition, prompt engineering is an efficient method that does not rely on large-scale computing resources. It can narrow the gap between the pretraining and fine-tuning stages, improve the model’s learning ability and generalization ability on a small amount of data, and fully exploit the model’s potential performance [15].

Chain-of-thought (CoT) prompts were proposed by Wei et al [17], who experimented with the effect of CoT prompts on multiple tasks, including mathematical problems, logical reasoning, reading comprehension, and common sense reasoning; they compared it with other prompt engineering techniques and pointed out that CoT prompts could significantly improve the model’s performance on these tasks and even allow the model to show complex reasoning abilities, such as induction, deduction, and analogy. The basic idea of CoT prompts is that, when giving a question or task, instead of directly asking the model to give an answer or result, the user asks the model to give a CoT, that is, a series of intermediate reasoning steps in which each step is a complete sentence, and the last step is the answer or result. The advantage of this is that it can make the model better understand the meaning and goal of the question or task, avoid irrelevant or wrong outputs, and also make it easier for human users to check and evaluate the model’s output.

The goal of self-consistency prompts is to improve the quality and consistency of the generated results by requiring the model to make consistency judgments on the previously generated text [18]. When using self-consistency prompts, the user first provides an initial text as a prompt and then lets the model continue to generate the subsequent text. Next, the user replaces the “greedy decoding” in the CoT prompt with sampling from the language model’s decoder to generate a set of diverse reasoning paths; finally, the user marginalizes the reasoning paths and aggregates them by selecting the most consistent answer in the final answer. This can force the model to maintain self-consistency when generating text, avoiding contradictions and incoherence.

This paper delves into the potential of LLMs for zero-shot or unsupervised learning in the domain of standardizing diagnostic terminology in obstetrics. By leveraging a composite approach that merges different prompt engineering techniques with LLMs, our goal is to identify the most fitting pipeline for unsupervised scenarios.
As most of the LLMs used in the Chinese domain use the Chinese version of the International Classification of Diseases, 10th revision (ICD-10-CN), as their core training corpus [19], in order to compare the performance of LLMs and supervised learning algorithms horizontally on a baseline, we used standard diagnostic terminology in the ICD-10-CN as the alignment target throughout this study.

**Methods**

**Task Overview**

The approach can be divided into 4 steps: (1) mapping the diagnosis in EMRs to the observation domain of the ICD-10-CN via embedded similarity; (2) collecting the candidate mapping terms with similarity above the threshold as the training data set; (3) using 2 LLMs, ChatGLM2 [20] and Qwen-14B-Chat (QWEN) [21], with zero-shot learning to generate the optimal mapping terms; and (4) using 3 pretrained bidirectional encoder representations from transformers (BERTs), BERT [22], whole word masking BERT (BERT-WWM) [23], and momentum contrastive learning with BERT (MC-BERT) [24], for unsupervised generation of the optimal mapping terms for performance comparison. The entire workflow is illustrated in Figure 1.

**Data Preparation**

In this study, the raw data were collected from the obstetric EMR data of the People’s Hospital of Guangxi Zhuang Autonomous Region from April 2014 to April 2022; these data contained only diagnostic reports. Sample data are shown in Textbox 1.

**Textbox 1.** A sample data of diagnoses for ID 720444 is listed below with a translated version. All data processed in this research were in Chinese.

The raw data set underwent data preprocessing by removing punctuation marks and meaningless special symbols to avoid potential interference with subsequent word segmentation operations.

We implemented LLMs in an intranet security environment. Both ChatGLM2 and QWEN were used exclusively on physically isolated graphical processing units, with access facilitated via OpenAI format and FastAPI (built on PyTorch 2.0). Temperature settings for the LLMs were configured at 0, with max_token parameters tailored on a task-by-task basis.

The standard vocabulary referred to in the following text consists of the diagnostic categories belonging to the observation domain of ICD-10-CN.
Embedding Learning

We used the conditional random fields (CRF) model [24] to segment the text and obtained original-diagnosis raw data aligned with standard vocabulary terms. The principle of CRF is to treat word segmentation as a character position classification problem. Character position information is often defined as follows: $B$ represents the beginning of a word, $M$ denotes the middle of a word, $E$ signifies the end of a word, and $S$ indicates a single-character word. Feature functions are constructed to describe the relationship between each character and label and the transition between adjacent labels. Using training data, we learn the weights of feature functions to maximize conditional probability. The Viterbi algorithm predicts new input sequences and finds the most probable label sequence; according to the label sequence, we construct word segmentation results from characters between $B$ and $E$ and single characters $S$. As shown in Textbox 2, we conducted CRF word segmentation on diagnoses in EMRs.

To calculate the similarity between diagnoses in the raw data set and terms in the standard vocabulary, we used the BERT-medicine model to transform diagnoses and terms into embeddings for storage. The BERT-medicine model is specifically designed to improve the model’s understanding of medical terms and symptoms by introducing a medical domain–specific vocabulary list, lexicon, and pretraining tasks.

The main structure of the BERT-medicine model is the BERT, and the main inputs are the raw word vectors of each word or phrase in the text. In this study, we used diagnoses in the raw data set as the input text sequences. The BERT model extracted the contextual information of the text through a self-attention mechanism and learned the bidirectional linguistic representations, so as to obtain a semantic representation of each word in its context. The final output embedding vector is represented by the sum of character embedding, partition embedding, and position embedding, which constitute the input sequence.

Similarity Computation

The feature embedding of the diagnosis is denoted by $\mathbf{d}$, the feature embedding of the standard terms is denoted by $\mathbf{t}$, and their similarity is calculated using the cosine similarity with the following formula:

$$ \text{similarity} = \frac{\mathbf{d} \cdot \mathbf{t}}{\|\mathbf{d}\| \cdot \|\mathbf{t}\|} $$

The proposed approach is evaluated through the following steps: Standard terms with a similarity score higher than 0.9 are considered candidates for diagnosis keywords and are then verified by medical experts. The normalized precision and recall are calculated, and the precision-recall curve is obtained. Since a particular diagnosis might have multiple similar standard terms, we aimed to identify as many similar terms as possible, and we thus expected high recall and precision. To obtain candidate terms, we collected the original diagnosis and the 10 most similar standard terms having a similarity score greater than or equal to 0.855.

Optimal Term Selection

To comprehensively evaluate the performance of LLMs in the standardization of obstetric diagnostic terminology, we used 4 different prompts, with the prompt design ranging from simple to complex. This started with the prompt trained on zero samples (the zero-shot learning prompt); next were the prompt trained on a small number of samples, the in-context learning prompt, the CoT prompt, and finally the self-consistency prompt. The specific flow chart of LLM training is shown in Figure 2.
Figure 2. Prompt examples under 4 distinct prompt engineering methods: (A) the zero-shot learning prompt, (B) the in-context learning prompt, (C) the chain-of-thought prompt, and (D) the self-consistency prompt. In the experiment, the raw data being in Chinese led us to use Chinese prompts, which are translated for readability purposes. However, “diagnosis” and “candidate terms” are displayed in their original Chinese format. LLM: large language model.

The zero-shot learning prompt was meant to guide the LLMs’ output by directly telling them the purpose of this study. The target task of this study was to find the standard-term expression for the diagnosis, that is, to let the LLMs determine the word with the highest similarity. Therefore, we directly told the LLMs to find the most similar word to the input word among the candidate words for the standard term. The LLMs determined the similarity between words based on their own learned knowledge, and then output the word with the highest similarity to the input word as the output result.

The purpose of in-context learning prompts is to give context hints and let LLMs learn by analogy from few shots to output results that more closely meet the requirements [25]. Its input is in the form of {question, answer}, that is, in the input, the question and result are given to the LLM as a template, and it answers the same type of questions in a specific way according to the specific answer.

The input form of CoT prompts is similar to in-context learning prompts, that is, {question, answer}, with the difference that the answer contains the intermediate steps of thinking. In order to reduce human costs, we used LLMs to generate CoT prompts, and then encapsulated them into the prompt inputs.

The key method of self-consistency prompts in this study was to input the CoT prompts from the previous section multiple times, obtain multiple results, randomly sample a group of output results, and use the majority voting method to decide the final result. Next, we will demonstrate the experimental process with different prompts through specific examples, shown in Figure 3.
**Figure 3.** Detailed illustration of the technical intricacies underlying this study. The process of mapping nonstandardized local diagnostic text to standardized International Classification of Diseases, 10th revision, Chinese version (ICD-10-CN) terms involves preliminary similarity-based selection through the vector database, followed by optimal solution selection performed by large language models (LLMs) based on semantic comprehension.

**Evaluation**

The evaluation metrics in this study to assess the model’s performance were precision, recall, and $F_1$-score [26]. We classified words that matched the original word and the standard word as positives, and those that did not match as negatives. There were 4 possible classification outcomes: true positive, in which the model correctly identified a positive as positive; false negative, in which the model mistakenly classified a positive as negative; true negative, in which the model correctly identified a negative as negative; and false positive, in which the model mistakenly classified a negative as positive. Using these classification outcomes, we could calculate precision, recall, and $F_1$-score to evaluate the model’s performance in standardizing diagnoses.

Precision, recall, and $F_1$-score (the reconciled mean of precision and recall) were defined as follows:

**Ethical Considerations**

The study was approved by the People’s Hospital of the Guangxi Zhuang Autonomous Region in China (KT-KJT-2021-67), and all pregnancy data were deidentified and anonymized.

**Results**

**Overview**

For similarity computation, according to experimental tests, an average precision of 0.88 met the requirement for high precision and recall. The corresponding threshold value at this point was 0.855. Therefore, the threshold value for calculations of similarity was determined to be 0.855, which was used to filter out standard terms that were not similar enough to the diagnosis.

After collecting the candidate data set, we used 2 LLMs and 4 techniques for prompt engineering. Subsequently, we mapped the LLM outputs to the most suitable candidate terms from the ICD-10-CN standard vocabulary, enabling us to calculate precision, recall, and $F_1$-score. In order to undertake entity normalization, we selected the classic BERT series, comprising BERT, MC-BERT, and BERT-WWM, as our comparison models. We then compared their performance with the results obtained using the LLMs with 4 different prompts. The outcomes of this comparison are presented in Table 1.
Table 1. Metric performance comparison across large language model and bidirectional encoder representations from transformers (BERT) series.

aPrompt engineering not applicable to these models.

It is evident from the table that the LLMs and BERT displayed comparable performance at their optimal levels, indicating that the LLMs provided a performance and time advantage under unsupervised conditions. Furthermore, the LLMs exhibited varied performance under different prompt engineering setups. Taking QWEN as an example, the implementation of the self-consistency approach improved the F₁-score by 5% and precision by 7.9% compared to the zero-shot method. Similarly, the same proportion of correctly generated responses was observed in ChatGLM2’s performance, with a range from 9.19% to 18.02%. Thus, QWEN achieved better performance than ChatGLM2 in all 4 prompt engineering approaches.

The BERT series were additional comparison models and exhibited more comparable results in this task. Among the 3 models shown in Table 2, MC-BERT delivered the best performance. However, in this study, the disparity between the 3 versions of BERT was relatively small.

aNot applicable.
Additional Research
In this study, we used the Louvain algorithm to mine terms from the standard data set output by the LLMs and obtained 1100 relatively common diagnostic terms. In the medical field, different medical institutions and professionals may use different terms to describe the same or similar clinical diagnoses, which can cause difficulties and misunderstandings in data exchange, statistics, and analysis. Therefore, standardizing clinical diagnostic terms is an important task. The standardized terms can be used to unify treatment plans and disease statistics, as well as to build clinical diagnostic knowledge bases. The data in our study were clustered into 107 clusters, and each cluster was analyzed separately, resulting in a diagnostic clustering table. Part of the results of the clustering table are shown in Table 2.

Discussion
Principal Results
This paper proposes an effective unsupervised standardization method for obstetric diagnosis. Through a multi-metrics comparison of different LLMs under various prompt engineering strategies, we found that unsupervised LLMs coupled with effective prompt engineering can achieve performance comparable to supervised learning.

A comparison of different prompt engineering strategies showed that although the models’ baseline performance under zero-shot settings varied, they generally showed significant improvement after incorporating strategies such as CoT, which also highlights the importance of effective prompts for LLMs.

The goal of our alignment in this study is the ICD-10-CN terminology, which belongs to the core vocabulary of the Chinese medical field. LLMs trained on Chinese language data usually include it as part of the training corpus [19], and the performance of the baseline model allows prompt engineering to further improve the alignment performance.

Comparison With Prior Work
Compared to previous research that primarily relied on BERT-based methods to map diagnostic descriptions from EMRs to standard terminologies, this study explores a novel approach based on LLMs. Among BERT models, we identified MC-BERT as the top performer, achieving an $F_1$-score of 0.9235.

Beyond the conventional BERT methods, we examined 4 mainstream prompt strategies and found that the self-consistency method outperformed the others, achieving an $F_1$-score of 0.9233. This level of performance matches that of supervised learning, opening up new possibilities for terminology mapping research in the medical domain.

Limitations
As all data were sourced from real-world patient information, and even though we anonymized the data through multiple strategies and only used a portion of the diagnostic text information without any personal identifying information, there is still a risk associated with uploading patient data to an open network. Additionally, as our research objective was to align and standardize Chinese text based on Chinese target terminologies, the choice of LLMs used in this study was limited. The development of LLMs in the Chinese domain is advancing rapidly, and there are many newly released versions that we have yet to explore.

Moreover, our alignment target was for scientific exploration. In future studies, we will attempt to train target vocabulary that is more suited to the scientific research context into the model through methods such as global optimization and exploring semantic alignment scenarios.

Conclusions
This paper investigates the capability of LLMs in standardizing clinical medical terms. By using LLMs to standardize diagnostic terms extracted from real-world obstetric EMRs and designing 4 different prompts for LLMs, we were able to compare their output results with those of the BERT model. Our findings demonstrate that QWEN mostly achieved the best performance and had precision on par with the BERT model, which illustrates that an unsupervised approach improved the efficiency of aligning diagnostic terms in daily research and to uncover the hidden value of patient data information.

Abstract

Background: Tobacco smoking is an important risk factor for disease, but inaccurate smoking history data in the electronic medical record (EMR) limits the reach of lung cancer screening (LCS) and tobacco cessation interventions. Patient-generated health data is a novel approach to documenting smoking history; however, the comparative effectiveness of different approaches is unclear.

Objective: We designed a quality improvement intervention to evaluate the effectiveness of portal questionnaires compared to SMS text message–based surveys, to compare message frames, and to evaluate the completeness of patient-generated smoking histories.

Methods: We randomly assigned patients aged between 50 and 80 years with a history of tobacco use who identified English as a preferred language and have never undergone LCS to receive an EMR portal questionnaire or a text survey. The portal questionnaire used a “helpfulness” message, while the text survey tested frame types informed by behavior economics (“gain,” “loss,” and “helpfulness”) and nudge messaging. The primary outcome was the response rate for each modality and framing type. Completeness and consistency with documented structured smoking data were also evaluated.

Results: Participants were more likely to respond to the text survey (191/1000, 19.1%) compared to the portal questionnaire (35/504, 6.9%). Across all text survey rounds, patients were less responsive to the “helpfulness” frame compared with the “gain” frame (odds ratio [OR] 0.29, 95% CI 0.09-0.91; P<.05) and “loss” frame (OR 0.32, 95% CI 11.8-99.4; P<.05). Compared to the structured data in the EMR, the patient-generated data were significantly more likely to be complete enough to determine LCS eligibility both compared to the portal questionnaire (OR 34.2, 95% CI 3.8-11.1; P<.05) and to the text survey (OR 6.8, 95% CI 3.8-11.1; P<.05).

Conclusions: We found that an approach using patient-generated data is a feasible way to engage patients and collect complete smoking histories. Patients are likely to respond to a text survey using “gain” or “loss” framing to report detailed smoking histories. Optimizing an SMS text message approach to collect medical information has implications for preventative and follow-up clinical care beyond smoking histories, LCS, and smoking cessation therapy.

electronic health records; EHR; informatics; learning health system; lung cancer screening; smoking history
**Introduction**

Tobacco use is an important risk factor for multiple diseases, including lung cancer, and is one of the leading contributors to preventable death in the United States [1]. The collection of nuanced, complete, and accurate tobacco use histories has significant implications for clinical care. For example, determination of lung cancer screening (LCS) eligibility (eligibility criteria: adults aged between 50 and 80 years with a 20 pack-year smoking history and who are either currently smoking or have quit within the past 15 years) [2] requires full documentation of pack-years (calculated by multiplying the number of packs of cigarettes smoked per day by the number of years the person has smoked) [3]. Clinicians across specialties discuss smoking histories with patients and record them in structured (eg, within a dedicated place in social history) and unstructured data fields (eg, within the clinical note) in the electronic medical record (EMR). Despite this theoretical wealth of longitudinal smoking information, past research illustrates that smoking history data documented in the health record are usually inaccurate, internally inconsistent, incomplete, or outdated [3-8]. Further, while unstructured data may be more accurate, it is limited in its ability to be extracted quickly and easily for clinical care [9,10]. Interventions aimed at improving the documentation and use of patient tobacco histories may have significant implications for interventions that seek to accurately identify patients eligible for LCS, cardiovascular risk reduction, and smoking cessation interventions [4,11,12].

A learning health system (LHS) systematically integrates clinical care, informatics, and research and engages patients to provide opportunities to implement new knowledge rapidly and iteratively [13]. Patient-generated health data (PGHD) is one promising modality to engage patients and build components of a LHS [14]. One challenge, however, is determining the best approach to engaging patients for self-reported data and scaling interventions for use across the health care system. Implementation of initiatives using patient surveys to generate health data are most effective when systematically designed and studied to determine effectiveness and scalability [15,16]. For example, which technology to use and which message framing to use are important considerations to optimize PGHD. Framed messages describe a choice in terms of how participation may provide gain or loss to the individual or helpfulness to the clinician.

We used a PGHD approach to address the issue of poorly documented smoking history, a previously highlighted barrier to uptake of LCS at our institution [7]. Given the clinical relevance of smoking histories to LCS and smoking cessation counseling, the primary objective of this study was to evaluate the impact of patient-generated methods to improve smoking history documentation. To this end, we designed a quality improvement intervention to evaluate three questions about patient-generated smoking history data: (1) “What is the effectiveness of portal questionnaires versus SMS text message–based surveys?” (2) “What is the most effective message framing accompanying the survey link?” and (3), “What is the optimal approach to following up on uncompleted surveys to increase response rates?”

**Methods**

**Setting and Cohort**

We conducted this trial at a large academic safety net hospital in the northeast United States [17]. The institutional review board determined this project qualified for an exemption determination as quality improvement research. We carried out our pragmatic trial from October 2022 to January 2023 in the general internal medicine practice, the largest adult primary care clinic at our hospital. Our hospital uses EPIC (Verona), referred to as “EMR” throughout this manuscript.

**Participants**

A quality analyst generated random patient lists from the EMR for portal questionnaires and text survey cohorts. Our inclusion criteria were a history of tobacco use (current or former), being aged between 50 and 80 years, and having English as a preferred language. We based the patient’s smoking status on their recorded substance use history within the structured social history section of the medical record. In addition to smoking status, this included entry fields for cigarette smoking start date, quit date, cigarette packs per day, cigarette use years, and a pack-year calculated field, which multiplied the packs per day and years. Not all fields were complete for every patient. Because this trial was designed to increase uptake of LCS by gathering an accurate smoking history, we excluded patients who had LCS or an existing LCS order pending since presumably a more accurate smoking status already existed. Additionally, the portal cohort had to have an active portal account, whereas the SMS text message survey cohort needed to have a recorded mobile or home number documented. Finally, we excluded patients from the text survey cohort if they received the portal questionnaire message, so that each cohort was mutually exclusive.

The portal questionnaire cohort consisted of 500 patients, and the text survey cohort consisted of 1000 patients from general internal medicine clinics. The sample size was determined through a judgment sampling approach [18]. Time and resource limitations (our text survey contract was capped at 1000 patients) played a role in the determination of the judgment sample size. The chosen sample size sought to balance meaningful insights and adherence to practical constraints.

**Smoking History Query Interventions**

We evaluated 2 modalities; an electronic health record portal questionnaire using EPIC’s MyChart (Verona) and a text survey using Patient Navigation Manager CareTour (Philips Healthcare), a texting platform. The EPIC MyChart questionnaire is referred to as the “portal questionnaire,” and the Philips Healthcare texting platform is referred to as the “text survey” throughout this manuscript. For both modalities, questions pertaining to obtaining an accurate smoking history were designed based on a review of the literature and in consultation with pulmonary and critical care specialists with expertise in tobacco dependence treatment and written in plain language to promote readability and interpretability (Table S1 and Figures S1 and S2 in Multimedia Appendix 1 provide information on the survey questions and user interface). We
also used an intentional phased approach for both surveys to assess technical issues, identify remediable issues, and scale more widely. Given that this study used patient-generated smoking history queries, which required participant comprehension and engagement, blinding participants to the study’s purpose was deemed impractical.

**Message Framing**

We reviewed the behavioral economic theory literature to inform our approach and to use message framing that we hoped would best engage patients [15,16,19,20]. We chose to evaluate 3 message framings: “gain,” “loss,” and “helpfulness” (Table 1). Gain- or loss-framed messages have been shown to be effective in smoking cessation, cancer prevention, and vaccination work [21,22]. We also included a helpfulness message, which has been explored within the web-based industry and marketing research but has been underexplored in health care settings [23,24]. We tested these different message frames in the text survey. The EPIC MyChart questionnaire portal system is configured to send users a general email that reads, “You have a portal questionnaire message.” This is a global configuration setting that cannot be modified on a per-project basis. Thus, we did not test different message frames in the portal questionnaire.

**Survey Modalities**

**Electronic Health Record Portal Questionnaire**

The portal questionnaire to assess smoking status consisted of up to 6 questions, which were a combination of multiple-choice or open-ended questions with answers restricted to numeric-only values (Table S1 and Figure S2 in Multimedia Appendix 1). The portal questionnaire design permitted the conditional display of questions tailored to their smoking status. For example, only people who formerly smoked saw the question, “How old were you when you stopped smoking?” Once the message was accessed, a “helpfulness” frame (Table 1) was shown in the portal message’s subject and body (Multimedia Appendix 1 provides full details of surveys).

| Table 1. Comparison of features tested in portal questionnaire and text survey. |
|---|---|---|---|
| Survey modality | Message framing options | Conditional display of messages | Nudge message |
| Portal questionnaire (EPIC’s MyChart; Verona) | • “Helpfulness” frame for all patients: Help your [hospital name] healthcare team give you the best care possible by answering a few questions about your health. (Msg/data rates may apply. Reply STOP to stop msgs) | Yes | No |
| Text survey (Patient Navigation Manager CareTour texting platform; Philips Healthcare) | • “Gain”: Please answer a few questions for your [hospital name] healthcare team to help you get screenings to keep you healthy. (Msg/data rates may apply. Reply STOP to stop msgs)  
• “Loss”: Please answer a few questions for your [hospital name] healthcare team so you don’t miss out on any screenings. (Msg/data rates may apply. Reply STOP to stop msgs)  
• “Helpfulness”: Help your [hospital name] healthcare team give you the best care possible by answering a few questions about your health. (Msg/data rates may apply. Reply STOP to stop msgs) | No | Yes |

We deployed the portal questionnaire in 3 steps to support iterative optimization (Figure 1). The portal notified patients that there was a new questionnaire in their portal through a general email or a pop-up on their smartphone app. Patients were required to have an active portal account and had to log into the account to complete the questionnaire. For both round 1 and round 2, we held our date and time fields constant by sending the message on Tuesdays at 10:20 AM Eastern Daylight Time (EDT).
A total of 16 participants were sent the survey both in the pilot and in the subsequent rounds of the portal questionnaire rollout (5 in round 1 and 11 in round 2). These participants were only included for analysis based on their initial participation in the pilot and were excluded from analysis in round 1 and round 2.

SMS Text Message Survey

The text survey to assess smoking status consisted of 4 questions, which were either multiple-choice or open-ended (Table S1 and Figure S1 in Multimedia Appendix 1). This software would not allow for the restriction of numeric-only values. Conditional display of questions was not possible with the text survey platform, so all patients saw all questions. As a result, we added the leading text “If you stopped” to the question “How old were you when you stopped smoking?” We also evaluated response rates by message framing (Figure 1).

As in the portal questionnaire, we deployed the text survey using a 2-round phased approach to support iterative optimization (Figure 1). We randomly assigned patients to receive 1 of 3
messages: “gain,” “loss,” or “helpfulness” (Table 1). Patients were randomized in Excel (Microsoft Corporation) using the RAND function to assign each participant a random number and the RANK and ROUNDUP functions to evenly distribute participants in each of the 3 message groups. We sent an initial SMS text message on Tuesdays at 10:20 AM EDT, consistent with the portal questionnaire. Participants could either respond, not respond, or unsubscribe. We then sent a nudge or second message to all nonresponders who had not unsubscribed, such that 50% of the nonresponders received the same message as the index message, while 50% received a different message, split evenly among the other 2 framing options (Figure S3 in Multimedia Appendix 1 depicts the message trial schema). We sent the nudge message 2 days after the initial message on Thursday at 10:20 AM EDT.

**Statistical Approach**

All statistical analyses were performed using R (version 4.1.0; The R Project for Statistical Computing). For analyses including 2 variables (portal vs text survey and same vs different second push messages), Fisher exact test was used. For comparison of framing, we performed a random effects logistic regression model for outcome of response and exposure of survey with random intercept for patients’ to account for repeated measures.

The primary outcome measure was the proportion of surveyed patients who responded based on survey modality (portal vs text survey). As a secondary outcome, we assessed response rates for the text survey based on framing and repeated pushes (first or second). Odds ratios (ORs) were calculated for each of these comparisons.

As an additional secondary outcome, we also compared the data obtained from survey responses to those already existing in the smoking history captured in EPIC. Using Fisher exact test, we compared the number of patients with complete smoking histories, defined as adequate information to determine LCS eligibility (pack-years and time since quitting). We also analyzed the concordance between EPIC data and the data gathered from completed surveys for LCS eligibility, smoking status, and pack-years reported. We used the Cohen $\kappa$ coefficient to compare LCS eligibility and smoking status. We used a 2-way random effects intraclass correlation coefficient to compare agreement in reported pack-years between the EMR and completed surveys [25]. A level of significance of $\alpha=0.05$ was used.

**Results**

### Survey Response Rates

Overall, the characteristics of responders and nonresponders for both survey modalities were similar, except that responders to the text survey were more likely to identify as White and to have stopped smoking compared with text nonresponders (Table 2).

The response rate for the portal questionnaire was 6.9% (35/504) and the response rate for the SMS text message–based survey was 19.1% (191/1000) with an OR of 3.18 (95% CI 2.16–4.79; $P<0.05$) (Figure 2). Across all survey rounds, patients were less responsive to the “helpfulness” message compared with the “gain” message (OR 0.29, 95% CI 0.08–0.99; $P<0.05$) and compared with the “loss” message (OR 0.32, 95% CI 0.09–0.91; $P<0.05$); however, there was no difference in responses between the “gain” and “loss” messages (OR 0.89, 95% CI 0.31–2.55, $P=0.82$) (Figure 2). There was no significant difference in response rates to different message frames when comparing responses from only the first push survey round or responses from only the second push survey round. In reference to the first push message frame, there was also no difference in response rate if the same message framing or a different message framing was used in the second push (OR 1.3, 95% CI 0.74–2.17; $P=0.44$). The overall unsubscribe rate for the text survey was 5.5% (55/1000). There was no significant difference in unsubscribe rates depending on the message framing.
Completed Smoking History Data Analysis

Both the portal questionnaire and text survey were significantly more likely to obtain complete data compared to the available data in the medical chart (Table 3).
Of the responses that did not provide completed data, patients reported “do not remember” (n=0 in the portal and n=3 in the text), submitted nonnumeric answers such as “only tried briefly” (n=0 in the portal and n=7 in the text), or submitted answers that were extreme outliers (n=4 in the portal and n=5 in the text), leading to exclusion. Furthermore, 6 individuals who reported current smoking and responded to the text survey reported gaps in their smoking history. Since we could not discern whether these “gaps” represented periods where patients had stopped smoking versus incomplete data, we instead used current age to calculate total pack-years.

The portal questionnaire generated 24 newly complete smoking histories to determine LCS eligibility for those whose EPIC data were not complete. The number of patients who had complete data for both the existing information in EPIC and the new data obtained from the portal questionnaire was low (7 out of 504). This small sample size limited our statistical analysis of the concordance for LCS eligibility and current smoking status between the medical chart data and the data gathered in the portal questionnaire. However, our raw data demonstrates relative agreement, with 6 of 7 responses in agreement for LCS eligibility (eligible or ineligible) and 7 of 7 responses in agreement for smoking status (current or former). The average number of pack-years recorded in EPIC for this group was 10.82, and the average number of pack-years recorded by the portal questionnaire was 9.27, with a good correlation between the 2 sets of data (intraclass correlation [ICC] 0.81, 95% CI 0.28-0.96).

The text survey generated newly complete data to determine LCS eligibility for 89 patients, whose EPIC data were incomplete. Complete data to determine LCS eligibility in both the medical chart and the text survey were available for 87 patients. However, there was poor agreement between the existing data in the medical chart and those collected by the text survey. The 2 sets of data were discordant in identifying whether patients were eligible for LCS (Cohen κ 0.32, 95% CI 0.029-0.62) and in identifying current smoking status (Cohen κ 0.008, 95% CI –0.0077 to 0.024). The average number of pack-years for this group recorded in the medical chart was 14.83, and the average number of pack-years recorded by the text survey was 9.81, with a poor correlation between the 2 data sets (ICC 0.27, 95% CI 0.04-0.48).

### Discussion

Improving our health systems’ ability to capture accurate and complete smoking histories could have significant implications for the delivery of care, specifically for LCS and smoking cessation counseling. We found that a PGHD approach using patient-generated survey data is a feasible way to engage patients and collect smoking histories. Our trial provides a model for robust, pragmatic evaluation of digital interventions for quality improvement. We were able to test 2 types of survey delivery methods and 3 different survey message framings, all with significant equipoise in the literature. Overall, the portal questionnaire was less effective in generating responses compared to the text survey, and the “helpfulness” framing was less effective in generating responses compared to the “gain” and “loss” framings. A major finding was that both the text survey and the portal questionnaire generated more complete smoking histories to determine LCS eligibility when compared to the existing information available in the EMR.

Previous studies report a wide range of response rates to web-based surveys, with multiple factors contributing to decisions to respond, such as type of information collected, framing, number of reminders, and patients’ health care use [5,26-30]. Our SMS text message survey generated a response rate of 19.1% (191/1000), which is within the range reported in previous studies evaluating web-based surveys and significantly higher than that generated by the portal questionnaire [5,26-30]. The lower response rate to the portal questionnaire may have been influenced by the inability to test framing or deliver nudging messages. However, if we maintain the assumption of an equivalent increase in response rate due to framing (1.8%) and separately due to nudging (6.3%), then we can infer a response rate of 15% (compared to the actual response rate of 35/504, 6.9%). This demonstrates that while framing and a lack of nudging likely had a significant impact, other factors also contributed. One possible explanation is that while the text survey used an interruptive design of direct messaging that could be accessed immediately, the configuration of the portal messaging required access to an app or email and a separate login into the portal, making it less accessible.

Our findings demonstrated improved engagement with “gain” and “loss” framing as opposed to “helpfulness” framing. It is well documented that “gain” and “loss” framing improves patient engagement, attitudes, and motivation [31-36], which, based on our data, likely extends to patient engagement to report smoking history data. However, direct comparisons to “helpfulness” messaging are limited. In fact, the use of “helpfulness” messaging is better documented in nonmedical survey methodology [24]. One potential explanation for the superior performance of “gain” and “loss” framing compared with “helpfulness” framing is that the messages used for the “gain” and “loss” framing center on the implications of responding for the patient, while the “helpfulness” framing centers on the implications of responding for the health care provider. User-centered design has been shown to improve patient engagement [37-39]. Further evaluation of the reasons underlying differential engagement based on message framing, for example, with qualitative analysis, is needed in future studies.

[a] OR: odds ratio.
As in this study, where the PGHD generated more complete smoking histories compared to the EMR, other studies have highlighted how dedicated structured data fields are missing key information needed to assess eligibility, such as packs per day, pack-years, and years since quitting [3,6,8,40]. In our health system, some individuals, such as medical assistants and tobacco treatment specialists, may update smoking history in structured fields, but many clinicians are more likely to document smoking history in unstructured notes. As a result, the structured data fields may be more vulnerable to becoming outdated over time and more likely to underreport smoking histories [4]. Survey instruments, in contrast, can be designed to force complete data entry and can be clarified with the patient in the context of a shared decision-making conversation. This could further alleviate completeness issues.

While the data generated from the surveys were more complete than the EMR, it is difficult to ascertain which history is most accurate. Previous research has found substantial agreement between self-reported smoking history comparing a baseline survey and a 1-month follow-up, with a higher likelihood of inconsistent reporting from individuals currently smoking as compared with individuals who have stopped smoking [41]. This reproducibility could be considered a proxy for accuracy. Other studies have treated the history obtained from shared decision-making as the source of truth. Modin et al [6] found a high degree of underreporting in the health record compared to the history obtained in a shared decision-making discussion. It is difficult to know whether the robustness of a nuanced history elicited by a trained clinician could produce a more true result or if other factors, such as time from the last history ascertainment, may influence accuracy. Which of the tobacco use histories is most accurate is particularly salient for the text survey, which demonstrated significant disagreement with the data in the EMR. While the portal questionnaire data suggested closer agreement with the EMR, this is likely an effect of the very small sample size of patients who had complete portal questionnaire data and EMR data. Future studies might use larger sample sizes and repeated measures to better ascertain the connection between completeness and accuracy.

The feasibility of web-based surveys to engage patients and obtain medical data has important implications for a LHS structure for clinical use. This study was strengthened by testing multiple modalities and multiple message frames to determine the most effective method for engaging patients to self-report tobacco use history. However, this study has some limitations. The use of specific web-based technologies to obtain smoking history data and only English-language data may limit generalizability. Judgment sampling may introduce selection bias, which larger sample sizes would mitigate. However, the cohort characteristics would suggest a diverse cohort that was balanced across intervention groups. Furthermore, obtaining information on smoking history, regardless of modality, can be impacted by social desirability bias, recall bias, and recency bias, all of which may have contributed to the data obtained in this trial [4,45]. We were unable to test message frames in the MyChart Questionnaire portal system due to the unmodifiable global configuration of the initial email message. Also, the CareTour texting platform is designed for appointment reminder functionality. As we were using it for an alternate purpose, we were limited by the lack of conditional display and the inability to restrict data entry on field types, leading to the collection of unusable data. While this modality was able to capture dynamic histories of starting and stopping smoking, it was unclear how to easily translate this into a functionally detailed history. In fact, it remains unclear whether open-ended, “yes” or “no” questions would be most effective in capturing enough of a detailed smoking history to identify patients for interventions such as LCS [46]. Identifying the optimal questions and technology to navigate these limitations should be prioritized in future projects.

This study demonstrates that patients are likely to engage with a text-based survey using “gain” or “loss” framing to report detailed and complete smoking histories. Optimizing web-based surveys to collect tobacco use history and other medical data directly from patients is an appealing approach to improving health care delivery, especially if fully integrated into the EMR, as this could allow health care providers to proactively engage patients in LCS shared decision-making or smoking cessation counseling. Future work should focus on the validation of patient-generated history and the patient experience with receiving and completing a self-reported smoking history survey to allow for further optimization and implementation.

Acknowledgments

The authors would like to thank Corey Dolan, Philips Implementation Manager, for help developing and deploying the text-based survey, David Meter, EpicCare Ambulatory Analyst, for help developing and deploying the portal questionnaire, and all participants who engaged with our surveys.

Abstract

Background: An increasing number of health care professionals are using mobile apps. The mHealth App Usability Questionnaire (MAUQ) was designed to evaluate the usability of mobile health apps by patients and providers. However, this questionnaire is not available in French.

Objective: This study aims to translate (from English to Canadian French), cross-culturally adapt, and initiate the validation of the original version of MAUQ for stand-alone mobile health apps used by French-speaking health care providers.

Methods: A cross-cultural research study using a well-established method was conducted to translate MAUQ to Canadian French by certified translators and subsequently review it with a translation committee. It was then back translated to English. The back translations were compared with the original by the members of the committee to reach consensus regarding the prefinal version. A pilot test of the prefinal version was conducted with a sample of 49 potential users and 10 experts for content validation.

Results: The statements are considered clear, with interrater agreement of 99.14% among potential users and 90% among experts. Of 21 statements, 5 (24%) did not exceed the 80% interrater agreement of the experts regarding clarity. Following the revisions, interrater agreement exceeded 80%. The content validity index of the items varied from 0.90 to 1, and the overall content validity index was 0.981. Individual Fleiss multirater κ of each item was between 0.89 and 1, showing excellent agreement and increasing confidence in the questionnaire’s content validity.

Conclusions: This process of translation and cultural adaptation produced a new version of MAUQ that was validated for later use among the Canadian French–speaking population. An upcoming separate study will investigate the psychometric properties of the adapted questionnaire.

Introduction

Background

Mobile health (mHealth) is increasingly used in healthcare systems, and this fast-growing technology has immeasurable potential to improve the quality and accessibility of healthcare care worldwide [1]. There is no exact figure for the number of mHealth apps available worldwide, as this number is constantly changing owing to the launch of new apps and the removal of existing ones. Globally, the number of mHealth apps for patients and health-care providers exceeded 350,000 in 2021 [2]. For care providers, mHealth apps are a fast and effective way to improve communication between patients and interdisciplinary teams. They also enable more accurate data collection at patients’ bedside, facilitate documentation, and increase the availability of care for people living in rural or remote areas [1]. The effectiveness and efficacy of mHealth apps must be guaranteed to optimize the use of this limitless resource, improve user experience, and benefit from the subsequent reduction in healthcare system costs [3].

Ensuring the usability of mHealth apps is an important step in their development and evaluation. However, literature indicates a lack of evidence regarding the quality of mHealth apps and no legal framework at the national policy level [4,5]. In mHealth, usability refers to the ease and efficiency with which users will use a tool to satisfactorily accomplish a specific task [6]. This includes aspects such as ease of use, operability, clarity of instructions, risk of errors and possibility of correcting them, and user-friendliness of the interface [7].

Currently, several questionnaires are available for evaluating mobile apps. The Mobile Application Rating Scale (MARS) and the user version of MARS for evaluating the quality of mHealth apps in the broadest sense are among the most widely used measures [8,9]. A systematic review, including 87 studies published between 2000 and 2018 [10], highlighted that the usability scales used to evaluate mHealth apps were all initially created to obtain the perspective of developers and researchers. Questionnaires for assessing the usability of mHealth apps by different users have since been created but not yet validated. One of these questionnaires is the multidimensional App Quality Assessment Tool for Health-Related Apps that can be used by experts and users to quickly determine the quality of health-related and mental health-related apps [11]. The MHealth App Usability Questionnaire (MAUQ) is the only questionnaire specifically validated for stand-alone mHealth apps used by health care providers [12]. It is originally available in English, and MAUQ for stand-alone mHealth apps for patients was translated to Malay and validated by a Malaysian research team [13].

The Need for a Canadian French Questionnaire

It is well known that cultural differences can influence how participants respond to questions associated to the measurement tools owing to dissimilarities in language and social and professional norms [14]. Therefore, cultural bias can creep into study results and influence their interpretation [15]. Ensuring the translation, cross-cultural adaptation, and validation of measurement tools beforehand is a recognized process for minimizing this bias and ensuring the validity of study results [16,17]. With 321 million speakers, French is the fifth most spoken language in the world [18]. As a member state of Francophonie, Canada has a vast territory that is rich in linguistic diversity. Spanning 5514 km between the Pacific and Atlantic oceans, Canada has 2 official languages: English and French. The proportion of Canadians with French as their mother tongue is 20.9% [19], and the number of French-speaking researchers is 63,455 [20]. Although both languages are spoken across the country, French remains as the majority language in the province of Quebec, which accounts for 85.5% of Canadians with French as their mother tongue [19]. Francophone Canadian researchers are also interested in the contribution of mobile technologies to health but have access to very few reliable and valid instruments in French. Clearly, the lack of valid measurement tools in French affects the ability to study this population [20]. This puts francophone health care providers at a disadvantage, as they are often left out of studies available exclusively to anglophone participants. Thus, their experiences are less represented in literature [21].

Currently, there are only few measurement tools available in French such as MARS [22] or Unified Theory of Acceptance and Use of Technology 2 [23,24]. So far, there is no French version of MAUQ. Consequently, there is a necessity for a measurement tool that is translated, cross-culturally adapted, and validated for use with Canadian French health care providers.

This study was the first of 2 phases of a methodological study. The aims of the first phase were the Canadian French translation and cross-cultural adaptation of MAUQ and the initiation of its validation to allow Canadian French health care providers to eventually evaluate the usability of mHealth apps.

Methods

This paper has described the Canadian French translation, cross-cultural adaptation, and validation of the original version of MAUQ. The second step in the assessment of the psychometric properties of the translated version will be described in a later publication.

Instrument

The original version of MAUQ was developed to quantitatively measure the usability of mHealth apps by patients and health care providers regarding ease of use, interface design, user satisfaction, and usefulness, before their launch to the general public [12]. Originally in English, MAUQ was created and validated by health informatics professor Leming Zhou and his colleagues at the University of Pittsburgh [12]. The authors point out that there are no licensing fees for using the questionnaire, and it is not necessary to request permission before using it. The questionnaire is freely accessible on the website [25] and is available in 4 versions, according to app type (interactive or stand-alone) and target population (patients or health care providers). This study was conducted using MAUQ for stand-alone mHealth apps used by health care providers.
MAUQ for stand-alone mHealth apps used by health care providers consists of a short guideline for completing the questionnaire, followed by 18 statements and an open question for comments. The statements address 3 domains: ease of use (questions 1-5), interface and satisfaction (questions 6-12), and usefulness of the mobile app (questions 13-18). The statements were developed based on a systematic literature review of 312 unique questionnaire statements from 38 questionnaires. People completing MAUQ are asked to rate their level of agreement on a Likert scale ranging from 1 (disagree) to 7 (agree). App usability is determined by the total average of all scored items for each participant: the higher the average, the better the app’s usability. It is also possible to evaluate the responses to each item to assess a specific component of usability and compare the averages.

The validity study conducted by MAUQ authors used only the 2 patient versions [12]. The authors report that the differences between the patient and health care provider versions are negligible. Initially conducted with 128 participants from the University of Pittsburgh’s academic community, the validity study of MAUQ designed for stand-alone mHealth apps demonstrated strong internal reliability, with an overall Cronbach α value of .914 for the entire questionnaire and .847, .908, and .717 for ease of use, interface and satisfaction, and usefulness, respectively [12].

**Translation, Adaptation, and Validation Processes**

The accepted method of instrument translation and cultural adaptation suggested by Sousa and Rojjanasrirat [17] was retained for this study (Table 1). This 7-step sequential method incorporates the recommendations of the most established methodological approaches in a clear and detailed guideline. Moreover, it aims to provide a symmetrical translation, which is the most recommended because it remains true to the intended meaning and linguistic expression in equal measure between the 2 languages (that of the source instrument and the target instrument) [17,26,27]. Ultimately, the objective of this method was to achieve equivalence between the original and translated versions of the questionnaire. The cross-cultural equivalence is broken down by Flaherty et al [28] into 5 mutually exclusive equivalences of semantic, technical, conceptual, content, and criterion origin (defined in Textbox 1).

<td>• The interpretation of the measurement of each variable and of the results is the same when compared between the 2 cultures.</td>
<td>• The theoretical constructs evaluated and the concepts used are the same in both cultures.</td>
</tr>
</tbody>
</table>

Step 1
Step 1 consisted of the independent and anonymous forward translation of the original MAUQ from English to French by 2 professional translators with French as their mother tongue. One of the 2 translators was familiar with digital health terminology, and the other was familiar with the cultural and linguistic nuances of French.

Step 2
In step 2, a comparison of the 2 translated versions with the original was performed by a team comprising the 2 translators, a nurse (JG; member of the research team), and a third-party translator to assess the degree of equivalence of the translation. Ambiguities and differences between words, phrases, grammar, and meanings were discussed in a virtual meeting to reach consensus regarding the first version of the translated MAUQ.

Step 3
Step 3 involved the independent and anonymous back translation of the translated version to English by 2 other certified translators with English as their mother tongue and no previous knowledge about the original MAUQ. They had to consider the French version as the original.

Step 4
In step 4, a committee (n=6) compared these 2 back-translated versions with the original MAUQ version to assess the degree of equivalence of the back translations. This committee, which included all 4 bilingual and bicultural translators who worked in steps 1 and 3, a nurse (JG; member of the research team), and a health care provider (an experienced acute care nurse), was formed to discuss ambiguities and differences between words, phrases, grammar, and meanings. Consensus for each of the statements was established during a virtual meeting, ensuring consistency and clarity of formulation according to the Canadian French language and culture. The prefinal version of the translated and adapted questionnaire was consolidated and named MAUQ en français (MAUQ-FR).

At each of these first 4 steps, 1 of the 2 certified translators was familiar with digital health terminology, ensuring that the constructs of the tool were understood. All the involved individuals were bilingual experts.

Step 5
Step 5 consisted of pilot-testing MAUQ-FR with target users and a panel of unilingual experts. For the target population, Sousa and Rojjanasrirat [17] define participants as people whose language is the target language of the instrument and who should be recruited from the target population in which the instrument will be used. A group of 49 registered nurses with French as their mother tongue completed a 5-minute SurveyMonkey (Symphony Technology Group) questionnaire asking them to rate the clarity of the instructions and each translated MAUQ statement dichotomously (clear or unclear) [17,29]. If they selected unclear, a textbox appeared, so that they could indicate how to rewrite the statement to make it clear. Recruitment with voluntary sampling was conducted among graduate nurses from a Quebec university.

The same approach was used with an expert panel, in addition to rating the relevance of each statement regarding their experience with Canadian health care. To achieve this, a Likert scale ranging from 1 (not relevant) to 4 (very relevant) was used to avoid a neutral position [30,31]. Sousa and Rojjanasrirat [17] indicate that the panel should consist of experts “who are knowledgeable about the content areas of the construct of the instrument and the target population in which the instrument will be used and whose mother language is the target language of the instrument.” A search was conducted across Canada to find experts who are using mobile technology at work and with French as their mother tongue. Following the target number of 6 to 10 experts [30,32], the 10 people who assessed content validity were 2 (20%) professors in nursing, 1 (10%) person in public health who works on the evaluation of information and communication technologies and its specific terminology, 3 (30%) doctoral candidates and professors in nursing, 1 (10%) physician and clinical professor in medicine, 1 (10%) mobile app developer, and 2 (20%) health-related practitioners who use mHealth (1 nurse manager and 1 medical specialist). Experts were recruited from the Canadian provinces of Manitoba, Ontario, Quebec, and New Brunswick through networking.
(colleagues and contacts). Participation in this study was entirely voluntary.

As recommended by Sousa and Rojjanasrirat [17], this first study only covered steps 1 to 5. Steps 6 and 7 involving the evaluation of the psychometric properties (Cronbach α) and the measurement of the internal consistency reliability (Lin concordance correlation coefficient) of MAUQ-FR with a bilingual, French-English sample (target n=90) and the target population (target n=180) will be conducted in 2 subsequent studies.

**Analyses for the Validation of the Instrument**

The quantitative data obtained during the pilot test were extracted directly from the SurveyMonkey website and analyzed using descriptive statistics presented as frequencies and percentages, including interrater agreement. The minimum interrater agreement was set at 80% [17]. The research team revised and reevaluated the statements rated as unclear by at least 20% (2/10) of the sample, in addition to considering all feedback obtained from unclear responses to improve MAUQ-FR.

Data collected from the expert panel made it possible to assess content validity with the content validity index (CVI); CVI at item level (I-CVI) and CVI at scale level (S-CVI). Relevance scores were previously dichotomized: scores of 1 and 2 were coded as 0 (not relevant) and scores of 3 and 4 were coded as 1 (relevant) [30]. With 10 experts, the minimum thresholds to reach were at least 0.79 for I-CVI [30] and at least 0.80 for the averaging calculation at S-CVI [32,33]. Considered as the average of the proportion of items deemed relevant across the various judges, S-CVI was calculated by adding I-CVIs and dividing by the number of items [33].

Members of the research team considered and discussed the statements with a relevance score of 1 (not relevant) or 2 (unable to assess relevance). Items that failed to meet the previously indicated I-CVI thresholds were revised and reevaluated by the expert panel. New validity indices were then calculated until acceptable I-CVIs were reached. The modified κ coefficient of agreement (Fleiss multirater κ) was also calculated to determine interrater agreement among experts [34,35]. A κ of 0.60 is considered as the minimum acceptable coefficient to determine good agreement, whereas a value ≥0.75 is considered as excellent [34,36]. All statistical analyses were performed using Microsoft Excel.

**Step 5: Pilot Test (Target Population)**

For face validation, the French-speaking registered nurses (n=49) considered the statements to be clear, with interrater agreement of 99.14% (Table 3). In total, 5 comments were collected and considered to improve the questionnaire. This pilot test provided additional support for conceptual equivalence.
(clarity) and content equivalence (relevance) in the Canadian French cultural context.

<sup>a</sup>Interrater agreement within the target population=99.14.

<sup>b</sup>Interrater agreement among round-1 experts=90.

<sup>c</sup>Interrater agreement among round-2 experts=93.

<sup>d</sup>N/A: not applicable.

**Step 5: Expert Panel**

The experts (n=10) considered the statements to be clear, with interrater agreement of 90% (Table 3). The 5 statements that did not exceed 80% interrater agreement were revised by the research team and reevaluated by the expert panel (9/10, 90%) to achieve content-related validity. Interrater agreement for the modified statements was 93%.

I-CVI for each statement ranged from 0.90 to 1, and S-CVI was 0.981 (Table 4). Individual Fleiss multirater κ for each item ranged from 0.89 to 1, increasing confidence in the questionnaire’s content validity [35]. There were 32 comments, which improved the accuracy of the statements.

Step 5 helped to reinforce the conceptual, semantic, and content equivalence and prepare a translated and adapted version. The sample sizes required were achieved and even exceeded for the pilot test with the target population.

In short, all the items and the title, instructions, and conclusion met the thresholds for psychometric testing. The example in Table 5 illustrates the entire process of steps 1 to 5.

Discussion

Principal Findings

This study made it possible to translate, cross-culturally adapt, and initiate the validation of the original, English MAUQ in Canadian French. Study results indicate that MAUQ-FR has high content validity. CVI is high for all individual items (>0.90) and for the overall scale (0.981), exceeding the minimum thresholds of 0.79 and 0.80, respectively [30,32]. These results are comparable with I-CVIs of the version translated to Malay, which varied between 0.9 and 1, and the overall S-CVI of 0.983 [13]. It is important to distinguish between item-level (I-CVI) and scale-level (S-CVI) content validity as it helps to identify specific elements of the scale that do not effectively measure the desired construct. The $\kappa$ statistic showed excellent interexpert agreement. These results suggest that MAUQ-FR has been accurately translated and adapted for future francophone users in Canada.

A renowned, systematic method was used to ensure linguistic and cultural equivalence [28,29,37]. The guideline by Sousa and Rojjanasrirat [17] for achieving the objectives provided a clear and precise approach. Translation and cross-cultural adaptation studies must follow a rigorous process, as instruments simply translated from one language to another may lose their validity and no longer measure what they intended to measure, in addition to jeopardizing safety and research ethics [38].
Sperber [39] points out in his methodological paper, the translation, cross-cultural adaptation, and validation processes are often treated as afterthoughts in research protocols. Forward translation by uncertified translators is also a commonly used methodological approach [17]. Nevertheless, it is not only essential to translate words in the literary sense but they must, most importantly, also be closely related to the context [40]. This premise is especially critical here, considering that idiomatic expressions vary in each French-speaking region of the vast Canadian territory. Being aware of possible variations involving colloquialisms and jargon, the certified translators, consensus committee members, and experts involved in this study sought to use the most common and neutral vocabulary possible, while paying close attention to cultural nuances (hence the importance of involving translators who come from both cultures or who are bicultural). Beck et al [41] used the same qualitative approach for their cross-cultural study, in which the authors highlighted the need to go beyond the search for equivalence in the denotative meaning of words. Rather, there is a great need to grasp their meaning and connotation within the cultural context they are used. All things considered, the approach was a success, and the results were validated by the group of experts from different French-speaking regions of Canada.

Despite the methodological process, the adaptation of measuring instruments between 2 cultures rarely results in perfect transposition [28]. Some equivalences are more strongly achieved than others. In this study, combining the expertise of translators, researchers, IT specialists, and health care providers favorably contributed to the thorough evaluation of semantic and conceptual equivalences [42]. Choosing qualified and certified translators and having a second independent team for back translation enabled the development of a high-quality instrument by minimizing idiosyncratic bias. Moreover, back translation has long been recognized as a key method for achieving semantic equivalence by ensuring that the translation matches the characteristics of the original instrument [26]. It also allowed the research team to verify the quality of the translation by comparing the 2 English versions of MAUQ (the original and retranslated versions). Few errors were found, attesting to the quality of the previously completed translation and consensus work.

The sequential form of the study allowed for the progressive improvement of MAUQ-FR by identifying ambiguities or terminological imprecision that had not been raised by the translation team. For example, the translation of the item, “The navigation was consistent when moving between screens,” did not exceed the 80% threshold of agreement between the experts, highlighting a lack of clarity in the translated version. Corrections were made by the research team based, among other things, on the feedback received. I-CVI of the revised version of this item finally reached 100%, ensuring conceptual equivalence. An essential element in the process was the outstanding collaboration with the principal author of the original questionnaire, which enabled fluid communication and clarification of the original meaning of certain items. Finally, the equivalences were deemed to have been satisfactorily achieved, making it possible to proceed to the evaluation of the psychometric properties of MAUQ-FR.

Once the cross-cultural validation process is completed, it will be possible to use MAUQ-FR in a comparable way in different cultures while ensuring data comparability. This will ultimately make it possible to distinguish significant differences between cultures. MAUQ-FR will enable even unilingual anglophone researchers to collect data from francophone Canadians, a population that is currently understudied [20]. Given that French is the world’s fifth most spoken language [18], MAUQ’s French translation can help to create opportunities for other cultural adaptations.

**Limitations**

This study has its limitations. First, the sociodemographic data of the participants were not collected, as they are not required by the chosen method [17]. However, this prevents certain factors from being considered during the validation process, such as professional experience, age, sex, and gender.

Another limitation is that the pilot test in the target population was conducted exclusively by nurses, whereas the questionnaire could be used by other health care providers. This excluded other potential participants, such as physicians, physiotherapists, respiratory therapists, and other health care providers. In addition, the target population sample was drawn from a university in Quebec (Canada), the province with the largest number of French speakers in the country [19]. These constraints make it impossible to generalize the results to all French-Canadian health care providers. The same applies to the experts surveyed. Although they come from different Canadian provinces, it would be essential to eventually include participants from other French-speaking minority regions such as the Yukon Territory and British Columbia [19]. In addition, the recruitment of experts through networking may have induced a selection bias within the panel. The participants selected were nonetheless representative of the majority of mHealth app users and able to provide a reliable evaluation of the questionnaire.

Although the pilot test allowed for the assessment of conceptual equivalence, question comprehension, and content validity, it does not guarantee construct validity, internal consistency reliability, or fidelity [17,29]. Additional studies must be conducted with full psychometric testing of a large sample of health care providers to establish Cronbach α, internal consistency reliability (Lin concordance correlation coefficient), stability reliability (test-retest), homogeneity, construct-related validity with scale and item analysis, Pearson correlations, and exploratory and confirmatory factor analysis.

**Conclusions**

In summary, this study is based on the domains of equivalence by Flaherty et al [28] and was conducted in accordance with the methodology by Sousa and Rojjanasrirat [17] to achieve the translation from English to Canadian French, cross-cultural adaptation, and initiation of the validation of MAUQ. Initial tests performed with MAUQ-FR show excellent validity. As part of a doctoral research project, this adaptation was necessary to meet the specific circumstances of the population to be studied, and to ensure the methodological rigor of future studies.
Finally, this study was the first phase of a methodological study and will enable the continuation of work with the psychometric evaluation of MAUQ-FR. The data collected will be shared with the authors of the original MAUQ to undertake further analyses and improve the use of the questionnaire.

Acknowledgments
The authors would like to thank Dr Leming Zhou for granting the permission to translate the mHealth App Usability Questionnaire from English to French. The authors would also like to thank all the participants and experts involved in this study. Finally, the authors would like to thank Lucie Charbonneau, research officer at Université du Québec, for her feedback following the expert panel’s modifications. This study is a part of a PhD project funded by the Canadian Institutes of Health Research Doctoral Research Award (202111FBD-476880-67262), Fonds de recherche du Québec Santé (2022-2023-BF2-319284), and University of Ottawa.

Abstract

Background: Approximately 60% of US adults live with chronic disease, imposing a significant burden on patients and the health care system. With the rise of telehealth, patient-reported outcomes measures (PROMs) have emerged as pivotal tools for managing chronic disease. While numerous PROMs exist, few have been designed explicitly for telehealth settings. The Parsley Symptom Index (PSI) is an electronic patient-reported outcome measure (ePROM) developed specifically for telehealth environments.

Objective: Our aim is to determine whether the PSI predicts changes in the established Patient-Reported Outcomes Measurement Information System-10 (PROMIS-10) Global Health, a 10-question short form.

Methods: We conducted a retrospective cohort study using data from 367 unique patients, amassing 1170 observations between August 30, 2017, and January 30, 2023. Patients completed the PSI and the PROMIS-10 multiple times throughout the study period. Using univariate regression models, we assess the predictive criterion validity of the PSI against PROMIS-10 scores.

Results: This study revealed significant relationships between the PSI and PROMIS-10 physical and mental health scores through comprehensive univariate analyses, thus establishing support for the criterion validity of the PSI. These analyses highlighted the PSI’s potential as an insightful tool for understanding and predicting both mental and physical health dimensions.

Conclusions: Our findings emphasize the importance of the PSI in capturing the nuanced interactions between symptomatology and health outcomes. These insights reinforce the value of the PSI in clinical contexts and support its potential as a versatile tool in both research and practice.

Introduction

Approximately 60% of US adults live with one or more chronic diseases [1]. Due to the growing population of adults aged 65 years or older and increased risk factors, chronic disease is expected to impact over 221 million people in the United States by 2050 [2]. Developing tools and strategies to promote health is increasingly important as a way to alleviate the enormous burden that chronic disease places on patients, providers, and health care systems [3]. Compared with people without chronic disease, people with chronic conditions have higher health care costs and require more time to manage their care than primary care providers have available [4]. Many new care models, such as the Chronic Care Model, have been implemented [5-7] to overcome these challenges; however, more work is needed to increase access to effective chronic disease care that reduces resource constraints and improves patients’ health.

Emerging telehealth tools, which have become increasingly popular and widespread since the COVID-19 pandemic [8], are proving capable of creating meaningful changes in chronic disease management [9]. Care provided through telehealth has been shown to alleviate many of the burdens of chronic diseases, such as lowering health care costs, reducing missed appointments, and increasing access to timely care [10]. Telehealth tools have also been shown to encourage collaborative disease management, incentivizing patients to participate in their care [11,12].

Patient-reported outcomes measures (PROMs) are patient-oriented, self-reporting tools that can be implemented in a range of settings to improve care processes and track outcomes [13]. PROMs have been found to help facilitate patient- clinician communication [14] and save valuable time and resources for both patients and providers [15], making them a crucial tool in chronic disease management.

Several powerful PROMS exist to capture patients’ perceptions of their health and well-being, such as the Patient Reported Outcomes Measurement Information System (PROMIS) [16,17], the 36-Item Short Form Health Survey [18,19], and the Medical Symptom Toxicity Questionnaire [20]. However, few validated PROMS were designed for telehealth settings first, as opposed to paper and pen PROMs retrofitted for a telehealth environment.

In response to a need for a validated, digital-first electronic patient-reported outcome measure (ePROM), Parsley Health—a subscription-based, holistic medical practice—designed the Parsley Symptom Index (PSI) [21]. To our knowledge, the PSI is the only multi-item ePROM designed for and within a telehealth environment with internal validity. The Medical Symptom Toxicity Questionnaire, a conceptually similar functional medicine tool created over 20 years ago, was initially paper-based and has yet to be validated.

In previous validation studies, the use of the PSI in clinical practice was found to be feasible and acceptable to patients and clinicians [21,22]. The PSI also demonstrated internal validity when compared with the single-rated health (SRH) item for adults with chronic disease in a telehealth setting [22]. While there was a moderate level of association and agreement between the PSI and the SRH and the 2 instruments had conceptual similarities, the PSI captured additional granular changes in symptoms with treatment over time compared to the SRH measure, which remained relatively static [22]. This difference was expected, as the PSI is a 45-item ePROM and the SRH is a single question with a 5-item Likert scale response. As such, there is a need to compare it to a PROM that is closer in design and concept to the PSI, as well as to externally validate the PSI to determine its generalizability for use with different patient populations with chronic disease [23].

The primary objective of this study was to assess the criterion validity of the PSI against a validated, conceptually aligned, multi-item PROM (ie, the Patient-Reported Outcomes Measurement Information System-10 [PROMIS-10] Global Health, a 10-question short form) [16,17]. We aimed to ascertain whether the PSI could predict alterations in the widely accepted PROMIS-10 tool.

Methods

Ethical Considerations

This study used patient-reported survey data that were recorded so that participants were unidentifiable to the researchers. The institutional review board at Stony Brook University considered this study exempt (IRB2020-00429) from the Code of Federal Regulations Title 45 requirements.

Study Design

This retrospective cohort study took place at the “Family to Family” medical clinic in the Southeast region of the United States between August 30, 2017, and January 30, 2023, among a sample of 367 participants with a range of chronic diseases. Additionally, for the purpose of PSI to PROMIS T-score calibration, an independent data set consisting of 122,591 assessments from 29,353 customers of Parsley Health was used to establish the PSI T-score conversion table detailed in Multimedia Appendix 1.

The PSI

The PSI is a 45-item ePROM, similar to a Review of Symptoms, focusing on bodily domains and the most commonly reported symptoms associated with chronic diseases for each domain. The PSI assesses a patient’s perception of symptom burden. The PSI was developed using the Federal Drug Agency’s guidance for PROM development [24]. Items are grouped into 9 systems and ranked on a scale from 0 (asymptomatic) to 10 (extremely symptomatic). A total score is calculated with the following 4 cutoff ranges: “well” (0-24), “symptomatic” (25-43), “very symptomatic” (44-71), and “sick” (≥71). The PSI has shown clinical validity for use in clinical practice [22].

The PROMIS-10

The PROMIS-10 is a single, generalizable, and validated PROM that can be used for various diseases and conditions. It is a shortened version of PROMIS that was developed to minimize respondent burden. This version is a 10-item, patient-reported questionnaire that was created as a general health assessment tool. Nine out of 10 questions on the PROMIS-10 are answered...
using a 5-point Likert scale, with the tenth question answered using a numeric rating scale. Results can be tracked in three different ways: (1) answers to each of the 10 questions can be evaluated separately, (2) answers can be grouped together to provide a global summary score, or (3) answers can be split into 2 groups to provide a global physical health score and a global mental health score.

We compared the PSI to the PROMIS-10, as it is similar to other general health short-form surveys and is widely adopted due to its ease of use. The PROMIS-10 has been shown to be valid and reliable in clinical settings for patients from the general population [16] and those living with chronic diseases [25,26]. Similar to its more extensive counterpart, the PROMIS-10 has undergone rigorous testing and validation across diverse age groups, including younger and older adults [27,28], and has proven to be reliable across a variety of clinical populations [29-31].

Study Setting and Population

Family to Family is a hybrid (remote and in-person) functional and holistic medicine clinic for adults and children located in the Asheville, North Carolina, metropolitan area. The average patient age was 53.7 years old, and patients predominantly identified as female (73%). While race data were not available, the 2 clinicians at this practice report that their patients are predominantly White.

Procedure

Patients and their caregivers were prompted to complete both the PSI and the PROMIS-10 through a password-protected electronic medical record web-based portal before each clinical visit. The PSI was added as a PROM to complete along with the PROMIS-10 because the clinicians believed it provided different insight as a Review of Symptoms to capture a more comprehensive view of patients’ symptomatology and progress over time.

Patients were required to complete the PSI and PROMIS before their first clinical visit. If both ePROMs were not completed before a patient’s first clinical visit at Family to Family, the visit was postponed or rescheduled. For all subsequent visits, completing the ePROMs was optional but encouraged. Participants were not compensated for completing the ePROMs. When preparing for the patient’s visit, Family to Family clinicians could view responses to both ePROMs in a patient’s electronic health record and use these responses to guide a clinical encounter.Clinicians were able to ask targeted questions about a patient’s symptoms and identify triggers that might contribute to the symptoms.

Data Analysis Software

The data analyses were conducted using Python (version 3.10; Python Software Foundation) [32].

Statistical Methods

We conducted an analysis to explore the relationship between the PSI and the PROMIS-10. Initially, the raw scores of the PSI and the PROMIS-10 were transformed into T-scores [33,34]. The approach for PSI T-score conversion is detailed in Multimedia Appendix 1. Following T-score conversions, the underlying distribution characteristics of PSI T-scores, PROMIS physical T-scores, and PROMIS mental T-scores were evaluated for normality and distribution. D’Agostino and Pearson normality test were applied to each set of scores to assess the normality. Measures of skewness and kurtosis were calculated for each set of scores to provide insights into the distribution’s symmetry. Histograms with overlaid box plots were created for each set of scores to visually inspect their distributions.

Univariate Regressions

We performed 2 univariate regression models to assess the predictive criterion validity of the PSI T-scores on the PROMIS physical and mental T-scores. Due to the observed nonnormal distribution of the PSI T-scores ($\chi^2_{1166}=183.324; P<.001$), generalized linear models with a Gaussian family and identity link function were chosen as the appropriate modeling approach. This choice accommodates the nonnormal distribution of the PSI T-scores by allowing for a linear relationship between the predictors and response without assuming that the residuals are normally distributed. The flexibility in the Gaussian family made it suitable for modeling the specific distributional properties of the PSI T-scores.

Our first univariate model examined the relationship between PSI T-scores (an independent variable) and PROMIS mental T-scores (a dependent variable), aiming to understand how the PSI is predictive of mental health as quantified by the PROMIS scale. The second univariate model focused on the relationship between PSI T-scores (an independent variable) and PROMIS physical T-scores (a dependent variable), aiming to understand how the PSI is predictive of physical health as quantified by the PROMIS scale. This approach provides insights into the effects of PSI on mental and physical health that are robust to distributional assumptions. Coefficients, SEs, and significance levels were reported to highlight the specific relationships.

Tables

Pivot tables were used to summarize the mean (SD) of the PSI T-scores, PROMIS physical T-scores, and PROMIS mental T-scores. The data were stratified by time order, reflecting different periods of assessment. Multiple pivot tables were generated to encapsulate the mean (SD) for each measurement, organized by the time period.

Results

Overview

In our data set, we analyzed a total of 1170 observations from 367 unique patients recorded between August 30, 2017, and January 30, 2023, from Family to Family. On average, participants completed the PSI 3.2 times and the PROMIS 3.4 times during the study period. Adhering to the guidelines for good reporting practices, the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) [35] is included in Multimedia Appendix 2. Detailed patient demographics and general descriptions of the sample are delineated in Table 1. On average, participants reported experiencing 8 distinct symptoms or conditions. Excluding nutrient deficiencies, the most commonly reported diseases and health problems, as classified...
by International Statistical Classification of Diseases, Tenth Revision (ICD-10) codes, were other fatigue (82/367, 22.3%), anxiety disorder (81/367, 22.1%), hypothyroidism (81/367, 22.1%), and chronic fatigue (65/367, 17.7%), as outlined in Table 2.

The mean value for the PSI T-score is 40.808 (SD 7.00), with a minimum and maximum range of values between 25 and 56, indicating a broad spectrum of reported symptom states within the sample. Since the expected average for a typical population is 50, this lower mean suggests that the sample population exhibits a higher level of symptoms or less optimal health than the general population. The mean value for the PROMIS physical score is 47.952 (SD 8.114), which is slightly below the expected average of 50. This result also implies that the physical health of the sample population is somewhat below average. The minimum and maximum values for the physical T-scores range from 19.9 to 67.7, indicating a broad spectrum of physical health states within the sample. The mean value for the PROMIS mental score is 46.638 (SD 8.551), which is also below the expected average of 50. This suggests that the mental health of the sample population is also somewhat lower compared to the general population. The PROMIS mental ranges from a minimum of 21.2 to a maximum of 67.6, further indicating variation in mental health states within the sample. Additional descriptives for PSI and PROMIS T-scores across time are provided in Table 3.

\(^a\)PSI: Parsley Symptom Index.

\(^b\)PROMIS: Patient-Reported Outcomes Measurement Information System.

\(^c\)Of the 367 unique participants, 5 were excluded from time point 1 due to corrupted data files for the PSI or PROMIS assessments. This resulted in a sample size of 362 for the initial time point.

Distributions And Normality

The distribution characteristics of the PSI and PROMIS T-scores were assessed for normality. The PSI T-scores were found to follow a non-normal distribution ($\chi^2_{1169}=183.324; P<.001$). The skewness of 0.577 in the PSI T-scores indicates a distribution with a longer right tail and a concentration of scores on the left, reflecting a higher frequency of lower scores and thus a less healthy population. The negative kurtosis of –0.858 signifies a platykurtic kurtosis and that extreme outliers (very high or low) are less frequent in this data set than they would be in a normally distributed data set. In contrast, the PROMIS physical and mental T-scores were found to follow a normal distribution ($P=.10$ and $P=.46$), with a minor skewness of –0.145 and a kurtosis of 0.100 for the physical, while an almost perfect skewness of –0.015 and a slight platykurtic kurtosis of –0.173 for the mental.

Univariate Regressions

Model 1: PSI T-Scores Predicting PROMIS Mental T-Scores

The first generalized linear regression model was fit using the Gaussian family with an identity link function, revealing a significant positive association between the PSI T-scores and PROMIS mental T-scores (Table 4). Specifically, a 1-unit increase in the PSI T-score corresponded to a 0.627-unit increase in the PROMIS mental T-score (95% CI 0.567-0.687; $z=20.462; P<.001$). The intercept was estimated at 21.0487 (95% CI 18.562-23.536). The model’s pseudo $R^2$ value (CS) was 0.3008, indicating that it explained approximately 30.08% of the variability in the PROMIS mental T-scores. The deviance statistic, which measures the goodness of fit, was 62,925, and the Pearson chi-square value was approximately 62,900, further supporting the model’s fit to the data.

Model 2: PSI T-Scores Predicting PROMIS Physical T-Scores

The second generalized linear regression model was fit using the Gaussian family with an identity link function, revealing a significant positive association between the PSI T-scores and PROMIS physical T-scores (Table 4). Specifically, a 1-unit increase in the PSI T-score corresponded to a 0.6479 unit increase in the PROMIS physical T-score (95% CI 0.593-0.703; $z=23.064; P<.001$). The intercept was estimated at 21.0487 (95% CI 18.562-23.536). The model’s pseudo $R^2$ value (CS) was 0.3653, indicating that it explained approximately 36.53% of the variability in the PROMIS physical T-scores. The deviance statistic, which measures the goodness of fit, was 52,883, and the Pearson chi-square value was approximately 52,900, further supporting the model’s fit to the data.

Discussion

Overview

Previous studies found the PSI to be a valid tool that can be deployed, completed, and helpful to both patients and clinicians [21,22,36]. This study examined differences in use between the PSI as compared to the PROMIS-10 short form when used in clinical settings with patients with chronic disease. The PSI and PROMIS-10 were chosen for this retrospective study because the clinicians believed it was useful for patients to complete both forms as they provide slightly different insights into how patients perceive their health status. While the differences between the PSI and PROMIS-10 reveal ways that each has its place in clinical practice, they overlap enough to demonstrate a moderate correlation to support validation of the PSI when compared to the PROMIS-10.

The overall mean (SD) statistics for the PSI and PROMIS-10 paint a picture of a sample population that is generally less healthy than the average population, both in terms of physical and mental well-being, as well as symptomatology. The lower PSI score, in particular, stands out, indicating a higher level of symptoms. These findings set the stage for further analysis to understand the underlying factors, relationships, and potential interventions that may be relevant to this specific population.

Univariate Regression Analysis: Generalized Linear Model

The univariate generalized linear regression analyses conducted in this study used the Gaussian family with an identity link function to explore the relationship between the PSI T-scores and both mental and physical health as measured by the PROMIS scales. The consistency in the direction and significance of the relationships between the PSI across both mental and physical health domains defined by the PROMIS, as revealed in the univariate analyses, lends credibility to the models and provides a robust foundation for further exploration. The positive associations demonstrate the criterion validity of the PSI, illustrating its potential to predict changes in both mental and physical health as measured by the PROMIS scales. The substantial explanatory power of the models, as evidenced by the pseudo R² values and supported by the deviance statistics and Pearson chi-square values, adds to the robustness of the findings and their potential implications for the PSI as a validated health assessment. This validation underscores the use of the PSI and its capability of offering insights into overall well-being. Future research may benefit from examining these relationships in different populations or contexts, potentially extending the applicability of the PSI.

Limitations

This study bears several notable limitations. First, our data emanate from a single clinic where a significant majority of Family to Family participants identified as female (73%), with an average age of 53 years. Although race and ethnicity data were not available, the clinic reported that the patient population was predominantly White. Such skewness constrains the ecological validity of our findings.

Our sample size was not large enough to support a robust longitudinal analysis, thereby limiting the depth of insights we could derive. It is imperative for future validation studies to explore the PSI’s use within a more diverse demographic profile and over a more extended time frame. Such studies would not only deepen the understanding of symptom trajectories but also facilitate the evaluation of patient outcomes across a wider demographic landscape.

In terms of the PSI questionnaire itself, the Family to Family participants engaged with an earlier iteration. Based on patient feedback, Parsley Health implemented minor revisions to this version to enhance readability. Consequently, we made retrospective adjustments to ensure alignment with the updated version of the PSI, which encompassed an additional item but was more concise in terms of completion time since responses were no longer categorized as “resolved” or “ongoing.”

Additionally, the nature of this being a retrospective cohort study meant that the PSI and PROMIS-10 items were not presented to participants in a randomized manner, which could have potentially mitigated response biases. We advocate for the implementation of randomization, or A/B testing, in subsequent studies.

Conclusions

Although we know that telehealth tools can be used to deliver effective care to patients with chronic conditions, few—if any—tools exist that are designed as digital-first ePROMS. This predictive criterion study compared the PSI—a digital-first ePROM—to the PROMIS-10, a traditional PROM, in a functional medicine clinic for patients with a range of chronic conditions. This study revealed significant relationships between the PSI and PROMIS physical and mental health scores through comprehensive univariate analyses, thus establishing support for the criterion validity of the PSI. These analyses highlighted the PSI’s potential as an insightful tool for understanding and predicting both mental and physical health dimensions.

Overall, the findings of this study emphasize the importance of the PSI as a versatile clinical instrument. Future research is warranted to further dissect these relationships and enhance our understanding of the PSI’s applicability in various health contexts.

Abstract

Background: Globally, heart failure (HF) affects more than 64 million people, and attempts to reduce its social and economic burden are a public health priority. Interventions to support people with HF to self-manage have been shown to reduce hospitalizations, improve quality of life, and reduce mortality rates. Understanding how people self-manage is imperative to improve future interventions; however, most approaches to date, have used self-report methods to achieve this. Wearable cameras provide a unique tool to understand the lived experiences of people with HF and the daily activities they undertake, which could lead to more effective interventions. However, their potential for understanding chronic conditions such as HF is unclear.

Objective: This study aimed to determine the potential utility of wearable cameras to better understand the activities of daily living in people living with HF.

Methods: The “Seeing is Believing (SIB)” study involved 30 patients with HF who wore wearable cameras for a maximum of 30 days. We used the E-Myscéal web-based lifelog retrieval system to process and analyze the wearable camera image data set. Search terms for 7 daily activities (physical activity, gardening, shopping, screen time, drinking, eating, and medication intake) were developed and used for image retrieval. Sensitivity analysis was conducted to compare the number of images retrieved using different search terms. Temporal patterns in daily activities were examined, and differences before and after hospitalization were assessed.

Results: E-Myscéal exhibited sensitivity to specific search terms, leading to significant variations in the number of images retrieved for each activity. The highest number of images returned were related to eating and drinking, with fewer images for physical activity, screen time, and taking medication. The majority of captured activities occurred before midday. Notably, temporal differences in daily activity patterns were observed for participants hospitalized during this study. The number of medication images increased after hospital discharge, while screen time images decreased.

Conclusions: Wearable cameras offer valuable insights into daily activities and self-management in people living with HF. E-Myscéal efficiently retrieves relevant images, but search term sensitivity underscores the need for careful selection.

Introduction

Heart failure (HF) refers to when the heart does not work as well as it should in pumping blood and oxygen around the body [1]. HF is one of the most common chronic conditions, affecting 64 million people worldwide [2]. Despite advancements in medical treatment, people diagnosed with HF remain at an increased risk of hospitalization, hospital readmission, and
Understanding what behaviors people with HF engage in, and when, is important to understand how to support people with HF to better manage their condition. However, previous research has often relied on self-report methods to achieve this; self-report is subject to recall and social desirability biases, and memory impairment [8-11]. Digital technologies, such as wearable cameras, can provide valuable insights into health management behaviors, including contextual information such as location, time of day, and setting. Further, wearable cameras also offer a unique tool for researchers and health care providers to gain a better understanding of people’s lived experiences, which could lead to more tailored and effective interventions and treatments [12].

However, using wearable cameras generates large data sets, requiring the retrieval, processing, and analysis of relevant images for practical utility. This involves assigning semantic contexts like visual descriptions, time, and location [13,14]. Various computer vision models are employed, such as object detection, activity recognition, and optical character recognition, in addition to embedding models [13,15-17]. Retrieval systems incorporate techniques such as query enhancement, visual similarity search, and temporal search [13,16]. Previous studies [18-20], including our own [21], have manually reviewed camera images, which is time-consuming. In this study, we used the E-Myscéal system [22] for efficient retrieval and review of relevant images depicting the daily activities of people living with HF.

Daily activities significantly impact the health and well-being of people with HF, and a balanced approach to activities such as physical activity, screen time, eating, drinking, and medication intake is crucial for effective symptom management and improved quality of life [23-25]. Thus, the overall aim of this study was to determine the utility of wearable cameras to better understand activities of daily living (ADLs) in people living with HF. This study focused on 7 daily activities: physical activity, gardening, shopping, screen time, drinking, eating, and medication intake behaviors. This study also aimed to evaluate the sensitivity of an image-processing software tool for identifying these activities.

Methods

Study Design

The Seeing is Believing (SIB) study was a large prospective observational pilot study that evaluated the feasibility and acceptability of using wearable cameras and point-of-care testing for self-care in patients with HF [21,26]. As a pilot study, no formal power calculations were performed to determine the optimum sample size. It involved 30 patients with HF in Melbourne, Victoria, Australia, who wore wearable cameras for a month and conducted regular self-assessments. However, in this study, we analyzed the wearable camera image data.

Study Population, Recruitment, and Setting

Participants, aged 18 years or older, were recruited from a single-center HF outpatient clinic in Melbourne if they had a documented HF diagnosis, had previous HF hospitalization, were on maximum tolerated medication, and were able to read and understand English. Exclusion criteria included severe HF symptoms (New York Heart Association class IV), advanced malignancy, cognitive impairment, and end-of-life care. Recruitment occurred during outpatient HF clinic visits by a cardiologist or researcher, followed by screening for eligibility by a Deakin University researcher. Eligible individuals underwent a baseline assessment and provided written consent.

Study Procedures

Participants were asked to attach the “Narrative Clip” wearable camera to their shirt or blouse during waking hours for a maximum of 30 days. The camera captured images every 30 seconds, resulting in a data set of approximately 2.2 million images. Baseline assessment included medical history, demographics, and physical measurements. A research assistant collected point-of-care test data, hospitalization information, and other variables twice a week during the 30-day study [26]. At the end of this study, participants underwent a brief interview about their camera usage experience. In the original SIB study, 10 individuals were hospitalized [26].

Wearable Camera Image-Processing and Retrieval

The wearable camera image data were processed and retrieved using the E-Myscéal web-based lifelog retrieval system. The E-Myscéal system uses deep learning algorithms to create embeddings (vector representations) of various lifelog data types such as images, text, and audio, enabling intuitive and web-based cross-media querying [22]. E-Myscéal uses the CLIP model to retrieve images similar in content to descriptive textual search terms, allowing users to search through lifelog data with great flexibility [27]. E-Myscéal was ranked as the top retrieval system at the Lifelog Search Challenge (LSC’22 challenge), outperforming others in terms of finding the highest number of relevant items in the shortest time across various retrieval tasks [28].

With E-Myscéal, users can enter any search terms, leading to a list of related images along with date or time and location metadata [22]. For instance, when “eating” was used as a search term, E-Myscéal retrieved all food-related camera images, enabling researchers to assess the frequency of the wearer’s...
Before applying the E-Myscéal system to our wearable camera data, we evaluated its capability to detect ADLs using a publicly available data set [29]. The results indicated a high precision in detecting ADLs such as physical activity, screen time, and shopping, with precision ranging from 0.8 to 1.0 [28]. Given these results, we decided to use the system with our data set. Detailed information on how E-Myscéal determined image counts can be found in Multimedia Appendix 1.

Figure 1. E-Myscéal user interface and event view window. Cam: camera.

Search Terms
Wearable camera images from the SIB study were uploaded to the E-Myscéal system [22]. Based on expert knowledge we developed search terms for each of the 7 daily activities (physical activity, gardening, shopping, screen time, drinking, eating, and taking medication), which were entered into E-Myscéal. Different search terms were used for each activity to identify the most appropriate ones for use. For example, for physical activity, search terms included “running,” “walking,” “yoga,” or “exercise,” which are common terms used to describe physical activity. Similarly, for gardening, search terms included “horticulture,” “cultivation,” “planting,” or “watering,” which are commonly used terms in gardening. This study assessed the relevance of search terms for each activity by analyzing the number and relevance of images returned.

Data Analysis
We performed a sensitivity analysis using the Wilcoxon test to evaluate E-Myscéal’s effectiveness in retrieving relevant images with different search terms. The analysis involved comparing the number of images retrieved for 7 daily activities, both with and without outliers. For each activity, we tested the following search terms: physical activity (physical activity vs exercise), gardening (gardening vs horticulture), shopping (shopping vs retail therapy), screen time (screen time vs screen viewing), taking medication (taking medication vs medication intake), eating (food intake vs food consumption), and drinking (fluid intake vs hydrating). We assessed the normality assumption of each search term using the Shapiro-Wilk test and then used the Wilcoxon test to examine significant differences in the number of images retrieved for both searches (with and without outliers).

Following the sensitivity analysis, descriptive statistics were performed for ADLs using the most sensitive search terms. The results are presented in tables and figure. Furthermore, we used the Wilcoxon test to determine if there were significant temporal differences in daily activity patterns (ie, before and after midday). Further, we examined the ADLs of the 10 participants who were hospitalized during the 30-day study period. We compared their ADLs before they were admitted to the hospital and after they were discharged and returned home.

Ethical Considerations
Ethical approval was granted by the Deakin University Human Research Ethics Committee (HREC/16/MH/55) and the Western Health Human Research Ethics Committee (2016.071). Participants were provided with study information through an information sheet and verbal explanation, with the option to withdraw at any time while retaining data collected to that point. All participants had an opportunity to ask questions about this study before they gave written informed consent. Participants could delete images from their wearable camera during this study. Upon completion, participants received an Aus $40 (US $28) voucher.

Results
Characteristics of Study Participants
In total, 30 adults (18 men) with HF agreed to participate and wore the wearable camera for up to 30 days. The median age...
of participants was 84 years, with a range of 47-96 years. Out of 30 participants, 20 were in New York Heart Association class III, and 10 were in class II. Among the 30 participants, 18 were diagnosed with HF within 5 years, and 10 were readmitted to the hospital due to HF exacerbation. For additional sample details, please refer to our previous publications [21,26]. No serious adverse events were reported with the use of the wearable camera.

**Activity Identification**

For each of the 7 daily activities, the number of images returned ranged from 12,575 to 26,812. Eating had the highest number of images returned at 26,812, followed by gardening with 25,583 images, drinking with 23,773 images, and shopping with 23,318 images (Table 2).

\textsuperscript{a}HF: heart failure.

Activity Patterns During the Day

Most of the activities were observed before midday (Table 3). For example, 17,980 (67.1\%) of images returned using search terms related to “eating” activity were captured before midday. Similarly, 17,065 (66.7\%) gardening images, 15,245 (65.4\%) shopping, and 15,219 (64\%) drinking images were captured before midday. Additionally, there were statistically significant differences between daily activity patterns pre- and postmidday.

Activity Patterns Before and After Hospitalization

For the 10 participants that were hospitalized, there were marked differences in the percentage of ADLs images captured by a wearable camera pre- and posthospitalization, except for physical activity (Table 4). To illustrate, a total of 10,144 medication images were identified using E-Myscéal. Of those, 3827 (37.7\%) were observed before hospital admission, while 6317 (62.3\%) were observed posthospital discharge. In contrast, there was a decrease in screen time images after hospital discharge 946 (32.1\%), compared to before admission 2003 (67.9\%).

\textsuperscript{a}HF: heart failure.
Discussion

Principal Findings

This study aimed to determine the potential utility of wearable cameras to better understand ADLs in people living with HF. Overall, we showed that wearable cameras can be used to capture specific daily activities, which could be used to help identify areas where interventions may be targeted to improve people’s overall health and well-being. The E-Myscéal search engine was critical to the potential utility of this technology by rapidly retrieving images of relevance. Beyond, these general observations, specific issues are discussed below.

Typically, the use of wearable cameras results in large data sets, which means we have to retrieve, process, and analyze images of relevance for these data to be useful. The most common approach to organizing, retrieving, and analyzing data from wearable cameras involves assigning semantic contexts to images, like visual descriptions, time, and location [13,14]. Various computer vision models are employed to extract visual information from the images, including object detection, activity recognition, optical character recognition [13,15], and embedding models [16,17]. A typical retrieval system would also incorporate different techniques, namely, query enhancement [13], visual similarity search [16], and temporal search [16]. We previously reviewed the SIB image data manually to determine the feasibility and acceptability of wearable cameras to assess self-care in people living with HF [21]. Other studies have also manually reviewed camera images [18-20], which is time-consuming and laborious. In this study, we used the E-Myscéal system [22] to rapidly retrieve and review images of relevance. The E-Myscéal system eliminated the need for manual image review, enabled cross-media querying, supported temporal queries, allowed data filtering and clustering, and provided fast retrieval of the most relevant images.

E-Myscéal was the top-ranked retrieval system at the LSC’22 challenge [28], achieving the highest number of relevant items in the shortest time, and represents the current state-of-the-art in lifelog inquiry and retrieval systems. E-Myscéal exhibits a heightened sensitivity toward certain search terms. For instance, the search term “taking medication” generated considerably higher scores compared to “medication intake,” leading to a significant difference in the number of images retrieved. Hence, the user needs to consider what search terms will work well for any category or daily activities. The flexibility of the E-Myscéal system allowed a wide range of search terms to be tested and evaluated for any category, which the user needs to consider in future research.

Using the E-Myscéal system, the most frequently observed activities were eating, drinking, and screen time. These findings suggest that people living with HF are sedentary and spend considerable time in the presence of some form of screen (eg, television and computer). However, it was not possible to determine from the images whether the person was watching the television. As highlighted above, the Narrative Clip used in this study captured images every 30 seconds and captured the presence of objects in front of the person (eg, television, book, or dinner plate), as well as the context (eg, sitting at a table, being inside or outside, or seated in a car); however, unless the camera captured the person lifting a cup to their mouth it was difficult to determine whether they actually performed the behavior. Thus, while the technology offers a potential for capturing potential activities, a process for confirming what the person was doing is needed. In previous studies [18-20], wearable cameras have been used to support traditional self-report methods or to provide a primary record of dietary intake, however, no studies have used wearable cameras as the primary method of data collection; future research is needed to address this.

If the recorded images do represent a fair reflection of what people with HF were doing throughout the day, then they highlight some interesting patterns. For example, excessive screen or sedentary time might highlight people’s preferences (eg, sitting and watching television) [30-32] or could indicate fatigue, a common symptom of HF. Further, the high number of recorded images of eating and drinking could give some indication of what people with HF were eating (eg, foods high in salt) [33], and the frequency of drinking fluids, which may be an issue for people with HF who are on fluid restriction [4,33]. Despite the importance of taking prescribed medications and engaging in physical activities such as gardening and shopping, the number of images recorded by wearable cameras for these activities was low. The lower number of medication-taking images may have resulted from people not wearing their cameras first thing in the morning or later in the evening when medications were taken. However, it is more likely that the sensitivity of E-Myscéal for detecting medication taking was lower than for other ADLs used in this study. In terms of physical activities, it is plausible that participants removed the camera when shopping or doing physical activity. However, this is unlikely. In the original SIB study, adherence to wearing the camera was high [26]. Moreover, previous research has shown that people wear these types of wearable cameras when undertaking physical activity and they are useful for providing contextual information on activity and sedentary behavior [34,35].

We also found that most images of ADLs were observed before midday. Further, I possible reason is that participants did not wear the camera in the afternoon—they may have removed the camera or forgotten [36] to put it back on, which would result in a lower number of images captured during this time. Another possibility is that the camera battery might not have been fully charged during the previous night, which resulted in the device turning off [37] in the afternoon and fewer images being captured. Additionally, it is possible that participants were spending their afternoons sleeping by taking naps or resting [38-40], which would result in fewer activities [41] being captured during this time. Lastly, issues with the wearable camera time set-up, which may have led to inaccurate time stamps on the images captured, could also have contributed to the observed differences in activity patterns.

Furthermore, there were observed changes in the participants’ daily activities both before hospital admission and after discharge, which could be attributed to the time participants wore the device or differences in performed ADLs. If the latter,
these findings suggest that participants in specific ADLs may have been influenced by their health condition or recovery process. For instance, if they were less active before hospitalization or had mobility limitations, it could result in fewer captured images during that period. The increase in medication images after discharge suggests a heightened focus on medication management and adherence during recovery. Conversely, the decrease in screen time images implies a shift in attention or engagement with electronic devices, possibly due to increased social interaction or involvement in other activities. These findings provide insights into potential changes in participants’ daily routines and behaviors, but further analysis, interpretation, and context are needed to fully understand the reasons behind these variations and their impact on overall well-being.

The temporal differences in the number of images recorded might have implications for managing HF in older adults, as health care professionals could use this information to optimize future self-care strategies such as designing customized interventions to promote medication taking, physical activity, minimizing sedentary behavior, and promoting a healthy diet [4,33]. The use of wearable cameras to augment self-care interventions was highlighted in a previous scoping review [42]. In that review, the authors suggested that people with a new diagnosis of HF could wear a camera for several days. On their return to an outpatient clinic, a nurse specialist or other health professional could review images alongside the individual to identify specific activities and use that as an opportunity to question them about self-care practices and offer tailored suggestions for improvement. The E-Mysecéal platform would permit such rapid review.

A strength of this study was the use of wearable cameras to record first-person perspectives of real-life experiences and associated contexts for people living with HF. This approach provides a rich source of data to better understand people’s lived experiences and context for self-management and could be used to enhance patient outcomes by enabling health care providers to access more personalized and precise information about a person’s condition, which could ultimately lead to better care and treatment. This study is also the first to use the E-Mysecéal system, a flexible and efficient solution for processing large volumes of images in a short time, addressing image preprocessing and classification challenges. However, a limitation of this approach is the sensitivity of E-Mysecéal to specific search terms, which may influence the number and types of images retrieved, which could affect interpretation. It is important to consider these factors when interpreting this study’s findings and drawing conclusions about the daily activity patterns of individuals living with HF. Future research is needed to investigate the reasons behind these differences and develop strategies to improve the accuracy and reliability of wearable camera data collection.

Conclusions

Wearable cameras are a valuable tool for understanding daily activities and self-management in people living with HF. E-Mysecéal efficiently retrieves images, emphasizing the need for careful search term selection. These findings suggest a potential for tailored HF interventions based on temporal activity patterns, despite challenges in confirming specific behaviors from images. Further research is needed to address observed activity variations and enhance data accuracy.

Acknowledgments

The National Heart Foundation of Australia (Vanguard Grant #101348) provided funding for this study. However, the funding agency did not play a part in the design, execution, analysis, or interpretation of this study. The authors would like to express their gratitude to the recruitment staff at Western Health, as well as all the participants who took part in this study.

Data Availability

The data sets generated and analyzed during this study are not publicly available as the camera images include identifiable information. However, other data are available from the corresponding author on reasonable request.

Conflicts of Interest

None declared.

Multimedia Appendix 1

The method by which E-Mysecéal determines the number of images for a given query.

Abstract

Background: Delay discounting quantifies an individual’s preference for smaller, short-term rewards over larger, long-term rewards and represents a transdiagnostic factor associated with numerous adverse health outcomes. Rather than a fixed trait, delay discounting may vary over time and place, influenced by individual and contextual factors. Continuous, real-time measurement could inform adaptive interventions for various health conditions.

Objective: The goals of this paper are 2-fold. First, we present and validate a novel, short, ecological momentary assessment (EMA)–based delay discounting scale we developed. Second, we assess this tool’s ability to reproduce known associations between delay discounting and health behaviors (ie, substance use and craving) using a convenience-based sample.

Methods: Participants (N=97) were adults (age range 18-71 years), recruited on social media. In phase 1, data were collected on participant sociodemographic characteristics, and delay discounting was evaluated via the traditional Monetary Choice Questionnaire (MCQ) and our novel method (ie, 7-item time-selection and 7-item monetary-selection scales). During phase 2 (approximately 6 months later), participants completed the MCQ, our novel delay discounting measures, and health outcomes questions. The correlations between our method and the traditional MCQ within and across phases were examined. For scale reduction, a random number of items were iteratively selected, and the correlation between the full and random scales was assessed. We then examined the association between our time- and monetary-selection scales assessed during phase 2 and the percentage of assessments that participants endorsed using or craving alcohol, tobacco, or cannabis.

Results: In total, 6 of the 7 individual time-selection items were highly correlated with the full scale (r>0.89). Both time-selection (r=0.71; P<0.001) and monetary-selection (r=0.66; P<0.001) delay discounting rates had high test-retest reliability across phases 1 and 2. Phase 1 MCQ delay discounting function highly correlated with phase 1 (r=0.76; P<.001) and phase 2 (r=0.45; P<.001) time-selection delay discounting scales. One or more randomly chosen time-selection items were highly correlated with the full scale (r>0.94). Greater delay discounting measured via the time-selection measure (adjusted mean difference=5.89, 95% CI 1.99-9.79), but not the monetary-selection scale (adjusted mean difference=–0.62, 95% CI –3.57 to 2.32), was associated with more past-hour tobacco use endorsement in follow-up surveys.
Conclusions: This study evaluated a novel EMA-based scale’s ability to validly and reliably assess delay discounting. By measuring delay discounting with fewer items and in situ via EMA in natural environments, researchers may be better able to identify individuals at risk for poor health outcomes.

Introduction

Background
Delay discounting quantifies a subject’s relative preference for more smaller, immediate rewards over larger, delayed rewards. Stated another way, delay discounting can be defined as the perceived value of a reward based on the temporal delay in the receipt of the reward. Greater delay discounting (ie, preference for smaller, short-term rewards over larger, long-term rewards) [1,2] increases the risk for several health conditions, including obesity [3], gambling disorder [4], anxiety, depression [5], substance use disorder [6], and poor substance use disorder treatment response [7-10]. Although some research describes delay discounting as an immutable trait [11], findings from laboratory and clinical studies suggest delay discounting varies by place, time, and other contextual factors [12,13]. Delay discounting’s malleability may represent a promising avenue for interventions or treatment to reduce the risk for myriad negative health outcomes. In this study, we present a novel tool to rapidly assess delay discounting in remote studies and natural environments. Below, we describe traditional methods to measure delay discounting, the potential for ecological momentary assessment (EMA) to improve delay discounting measurement, and this study’s goals.

Traditional Measurement of Delay Discounting
Delay discounting rates quantify consequence devaluation (eg, a monetary reward’s devaluation) by delay [14]. One method to calculate delay discounting rates considers the devaluation process as a hyperbolic decay [15], as shown in equation 1.

\[ V = A / (1 + kD) \]

V represents the indifference point or a small immediate reward’s value, A represents the long-term reward value, k represents the delay discounting rate, and D represents the long-term reward’s delay (ie, long-term reward’s waiting time). Short-term reward preference corresponds to a greater delay discounting rate (ie, future rewards’ steeper devaluation by delay), whereas long-term reward preference corresponds to a slower delay discounting rate.

Researchers often measure delay discounting with the Monetary Choice Questionnaire (MCQ) [16-19]. To obtain the delay discounting rate, the MCQ asks participants to choose between hypothetical smaller, sooner monetary rewards and various larger, later rewards varied by magnitude and delay [16,18]. Researchers often use the 27-item MCQ due to its intuitive administration and straightforward calculations [16]. There are numerous MCQ variations, including a 21-item version [17] and a 9-item version [19].

Although many studies use the MCQ, a continuous indifference point measure may better capture delay discounting rates due to reduced ceiling effects and faster data saturation. The MCQ has been criticized as constraining delay discounting rates, resulting in ceiling effects in populations with high delay discounting rates [18]. For example, although the MCQ was originally tested with people who use heroin, the MCQ’s current versions limit comparisons across or within populations because people who use drugs can reach maximum delay discounting rates (ie, ceiling effects) [18]. Directly measuring indifference points along a continuous measure (eg, how long are you willing to wait to receive US $100 instead of US $30 today?) may prevent ceiling effects. Some studies have implemented a continuous measure for the indifference point [20], but few have used EMA-based continuous measures. A continuous indifference point measure increases the set of possible discounting rate estimates [20] and may capture the delay discounting rate with fewer items than the MCQ. Repeatedly administering the MCQ may fatigue participants [21], but a continuous indifference point measure may allow researchers to quickly reach data saturation (eg, obtaining consistent delay discounting rates over fewer repeated measures) [20].

EMA of Delay Discounting
EMA-based delay discounting research can measure behavior in context, abbreviate delay discounting scales, and minimize bias compared to more traditional data collection methods. First, EMA methods collect repeated measures on participants’ behaviors in situ [22] throughout the day, capturing ephemeral behaviors and moods traditional methods may miss or mismeasure [23]. Indeed, EMA may identify place and time cues that increase the risk for greater delay discounting (ie, preference for sooner, smaller rewards) and increased maladaptive behavior risk [24]. For example, one EMA study identified a relationship between delay discounting and acute substance use withdrawal [25]. The study found constant MCQ scores for the first few hours after substance use, but MCQ scores peaked 4-6 hours after alcohol and cannabis use and after 2 hours for stimulant use [25]. Second, repeated delay discounting assessments may shorten scales with good reliability. Fewer questions varied in presentation may reduce study participation burden and fatigue [21] and straightforward (ie, giving the same answer to all questions) [26]. Other researchers have shortened existing delay discounting assessments to reduce participant burden [18], but EMA-based scales could further abbreviate scales with good reliability. Finally, EMA may have less bias than traditional data collection.
Less latency between the event occurrence and survey completion relative to traditional methods may reduce recall bias and measurement error [27]. Capturing delay discounting in situ may also decrease social desirability bias associated with stigmatized behaviors (eg, substance use) compared to face-to-face interviews [27].

The goals of this paper are 2-fold. First, we present and validate a novel, short, EMA-based delay discounting scale we developed. Second, we assess this tool’s ability to reproduce known associations between delay discounting and health behaviors (ie, substance use and craving) using a convenience-based sample.

**Methods**

**Participants**

We posted study advertisements on Facebook and Instagram via a Facebook profile. Phase 1 study advertisements appeared on mobile and desktop newsfeeds from December 2020 to February 2021. Study advertisements directed participants to “MetricWire” (MetricWire Inc), a digital research platform. Participants were instructed to download MetricWire’s iPhone- and Android-compatible smartphone app. We administered all surveys via MetricWire, a widely used research app designed for in-the-moment, contextual data collection. Study staff verified participants’ email addresses and phone numbers. Then, interested participants created a password-protected account and answered the screener in the app. Throughout the study, participants could anonymously contact study staff with questions or concerns through the app’s instant messaging (IM) system. Researchers emailed and invited phase 1 participants to join phase 2 in July 2021.

US residents aged 18 years or older with smartphones were eligible to participate. Eligible participants read study and consent materials through the MetricWire app. To ensure participants understood the study objectives, participants had 3 attempts to correctly answer 3 multiple-choice questions regarding the study’s purpose, length, and potential risks. Study incentives and anonymous recruitment risked individuals feigning their country of residence and reregistering under fake accounts. As a result, MetricWire removed participants with IP addresses already registered or abroad.

**Ethical Considerations**

This study received institutional review board approval from Johns Hopkins Bloomberg School of Public Health (IRB00011160). All participants provided informed consent and were informed they would receive US $10 for the completion of phase 1 and a maximum of US $75 for the completion of phase 2. The data analyzed were anonymous and deidentified.

**Sample Size**

For a diverse sample, we sought to equally recruit participants from 6 categories based on age (ie, 18-30, 31-50, and >50 years) and race (eg, White and non-White). In recruitment, we considered adults identifying as 2 or more races as non-White adults. We as aimed to recruit 33 adults for each quota, or 198 participants in total. These 198 participants would yield approximately 2821 observations (198 participants × [1 baseline survey + (6 days × 3 follow-up surveys)], assuming 75% compliance).

**Study Design**

We used a 2-phase EMA study via MetricWire’s smartphone app. In phase 1, participants completed the 8-item MCQ, a sociodemographic questionnaire, and our 2 novel 7-item continuous delay discounting surveys. Researchers invited participants who completed phase 1 to participate in phase 2 a few months later. Phase 2 comprised a survey on the first day (baseline) and 3 daily follow-up surveys on their smartphone for 6 consecutive days, amounting to 19 total surveys. Participants received the 3 follow-up surveys on their smartphones at random times between their self-reported wake and sleep times. In phase 2, the baseline survey included the original MCQ, health behavior assessments (eg, substance use and craving), and our 2 novel EMA-based delay discounting measures. At each daily follow-up, participants completed our EMA-based delay discounting tool and a health outcomes questionnaire (eg, past-hour substance use and craving). The phase 2 baseline survey duration approximated 20 minutes, and each follow-up survey approximated 5 minutes.

Participants received compensation based upon adherence. Phase 1 completion renumerated participants with US $10 credit for Tango, a third-party gift card provider. In phase 2, participants received US $20 Tango credit for baseline assessment completion, US $5 credit each day if they completed at least 1 follow-up survey, and US $25 bonus credit for completing at least 75% (14/19) of surveys upon the study’s end. Participants received links to their accrued credit through the app’s IM system. To improve adherence, text in the consent form encouraged participants to enable MetricWire notifications on their smartphones and to request technical support through the app’s IM system. Halfway through phase 2, study staff messaged participants their adherence rate and a reminder about the US $25 bonus credit.

**Measures**

**Time- and Monetary-Selection Measures**

We presented participants with 2 continuous delay discounting measures. For the first type, participants chose how long they would wait to receive the long-term reward rather than the short-term reward (eg, $D$ from equation 1), hereafter referred to as time-selection items. In the second type, participants chose how much money they would need to receive today rather than the long-term reward (eg, $V$ from equation 1), hereafter referred to as monetary-selection items. Textbox 1 outlines the time-selection and monetary-selection items.
**Textbox 1.** Modified ecological momentary assessment (EMA)–based time-selection and monetary-selection delay discounting items for a 2-phase EMA study assessing the validity of a novel delay discounting measure. Items were randomized during the study.

Figure 1 displays the time- and monetary-selection items’ in-app appearance. Participants used a sliding scale to select their wait time or monetary reward. Our novel measures comprised 7 time-selection and 7 monetary-selection items. Participants answered time- and monetary-selection items at phase 1, phase 2 baseline, and phase 2 follow-up. From the measured indifference point and long-term reward delay, the delay discounting rate \((k)\) was directly calculated via equation 1, since we knew \(V\) (the immediate reward’s value), \(A\) (the delayed reward’s value), and \(D\) (the time delay). The geometric mean across all items was then calculated to determine the average delay discounting rate for the time- and monetary-selection items.

**Figure 1.** Time-selection item (left) and a monetary-selection item (right) examples for a 2-phase ecological momentary assessment study assessing the validity of a novel delay discounting measure.
**Original MCQ**

The original MCQ was administered in both phase 1 and 2 baseline surveys to validate our time- and monetary-selection measures. Participants answered 7 “Would you rather receive US $50 today or US $100 in 1 year?” variants. The long-term reward consistently displayed US $100, but the time delay and short-term reward amount varied. The time delay ranged from 2 months to a year, while the short-term reward amount ranged from US $10 to US $99. See Multimedia Appendix 1 for all administered items.

** Substance Use **

To determine our novel measures’ predictive use and ability to reproduce established associations between delay discounting and a health condition, we asked participants if they used or craved substances within the last hour during phase 2. Surveyed substances included (1) alcohol; (2) tobacco, cigarettes, cigarillos, cigars, vaping, and nicotine; (3) cannabis, marijuana, pot, grass, and hash; (4) cocaine, coke, and crack; (5) prescription stimulants (eg, Ritalin and Concerta); (6) methamphetamines (eg, speed, crystal meth, and ice); (7) inhalants (eg, nitrous oxide and glue); (8) sedatives of sleeping pills (eg, Valium); (9) hallucinogens (eg, lysergic acid diethylamide and acid); (10) street opioids (eg, heroin); (11) prescription opioids (eg, fentanyl); and (12) others. We created individual-level variables reflecting the total percentage of phase 2 surveys endorsing using or craving alcohol, cannabis, or tobacco. We did not examine other use or craving of any other substance with very low base rates.

**Statistical Analysis**

**Overview**

Prior to conducting analyses, we examined the time- and monetary-selection items’ distribution. Participants identified as outliers or who provided invalid responses (ie, always selecting maximum or minimum values) were dropped. Additionally, we examined the delay discounting distributions for violations of normality and the need for log transformations.

The study objectives included identifying noninformative items in our time- and monetary-selection scales, examining scale stability across phase 1 and 2 baselines, validating time- and monetary-selection items with the phase 1 and 2 baseline MCQ, and determining the minimally sufficient set of time- and monetary-selection items required to capture delay discounting. All analyses were performed in R (version 4.0.4; R Foundation for Statistical Computing).

**Objective 1: Identify Noninformative Items Within New Measures**

We examined Pearson correlations between the phase 1 geometric average delay discounting rate of the 7-item time-selection scale and each time-selection item’s delay discounting rate. This was repeated for the monetary-selection items in phase 1. Then, we repeated the item-scale correlations separately for time- and monetary-selection items in phase 2. Items uncorrelated with the full scale were then dropped from analyses.

**Objective 2: Examine New Measures’ Test-Retest Reliability**

For the second objective, we compared the delay discounting function from phase 1 baseline to phase 2 baseline via Pearson correlations.

**Objective 3: Validate New Measures**

For the third goal, we compared time- and monetary-selection scales to the study’s gold standard—the traditional MCQ—via Pearson correlations. The correlation between the delay discounting rate derived from phase 1’s traditional MCQ and the delay discounting rate derived from both the time- and monetary-selection tools at phase 1 and phase 2 was examined. The correlation between the delay discounting rate derived from phase 2’s traditional MCQ and the time- and monetary-selection tools at phase 2 was additionally assessed.

**Objective 4: Shorten New Scale**

For the fourth goal, we iteratively examined the Pearson correlation between the geometric average delay discounting rate of a randomly chosen set of the informative items and the full 7-item scale using phase 1 data.

**Objective 5: Assess the Association Between New Delay Discounting Measures and Substance Use**

Finally, we tested the association between delay discounting and substance use to assess our time- and monetary-selection measures’ predictive use. Linear regression analyses were conducted to examine associations between the predictors (ie, phase 2 baseline delay discounting rates calculated from our time- and monetary-selection measures) with 6 outcomes (ie, percentage of assessments participants reported using or craving alcohol, cannabis, or tobacco). Participant’s age, sex, and completed number of surveys were adjusted. We mean-centered continuous predictor variables and conducted analyses with completed surveys only.

**Results**

**Overview**

In phase 1, a total of 186 participants were recruited, of whom 111 agreed to participate in phase 2. To identify potential outliers, the delay discounting rate’s SD was calculated at each phase separately for the 7 time- and monetary-selection responses. The 4 resulting plots were then visually inspected. From the phase 1 monetary-selection geometric average delay discounting rate distribution, 6 data points were identified as outliers that were 3 SDs from the standardized mean. For phase 1 time-selection delay discounting items, individuals who consistently selected only the minimum time delay (1 day, n=2) or the maximum time delay (52 days, n=1) were removed. We excluded 8 total participants, noting them as outliers, from our phase 1 analytical sample. For phase 2 time-selection delay discounting items, 3 individuals were identified as outliers that were 3 SDs above the standardized mean—1 individual consistently selected the minimum time delay (1 day) and 2 individuals consistently selected the maximum time delay (52 days). For phase 2 monetary-selection delay discounting items, 5 individuals were excluded as outliers that were 3 SDs above...
the standardized mean. The phase 2 raw sample included 9 outliers in total. The 8 participants from phase 1 and 9 participants from phase 2 were excluded from the analyses. Our analytic sample included individuals with valid phase 1 and phase 2 data, resulting in a sample of 97 participants (Figure 2).

Figure 2. Analytical sample flowchart for a 2-phase ecological momentary assessment (EMA) study assessing the validity of a novel delay discounting measure. Participants were recruited from Facebook and Instagram to participate in a mobile-based EMA study.

There were some differences in demographic characteristics between those who completed phase 1 only versus those in our analytic sample who completed phases 1 and 2. In particular, there was a greater proportion of individuals who identified as African American or Black who completed phase 1 only (33/89, 37%) compared to those who completed phases 1 and 2 (9/97, 9%; $\chi^2 = 21.4; P < .001$). A greater proportion of individuals identified as White (55/97, 57%), Asian (25/97, 26%), or 2 or more races (33/97, 34%) who completed phases 1 and 2 relative to phase 1 only (White: 39/89, 44%; Asian: 12/86, 14%; 2 or more races: 8/97, 8%). There were no differences in terms of the completion of the study based on participant sex, ethnicity, or income.

Among participants who completed phase 1 and phase 2 (ie, our analytic sample; N=97), most participants identified as female (n=72, 74%) and as White (n=56, 58%). Approximately 80% (n=79) of participants were 50 years and younger of age, and 70% (n=68) reported an annual income below US $75,000 (Table 1). On average, participants completed 16 (SD 4) of 19 surveys. On average, 4% (SD 9%; n=0.8) of a given participant’s surveys endorsed alcohol use, 6% (SD 21%; n=1.22) endorsed tobacco use, 7% (SD 22%; n=0.004) endorsed craving tobacco, and 8% (SD 18%; n=1.60) endorsed craving alcohol.
Table 1. Characteristics of US adults participating in a novel 2-phase ecological momentary assessment–based study assessing the validity of a novel delay discounting tool, 2020-2021 (N=97).

The delay discounting rate distribution generated from the time- and monetary-selection items and the original MCQ, which manifested a positively skewed distribution, was inspected. Thus, the delay discounting rates were log-transformed to obtain normally distributed variables for analyses examining the relationship between delay discounting and other measured characteristics. Below, we present findings from the study’s 5 objectives.

Objective 1: Identify Noninformative Items Within New Measures

The Pearson correlations between each item’s delay discounting rate and the 7-item scale’s geometric average delay discounting rate were examined. In phase 1, we found high correlations (r range=0.89-0.96) for 6 of the 7 time-selection items (Multimedia Appendix 2). The poorly performing item (r=0.38 in phase 1) asked participants to choose between US $99 today or US $100 in the future. The small difference in the immediate versus delayed reward may have yielded poor discrimination between individuals with high versus low discounting. In subsequent analyses, this item was dropped. We reproduced the finding in phase 2 (Multimedia Appendix 3)—6 of the items strongly correlated with the scale (r range=0.88-0.94), and phase 1’s poor-performing item continued to perform poorly in phase 2 (r=0.35 in phase 2). In phase 1, a relatively low correlation was found (r range=0.45-0.85) between individual money-selection items and the 7-item scale’s geometric average delay discounting rate (Multimedia Appendix 4). Moreover, the item-to-scale correlations were not consistent between phase 1 and phase 2, and only 3 items were consistently correlated (r>0.75) across phases 1 and 2 (Multimedia Appendix 5).

Objective 2: Examine New Measures’ Test-Retest Reliability

Delay discounting rates from phase 1 to phase 2 for both the novel time- and monetary-selection measures were compared. We found moderate to high correlations between phase 1 and 2 time-selection (r=0.66; P<.001) and money-selection delay discounting (r=0.41; P<.001), indicating good and acceptable test-retest reliability, respectively (Table 2).

aMCQ: Monetary Choice Questionnaire.

bNot available.
Objective 3: Validate New Measures

The correlations between the traditional MCQ and the novel time- and monetary-selection approaches were examined (Table 2). Excellent and acceptable correlations were observed between the phase 1 traditional MCQ–derived delay discounting rate with the phase 1 time-selection delay discounting rate ($r=0.76; P<.001$; Table 2 and Figure 3) and the phase 2 time-selection delay discounting rate ($r=0.45; P<.001$), respectively. Moderate to small positive correlations were noted between the phase 1 MCQ–derived delay discounting rate with phase 1 monetary-selection delay discounting rate ($r=0.57; P<.001$; Figure 4) and phase 2 money-selection delay discounting rate ($r=0.22; P=.03$). The phase 2 traditional MCQ delay discounting rate was highly positively associated with the phase 2 time-selection ($r=0.72; P<.001$) and moderately positively associated with the monetary-selection delay discounting rate ($r=0.50; P<.001$).

Figure 3. Correlations between phase 1 MCQ log(delay discounting rate) and phase 1 six-item time-selection log(delay discounting rate). Data are from a mobile-based ecological momentary assessment study assessing the validity of a novel delay discounting tool across 2 phases between 2020 and 2021. Participants were US adults recruited from social media. An example of a time-selection item is “How long would you be willing to wait to get US $100 instead of US $50 today?” MCQ: Monetary Choice Questionnaire.
Figure 4. Correlations between phase 1 MCQ log(delay discounting rate) and phase 1 seven-item monetary-selection log(delay discounting rate). Data are from a mobile-based ecological momentary assessment study assessing the validity of a novel delay discounting tool across 2 phases between 2020 and 2021. Participants were US adults recruited from social media. An example of a monetary-selection item is “How much money would you take today instead of US $100 in a year?” MCQ: Monetary Choice Questionnaire.

Objective 4: Shorten New Scale
We also examined if an abbreviated scale could approximate the full 6-item scale of the time-selection approach. To construct the abbreviated scale, we randomly selected N (between 1 and 5) items across 100 iterations at each N and calculated the correlation between the N item’s geometric average delay discounting rate and the full 7-item time-selection scale’s geometric average delay discounting rate. A high correlation was found between randomly selected 1 (r=0.94) or 2 (r=0.97) item scales and the full 6-item scale, indicating a relatively small number of items can approximate the full scale (Figure 5). The analyses were repeated with the monetary-selection approach, and a relatively weak correlation was found between randomly selected 1 (r=0.74) or 2 (r=0.86) item scales and the full 7-item scale (Figure 6).
Objective 5: Assess the Association Between New Delay Discounting Measures and Substance Use

Participants with greater phase 2 baseline delay discounting rates from the MCQ and our time-selection measure had a higher proportion of surveys endorsing tobacco craving and use. There were trend-level significant associations between the original MCQ delay discounting rate (adjusted mean difference=3.46, 95% CI –0.63 to 7.55; \(P=0.10\)) and the time-selection delay discounting rate with tobacco craving (adjusted mean difference=3.92, 95% CI –0.12 to 7.95; \(P=0.06\;\) Table 3). Significant associations were observed between the original
MCQ delay discounting rate (adjusted mean difference=4.32, 95% CI 0.29-8.34; \( P = .04 \)) and time-selection delay discounting rate (adjusted mean difference=5.89, 95% CI 1.99-9.79; \( P = .003 \)) with the percentage of surveys endorsing tobacco use. No significant associations were observed between the phase 2 baseline monetary-selection delay discounting rate and substance use or craving (all \( P > .05 \)). There were no significant differences between alcohol or cannabis use or craving and the delay discounting rate derived from both the MCQ and our novel measures (all \( P > .05 \)).

### Discussion

#### Principal Findings

In this study, a novel EMA-based tool was developed to overcome the limitations of existing delay discounting measures. In contrast to traditional delay discounting measures captured at a single time point (eg, the MCQ), our EMA-based delay discounting measure used a continuous indifference point to minimize ceiling effects, abbreviate delay discounting scales, capture state-like fluctuations in delay discounting, and reduce measurement error. We showed that a time-selection, EMA-based method could accurately assess delay discounting. In addition, the novel tool successfully reproduced some associations between delay discounting and substance use behaviors observed in the literature, specifically the established association between delay discounting and tobacco use.

To develop the EMA-based scale, we analyzed the scales’ reliability across 2 phases and its validity in comparison to the MCQ. In total, 6 of the 7 time-selection items correlated with the full scale. We dropped the uninformative, 7th time-selection item—“How long would you be willing to wait to get US $100 instead of US $99 today?” The US $1 difference may have failed to provide sufficient response variability, because even short delays (eg, 1 week) would result in devaluing US $100 over US $99 [28]. Overall, the time-selection EMA measure reliably and validly measured delay discounting.

However, the monetary-selection items did not consistently contribute to delay discounting measurement. There are a
number of reasons to explain this lack of performance of this measure. First, we believe participants simply may have struggled to decide which amount they would take today over the longer-term reward. Second, the monetary-selection measure comprised fuzzy units (eg, cost of one’s patience for a specific period), and studies have shown fuzzy units increase short-term reward preferences compared to discrete units (eg, how long one would wait) [29,30]. Participants may not have as much behavioral experience to quantify the abstract monetary cost to wait for an already specified duration. Participants, however, may reliably draw from personal experience and past behaviors to assess their capacity for patience, as conveyed in the time-selection items. Third, framing time as a date (as in the time-selection items) or as days (as in the monetary-selection items) may have influenced participants’ delay discounting rates [30]. Finally, monetary-selection items may have needed a larger, long-term reward to capture variability in long-term reward devaluation. When asked to wait a year to receive US $100, participants choose a short-term reward as close as possible to the long-term reward, but if given a larger, long-term reward, participants may choose a smaller, short-term reward relative to the long-term reward [31].

After assessing the measures’ validity and reliability, we determined that randomly selecting 1 to 2 time-selection items could sufficiently capture delay discounting. Similarly, another study also captured delay discounting with 2 items with no sensitivity loss [32]. An abbreviated EMA-based scale can minimize participant fatigue and sustain participant attention during data collection.

Additionally, our tool successfully reproduced some established associations between delay discounting and substance use or craving. Based on the time-selection items and the original MCQ, tobacco use and cravings often increased with greater delay discounting. Other studies have similarly evidenced a preference for smaller, immediate rewards over larger, long-term rewards (ie, greater delay discounting) when involving nicotine use [33,34]. On the other hand, we found no relationship between delay discounting and alcohol or cannabis use or craving. Other studies have found positive, modest associations between delay discounting and alcohol or cannabis use or craving. Our abbreviated scale may overcome data collection barriers related to participants’ attentional capacity and measurement barriers due to ceiling effects [18]. Beyond aiding delay discounting–specific research, our transdiagnostic tool may help with intervention assessment and rapid detection of individuals at risk for specific health conditions. In terms of intervention assessment, delay discounting may serve as an outcome for measuring the effectiveness and efficacy of behavior change interventions. For example, an intervention targeting binge eating may seek to assess the intervention’s momentary effect on how an individual values the immediate reward of binge eating over the long-term health benefits of abstaining from binge eating. In this case, delay discounting may serve as a rapid proxy to assess the intervention’s effect on reward valuation. Additionally, our tool may also help detect individuals at higher risk in a high-risk population associated with greater impulsivity. For example, one study suggested delay discounting tools may be adapted to discern HIV risk among individuals with and without cocaine use disorder [43]. Future studies should test the time-selection measures’ predictive use in clinical, high-risk populations.

Conclusions
We found that 1 or 2 randomly selected items from our novel EMA-based time-selection measure can sufficiently assess delay discounting. Our abbreviated EMA-based scale may overcome data collection barriers related to participants’ attentional capacity and measurement barriers due to ceiling effects [18]. Beyond aiding delay discounting–specific research, our transdiagnostic tool may help with intervention assessment and rapid detection of individuals at risk for specific health conditions. In terms of intervention assessment, delay discounting may serve as an outcome for measuring the effectiveness and efficacy of behavior change interventions. For example, an intervention targeting binge eating may seek to assess the intervention’s momentary effect on how an individual values the immediate reward of binge eating over the long-term health benefits of abstaining from binge eating. In this case, delay discounting may serve as a rapid proxy to assess the intervention’s effect on reward valuation. Additionally, our tool may also help detect individuals at higher risk in a high-risk population associated with greater impulsivity. For example, one study suggested delay discounting tools may be adapted to discern HIV risk among individuals with and without cocaine use disorder [43]. Future studies should test the time-selection measures’ predictive use in clinical, high-risk populations.

Abstract

Background: Documenting the grant acquisition characteristics of a highly selective group of researchers could provide insights into the research and faculty development of talented individuals, and the insights gained to foster such researchers will help university management strengthen their research capacity.

Objective: This study examines the role of human connections in the success of biomedical researchers in Japanese universities.

Methods: This study used grant data from the Grants-in-Aid for Scientific Research (GIA) program, the largest competitive research funding program in Japan, to collect information on projects and their implementation systems obtained throughout the participants’ careers. Grant success was measured by the number and amounts of the awards obtained while participants occupied the role of principal investigator. Human connections were quantified by the number of projects in which the participants took part as members and were classified by their relationship with the project leader. Data were matched with information on career history, publication performance, and experience of the participants with government-funded programs apart from GIA and were analyzed using univariate and multivariate regression analyses.

Results: Early-career interpersonal relationships, as measured using the h-index value of the researchers who provided the participants with their initial experience as project members, had a positive effect on grant success. The experience of contributing to prestigious research programs led by top researchers dramatically increased the cumulative amount of GIA awards received by the participants over time. Univariate logistic regression analyses revealed that more interactions with upper-level researchers resulted in fewer acquisitions of large programs (odds ratio [OR] 0.67, 95% CI 0.50-0.89). Collaboration with peers increased the success rate of ≥2 research grants in large programs in situations in which both the participant and project leader were professors (OR 1.16, 95% CI 1.06-1.26). Tracking the process of research development, we found that collaboration during the periods of 10 to 14 years and 15 to 19 years after completing a doctorate degree determined the size of the project that the participant would obtain—interactions with peer researchers and subordinates during the 10- to 14-year postdegree period had positive effects on ≥2 large-program acquisitions (OR 1.51, 95% CI 1.09-2.09 and OR 1.31, 95% CI 1.10-1.57, respectively), whereas interactions with subordinates during the 15- to 19-year postdegree period also had positive effects (OR 1.25, 95% CI 1.25-1.07). Furthermore, relationships that remained narrowly focused resulted in limited grant success for small programs.

Conclusions: Human networking is important for improving an individual’s ability to obtain external funding. The results emphasize the importance of having a high-h-indexed collaborator to obtain quality information early in one’s career; working with diverse, nonsupervisory personnel at the midcareer stage; and engaging in synergistic collaborations upon establishing a research area in which one can take more initiatives.

Introduction

Background
The university sector has played a major role in the production of scientific knowledge by facilitating research based on the unique conception of researchers and has supported important societal benefits by helping companies source innovation [1]. As the world becomes increasingly unstable, the university sector will be required to create more knowledge and supply more human resources, leading to breakthrough innovation. However, as knowledge accumulates and science becomes more specialized, fewer remarkable discoveries are made [2]. In addition, conducting research that answers simple but major questions is becoming difficult under the recent system of university performance evaluation, which emphasizes short-term outcomes against a backdrop of the demand for accountability in the allocation of public funds [3,4]. This emphasis on short-term results is significant from the perspective of university management in countries where public funds are the primary source of university revenue. For example, Japanese universities need to equip faculty members with strong research skills to receive more government resource allocation, especially after 2019, when performance-based allocations were introduced [5].

High competitiveness in research is measured by the number and impact of publications and the acquisition of external funding; the latter is particularly important from the perspective of university management. Importantly, in the long run, the ability to draw a vision will influence the future direction of the research field and attract young researchers. This innovative power—that is, creating a common understanding that a research field that did not previously exist will exist in the future—is expected to materialize as large research projects supported by significant funding. Therefore, it is important to understand how personnel are capable of obtaining vast amounts of external funding. By examining the existing funding framework in Japan, this study observed that the larger the funding program, the more broadly the disciplines are grouped to form review committees. Therefore, project leaders must convince reviewers from diverse fields of the significance of a project [6]. Project leaders of a group of researchers spanning multiple disciplines are required to be capable of discussing the worldview that the research can present.

Factors such as the exchange of ideas and expansion of knowledge are important for fostering visionary researchers. Accordingly, the effectiveness of international mobility and academic industry collaboration has been evaluated from the perspectives of higher education, research, and innovation policy [7-9]. In addition, the literature has emphasized the importance of “productive interactions” between researchers and social actors in studies that assess the social impact of scientific research [10,11]. These examples demonstrate that learning from others regarding perspectives beyond the scope of one’s research can lead to innovative ideas. However, few studies have focused on the impact of such “productive exchanges” on the human resource development of individual researchers.

Chan et al [12] analyzed the coauthorship patterns of Nobel laureates and found that encounters of heterogeneous ideas from different researchers, which occur early in the collaboration life cycle, generate the most innovative ideas that emerge from the collaborative relationship. This cross-fertilization of ideas is considered effective not only in the research development process of Nobel laureates but also in the process of cultivating creativity among researchers in general. Studies on creativity have shown that acting as a broker of valuable knowledge (ie, having a high level of “betweenness centrality” in a network) can facilitate information flow so as to generate new ideas [13].

A study of young researchers in biomedical sciences showed that effective collaboration with “nonsupervisor” peers is important for learning [14]. In the academic community, where the culture of apprenticeship is strong, handing over a research theme between a supervisor and an apprentice and taking over a network of people working on such a theme are effective methods for increasing one’s visibility in the field. In this context, how researchers relate not only to their immediate supervisors but also to their colleagues and researchers in other institutions is key to improving their competitiveness in grant acquisition, as previously demonstrated using selective groups of researchers with high betweenness centrality [15].

Objectives
This study explored the objective metrics of success in grant acquisition using information from Grants-in-Aid for Scientific Research (GIA) projects and focusing on interpersonal relationships. By doing so, we aimed to identify the requirements for developing researchers capable of winning external funding for university management and who, ultimately, can influence research trends through innovative ideas and high-level capabilities in project realization.

Methods

Overview
In Japan, GIA provides fundamental financial assistance for academic research activities that cover all fields with the objective of promoting scholarship and advancing creative research [6]. It is the largest competitive research funding program in Japan, which began in the 1950s. Even after the introduction of government funding programs for various purposes, it continues to account for most funds that support “bottom-up” researcher-led projects [16,17]. GIA includes basic programs (classified according to the amount awarded), innovation programs that take on new challenges, and specially promoted research programs that support outstanding original research that pioneers new scholarship. Other programs are also available to young researchers. Screening of GIA projects through peer review, although the breadth of the reviewers’ fields varies according to the program size [6]. Therefore, GIA award acquisition performance is considered an indicator that
quantifies the academic creativity of researchers who have reached a certain level regardless of external conditions such as top-down policy requirements. This study focused on the implementation structure and member composition of projects supported by GIA.

Data Sources
The grant acquisition history of the participants, that is, the research projects in which they were involved, was obtained from the GIA database, wherein participants' names can be used as search terms to obtain information on their positive GIA awards (National Institute of Informatics, Japan) [18]. Although the GIA system has undergone several modifications and programs have been established or abolished over time, we focused on programs that most researchers currently in professorial positions are familiar with. Information on rejected projects was not included in this study.

Data on degree types were obtained from the doctoral dissertation database [19]. These data were introduced as an alternate indicator for understanding the effect of age as the exact age of each researcher is not publicly available. This indicator discriminates whether a degree was obtained by either enrolling in a graduate school and submitting a dissertation or submitting a dissertation and passing an examination even if the person was not enrolled in a graduate school (doctorate obtained by thesis). The latter is a unique system in Japan, and the degrees of this type are primarily awarded to people who conducted their research as employees of a company.

The productivity, contributions, and research impact of each researcher, as measured by the citation counts, were calculated from the publication history data obtained from the Scopus database under the license of the University of Tsukuba using the Scopus IDs as the search key (Elsevier) [20]. Factors that could not be determined through the aforementioned indicators were examined using a database that covered most government funding programs by entering the participants' names (BIOIMPACT, Japan) [21].

Ethical Considerations
This study did not require ethics approval as it did not collect data from human or animal participants. The names of the professors, external funding obtained, and publication records are publicly available. The 2 databases of grants were constructed to ensure transparency in public research funding allocation and allow users to search for the latest research information in Japan—one records the GIA program of the Ministry of Education, Culture, Sports, Science, and Technology of Japan [22] and the other records other government funding programs of the Cabinet Office; Ministry of Internal Affairs and Communications; Ministry of Health, Labour, and Welfare; Ministry of Agriculture, Forestry, and Fisheries; Ministry of Economy, Trade, and Industry; Ministry of Land, Infrastructure, Transport, and Tourism; Ministry of the Environment; and Ministry of Defense [23]. The analysis plan was not preregistered as this was a secondary analysis of open data extracted from public databases.

Researcher Characteristics
This study considered the following characteristics in terms of the researchers' competitiveness: the sum of the maximum allocated amount of projects obtained as principal investigators, total allocation earned as a principal investigator during the first 10 years after obtaining a PhD, and the number of projects obtained as principal investigators in large programs, such as Grant-in-Aid for Specially Promoted Research and Grant-in-Aid for Scientific Research (S), or small programs, such as Grant-in-Aid for Scientific Research (C). In terms of their personal attributes, we considered the number of years since obtaining a doctoral degree, whether the doctorate was obtained by thesis, sex, experience in nonuniversity institutions, the rankings of the university in which the researcher obtained their doctorate, and where the researcher is currently affiliated. To measure each researcher's productivity, we considered the number of papers published, first-authored papers, and last-authored papers.

To clarify the effect of human connections, we included the following attributes: the number of coauthors connected with through GIA projects throughout their career, the betweenness centrality score based on people-to-people connections in GIA projects, the h-index of the researcher with whom the participant researcher first became a member of GIA projects, the number of government-funded programs participated in as a project member, and the total h-indexes of the researchers with whom the participant researcher interacted through other government-funded programs. To measure the researchers' interpersonal relationships, we considered the number of researchers who designated the participants as their GIA project members (upper level, peer, or subordinate) throughout their careers. We also considered the number of projects a researcher participated in during each period after obtaining a doctorate (10-14 y and 15-19 y after the doctorate), categorized by the relationship of the project leader to the participant (upper level, peer, or subordinate).

Samples and Analysis Method

Analysis 1
This study focused on a single area of biomedical science to obtain detailed microstructural data on the relationship between research conception skills. Biochemistry was selected as the target field as it is the basis of today's medicine given its focus on molecular mechanisms and as the 54 professors in this field include 5 (9%) awardees of Grant-in-Aid for Specially Promoted Research or Grant-in-Aid for Scientific Research (S) and 16 (30%) awardees of Grant-in-Aid for Scientific Research (A). These numbers exceed those in the field of hematology, with 3% (1/35) of awardees of Grant-in-Aid for Specially Promoted Research or Grant-in-Aid for Scientific Research (S) and 9% (3/35) of awardees for Grant-in-Aid for Scientific Research (A), and dermatology, with 5% (2/39) of awardees for Grant-in-Aid for Specially Promoted Research or Grant-in-Aid for Scientific Research (S) and 18% (7/39) of awardees for Grant-in-Aid for Scientific Research (A). This indicates that biochemistry is a suitable field for analyzing the competitiveness of researchers in Japan.
The names of the researchers who held professorships in biochemistry at the medical schools of Japanese universities between 2020 and 2022 were extracted from the websites of each university. In total, the study identified 54 researchers, including 2 (4%) female researchers, from 11 schools belonging to the top university group and other national universities. Academic and professional histories were obtained from their websites. In terms of education, 72% (39/54) graduated from schools of medicine, 87% (47/54) obtained PhDs in medicine, and 69% (37/54) obtained their bachelor’s and doctorate degrees in the same university. The mean number of years since receiving the degree was 29 (SD 6). We extracted 1473 GIA projects, of which 803 (54.51%) were implemented by the 54 participants as principal investigators (Table 1). For analysis 1, we summed the maximum allocated amount that each researcher won as the principal investigator and used it as the dependent variable. The independent variables were calculated using data obtained from each source. We controlled for sex (female) and experience at nonuniversity institutions (nonuniversity institutions). In this analysis, nonuniversity institutions refers to corporations and their associations. A lagged variable was designated for the total allocation of projects won by the participants as principal investigators for 10 years after each researcher obtained a PhD. Finally, researchers with missing data were excluded, and 52 were included in the analysis. Multiple regression analysis was performed using the XLSTAT statistical software (Addinsoft).

Table 1. Data on the researcher population used in the study and their characteristics.

^aThe count includes duplicates because of, for example, changes in principal investigator. N_1 is the number related to participants and N_2 is the number related to acquired projects.

^bThe analysis includes Grant-in-Aid for Scientific Research (S), (A), (B), or (C); Grant-in-Aid for Specially Promoted Research; and Grant-in-Aid for Young Scientist (S) and (A) for analysis 2.

^cPI: principal investigator.

Analysis 2

We obtained people-to-people connections up to the third level by counting 54 participants based on the team member list of projects throughout their careers. The researchers extracted in the second tier of connections, that is, those who had primary relationships with the 54 participants, totaled 982 and conducted 11,437 projects, of which 4381 (38.31%) were implemented by the 54 participants as principal investigators (Table 1). The types of colleagues were analyzed using the data of the research members for each project. We categorized the researchers who designated the participants as their project members based on whether they were upper-level or peer researchers of the participants. If they were peer researchers, we further categorized the person according to position rank. Connections with the participant were then classified according to their relationship. Analysis 2 focused not only on the totaled highest amount allocated for each project r of projects but also on the type of programs won. The number of large or small projects won as principal investigators was used as the dependent variable. Furthermore, we categorized the projects in which each participant took part as a project member according to the period in which each of them obtained a PhD to obtain information on when interactions are important over time. Principal component analysis and multiple regression analysis were conducted using the XLSTAT statistical software.

Results

Analysis 1

Multimedia Appendix 1 presents the descriptive statistics of the variables used in the analysis. When we regressed the totaled highest amount allocated for each project of the 52 selected researchers on their h-index, which represents the overall competitiveness of a given researcher with respect to publications, we found a positive correlation (Figure 1A). This result suggests that the variable defined previously is consistent with a researcher’s perceived competitiveness. The relationship between the dependent variable and the number of projects in which each researcher participated as a project member is shown in Figure 1B. We analyzed the determinants that contributed to success in obtaining GIA awards as principal investigators and focused on interpersonal relationships in the projects in which they participated as project members (models 1–4 in Table 2).
Figure 1. (A) Regression of the $h$-index value against the amount allocated to each participant as principal investigator (PI; includes Grants-in-Aid for Scientific Research, Grants-in-Aid for Specially Promoted Research, and Grants-in-Aid for Young Scientists). (B) Regression of the amount allocated to each participant as PI against the number of projects in which they participated as project members (N=52).
Model 1 is the base model that includes the researchers’ attributes, human connections in the history of GIA grant success, and research performance. The effect of human connections was examined using networking level as measured using the value of betweenness centrality and quality of connections expressed through the h-index of the coresearcher. To examine the effects of publication performance, we included the number of papers and last-authored papers published. Model 2 controls for early career success in obtaining GIA awards to mitigate endogeneity, and model 3 includes variables for university rank at various stages in the researchers’ career. Model 4 is a simplified model with variables that were found to be highly influential throughout the analysis. Regarding the control variables, the coefficients of not having experience at nonuniversity institutions were significantly negative (P<.001). Difference based on sex exhibited no significant effect, but the number of female researchers in the analysis was small; thus, this result is not definitive. Considering research performance, the impact of last authorship was large (models 1-4).

Regarding human connections, researchers with fewer collaborative partners tended to win more grants; however, this trend was inconsistent with the correlation coefficients shown in Multimedia Appendix 1. Betweenness centrality, which indicates the visibility of each researcher within the collaborative network, did not exert a significant effect on lifetime grant acquisition (models 1-4). The h-index value of the researcher who first invited the participant to become a project member had a significant positive impact on the participant’s grant acquisition (models 1-4).
success (model 1). The effect of these 3 variables remained significant even after incorporating variables related to grant success in the early stages of the researchers’ career (model 2). The correlation between university rank and grant success shows that researchers affiliated with higher-ranked universities tend to be more successful (Multimedia Appendix 1); however, when considering the regression models, the rankings of the universities where a researcher obtained their PhD degree and where they were currently working did not, by themselves, affect grant success. When university ranks were incorporated into the regression model, the effect of the $h$-index value of the researcher who first invited the participant to become a project member was not significant (model 3). Overall, the result of the $h$-index value indicates the importance of having a good research guide as the first step but also suggests that a researcher’s grant success can be affected by the new connections established during career development. Finally, model 4, which retains this variable together with last authorship and number of collaborative partners, has the smallest Akaike information criterion value and was considered the best-fit model.

Initially, we assumed that the researchers who first invited the participants to become a project member were laboratory heads and direct superiors, but this was not always the case (Table 3). Only 29.6% (32/108) of the researchers were direct superiors, 5.5% (6/108) were subgroup heads other than professors, and 7.4% (8/108) were peers or subordinates in their own institution. Notably, 8.3% (9/108) were external upper-level professionals (ie, from other institutions; Table 3). The correlation matrix in Multimedia Appendix 1 shows that being a project member of a government-funded program leads to a significant positive correlation with grant success. Therefore, as an in-depth examination of the effect of human resources, we tested whether project experience in a prestigious government-funded program, often led by top researchers, would increase the likelihood of GIA success for the participants using the Japan Science and Technology Agency Strategic Basic Research Program (SBRP) as a case study [17].

*All the projects won in the year in which each participant obtained projects for the first time were counted.

Figure 2 plots the cumulative average GIA award values obtained as principal investigators over time; the 2 groups are established based on the presence or absence of SBRP experience among the 52 participants. Researchers who had been project members of the Core Research for Evolutional Science and Technology subprogram were selected as the treatment group from a total sample of 52, whereas those who had been PIs of this program were excluded. Researchers with similar $h$-index values and career lengths as those in the treatment group were then selected as the comparison group. The mean $h$-index value was 63.7 (SD 40.4) for the treatment group and 61.3 (SD 20.9) for the control group, and the mean career length was 33.4 (SD 5.2) and 25.1 (SD 5.4), respectively. The timeline was anchored on 0 for the start year of the projects in which the treatment researchers participated. For the control group, we fixed the 13th year since obtaining a doctoral degree to 0, which is the average career length at the time participants in the treatment group joined the SBRP projects (n=7 for each group).

The 2 groups begin at the leftmost point with low cumulative grant amounts. In the period leading up to the zero point, we observe no evident difference between the 2 groups, with similar funding gains. However, after participating in the SBRP, the gains of the treatment groups increased dramatically (Figure 2). By the end of the observation period, the treatment group received a higher award amount than the control group.
Analysis 2

To conduct a broader analysis of interpersonal relationships, we included 982 researchers, including 55 (5.6%) female researchers, identified as having collaborated with the researchers in the previous section (Table 1). The relationship between the number of years since obtaining a PhD and the amount earned as a principal investigator peaked at approximately 40 years after receiving the degree (Figure 3A).

Using principal component analysis to evaluate each researcher’s grant success in terms of research impact, namely, the number of projects obtained, project acquisition rate for large programs, and project acquisition rate for small programs, we divided the researchers into 3 groups (Figure 3B). The term “%Small” indicates the percentage of projects from the Grant-in-Aid for Scientific Research (C) (either number of projects or amount awarded), which represents the smallest category, in the total number of projects obtained as PI. Similarly, the term “%large” indicates the Grant-in-Aid for Scientific Research (S) and Grant-in-Aid for Specially Promoted Research, which are considered large categories.

We conducted univariate logistic regression analyses to identify the factors that produced researchers with high grant success records in both large- and small-program categories (Table 4). Career length had a positive effect for large programs (odds ratio [OR] 1.07, 95% CI 1.04-1.10 for stratum 1) and a negative effect for small programs (OR 0.95, 95% CI 0.94-0.97 for stratum 1). Conversely, the variable “doctorate obtained by thesis,” which was introduced to observe the effect of age, had no significant effect. However, among the 30.8% (184/597) of researchers who received their PhD later in life, there were prominent researchers who had served as university presidents or on government committees. Earning a degree earlier or later in life did not uniformly affect a researcher’s competitiveness, and individual differences are likely to have a greater impact.

Regarding differences based on sex, male researchers exhibited a negative effect on project acquisition of small programs (OR 0.29, 95% CI 0.12-0.70 for stratum 4). This indicates that male researchers are likely to move from small to larger programs.

Figure 2. Cumulative average Grants-in-Aid award values obtained as principal investigators (PIs) before and after participating in projects in the Strategic Basic Research Program (SBRP) as project members.
Upon examining the impact of interaction with upper-level and peer researchers on grant success as principal investigators, we observed the following results (Table 4). More interactions with upper-level researchers resulted in fewer acquisitions of large programs (OR 0.67, 95% CI 0.50-0.89 for stratum 1) and more acquisitions of small programs (OR 1.21, 95% CI 1.07-1.36 for stratum 1) compared with the reference stratum. The differences in the ORs among the strata with different numbers of projects awarded indicated that the stronger the relationship with upper-level researchers, the higher the success rate in the smaller programs (OR 1.43, 95% CI 1.27-1.60 for stratum 4; Table 4).

After examining the impact of interaction with peer researchers separately at each stage of their careers, such as professor, associate professor, and assistant professor, we found that, in large programs, professor-professor interaction had a significant impact on the success rate of ≥2 research grants (OR 1.16, 95% CI 1.06-1.26 for stratum 2), which is not the case for the success of only 1 project (Table 4). More professor-professor interactions led to fewer acquisitions of ≥2 projects in the small category (OR 0.85, 95% CI 0.77-0.93 for stratum 2; Table 4). Interaction with peer researchers at the associate professor level and below had no significant effect on either large or small programs.

---

<sup>a</sup>The number of projects obtained by the participants as principal investigators was used as the dependent variable. The term *large* indicates projects from the Grant-in-Aid for Scientific Research (S) and Grant-in-Aid for Specially Promoted Research, which are considered large categories. Similarly, the term *small* indicates the Grant-in-Aid for Scientific Research category (C), which is considered the smallest category.

<sup>b</sup>Number of projects obtained. Cases with no corresponding acquisitions were designated as stratum 0 and used as a reference. Cases with ≥2 corresponding acquisitions were defined as stratum 2 for large categories, and cases with ≥4 acquisitions were defined as stratum 4 for the small category.

<sup>c</sup>Wald test (P<.05).

<sup>d</sup>P<.001.

<sup>e</sup>Doctoral degree conferred by submitting a doctoral thesis and passing its examination. We used this as a control variable and conducted an analysis by assigning a value of 0 for a regular degree and 1 for a doctorate obtained by thesis.

<sup>f</sup>Interaction among researchers in the same position was expressed as the number of researchers who made the participant a project member.

<sup>g</sup>P<.01.

<sup>h</sup>P<.05.

<sup>i</sup>No results were output by XLSTAT software for this stratum.

**Figure 4** shows the number of projects in which the researcher participated as a coinvestigator based on the years after obtaining a PhD. The researchers were divided into 3 groups based on their performance level, as shown in **Figure 3B**. The groups with higher research achievements had a greater number of projects during the 10- to 14-year postdegree period. Group 3, the group with the highest research achievements, had the largest number of projects during the 15- to 19-year postdegree period (**Figure 4**). Table 5 focuses on these years as key periods and presents the average scores of several indicators of grant success and interpersonal relationships. Although the most active researchers (group 3) obtained large-program grants and interacted with more researchers during the indicated periods, the less active researchers (group 1), who primarily won small-program grants, interacted with fewer researchers during this period, many of whom were upper-level researchers (Table 5).

Table 6 presents the results of the univariate logistic regression analyses on the impact of the frequency and quality of connections using the number of project acquisitions in large and small programs as dependent variables. When the frequency of interactions during the periods was categorized by the job relationships between the partner and the participant, the results showed that interactions with peer researchers and subordinates during the 10- to 14-year postdegree period had positive effects on ≥2 large-program acquisitions (OR 1.51, 95% CI 1.09-2.09 and OR 1.31, 95% CI 1.10-1.57, respectively; Table 6). Interactions with subordinates during the 15- to 19-year postdegree period also had positive effects (OR 1.25, 95% CI 1.25-1.07). In contrast, for the small programs, interaction with upper-level researchers was important both in the 10- to 14-year and the 15 to 19-year postdegree periods, with significant positive effects (Table 6). Notably, these results show that the frequency and quality of human interaction had opposite effects on acquisitions of large and small programs.

### Discussion

#### Principal Findings

This study aimed to identify factors that influence researchers’ potential to obtain external research funding by surveying their stage of career development and the types of people they interacted with using the GIA project implementation structure. Early-career interpersonal relationships, as measured using the h-index value of the researcher who provided the participants with their initial experience as project members, had a positive effect on grant success (Table 2). The results revealed the importance of having a good guide. We propose that a good guide can broaden project members’ perspectives by demonstrating the “behind-the-scenes” elements of effective project implementation. A good guide, not necessarily an immediate supervisor, also serves as a channel for informing fellow researchers of the perspectives required to obtain larger funds.

The results based on nonuniversity experiences (Table 2) suggest that creating an attractive proposal based solely on individual research curiosity may be difficult. The breadth of scientific expertise expressed within a research group rarely matches that expressed by an academic committee [24]. Enhancing one’s perspective by participating in large, purpose-driven projects such as those conducted by companies is important. The fact that experiencing the SBRP (a prestigious government program) as a project member facilitated subsequent grant success also confirms this hypothesis (Figure 2). A unique feature of the SBRP is that a star researcher, as the research director, conducts various interventions to modify the proposed research plan [17]. This provides the project members with opportunities to learn not only about the research conception of the principal investigator but also about the overall view of the research field held by the star researcher above the principal investigators and the strategic goals determined by policy objectives.

The effect of human connections varies depending on the career stage at which the research collaboration occurs. We found that the signs of the coefficients for the number of co-researchers were inconsistent between Multimedia Appendix 1 and Table 2. This may be due to the fact that Table 2 shows the actual relevance of the indicator to researchers’ competitiveness at the individual level, whereas Table 2 shows the macro trends. Although a larger number of collaborators indicates a larger number of projects and more grant amounts obtained in general (positive coefficient in Multimedia Appendix 1), it also suggests the importance of implementing a small number of elite projects...
Our results suggest that greater collaboration among professors increases the number of large projects obtained (Table 4). After establishing one’s specialty and becoming a professor, collaborating with researchers in different fields and leveraging synergies to obtain greater funding is easier than when one is young [25]. It is assumed that highly competitive researchers who become professors early in their careers have more opportunities to conduct collaborative research among professors, and this collaboration and friendly competition with peers may stimulate their motivation to generate new ideas worthy of being supported by large programs. Meanwhile, factors that influence midcareer grant success remain largely unexplored despite challenging expectations regarding human resource development at universities and research institutions. This study did not present significant results regarding the midcareer level (Table 4); this is because collaboration during the earlier period may include protected time until each researcher refines their research and reconciles it with that of other researchers, after which truly meaningful collaboration occurs [26,27]. Tracking the process of research development, we found that interaction with others during the periods of 10 to 14 years and 15 to 19 years after obtaining a PhD determines the size of the project that the participant will obtain (Tables 5 and 6).

This study initially attempted to identify the factors that produce researchers with high grant success records, but as grant success depends on various factors, including the assignment of reviewers and other random factors, and given cases in which initial success may have been leveraged in subsequent years [28], it was difficult to obtain clear results when focusing on large programs alone (Tables 5 and 6). Interpreted in conjunction with the results from the project acquisition rate of small programs (Tables 5 and 6), midcareer relationships that remain narrowly focused, such as immediate supervisors, keep participants’ grant success limited to small programs throughout their careers and do not lead to the acquisition of large programs (Table 6). Liu [29] pointed out that the relationship between scholar productivity and tie strength exhibits an inverted U shape using data from tourism scholars. Researchers who devote their efforts to others’ research cannot concentrate on deepening their own studies. Considering the trade-off in collaboration between acquiring ideas and paying for effort instead of undertaking part of the supervisors’ initiatives, getting involved in diverse projects by peers and subordinates is important. In particular, participating in projects by subordinates is an effective way to be exposed to the fresh ideas of a younger person and look over their projects critically as an experienced person. This will ultimately help researchers become established figures who can conduct large-scale research projects as principal investigators.

Limitations

A limitation of this study is that we experienced some difficulties in obtaining clear data and subsequent results on the factors that influence the most prominent figures, such as those who had ≥3 projects in large programs (8/982, 0.8% in analysis 2), because of their rarity and the particular nature of their careers and research histories. These researchers tended to obtain large projects early in their careers instead of obtaining projects gradually increasing in size, which is related to the fact that they returned after international education pursuits or worked at nonuniversity institutions. Although initial success is likely to be influenced by almost uniform factors that apply to all researchers, such as publication performance relative to age, continued success is likely to be heavily influenced by individual enthusiasm and willingness to acquire large projects. Therefore, contextual analysis, such as interview surveys, will be necessary to identify the factors that produce prominent figures with outstanding achievements.

Another constraint is that the results of this analysis are limited to positive grant awards as, unlike positive awards, information on rejected projects is not publicly available. Under the Japanese grant system, the range of acceptance rates among researchers is not considered to be very large as proposals are submitted only once a year and the number of projects that can be applied for in a given year is limited by the grant system’s restrictions on duplicate applications. However, the differences among researchers with different application rates should be explored in a future study to better clarify the factors affecting researchers’ competitiveness.

Conclusions

This study explored objective measures of success in obtaining GIA with a focus on interpersonal relationships. Our results have several implications for future research. To improve one’s ability to obtain external funding, the following are necessary aspects: developing links with channels enabling access to quality information, gaining experience in collaborative research at the midcareer stage, and developing a research area in which one can take more initiatives in the future. The function of systematically training researchers has not been sufficiently developed in the Japanese medical community, and whether one can grow as a researcher is left entirely up to the individual. Researchers must broaden the scope of their research and increase their visibility in the academic field to actualize innovative ideas. In summary, individuals should understand the power of a collaborative network and strategically choose cooperative partners.

Abstract

Background: The development of digital health tools that are clinically relevant requires a deep understanding of the unmet needs of stakeholders, such as clinicians and patients. One way to reveal unforeseen stakeholder needs is through qualitative research, including stakeholder interviews. However, conventional qualitative data analytical approaches are time-consuming and resource-intensive, rendering them untenable in many industry settings where digital tools are conceived of and developed. Thus, a more time-efficient process for identifying clinically relevant target needs for digital tool development is needed.

Objective: The objective of this study was to address the need for an accessible, simple, and time-efficient alternative to conventional thematic analysis of qualitative research data through text analysis of semistructured interview transcripts. In addition, we sought to identify important themes across expert psychiatrist advisor interview transcripts to efficiently reveal areas for the development of digital tools that target unmet clinical needs.

Methods: We conducted 10 (1-hour-long) semistructured interviews with US-based psychiatrists treating major depressive disorder. The interviews were conducted using an interview guide that comprised open-ended questions predesigned to (1) understand the clinicians’ experience of the care management process and (2) understand the clinicians’ perceptions of the patients’ experience of the care management process. We then implemented a hybrid analytical approach that combines computer-assisted text analyses with deductive analyses as an alternative to conventional qualitative thematic analysis to identify word combination frequencies, content categories, and broad themes characterizing unmet needs in the care management process.

Results: Using this hybrid computer-assisted analytical approach, we were able to identify several key areas that are of interest to clinicians in the context of major depressive disorder and would be appropriate targets for digital tool development.

Conclusions: A hybrid approach to qualitative research combining computer-assisted techniques with deductive techniques provides a time-efficient approach to identifying unmet needs, targets, and relevant themes to inform digital tool development. This can increase the likelihood that useful and practical tools are built and implemented to ultimately improve health outcomes for patients.

Introduction

Digital health tools have the potential to advance health care efficiency, precision medicine, and patient health outcomes. Yet even the most high-performing digital tools using cutting-edge artificial intelligence and machine learning techniques are likely to be shelved if they do not address shared priorities among stakeholders [1] and their associated real-world unmet needs, leaving the promise of artificial intelligence and machine learning in health care unrealized [2]. There are currently 350,000 digital health apps worldwide that aim to address a range of functions (eg, condition management, wellness and prevention, and patient experience) and health conditions (eg, diabetes [3], neurological conditions [4], and psychiatric illnesses [5,6]). However, most of these apps are not regulated or clinically validated, and most are not widely used or integrated into clinical practice [7,8]. Although evidence suggests digital health tools are acceptable to both patients and clinicians, there are diverging needs, priorities, and attitudes among stakeholder groups within the digital tool ecosystem [1].

Gathering insights from key stakeholders is an essential step to ensure the development of digital tools that meet the needs of both patients and clinicians toward the goal of providing high-quality patient-centered care [9,10]. Using upstream stakeholder engagement methods can reveal actionable—but otherwise unforeseen—needs for targeted design and development of clinically impactful patient-facing digital tools with increased potential for widespread adoption [11,12]. Previous work has shown the benefits of qualitative research to assess hypothetical smartphone apps with content and function designs [13,14]. However, that work does not consider the motivation, or genuine need, for the app. Here we focus on the use of upstream qualitative research to first identify areas of real-world unmet need to serve as the foundation for hypothetical smartphone app ideation, design, and prototyping.

Qualitative research often involves designing and conducting a group of individual interviews and applying thematic analysis to transcripts of the resulting data. Conventional thematic analysis typically involves multiple researchers reviewing a subset of interview transcripts to identify themes [15] and developing a hierarchical system (codebook) of themes and subthemes (codes) to apply to sections of text (segments). The results of a conventional thematic analysis are typically presented in a table with broad summary themes, nested subthemes, and illustrative quotes from interview transcripts. The process of constructing the codebook can be time-consuming (eg, 3–5 times the amount of time taken to collect the data needed to review each interview [16]), subjective, and not always replicable [17,18].

While conventional thematic approaches are powerful for extensive investigations into a particular research area, a more time-efficient, scalable, and reproducible method is needed for digital health tool developers working in industry to swiftly identify key areas for the development of clinically meaningful tools. Indeed, in many settings of the digital health ecosystem, it is not feasible for researchers to dedicate substantial time to complete conventional thematic analysis. In some cases, it might be more appropriate to apply an automated text analysis that can be easily implemented by researchers, developers, and clinician scientists [19] to guide the identification of unmet needs and potential solutions. For example, recent work has applied text analysis to large qualitative research data sets to quickly identify common themes based on word frequency analysis [20–22]. Word combination frequency analysis provides a data-driven and repeatable approach to quickly identify frequently mentioned topics across a set of qualitative interview transcripts and potentially reduce the introduction of personal bias. Such approaches enable a faster and more convenient method to analyze a large amount of qualitative text data obtained from interviews with stakeholders [23]. Further, hybrid approaches that combine conventional thematic analysis with a data-driven inductive approach have the potential to leverage the strengths of both methods [24]. Importantly, such computer-assisted approaches to upstream qualitative research can be applied to engage and research any stakeholder group, including patients, to inform the development of clinically meaningful digital tools.

Given the limitations of conventional qualitative analysis—including the substantial time required for theme development—we demonstrate the utility of a hybrid approach leveraging the simplicity and accessibility of text analysis to identify stakeholder themes to support the initial stage of concept development for digital health tools. Specifically, we applied word combination analysis to a set of semi-structured interviews with US-based psychiatrists specializing in treating outpatients with major depressive disorder (MDD) to reduce the amount of text for thematic analysis fivefold to facilitate uncovering common themes and unmet needs of clinicians and patients across advisors. We opted to demonstrate the use of simple text analysis over some of the more advanced natural language processing techniques to increase accessibility to those without advanced backgrounds in coding or computational techniques. We propose that this approach could serve as a straightforward and repeatable framework to identify unmet needs before concept development and implementation. We will discuss our findings around unmet needs in treating MDD and how this might affect digital tool development in psychiatry as an end-to-end demonstration of this method.

Methods

Ethical Considerations

The interviewed psychiatrists were originally recruited for market research purposes using the Guidepoint Expert Network (Guidepoint Global). The BRANY Institutional Review Board determined this study was exempt from review under category 4ii in 45 CFR 46.104(d). Participants were compensated for their time and participation. All reported data were stored in password-protected databases accessible only to approved study personnel.

Recruitment and Data Collection

We used purposive criterion sampling to recruit 10 US-based psychiatrists specializing in treating MDD outpatients in a variety of practice settings, including academic medical centers and teaching hospitals, community-based mental health clinics,
and private practices spanning urban and rural settings in the United States (Table 1). With only 2 exceptions, we recruited and interviewed psychiatrists who spent most of their time (≥50%) on direct MDD outpatient patient care and who had 10 or more years of experience postresidency. The interviewed psychiatrists were originally recruited for market research purposes using the Guidepoint Expert Network (Guidepoint Global).

aMDD: major depressive disorder.

Regarding sample size, previous work suggests most qualitative research data sets reach saturation—the point during data collection in which themes begin to repeat, new insights begin to wane, and future data collection becomes redundant—between 9 and 17 interviews [25]. Moreover, our inclusion criteria were designed to recruit a relatively homogenous sample of experienced clinicians specializing in outpatient MDD care, as we did not require any between-subject comparisons.

One researcher conducted individual, 1-hour, single-blinded, semistructured, recorded audio interviews following a predesigned interview guide (Multimedia Appendix 1). The interview guide was designed to include open-ended questions primarily targeted at understanding the clinicians’ experience in care management for MDD as well as the clinicians’ perceptions of patient experience in care management for MDD. We used MAXQDA Analytics Pro 2022 (version 22.1.1; VERBI GmbH) [26] to process and analyze the quality-checked interview transcripts (their official website provides help with using specific features). However, one can use other available software or open-source approaches to execute the simple word combination text analysis steps below.

Data Preparation and Overview

All transcription text segments were auto-coded as either “interviewer” or “advisor,” depending on the speaker. Only “advisor” text was used during the text analysis stage. The data-driven hybrid approach to identifying relevant themes involved a 4-step process (Figure 1): (1) During the computer-assisted stage, use MAXQDA (or other) software to identify the most frequent n-grams (n-word word combinations, n=2+ words) across the interview data set. (2) Extract the sentences containing each of those n-grams, along with the preceding and succeeding sentences relative to the sentence containing each n-gram. (3) During the “hybrid stage,” work iteratively with at least 1 other researcher to read and reread each computer-extracted text segment in order to inductively identify key content categories and assign a content category label to each text segment until 100% agreement is reached among researchers. Discordant content category assignments among researchers can be resolved during discussion. (4) Finally, in the “deductive stage,” manually examine the full list of key content categories to develop overarching themes and nest the key content categories under the broader themes characterizing priorities in the process of care management in treating MDD.
Figure 1. Visual depiction of the hybrid data-driven method to identify key themes and content categories. The dashed lines denote the 2 key differences between conventional thematic analysis and the present approach: a computerized text reduction step and a set of n-grams and their corresponding quotes that provide an organizing layer to assist with manual identification and the development of content categories.

Data Analysis

Identifying Word Combinations

First, we used the “word combination” feature in MAXQDA to identify the most frequently used phrases in the advisor’s responses. We used MAXQDA, but any software capable of word combination analysis can be used. We used n-word combinations instead of single-word frequencies to increase the specificity of theme identification. Within the search parameters, we required the resulting words to be at least 4 characters long. All words were lemmatized in English, and we applied the MAXQDA English language stop list [27] to remove articles, conjunctions, and other words likely to be redundant in the analysis. We additionally added word combinations that co-occurred with our disease state of interest to the stop list (eg, “major depression” and “mental health”), as these were unlikely to yield meaningful insights. Next, we filtered the resulting word combination frequencies to word combinations that also appeared in a majority (at least 60%) of the interviews. We opted for a majority threshold cut-off based on our sample (word combinations that appeared in at least 60% of interviews) to limit the subsequent research steps to a more focused set of word combinations that were not likely spoken just by random chance (ie, ≤50%). Our goal was to maximize the chance of developing a solution that would be impactful for the majority (>50%) of clinicians. However, depending on the goals, users may elect to use different thresholds. For completion, word combinations that appeared in 50% or more of the interviews were included in the subsequent analysis.

Broadly, this first step served as a data-driven text analysis to identify commonly discussed themes or frequent expressions when discussing the care management process of the disease state of interest. Identifying key phrases used across stakeholders in a sample can give a sense of widely applicable needs and daily experiences. Identifying n-grams or word combinations is the crucial time-saving inductive step; however, to build meaning around the phrases, we recommend identifying key content areas by conducting follow-up deductive analyses of the context surrounding the word combinations.

Identifying Key Content Categories

Next, we extracted the resulting n-grams and their surrounding context for further analysis of the context in which these word combinations were uttered. Specifically, for each n-gram, we extracted the sentence containing the n-gram along with the 2 sentences before and after the appearance of each n-gram to provide context.

Next, 2 researchers systematically read the sentences surrounding each extracted word combination to understand the context in which the word combination was uttered. The researchers then worked iteratively through discussion and multiple independent readings to generate and assign relevant content categories for each n-gram. For expediency, the 2 researchers reconciled discordant labels through discussion until they reached 100% agreement. The researchers aimed to create content category labels for each word combination with definitions that were broad enough to accommodate multiple text segments but specific enough to distinguish among text segments from a given word combination. These researcher-generated content categories ultimately reflected the context surrounding the n-grams and provided a more in-depth understanding beyond the n-grams alone. Extracting and reviewing text around frequent and common n-grams helped to both focus the reading and deductive analysis of the text and substantially reduce the amount of text needed for review.

Next, we selected representative quotations for each content category to provide canonical examples of each of the chosen themes (Table S1 in Multimedia Appendix 2). This step represents a bridge between the text-analytic approach and the conventional deductive approach, in which researchers manually evaluate all the text to determine the appropriate content category represented in the segment. During this state, researchers review the text segments and apply their subject-matter expertise to sort the resulting text into subthemes.
However, the text analytic step saves time and increases process transparency by examining only the segments in each interview where the n-gram appears. This should ultimately limit the scope of the analysis to pertinent segments constrained by the list of word combinations established in the first step.

Researchers may choose to stop at this level of analysis and proceed with the development of digital tool concepts if unmet needs and potential challenges are adequately identified. The word combinations and content categories may be substantial enough to provide sufficient context to understand how to proceed with digital tool development. Here, we further analyzed the word combinations and content categories in order to identify overarching themes, bringing the results of the hybrid method even closer to those yielded from conventional analysis.

**Developing Overarching Themes**

Once the content categories were identified as described in the previous step, key overarching themes emerged across the content categories and word combinations. At this stage, we also included word combinations that appeared in 50% of interviews to help guide the identification of more robust overarching themes that accommodated more word combinations. During reading and analysis of the resulting n-grams and their corresponding text segments, themes should start to emerge that may have been deduced using the more conventional analysis approach. In essence, the word combinations and key content categories established in the first and second steps are essentially transposed to develop these overarching summary themes, highlighting areas of need. In this approach, the word combinations are reorganized and presented with word combinations nested within broad summary themes. The goal of this final step is to summarize the findings from the first 2 steps into an alternative table structure that may assist in conceptualizing unmet needs for patient-facing digital tool development. By following the first 2 steps, theme identification in this final step becomes a much more efficient and transparent process as compared to a more conventional approach.

**Results**

**Identifying Word Combinations**

All word combinations appearing in 50% or more of the interviews are shown in Table 2. Only bigrams resulted from the analyses. There were no word combinations of ≥3 words. For a full summary of word combinations, content categories, detailed descriptions, and representative quotations, please refer to Table S1 in Multimedia Appendix 2.

Critically, after extracting the sentences containing the set of word combinations and their preceding and succeeding sentences, we observed that the total advisor text word count to manually review reduced to 21% of the original stakeholder text word count, demonstrating the use of the approach to assist with focusing theme extraction on key areas of text containing n-grams (ie, the highly repeatable text reduction step).

**Identifying Key Content Categories**

After each researcher completed multiple readings of all word combinations and their surrounding contextual sentences, up to
5 content categories for each word combination were identified, resulting in a total of 14 unique content categories across phrases (Table S1 in Multimedia Appendix 2): administration, care management, common side effects, conceptualization, desired clinical information, differential diagnosis, medical comorbidities, medical history, medication monitoring and management, patient experience, risk assessment, risk for substance use, side effect monitoring, and treatment planning. The researchers aimed for ≤5 content categories for each word combination to balance specificity with generality. However, this target can be changed to accommodate larger or smaller studies that might require a higher or lower threshold to balance these goals. In total, there were 14 unique content categories, as some content category labels emerged under multiple word combinations (e.g., care management emerged as a content category relevant to 2-word combinations, “side effects” and “primary care”).

Developing Overarching Themes

In the final step, we identified overarching summary themes by transposing the word combinations and content categories identified in steps 1 and 2. In this analysis, we included word combinations uttered by 50% of advisors, which returned 11 additional word combinations (e.g., “bipolar depression” and “facial expression”). The full results expanding on these overarching themes can be found in Table 3, with the word combinations listed as relevant word combinations that support content categories and overarching themes. Through this process, we identified four overarching summary themes: (1) evaluation, (2) medication decisions, (3) tracking symptom progression, and (4) factors contributing to treatment adherence.

To create overarching themes, the researchers applied a similar process to the content category labels as they did to the word combinations—identifying a label and definition that would provide an appropriate umbrella term under which to nest multiple of the key content categories. To illustrate how we arrived at these broader themes, we will walk through the development of the “evaluation” theme. Analysis of the retrieved segments in the sentences surrounding the word combinations “bipolar depression,” “make sure,” and “substance [ab]use” converged on a content category best summarized as “differential diagnosis.” Through a similar process, segments surrounding the word combinations “suicidal thought,”
“treatment resistant,” “facial expression,” “family history,” and “family member” converged on a content category best summarized as “conceptualization.” Ultimately, “differential diagnosis” and “conceptualization” fit together with “medical comorbidities,” “risk assessment,” and “desired clinical information” under the broad and overarching theme of “evaluation.”

Discussion

Overview

To ensure the development of clinically meaningful digital tools, developers must address real-world, unmet stakeholder needs. Understanding these needs at the outset of concept ideation and tool development ensures that developers are solving the most urgent challenges. Qualitative research is a powerful tool to understand the daily experiences of patients and clinicians and to better understand how potential digital tools will provide value and integrate seamlessly into a given environment. Here, we presented a hybrid data-driven approach to facilitate time-efficient discovery of unmet clinician needs to inform the direction of digital tool development in health care settings. With this approach, in the context of care management in MDD, we identified several key areas that are of interest to clinicians and would be appropriate targets for digital tool development.

Using Key Content Categories to Inform Digital Tool Development

The key content categories are consistent with challenges identified in the literature, suggesting this approach can highlight real-world problems and point developers to further information in previously unknown areas of research literature. For example, the phrase “side effect” consisted of the following content categories: treatment planning, side effect monitoring, care management, patient experience, and common side effects. Further investigation into the literature encompassing this topic provides additional support for the selection of this area as a target of digital tool development. Burdensome treatment-related side effects are a leading cause of nonadherence and discontinuation of antidepressant medications [28] and have a negative impact on treatment outcomes [29]. Patients frequently experience side effects early in antidepressant treatment [30], but a lack of understanding of side effects [31] and barriers to communicating these side effects to clinicians, especially primary care providers [32], lead to early discontinuation and poor outcomes [29]. Some evidence exists that interventions addressing these early barriers to adherence, which include side effects, could improve adherence, communication between patient and provider, and, ultimately, treatment outcomes [33,34].

In the context of MDD care management, building digital tools that address patient and clinician concerns related to side effects, medication adherence due to side effects, and medication decisions based on side effects might best address one aspect of the current needs of clinicians as expressed through the interviews. The strengths of digital tools that could be leveraged in this context include facilitating side effect monitoring and reporting in between visits using smartphone capabilities, increasing patients’ understanding and expectations around side effects with on-demand psychoeducation through a mobile app or customized website, increasing clinicians’ awareness of the emergence of side effects through smartphone-based remote monitoring, or increasing and enhancing patient-provider communication through digital platforms.

Using a single topic as a guide for concept development may be a reasonable starting point for digital tool development; however, it is important to consider other related content categories that arise from this procedure. Incorporating other themes or content categories may bolster the initial concept and increase the likelihood that patients or clinicians will adopt a tool in clinical practice. In the context of MDD care management, the content category “administration” emerged as an important consideration for clinicians, signaling that workflow and administrative components of care management are also important to keep in mind while developing digital tools to ensure consideration of practical integration into workflows.

Incorporating New Ideas With Existing Best Practices

Overall, the topics identified through the approach outlined in this study should line up with current thinking and best practices around digital tool development in health care. This includes, but is not limited to, prioritizing ethical considerations around data sharing and privacy [35,36], considering the legal implications of digital tool implementation [37], and considering the balance between addressing unmet needs and integrating tools into the current care management workflow [38]. While identifying specific themes and content categories for a given disease state will elucidate current unmet needs for clinicians, established guidelines around digital tool development should be included as well.

Limitations

The approach outlined in this study has the potential to facilitate digital tool development across numerous clinical environments due to its ease of use and relative efficiency. Nevertheless, the comprehensive nature of conventional qualitative analysis may yield more nuanced findings from stakeholder interviews using a more deductive coding process. Moreover, limiting the amount of text for analytical review to those sentences surrounding frequent key word combinations across advisors is both a strength and a limitation of this method. While this approach increases efficiency, there could be a loss of sensitivity to important learnings outside of the extracted text segments, as well as some important one-off learnings uttered by only 1 advisor that could potentially be excluded from the text extracted for deductive analysis. Although the current sample size falls within a reasonable range to reach theme saturation across interviews [25], a more expanded sample size has the potential to reveal even more insights and accommodate analysis by psychiatry subspecialties (eg, addiction, child, adolescent, and geriatric psychiatrists). Furthermore, given that this method seeks to find consensus among spoken terms describing themes or content categories may bolster the initial concept and categories that arise from this procedure. Incorporating other themes or content categories may bolster the initial concept and increase the likelihood that patients or clinicians will adopt a tool in clinical practice. In the context of MDD care management, the content category “administration” emerged as an important consideration for clinicians, signaling that workflow and administrative components of care management are also important to keep in mind while developing digital tools to ensure consideration of practical integration into workflows.

(page number not for citation purposes)
confirmability (ie, results confirmed by an independent set of researchers) [39].

**Future Directions**

Here, we first interviewed clinicians because they are uniquely positioned within the digital health ecosystem to simultaneously identify and communicate patient needs, unmet clinician needs, potential for real-world clinical impact, and influence patient engagement with appropriate apps due to the trust patients place in their clinicians [1,7]. One challenge that blocks patient engagement with relevant digital tools is integration into clinician workflow [1], because clinicians have limited bandwidth to integrate patient-facing digital tools into their workflow. However, to ensure the most clinically relevant tools are created for and with patients, future work is needed to identify overlapping priorities between patients and clinicians. The method outlined here could be applied to patient interviews to reveal common and frequent unmet needs among patients.

The current framework provides a foundation for developers in the technology space to identify concepts that are worthy of further investigation and validation. Researchers following this framework may consider validating findings from this approach through follow-up methods such as: (1) triangulation studies (eg, test for convergence of results from this framework with focus group results or text from other sources, such as peer-reviewed articles about MDD), (2) quantitative survey methods, and (3) member-checking by presenting responses with the results to confirm the interpreted data and identified concept results resonate with their experience (respondent validation) [40] before moving further into conceptualization and prototyping.

**Conclusions**

We presented a hybrid computer-assisted method for identifying unmet needs expressed in semistructured interviews, which provides an efficient and user-friendly approach to this problem. The presented method offers some of the efficiencies of a purely analytic approach (eg, topic modeling), while the incorporation of manual analysis of the surrounding context sentences offers some of the benefits of finding more interpretable and relevant concerns, as in a traditional qualitative analysis. By contrast, in topic modeling alone, researchers often consider the topics (lists of words) outside of their surrounding context when trying to interpret their meaning. Thus, this hybrid approach falls between these 2 approaches and gives digital health researchers a feasible approach for conducting upstream research to inform ideation and the development of high-impact patient-facing digital tools.

Abstract

Background: Digital screening and intervention tools have shown promise in the identification and reduction of substance use in health care settings. However, research in this area is impeded by challenges in integrating recruitment efforts into ongoing clinical workflows or staffing multiple study clinics with full-time research assistants, as well as by the underreporting of substance use.

Objective: The aim of the study is to evaluate pragmatic methods for facilitating study recruitment in health care settings by examining recruitment rates and participant characteristics using in-person–based versus flyer approaches.

Methods: This study compared recruitment rates at a Women’s Health clinic in the Midwest under 2 different recruitment strategies: in person versus via a flyer with a QR code. We also examined the disclosure of substance use and risk screener positivity for the 2 strategies. We also obtained information about the current use of technology and willingness to use it for study participation.

Results: A greater percentage of patients recruited in person participated than those recruited via flyers (57/63, 91% vs 64/377, 17%). However, the final number recruited in each group was roughly equal (n=57 vs n=64). Additionally, participants recruited via flyers were more likely to screen positive for alcohol use risk on the Tolerance, Annoyed, Cut Down, Eye-Opener alcohol screen than those recruited at the clinic (24/64, 38% vs 11/57, 19%; χ²₁=4.9; P=.03). Participants recruited via flyers were also more likely to screen positive for drug use risk on the Wayne Indirect Drug Use Screener than those recruited at the clinic (20/64, 31% vs 9/57, 16%; χ²₁=4.0; P=.05). Furthermore, of the 121 pregnant women, 117 (96.7%) reported owning a smartphone, 111 (91.7%) had an SMS text message plan on their phone, and 94 (77.7%) reported being willing to receive SMS text messages or participate in a study if sent a link to their phone.

Conclusions: The distribution of flyers with a QR code by medical staff appears to be an efficient and cost-effective method of recruitment that also facilitates disclosure while reducing the impact on clinic workflows. This method of recruitment can be useful for data collection at multiple locations and lead to larger samples across and between health systems. Participant recruitment via technology in perinatal health care appears to facilitate disclosure, particularly when participants can learn about the research and complete screening using their own device at a place and time convenient for them. Pregnant women in an urban Midwestern hospital had access to and were comfortable using technology.
Introduction

Screening, brief intervention, and referral for treatment (SBIRT) approaches proactively address substance use in primary care settings and potentially reach those at risk, regardless of willingness to seek treatment. Large proportions of at-risk groups can be reached with SBIRT, particularly in the perinatal period where most pregnant women seek prenatal care. The consequent need for proactive screening, together with the promising efficacy of brief interventions for alcohol use [1], has led to recommendations that SBIRT be a standard element of prenatal care [2]. However, studies comparing self-report of drug use to objective indicators show that underreporting is common [3-5], especially in settings where disclosure can have heightened negative consequences such as during pregnancy [4,6,7]. The disclosure of substance use during pregnancy can be both socially stigmatizing and increase the woman’s risk for potential legal consequences. Currently, 18 states view substance use during pregnancy as child abuse, and 15 states have laws stating that health care workers are mandated reporters for drug abuse during pregnancy. Laws such as these increase the social stigma and the internal shame and guilt women may feel. This in turn limits the proportion of women who are willing to disclose substance use to their providers, suppressing disclosure and impacting the health of them and their unborn child [8-10]. This underreporting is a substantial obstacle to proactive screening efforts that seek to identify at-risk pregnant and postpartum women, the majority of whom do not seek treatment for substance use [11].

Additionally, the implementation of SBIRT approaches has been challenging. First, there are considerable time, financial, and logistic obstacles to integrating screening and brief intervention programs into ongoing medical practice [12,13]. For example, one estimate suggests that conducting all recommended prevention-related activities would take a primary care physician 4.4 hours per working day [14]. This issue is exacerbated by the fact that such services are only recently and not consistently being reimbursed by third-party payers. Second, many medical professionals express discomfort with the screening and intervention process and report doubts about its effectiveness—even when voluntarily participating in a formal demonstration program [13]. This discomfort and skepticism may in part explain findings of very low levels of physician adherence to recommended brief intervention guidelines, even after training [12,14,15]. Training in brief approaches such as motivational interviewing is expensive, time-consuming, and may have modest or transient effects [16]. Technology provides an exciting option. It can be implemented consistently across patients, with minimal staff involvement, and conducted during natural waiting periods, integrating easily within the workflow of the clinic [17-19]. It has also been shown to improve disclosure of substance use in anonymous studies [20].

However, studies involving technology in health care settings often struggle with recruitment, particularly given time constraints on the part of clinic staff who must provide an initial introduction to the study. Typically, clinical trials are addressed via multisite trials using face-to-face recruitment. Despite being a time-tested gold standard, several limitations to this approach exist. First, the combination of a low base rate of substance use during pregnancy with high levels of underreporting makes recruitment lengthy and challenging even across multiple sites. Second, even multisite trials are only able to measure a limited range of participant characteristics specific to only a few geographic locations. Third, well-funded and tightly controlled trials often use methods (eg, a research assistant [RA] or study nurse) that do not readily translate to how the program could be implemented without research funding. Fourth, multisite research can also quickly become impractical if staffing each clinic with a full-time RA is required. There is increasing recognition of the need for highly pragmatic trials that take translational and implementation issues into account [21]. Research is therefore also needed on pragmatic methods for facilitating recruitment in these settings. The provision of flyers describing the study and allowing enrollment on the web is a possible solution, but relative recruitment rate for this approach, as compared to traditional approaches, is not known and is partly dependent on rates of technology ownership.

This study analyzes data exploring how to best leverage technology to identify risk during pregnancy, particularly whether different approaches in recruitment can increase disclosure. The study had 3 goals. The first goal was to obtain current substance use risk levels of women attending their prenatal care intake at a large Midwestern hospital’s outpatient clinic. The second goal was to compare the disclosure of substance use risk under 2 different recruitment strategies, in person versus via flyers, and determine recruitment rates for the 2 approaches. The last goal was to better understand the access and comfort of using smartphones and SMS text messaging for study participation. It was hypothesized that in-person recruitment would have a higher acceptance rate for study enrollment, but that participating in the study on their own device in the privacy of their home would increase disclosure.

Methods

Participants

Participants were 121 pregnant women attending a new pregnancy intake at an outpatient clinic that is part of a large health system in the Midwest. Eligibility criteria included being 18 years or older of age, understanding spoken English, and being pregnant with the intention to carry the pregnancy to term.

Recruitment

Data collection began in September 2018 and concluded in May 2019. An RA was present at the clinic on 2 half days per week;
during this time, willing participants were introduced to the RA by the nurse who was completing the intake with the patient. At all other times, clinic staff gave patients a flyer describing the study and provided a website (via QR code, along with a unique login ID) through which patients could enroll in and complete the study. The flyer was provided by intake nurses at the end of the appointment, and participants used their own device to complete the study.

Procedures
Participants who enrolled in the study completed a series of screening questions regarding substance use before and during pregnancy, as well as questions related to demographics, general health, and technology access. Those recruited by the RA were given a tablet to complete the study at the clinic following their intake appointment. Those enrolling in the study via the flyer used their own device and completed screening at a time and place convenient for them. In addition, those who screened positive for any substance were offered within the app to participate in a subsequent extended assessment (duration of 10 to 20 minutes) with separate consent. The app would link participants to the next screening if they agreed to participate.

Ethical Considerations
All procedures for the study were approved by both the university (#085518B3A) and health system (#12267) institutional review boards. The app used for data collection read aloud the consent form that explained to participants that the study has 2 parts. Electronic information sheets were used for the study. Participants agreed to participate in the study in the computerized questionnaire by clicking a box and then answering the questions. There were no physical copies of the consent form. Part I included content regarding broad health behaviors such as nutrition and sleep, as well as brief questions on smoking, alcohol, and marijuana use during the month before they became pregnant. For part II, participants who screened positive for smoking, alcohol, or marijuana use in the month before becoming pregnant were invited to complete a 15- to 20-minute survey asking additional questions about risk factors. This assessment included more sensitive information regarding substance use, traumatic experiences, partner violence, depression, and anxiety. Participants who completed part I received a US $10 Target gift card, and those who were eligible and completed part II received an additional US $20 Target gift card. No identifying information was collected until after participants completed the assessment items. Once participants completed the portions of the study they were eligible for, they were linked (within the survey) to a separate survey, where they could receive their gift cards and a copy of the consent form. The data participants gave in order to send the gift cards were kept in a separate password-protected spreadsheet from the rest of the data and were destroyed once the study was complete. Participants who completed the survey in the clinic received the consent form and gift card directly from the RA.

Measures
All participants were asked to complete 47 items regarding alcohol, marijuana, and tobacco use before pregnancy and during the past month, as well as questions about pregnancy and general health. These items included, but are not limited to, the following:

1. The Tolerance, Annoyed, Cut Down, Eye-Opener (T-ACE) alcohol screen [22] is a 4-item alcohol risk screening questionnaire that asks about the amount of drinks to feel high, if people have annoyed you by criticizing your drinking, if you have ever thought you should cut down, or if you need to have a drink first thing in the morning. Scores of 2 or higher result in a positive screen.

2. The Wayne Indirect Drug Use Screener (WIDUS) [23] is a 6-item screening instrument that identifies risk for drug use in the perinatal period by asking about correlates of drug use without directly asking about use. Scores above 3 are considered positive. Examples of true or false questions include “most of my friends smoke cigarettes” and “I get mad easily and feel the need to blow off steam.”

3. The National Institute on Drug Abuse (NIDA) Quick Screen [24] consists of 4 questions asking respondents to indicate the frequency with which they had 4 or more drinks in a day, use of illegal drugs, use of prescription drugs for nonmedical reasons, or use of tobacco products in the past year. The alcohol and drug use items have been validated as single-item questionnaires [25,26]. These items were adapted to evaluate use in the past month rather than the past year and to include a separate item for cannabis use.

4. Participants were also given 4 technology questions regarding technology access and use (smartphone ownership, having an SMS text messaging plan, willingness to receive SMS text messages, and willingness to participate in research via a link sent to their phone).

Statistical Analysis
Chi-square analyses compared differences between in-person–and flyer-based recruitment as well as differences in disclosure on the T-ACE, WIDUS, and each item of NIDA Quick Screen. Chi-square analyses used all available screening information from each participant. However, participants with missing items were dropped from that specific analysis. Two individuals had missing data for the NIDA Quick Screen binge drinking and tobacco questions. One person had missing data for the NIDA Quick Screen prescription drug and illegal drug use questions. There were no missing data for the T-ACE or WIDUS.

Results
Participant Characteristics
Study participants were primarily Black and African American (92/121, 76%) and had a mean age of 27.7 (SD 4.9) years (Table 1). Approximately half (66/121, 54.5%) of the participants had completed some education beyond high school.

**Risk Screen Positivity**

Between-group differences in positivity rates were examined for 2 validated screening tools, the WIDUS and the T-ACE. A total of 20 (31%) out of 64 participants recruited through flyers screened positive for drug use risk on the WIDUS versus 9 (16%) out of 57 participants recruited at the clinic ($\chi^2_{1}=4.0; P=.05$). Additionally, a total of 24 (38%) out of 64 women recruited through flyers screened positive for alcohol risk on the T-ACE versus 11 (19%) out of 57 participants recruited at the clinic ($\chi^2_{1}=4.9; P=.03$; Table 2).

**Disclosure of Past Month Substance Use**

Chi-square analyses compared the disclosure of substance use (on the NIDA Quick Screen) for participants recruited in person versus via the flyer. Questions included the frequency of binge drinking (4 or more drinks per day), tobacco use, prescription drugs for nonmedical purposes, and illegal drugs in the past month. Each NIDA Quick Screen item was treated as dichotomous reflecting either any or no reported use (Figure 1). There were no significant differences across groups in binge drinking ($\chi^2_{1}=0.1; P=.72$), tobacco use ($\chi^2_{1}=0.3; P=.58$), prescription drug use for nonmedical reasons ($\chi^2_{1}=2.0; P=.26$), or illegal drugs ($\chi^2_{1}=2.0; P=.15$).
Figure 1. Recruitment rate comparison for the in-person and flyer clinic recruitment methods for patients attending prenatal care between September 2018 and May 2019.

Recruitment Rates for Each Method of Recruitment

Of the 121 participants recruited overall, 57 were recruited directly by the RA, and 64 responded to the flyer. Nurses handed out 377 flyers resulting in 64 participants, representing 17% of those given the flyer. In contrast, of 109 patients completing a new pregnancy intake when the RA was in the clinic, 63 (57.8%) were introduced to the RA by the intake nurse, and 57 (91%) of the 63 agreed to participate and completed the screener (57/109, 52.3% of all available patients). Notably, flyer recruitment showed a stable increase over the course of the study (Table 2). This increase occurred following the introduction of a new approach, in which the RA and project coordinator began attending monthly staff meetings and updating nurses on the study progress, bringing in snacks, and building upon the relationships with the intake nurses in the clinic. This change in approach started in January, with an increase in nurse engagement and enthusiasm for the study happening in the next few months, resulting in an increase in flyer recruitment because many more were handed out. During the winter months of February and March, there were fewer intakes overall because of the weather. This decrease corresponds with an expected decrease in in-person recruitment during those months.

Technology Accessibility and Willingness to Use for Participation

Of the 57 participants who were recruited in the clinic and used the tablet provided by the RA, 56 (98%) reported owning a smartphone, and 55 (96%) reported having an SMS text message plan on their phone. In total, 44 (77%) of these participants said that they would be willing to receive SMS text messages as part of a research study, and these participants also said that they would be willing to participate in additional surveys or programs if sent a link on their phone.

Discussion

Principal Findings

This study was set up to obtain substance use risk levels for women attending prenatal care at a large Midwestern hospital’s outpatient clinic, compare 2 different recruitment methods to examine which had higher recruitment rates and disclosure rates, and document participants’ access and comfort using smartphones and SMS text messaging for study participation. Recruitment via flyers distributed by health care staff was less efficient than when those same staff introduced patients to an on-site RA (57/109, 52.3% vs 64/377, 17% enrollment). However, participants in the flyer group were more likely to report substance use risk than those in the on-site RA group (20/64, 31% vs 9/57, 16% for the WIDUS and 24/64, 38% vs 11/57, 19% for the T-ACE). Most study participants owned a smartphone (56/57, 98%) and had an SMS text message package on their phone (55/57, 96%). Additionally, of the 121 participants, 94 (77.7%) were willing to receive SMS text messages or a link to further study participation on their devices. Despite the lower overall enrollment compared to the on-site RA, the flyer approach requires less effort for medical staff and removes the need for a full-time RA at each study clinic. The flyer approach was also associated with greater disclosure on some measures of substance use. As is often the case, maintaining regular communication with clinic staff was particularly important in the flyer-based recruitment approach. These findings suggest that eligibility determination for substance use studies may be more successful and more representative (because of the wider possible reach with the same level of staffing) when using electronic screening with flyers rather than relying on full-time staff in the clinic. Flyer-driven recruitment appears to be a practical approach, given the high levels of access to technology among the pregnant urban participants and their willingness to use their personal
devices for research. These latter findings are consistent with national survey data suggesting that smartphone ownership rates are high [27], and research suggesting that low-income patients are willing to use their own smartphone to participate in research [28].

**Limitations**

The sample size, homogeneity of the sample, and preliminary nature of this research all contribute to clear limits in the generalizability of these findings. In addition, our sample size limited the ability to understand what variables may contribute to higher disclosure within the flyer recruitment group (ie, maternal age, parity, past substance use, or socioeconomic status).

**Conclusions**

Using electronic methods for eligibility determination appears to facilitate disclosure and, thus, recruitment efficiency. Although flyer-based approaches are less efficient than in-person recruitment with an on-site RA, they may also facilitate disclosure and can allow cost-effective recruitment at multiple sites. Even low-income patients in perinatal settings are very likely to own a smartphone and be willing to use their own device to participate in research. This method can allow for larger study samples by decreasing the amount of money needed to support full-time RAs in each recruitment site. Instead, 1 RA could be used across multiple sites, which can free up funds for a larger number of site locations. This can allow for a wider variety of participants across the country and could be more translatable and easier to replicate or continue once funding ends.

Abstract

Background: Research gaps refer to unanswered questions in the existing body of knowledge, either due to a lack of studies or inconclusive results. Research gaps are essential starting points and motivation in scientific research. Traditional methods for identifying research gaps, such as literature reviews and expert opinions, can be time consuming, labor intensive, and prone to bias. They may also fall short when dealing with rapidly evolving or time-sensitive subjects. Thus, innovative scalable approaches are needed to identify research gaps, systematically assess the literature, and prioritize areas for further study in the topic of interest.

Objective: In this paper, we propose a machine learning–based approach for identifying research gaps through the analysis of scientific literature. We used the COVID-19 pandemic as a case study.

Methods: We conducted an analysis to identify research gaps in COVID-19 literature using the COVID-19 Open Research (CORD-19) data set, which comprises 1,121,433 papers related to the COVID-19 pandemic. Our approach is based on the BERTopic topic modeling technique, which leverages transformers and class-based term frequency-inverse document frequency to create dense clusters allowing for easily interpretable topics. Our BERTopic-based approach involves 3 stages: embedding documents, clustering documents (dimension reduction and clustering), and representing topics (generating candidates and maximizing candidate relevance).

Results: After applying the study selection criteria, we included 33,206 abstracts in the analysis of this study. The final list of research gaps identified 21 different areas, which were grouped into 6 principal topics. These topics were: “virus of COVID-19,” “risk factors of COVID-19,” “prevention of COVID-19,” “treatment of COVID-19,” “health care delivery during COVID-19,” “and impact of COVID-19.” The most prominent topic, observed in over half of the analyzed studies, was “the impact of COVID-19.”

Conclusions: The proposed machine learning–based approach has the potential to identify research gaps in scientific literature. This study is not intended to replace individual literature research within a selected topic. Instead, it can serve as a guide to...
formulate precise literature search queries in specific areas associated with research questions that previous publications have earmarked for future exploration. Future research should leverage an up-to-date list of studies that are retrieved from the most common databases in the target area. When feasible, full texts or, at minimum, discussion sections should be analyzed rather than limiting their analysis to abstracts. Furthermore, future studies could evaluate more efficient modeling algorithms, especially those combining topic modeling with statistical uncertainty quantification, such as conformal prediction.

**Introduction**

**Background**

Scientific research relies on applying systematic scientific methods and actions to increase knowledge in fields or specific topics [1]. One essential first step in engaging in scientific research is identifying research gaps [2], where insufficient data, knowledge, or understanding limit our ability to draw conclusions in a given field or topic [3]. Research gaps can also be referred to as unanswered questions that have not yet been addressed or are underexplored in the existing body of knowledge, either due to a lack of studies or inconclusive results [4,5]. Research gaps can also serve as a starting point for research as well as motivate further research [6]. Researchers have classified research gaps into seven categories [3,6,7]: (1) evidence gaps—where contradictions in the findings of the previous research exist; (2) knowledge gaps—where knowledge may either not exist in the literature or the results deviated from what was expected; (3) practical-knowledge conflict gaps—where the goal is to discover the reasons and scope of differences between professionals’ behaviors versus their advocated behavior; (4) empirical gaps—where there is a need to empirically evaluate and verify research findings or propositions; (5) methodological gaps—where shortcomings may arise due to having a single methodology influencing the research results; (6) theoretical gaps—related to examining gaps that exist in theories and their models and compare them with prior research; and (7) population gaps—where a population is not adequately represented or underresearched in prior studies.

The sheer volume and accelerated pace of scientific research output present both opportunities and challenges. Identifying potential interventions, best practices, and policy recommendations, all backed up by evidence is made easier by the wealth of information available. However, researchers face challenges with staying up-to-date with the latest findings, identifying redundancies in research, and objectively identifying research gaps that need to be addressed. Therefore, it becomes paramount to accurately identify the research gaps to advance our understanding of the issue or topic, better use the allocation of resources, and better inform evidence-based policy making.

Traditionally, several methods are used to identify research gaps, including literature reviews, systematic reviews, expert opinions, and consensus-building activities (eg, developing guidelines). Yet, such methods require an intensive time commitment, are prone to bias, and can be labor intensive. Additionally, such methods may not be suitable to address issues, where the evidence or research subject is rapidly increasing in volume and pace or is time sensitive (eg, COVID-19). Consequently, there is a need for innovative and scalable approaches to systematically assess existing literature, identify research gaps, and prioritize areas for further study in the topic or field of interest.

Machine learning (ML) techniques have demonstrated great potential applications of scientific insights and discoveries by addressing challenges related to information retrieval, knowledge discovery, and natural language processing [8]. ML is a branch of computational science and a subset of artificial intelligence (AI); it focuses on the development of algorithms that enable machines to learn from [9-12] and make predictions or decisions based on data, without being directly programmed [13]. Broadly, ML algorithms can “learn” through supervised learning, unsupervised learning (eg, reinforcement learning), or a mixture thereof, referred to as semisupervised learning [14,15].

**Research Problem and Aim**

In the context of identifying research gaps, ML techniques may facilitate the discovery of research gaps by analyzing large volumes of scientific evidence in a systematic, scalable, and efficient manner. To understand the current status quo of scientific evidence available, several studies leveraged ML to perform natural language processing, bibliometric analysis, and text mining, which have yielded promising results in several domains, including health care [9-12], social sciences [16-19], and environmental sciences [20]. However, the application of ML and its potential for identifying research gaps in rapidly evolving fields remains underexplored. To the best of our knowledge, there are no previous studies that leveraged ML-based techniques for identifying research gaps.

This paper aims to propose an ML-based approach to detect research gaps in the literature. In this work, we use the novel COVID-19 pandemic, caused by the SARS-CoV-2 virus, as a case study due to the fast and time-critical pace it evolved, along with the urgent need to comprehend this global pandemic. Since its emergence in late 2019, COVID-19 has had a profound global impact which not only halted many activities, triggered economic fallout, and caused significant hardships, but it also claimed more than 6.8 million lives. In turn, the scientific community united to address the various challenges presented by the global spread of the virus.
Through unprecedented levels of scientific activities, researchers generated a vast amount of research output, with thousands of research papers being published each month, which discuss various aspects of the virus, its transmission, diagnosis, treatment, and prevention strategies [9,21,22]. However, with the rapid pace of information generation and dissemination, there is an increased risk of overlooking research gaps or underexplored areas that may be critical to understanding and mitigating the virus’s impact. Thus, this aims to propose an ML-based approach to detect research gaps in the literature using COVID-19 as a case study.

**Methods**

**Study Data Selection**

We used the COVID-19 Open Research (CORD-19) data set, produced by the Allen Institute for AI and made available on the Kaggle platform [23]. It was updated every week until June 2, 2022, to include the most recently published COVID-19 papers. We used the final version, which contains 1,121,433 entries. The search terms used by Allen Institute for AI to retrieve these studies were “Coronavirus” OR “Corona virus” OR “COVID-19” OR “2019-nCoV” OR “SARS-CoV” OR “Severe Acute Respiratory Syndrome” OR “MERS-CoV” OR “Middle East Respiratory Syndrome” [24]. The sources of studies in the CORD-19 data set were PubMed Central, PubMed, the World Health Organization’s (WHO) COVID-19 Database, arXiv, bioRxiv, and medRxiv [24]. The data set includes a CSV file containing meta-information about all the papers, such as article DOI, CORD UID, PMCID, PUBMED ID, title, abstract, journal, authors, and publication date. We removed duplicate papers, entries with empty and non-English abstracts, and papers published before January 1, 2020. We selected abstracts containing the keywords “novel coronavirus,” “coronavirus 2019,” “2019-nCov,” “COVID-19,” “COVID 2019,” “severe acute respiratory syndrome coronavirus 2,” and “SARS-COV-2” to include only COVID-19–related papers.

**Data Preprocessing**

We cleaned the abstracts and removed nonalphanumeric characters, punctuations, and sectioning keywords “BACKGROUND,” “OBJECTIVE,” “METHOD,” “RESULT,” “CONCLUSION.” We used the Python programming language in a Jupyter Notebook environment and Python libraries such as pandas, NumPy, langdetect, re, string, and TextBlob. We then searched abstracts that mentioned any term related to research gap: “unknown,” “not known,” “little is known,” “unrevealed,” “uncertain,” “undetermined,” “understudied,” “unexplored,” “not fully understood,” “literature gap,” “research gap,” “knowledge gap,” “future studies,” “future research,” “research problem,” “more studies,” “more research,” “further studies,” and “further research.” We decided to use these terms in an abstract search rather than a full-text search for 2 reasons. First, using these terms in a full-text search may lead to the inclusion of a significant number of unrelated studies, increasing the likelihood of inaccurately identifying research gaps that are not pertinent to the subject of interest. Second, the CORD-19 data set that we used in this study does not contain the full text of the studies. With this process, we identified 33,206 abstracts of scholarly papers published after January 1, 2020, related to COVID-19 and containing the gap words. We analyzed these abstracts, and from each abstract, we extracted 3 sentences: 1 sentence that includes the gap word, 1 sentence before, and 1 sentence after the sentence containing the gap word. We used a full stop (”.”) as a sentence marker. We converted the selected sentences to lowercase text. Next, we used the Python NLTK library to remove the stop words and tokenize the sentences. Finally, we used the clean sentences after the preprocessing steps for clustering.

**Analysis**

**Overview**

For clustering the sentences into semantically similar topics, we used the BERTopic algorithm [25]. The BERTopic algorithm is an unsupervised learning algorithm for topic modeling. It uses the Bidirectional Encoder Representations from Transformers (BERT). BERTopic does not require labeled data as it extracts topics from an input text in a supervised way [26]. BERTopic gained popularity due to its potential to capture context-aware information in a given input text and does not rely on a predefined number of topics [26]. Besides topic modeling, BERTopic is also useful in the clustering of documents and text summarization [26]. The BERTopic topic modeling method produces dense clusters by combining class-based term frequency-inverse document frequency (TF-IDF) and transformers (BERT embeddings). In addition, it makes it simple to comprehend and visualize the generated topics. The 3 stages in the BERTopic algorithm are presented in Figure 1 and discussed in the next subsections.
Embedding Documents

In this stage, the BERTopic algorithm extracts document embeddings using BERT sentence transformers. Each document embedding is generated using word embeddings, which represent each word in the document in multidimensional space. It ensures that words with related meanings have comparable representations. This way, words are represented by numbers in a vector space, where vectors are defined by TF-IDF weights. TF-IDF describes the importance of a term relative to a document in a corpus. Neural networks are the primary foundation of embedding models. Typically, word embeddings are used to compute document embedding into 2 phases. The word embedding is first applied to every word in the text and then the word embeddings are aggregated by averaging over each dimension to produce document embeddings.

Clustering Documents

Documents embeddings produced in the previous step are usually very sparse. Therefore, our first stage of the analysis uses uniform manifold approximation and projection to decrease the dimensionality of the embeddings [27]. Then, we use the hierarchical density-based spatial clustering of applications with noise approach to cluster reduced embeddings and produce clusters of texts with comparable semantic properties.

Representing Topics

In this stage, class-based TF-IDF weights are used to extract topics. These topics are reduced and further improved by finding the coherence of words using maximum marginal relevance. We used BERTopic to cluster the extracted sentences and found 191 clusters. Then, we applied the topics reduction technique of BERTopic and found a total of 50 clusters. We assigned labels to each cluster by checking their representative words. When it was challenging to assign labels to a cluster based on its representative words, we reviewed sentences containing the specified research gap terms, along with the sentence before and after in most studies within that cluster. After that, we merged clusters that had similar labels to identify 21 unique labels (research gaps). Finally, we grouped these clusters into 6 broader categories. Multimedia Appendix 1 shows the code used for the analysis of bibliographic data to identify research gaps.

Results

Search Results

By June 2, 2022, the CORD-19 data set contained 1,121,433 papers (Figure 2). Of those, we excluded 1,088,227 papers for the following reasons: (1) abstracts were unavailable (n=300,540); (2) the papers were published before January 1, 2020 (n=225,964); (3) the papers were written in a language other than English (n=6499); (4) papers did not contain search terms related to COVID-19 (n=195,498); and (5) papers did not contain search terms related to research gap (n=359,726). Consequently, we included 33,206 papers in the analysis of this study.
Results of Gap Identification

Overview

As mentioned earlier, 191 clusters of the 33,206 papers were generated by our analysis. Then, the number of clusters was reduced to 50 when we applied a topics reduction technique. We deleted 6 clusters as we could not identify the research gap from them. Further, 23 clusters were merged with other clusters as the same research gaps were identified in these clusters. Overall, we identified 21 different research gaps from 4646 papers. As shown in Table 1, these research gaps were grouped into 6 topics, which are discussed in the next subsections.
Table 1. Topics and the corresponding subtopics identified in this study (N=4646).

**Topic 1: Virus of COVID-19 (n=647, 13.9%)**

**Origin of COVID-19**
There are 318 studies related to the origin of COVID-19. Despite various theories and pieces of evidence, the exact source of SARS-CoV-2 remains unknown according to the majority of studies on this topic.

**Emerging Variants**
According to the 202 studies on this topic, the full extent of the impact of new variants on the course of the pandemic and the effectiveness of current prevention and treatment strategies on the new variants are still not known. Furthermore, it is uncertain how the emergence of new variants may affect the duration of immunity after recovery. In addition, it is not clear how accurate the prediction models are in predicting the emergence of new variants and their impact.

**Transmission of COVID-19**
A total of 75 studies have revealed several unknown aspects of the virus such as the role of asymptomatic carriers in the spread of the virus, the true level of global spread, and the extent to which COVID-19 may be circulating undetected in some areas, and the influence of environmental factors (e.g., temperature and humidity) on the transmission of COVID-19.

**Role of the Immune System**
In 52 studies related to this topic, several research gaps were identified. Specifically, while it is known that the virus elicits an immune response, it is still unclear the specifics of how the immune system responds, the duration of immunity after recovery, the relationship between the severity of illness and the strength of the immune response, and how the immune response may differ between individuals.
**Topic 2: Risk Factors of COVID-19 (n=142, 3.1%)**

**Obesity**

From 77 studies related to this topic, we found that the relationship between obesity and COVID-19 is still largely a mystery. While some studies have suggested that obesity may increase the risk of severe COVID-19 outcomes, the exact mechanisms behind this are still unknown. Additionally, it is unclear whether weight loss can reduce the risk of severe illness and death from COVID-19 in individuals with obesity. Furthermore, there is no consensus on the optimal BMI cut-off for identifying individuals with obesity who are at increased risk of severe illness and death from COVID-19.

**Ethnicity**

A total of 65 studies identified a significant research gap in understanding the relationship between ethnicity and COVID-19. Despite the numerous studies conducted, the reasons for these disparities remain largely unknown.

**Topic 3: Prevention of COVID-19 (n=631, 13.6%)**

**Vaccination**

A total of 447 studies have revealed that the long-term efficacy and safety of COVID-19 vaccines remain largely unknown. Although initial clinical trials have demonstrated promising results, it is uncertain how long the protection provided by the vaccines will last and what potential long-term side effects may be. Further, vaccine hesitancy and the factors that contribute to it are not fully understood. Moreover, the safety of COVID-19 vaccines in patients with chronic diseases (eg, chronic hepatitis, diabetes, heart failure, renal failure, and epilepsy) remains unknown.

**Precautionary Measures**

A total of 124 studies were related to precautionary measures implemented to prevent the spread of the virus. According to these studies, the effectiveness of many precautionary measures such as social distancing, wearing masks, hand hygiene, respiratory etiquette (eg, covering mouth and nose when coughing and sneezing), and ventilation systems is still unknown. Further, the duration of quarantine or isolation for individuals with COVID-19 remains uncertain.

**Wastewater Surveillance**

In total, 60 studies were related to using wastewater surveillance to detect the presence of the virus in communities. According to these studies, it is unclear how accurately wastewater surveillance can predict or track COVID-19 outbreaks and what the potential false-positive or false-negative rates may be.

**Topic 4: Treatment of COVID-19 (n=291, 6.3%)**

**Medications of COVID-19**

The role of medications (eg, remdesivir and corticosteroids) in managing severe cases of COVID-19 was discussed in 170 studies. According to these studies, the effectiveness of existing medications against new variants and new medications against multiple variants; the safety and efficacy of a combination of medications; the best combinations and dosages; the safety and efficacy of medication in children; and the effect of the combination of medication and dietary supplements.

**Herbal Medicine**

Herbal medicine was the main topic in 66 studies. According to these studies, much remains unknown about the effectiveness, safety, standardization, dosage, and potential interactions with other treatment regimens.

**Support System**

A total of 55 studies were related to support systems that provide several services (eg, social support, mental health, and financial assistance) to individuals affected by COVID-19. According to these studies, the effectiveness and long-term impacts of support systems on patients with COVID-19 remain largely unknown.

**Topic 5: Health Care Delivery During COVID-19 (n=555, 11.9%)**

**Telehealth**

The COVID-19 pandemic has seen a dramatic surge in the use of telehealth; yet, a total of 305 studies have revealed that there are still many unknowns about its effectiveness and accessibility. These unknowns have the potential to create new privacy and security risks, as well as to impact health care disparities.

**Surgeries**

According to the 158 studies discussing this topic, there is still no consensus on planning to maintain surgical care preparedness in ongoing and future pandemics. This includes understanding the risk of transmission, perioperative testing criteria, postoperative outcomes in specific populations, and effective strategies for resource allocation.

**Organ Transplantation**

A total of 92 studies have revealed that there is still much to be discovered about the best way to manage organ transplantation during the COVID-19 pandemic. Specifically, there is still much to be uncovered about COVID-19 in relation to organ transplant recipients, including identifying risk factors, developing strategies to minimize transmission, understanding outcomes for transplant recipients who contract COVID-19, and determining the best treatment for COVID-19 in organ transplant recipients considering their immunocompromised status.

**Topic 6: Impact of COVID-19 (n=2380, 51.2%)**

**Health Complications**

From 1552 studies, we found that the long-term health complications of COVID-19 remain largely a mystery. To be more precise, there is a lack of evidence on the long-term impact of COVID-19 on the respiratory system (eg, asthma and chronic obstructive pulmonary disease), cardiovascular system (eg, hypertension, deep vein thrombosis, and pulmonary embolism), neurological system (eg, confusion, dizziness, and headache), endocrine system (eg, diabetes, hepatic system (eg, liver injury),
olfactory system (loss of smell and taste), and mental health (eg, anxiety, depression, and posttraumatic stress disorder).

**Special Groups**

According to 434 studies, the impact of COVID-19 on special groups is still largely unknown. Specifically, there are still many unanswered questions related to the impact of COVID-19 on pregnancy. For example, what is its impact on the risk of preterm birth and respiratory distress? What is the long-term effect on fetuses and babies? And how is the virus transmitted from mother to baby during pregnancy, labor, or delivery? Further, there is still much to learn about the impacts of the virus on pediatric populations and patients with cancer in terms of diagnosis, treatment, and complications. The long-term effects of COVID-19 on health care workers remain uncovered.

**Education**

The COVID-19 pandemic has profoundly impacted education, with schools and universities shutting down or moving to web-based learning to slow the spread of the virus. A total of 136 studies on this subtopic revealed that there is still much unknown about the impact of COVID-19 on education.

**Media and Communication**

The COVID-19 pandemic has had a profound impact on media and communication, and while much research and analysis have been conducted, there are still many unknowns. A total of 109 studies explored this topic. From these studies, we found that there are still many unanswered questions related to media and communication. For example, Will the increased media consumption habits that have emerged during the pandemic persist in the long term, or will people revert to their prepandemic habits? How will media organizations adapt to the financial challenges posed by the pandemic, and will it lead to long-term changes in the media landscape? What will be the long-term effects of social media on the spread of misinformation and society as a whole? How will the increased reliance on digital communication tools, such as video conferencing and messaging apps, impact our relationships and social dynamics in the long term?

**Mortality**

A total of 87 studies were related to the mortality of COVID-19. According to these studies, there is a lack of evidence on factors affecting mortality rates over time and on whether new strains of the virus are more deadly or have different mortality rates than the original strain.

**Food Security**

In total, 62 studies have revealed that the impacts of COVID-19 on food security remain largely unknown. While some studies have suggested that the pandemic may worsen food insecurity in certain populations, the true extent of the problem is still unclear. In addition, the long-term effects of food insecurity during the pandemic on health and well-being are yet to be determined.

---

**Discussion**

**Principal Findings**

This study proposed an ML-based method to identify research gaps in the literature. We used COVID-19 literature as a case study. Our proposed method enabled us to identify research gaps in 21 subtopics that were grouped into 6 topics. The largest topic that was identified in more than half of the analyzed studies is the “impact of COVID-19” (topic 6). This is hardly surprising, since we, as a society, are still struggling to come to terms with the long-lasting impact of the pandemic, which continues to affect many aspects of our lives. Long-term health complications are still poorly understood, given the relatively short time since the initial outbreak, which is less than 4 years. In addition, understanding the precise impact of the disease on body systems and organs proves challenging given that it is a complex disease that affects multiple organs, there is a lack of data about the virus, and its impact may vary among different populations.

The second largest topic identified in this study is the “virus of COVID-19” (topic 1). The lack of knowledge about the COVID-19 virus is attributed to its novelty as a new strain of coronavirus not previously identified in humans. Further, tracing the origins of zoonotic diseases can be difficult as they may pass through multiple animal hosts before reaching humans. Moreover, due to its rapid evolution into new variants, studying each variation of the COVID-19 virus within a short timeframe poses a significant challenge.

Topic 3 (ie, prevention of COVID-19) was the third largest topic in this paper. The lack of knowledge in this area may be attributed to the limited long-term data on vaccine safety and efficacy. Additionally, the emergence of new variants may impact vaccine efficacy, raising concerns about the effectiveness of the current vaccines against these new variants. Further, a significant challenge in assessing the long-term effects of the COVID-19 vaccine is vaccine hesitancy, which is not fully understood and can hinder data gathering on long-term effects.

The COVID-19 pandemic has impacted health care delivery, and this was topic 5 in this study. One of the subtopics in this topic is telehealth, which has seen a significant surge. Telehealth is a relatively new technology that has only recently become widely available. As a result, there may not yet be enough data available to fully evaluate its effectiveness. Telehealth is often used in conjunction with other health care interventions, such as in-person visits or medications, which can make it difficult to separate the impact of telehealth from other factors. Importantly, there may be biases in the types of patients who are most likely to use telehealth. Thus, it is difficult to generalize findings to the broader population. Another subtopic in this topic is organ transplantation. Research gaps related to this subtopic may be attributed to the following reasons: (1) while there have been some studies on the impact of COVID-19 on organ transplant patients, the number of patients in these studies is often relatively small. These limited data can make it difficult to draw definitive conclusions about the impact of COVID-19 on this population; (2) organ transplant patients are a heterogeneous population, and the impact of COVID-19 may vary depending on factors such as age, comorbidities, and the
type of organ transplant; (3) organ transplant patients may be at increased risk of complications from COVID-19 due to their underlying health conditions and the immunosuppressant drugs they take to prevent organ rejection. Therefore, it can be difficult to isolate the impact of COVID-19 from these other factors.

We found that there are research gaps related to the treatment of COVID-19 (topic 4). This may be due to several factors. First, addressing research gaps related to this topic needs many rigorous clinical trials, which usually take several years to complete all 3 phases before the licensing stage. Second, such clinical trials are very expensive, and therefore only researchers with large funds can carry out these trials.

Critical gaps in our understanding of the relationship among obesity, ethnicity, and severe COVID-19 outcomes exist (topic 2). The relationship among obesity, ethnicity, and COVID-19 outcomes is likely influenced by a complex interplay of biological, behavioral, and environmental factors, making it difficult to determine the precise nature and extent of these relationships. Disentangling the effects of these different factors on health outcomes can be challenging, and limitations in the quality and availability of data on obesity and ethnicity in certain populations can make it difficult to accurately measure the relationship between these factors. Moreover, known statistical challenges are related to controlling confounding factors such as age, sex, and comorbidities that affect the nature, behavior, and interpretation of the relationship among these factors.

In February 2020, a 2-day meeting organized by the WHO brought together more than 400 participants worldwide [28]. The objective was to develop a research road map that would facilitate and expedite global research efforts aimed at controlling the transmission of COVID-19 [28]. The research road map identified many knowledge gaps and grouped them into 8 areas. All research gaps identified in this review were mentioned in the road map except for topic 6 (impact of COVID-19). This may be attributed to the fact that this topic was less important at that stage of the pandemic (2 months after the onset of COVID-19).

After 3 months of the WHO research road map, a mixed methods study was conducted on 4087 participants (researchers, policy makers, health care workers, etc) to check which of the early WHO road map priorities are still most pressing and identify any newly emerging priorities that warrant attention [29]. The study revealed that the WHO research road map is still globally applicable. However, it identified a number of new research priorities that align with the evolving nature of the pandemic and provide insights into areas where knowledge gaps exist. One of these new research priorities is the impact of COVID-19, which aligns with topic 6 in our study.

About 10 months after the onset of COVID-19, a team from the WHO Southeast Asia Region conducted a web-based survey of 48 experts to identify COVID-19 research priorities in the Southeast Asia Region [30]. The study identified 27 research priorities, which include all 6 research topics identified in this study.

Our findings are also in agreement with previous work [31] that similarly used the CORD-19 data set to determine research priorities during the COVID-19 pandemic. The earlier study identified 10 hotspots, 4 of which overlap with our identified research gaps: virus of COVID-19, risk factors of COVID-19, prevention of COVID-19, and treatment of COVID-19. Notably, our analysis further includes 2 additional topics, which are health care delivery during COVID-19 and the impact of COVID-19. The earlier study also identified additional areas: nursing and health care, diagnosis and testing, drugs and vaccines, social psychology, infection process, and clinical characteristics. The discrepancy between the 2 sets of findings may be attributed to the period when the studies were conducted. The prior study was conducted during the initial phase of COVID-19-related research (January to September 2020), during which the emphasis was predominantly on diagnosis, testing, infection processes, and clinical characteristics. At that early stage, the short- and long-term impacts of COVID-19 were less clear, as was its effect on health care delivery.

Limitations
This study has several limitations that need to be considered when interpreting the results. First, clusters generated by the BERTopic modeling algorithm were subject to noise. In other words, we noticed that several studies in a cluster are not relevant to that cluster. Therefore, not all studies on a topic reported a research gap related to that topic.

Second, the studies included in our analysis were limited to those published up to June 2022, given the Allen Institute for AI stopped updating the data set, and new research has been published since then. Therefore, it is likely that several research gaps identified in this review have been addressed and new research gaps have emerged.

Third, it is likely that this study missed other important research gaps for several reasons: (1) studies in the CORD-19 data set were retrieved from only 5 databases; therefore, the CORD-19 data set did not include studies from other common databases such as Scopus, Web of Science, Embase, and PsycheINFO; (2) our analysis relied on abstracts rather than full texts, in which especially introduction and discussion sections commonly identify research gaps; (3) this study only considers papers in English. Consequently, potential insights from studies published in other languages may have been overlooked; and (4) we cannot rule out that we missed some terms relevant to research gaps; therefore, it is likely that many studies relevant to this work were not included in the analysis.

Fourth, we do not attempt a trend analysis in favor of a compact and concise overview, and we do not yet provide automated means to analyze original research gaps that have been addressed since the publication of a given paper. However, we believe that the presented analysis is still useful as we observe clear “hot topics” that resonate with earlier thematic research areas defined by the WHO which are extremely unlikely to have been researched fully since formulating the gap.

Practical and Research Implications
This study’s aim is not to generate research topics automatically that, when worked on, guarantee impact or publication. Instead, we scope the landscape of research gaps outlined in the literature. This study should therefore be taken as a help to
identify and prioritize “hot” topics that need addressing. This study also does not seek to replace individual literature research in a chosen topic, but it can serve as a guide to formulate specific literature search queries in specific areas related to research questions left as future work by prior publications. Therefore, literature reviews or scoping reviews are still required. Nevertheless, we anticipate that with the advent of more advanced techniques like Large Language Models, the performance of such approaches will enhance in the foreseeable future, subsequently reducing the necessity for literature reviews or scoping reviews to identify research gaps.

To overcome the above-mentioned limitations of our approach, thereby improving the identification of gaps, future research should use an up-to-date list of studies that are retrieved from the most common databases in the target area (eg, MEDLINE, Scopus, Web of Science, Embase, PsycINFO, IEEE Xplore, and ACM Digital Library). If practical, researchers should also analyze full texts, or at least discussion sections, rather than only abstracts. Moreover, additional terms related to research gaps (eg, limited evidence, inconclusive findings, and insufficient evidence) should be used to identify the relevant studies and sentences appropriate for analysis. Further, there is a need to improve the performance of the BERTopic modeling algorithm in clustering studies, specifically with respect to removing outliers from the clustering. From a technical perspective, this may require further research to combine topic modeling with statistical uncertainty quantification, such as conformal prediction [32,33].

The process of clustering text documents is an essential technique used in the text mining area, as well as in a variety of applications including ML and pattern recognition. Since clustering text documents is an optimization problem, several meta-heuristics (MH) optimization algorithms have been presented as possible solutions to this nondeterministic polynomial-time hard problem. However, while obtaining the best solution, individual optimization MH algorithms may run into serious problems including poor convergence and being stuck in local optima. To address these issues, the hybridization concept was applied to combine the strengths of 2 hybrid search methods (ie, MH algorithms) and so avoid their weaknesses.

From the dominance of topic 6, we see that most research is needed to understand the long-term effects of the pandemic. Especially where COVID-19 “temporary” solutions have become established practice (telehealth, hybrid education, the logistics of resilient food supply, etc), more research is needed to answer questions regarding the efficacy and sustainability of such solutions. Long-term health complications will continue to be a topic for quite some time in the future, given that COVID-19 has only been studied for less than 4 years. As new complications and variants emerge, this subtopic arguably has the highest potential to serve humanity and create a real impact.

Conclusions

This paper showed that ML has the potential to identify research gaps in scientific literature. Our proposed method identified research gaps in 21 subtopics that were grouped into 6 topics: virus of COVID-19, risk factors of COVID-19, prevention of COVID-19, treatment of COVID-19, health care delivery during COVID-19, and impact of COVID-19. This study is not intended to replace individual literature research within a selected topic. Instead, it can serve as a guide to formulate precise literature search queries in specific areas associated with research questions that previous publications have earmarked for future exploration. Future research should leverage an up-to-date list of studies that are retrieved from the most common databases in the target area. When feasible, full texts or, at minimum, discussion sections should be analyzed, rather than limiting their analysis to abstracts. Moreover, additional terms related to research gaps should be used to identify the relevant studies and sentences appropriate for analysis. Furthermore, future studies could evaluate more efficient modeling algorithms, especially those combining topic modeling with statistical uncertainty quantification such as conformal prediction.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Authors’ Contributions

AA-A, AJN, and ZS developed the protocol for this paper. Data collection and preprocessing were carried out by ZS. Data analysis was performed by AA-A, AJN, and ZN. DA and WA wrote the introduction. The Methods section was written by ZS and HA. The Results section was written by AA-A and AJN. The Discussion and Conclusion sections were written by all authors. The paper was revised critically for important intellectual content by all authors. All authors approved the manuscript for publication and agree to be accountable for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic disrupted postgraduate certification examinations globally. The Colleges of Medicine of South Africa continued hosting certification examinations through the pandemic. This was achieved by effecting a rapid transition from in-person to web-based certification examinations.

Objective: This formative evaluation explored candidates’ acceptability of web-based structured oral examinations (SOEs) hosted via Zoom (Zoom Communications Inc). We also reported the audiovisual quality and technical challenges encountered while using Zoom and candidates’ overall experience with these examinations conducted during the early part of the COVID-19 pandemic. Additionally, performance in web-based certification examinations was compared with previous in-person certification examinations.

Methods: This mixed methods, single-arm evaluation anonymously gathered candidates’ perceptions of web-based SOE acceptability, audiovisual quality, and overall experience with Zoom using a web-based survey. Pass rates of web-based and previous in-person certification examinations were compared using chi-square tests, with a Yates correction. A thematic analysis approach was adopted for qualitative data.

Results: Between June 2020 and June 2021, 3105 candidates registered for certification examinations, 293 (9.4%) withdrew, 2812 (90.6%) wrote, and 2799 (99.9%) passed, and 1525 (54.2%) were invited to a further web-based SOE. Examination participation was 96.2% (n=1467). During the first web-based examination cycle (2020), 542 (87.1%) of 622 web-based SOE candidates completed the web-based survey. They reported web-based SOEs as fair (374/542, 69%) and adequately testing their clinical reasoning and insight (396/542, 73.1%). Few would have preferred real patient encounters (173/542, 31.9%) or in-person oral examinations (152/542, 28%). Most found Zoom acceptable (434/542, 80%) and fair (396/542, 73.1%) for hosting web-based SOEs. SOEs resulted in financial (434/542, 80%) and time (428/542, 79%) savings for candidates. Many (336/542, 62%) supported the ongoing use of web-based certification examinations. Only 169 technical challenges in using Zoom were reported, which included connectivity-related issues, poor audio quality, and poor image quality. The thematic analysis identified 4 themes of positive and negative experiences related to web-based SOE station design and content, examination station environment, examiner-candidate interactions, and personal benefits for candidates. Our qualitative analysis identified 10 improvements for future web-based SOEs. Candidates achieved high pass rates in web-based certification examinations in 2020 (1583/1732, 91.39%) and 2021 (850/1067, 79.66%). These were significantly higher (2020: N=8635; χ²₁=667; P<.001; 2021: N=7988; χ²₁=178; P<.001) than the previous in-person certification examination pass rate of 58.23% (4030/6921; 2017-2019).

Conclusions: Web-based SOEs conducted by the Colleges of Medicine of South Africa during the COVID-19 pandemic were well received by candidates, and few technical difficulties were encountered while using Zoom. Better performance was observed...
in web-based examinations than in previous in-person certification examinations. These early findings support the ongoing use of this assessment method.

KEYWORDS
web-based certification examinations; web-based structured oral examinations; medical education; specialist and subspecialist examinations; structured oral examinations; Colleges of Medicine of South Africa

Introduction

Background

The COVID-19 pandemic severely disrupted the postgraduate specialty and subspecialty certification examinations globally [1-5]. The Colleges of Medicine of South Africa (CMSA) continued hosting postgraduate certification examinations during the pandemic [6]. This decision ensured that the national pipeline of specialist workforce would not be disrupted and that the careers of international medical graduates completing postgraduate training in South Africa would not be unduly delayed. Hosting these examinations during the pandemic was achieved by effecting a transition from in-person to web-based written and oral examinations within a period of 8 weeks.

Prepandemic Certification Examinations

CMSA, a nonprofit organization founded in 1954, comprises 29 constituent member colleges, each representing a primary specialty practiced in South Africa, such as College of Pediatricians, College of Surgeons, College of Physicians, College of Family Physicians, College of Obstetricians and Gynecologists, College of Anesthesiologists, and so on [6]. CMSA conducts certification examinations at the beginning (entry level) and end of postgraduate training (exit level) for all specialties and subspecialties registered with the South African statutory medical licensing authority, the Health Professions Council of South Africa [7]. Currently, there are 65 specialties (pediatrics, internal medicine, general surgery, ophthalmology, otolaryngology, anesthesiology, etc) and 30 subspecialties (pediatric pulmonary medicine in the specialty of pediatrics, trauma surgery in the specialty of general surgery, gynecological oncology in the specialty of obstetrics and gynecology, etc) practiced in South Africa. For the purposes of this paper, the term, postgraduate certification examinations, denotes all postgraduate certification examinations conducted by CMSA for all specialties and subspecialties practiced in South Africa. These examinations are similar to other international postgraduate certification examinations such as board certification examinations offered by the American Board of Medical Specialties [8] or membership examinations offered by Royal Colleges in the United Kingdom, for example, the College of Anesthesiologists of Ireland [9]. Before the COVID-19 pandemic, CMSA certification included handwritten examinations, and successful candidates were invited for in-person, patient-based, clinical examinations and in-person, unstructured oral examinations (viva voce).

Transition to Virtual Certification Examinations

The transition occurred during the first 8-week hard lockdown phase of the pandemic, which included closure of all public facilities except for emergency care, food, and health care; complete ban on in-person meetings and any form of intercity travel; and national curfew from 9 PM to 6 AM [10]. Weekly web-based meetings were used to provide staff with information updates and training, supplemented by digital information manuals and web-based training sessions for all examiners and candidates learning to use Zoom (Zoom Communications Inc), an interactive web-based software meeting platform.

Handwritten examinations were replaced by web-based written examinations (short-answer questions and single, best-answer questions) using commercially available software. In-person, patient-based examinations were largely discontinued, except where geographically decentralized in-person clinical examinations could be offered in COVID-19–compliant settings. For all member colleges, a new emphasis was placed on developing web-based structured oral examinations (SOEs) to assess diagnostic reasoning, clinical decision-making, and patient management, which were previously assessed during real patient encounters. It was acknowledged that web-based SOEs could not assess bedside clinical skills (history taking and physical examination), as was previously done. This compromise, accepted as an emergency measure during the pandemic, was predicated on an agreement that implementation of workplace-based assessment in South African postgraduate training would be prioritized after the pandemic [10-12].

Design of Web-Based SOE

Web-based SOEs were designed as case scenarios, each comprising a case description with supplementary information including laboratory test results, photographs, video clips, and radiographic and histopathological images, where appropriate. The case scenarios were prepared by national panels of examiners working remotely via Zoom. Each scenario was prepared as a Microsoft PowerPoint presentation, which was screen shared with candidates during the oral examination hosted via Zoom. Candidates answered the standardized questions posed by examiners working alone or in pairs. Zoom calls were also attended by moderators and trainee examiners (observers). Examiners scored the candidates’ responses independently during Zoom calls using downloaded and printed memoranda, and examiners’ handwritten notes were digitally transcribed and submitted with final examination scores to conveners at the conclusion of the examination proceedings. All Zoom calls were booked and collated on timetables with embedded hyperlinks for individual calls, which were shared with the examiner panels 1 week before the examination events. Individual Zoom calls varied in length from 15 to 60 minutes, depending on the number of case scenarios discussed per call. Candidates undertaking a web-based SOE were typically
examined on 4 to 12 case scenarios, depending on the specialty or subspecialty.

**Conducting Virtual Certification Examinations**

CMSA set up 14 examination venues (8 in South Africa and 6 elsewhere in southern Africa) equipped with 12-inch laptop computers; 24-inch high-resolution monitors; and internet connectivity using wireless, microwave, and fiber technology. Owing to electrical power supply interruptions (load shedding) in South Africa, all examination venues were equipped with dual power supply arrangements. On-site IT support and on-site proctoring by trained staff were provided at all venues.

Candidates undertook all web-based examinations (written and oral) at an examination venue closest to their home (<3 h travel by road). Overnight accommodation was not permitted. National occupational health and safety COVID-19 protocols were observed at all examination venues [13]. Examiners joined the Zoom calls from their home or place of work, whichever was more convenient and had better bandwidth and a stable electricity supply.

**Process of Evaluation**

When CMSA implemented web-based SOEs for postgraduate certification examinations in early 2020, there were few reports in the literature. There was little reference to their use for high-stakes postgraduate specialist certification processes [14-17]. Most referred to in-person SOEs for undergraduate students [18-21]. Given the paucity of data, we set up a preliminary evaluation during the initial period of implementation to obtain early insights into candidates’ perceptions about the acceptability of this assessment method and their performance in web-based examinations as compared with in-person certification examinations. Despite its known limitations, we structured our evaluation process on the Kirkpatrick model of program evaluation (reaction, learning, behavior, and results) using four questions to address level 1 (reaction) and level 4 (results) of the model [22-25]:

1. Are web-based SOEs acceptable to examination candidates?
2. What technical challenges did examination candidates encounter while using Zoom?
3. On the basis of candidates’ experiences, how could we improve the web-based SOE experience?
4. Are pass rates for web-based and in-person certification examinations different?

**Methods**

**Design**

The evaluation was conducted as a cross-sectional observational study using a mixed methods design.

**Participants**

The study population included all postgraduate certification examination candidates who were invited to undertake web-based SOEs after successfully completing the written component of the national certification examinations in 2020 and 2021.

**Procedure**

The first cohort of examination candidates who undertook a web-based SOE between June 1, 2020, and November 15, 2020, was invited to complete the web-based survey immediately after completing their web-based SOE at one of the examination venues. A web-based study information leaflet was provided to potential participants before recruitment. The web-based questionnaire was administered on laptop computers at the examination venues. Participants were recruited to the study before releasing any examination results.

**Survey Design**

The survey, designed as a Google Form, consisted of 28 items (Multimedia Appendix 1). A total of 23 closed-ended questions focused on candidates’ perceptions of the adequacy, fairness, and quality of web-based SOEs and the technical adequacy and personal time and cost savings of using Zoom to host SOEs. Closed-ended questions required either a binary (yes or no) response or a 5-point Likert-scale response (completely disagree, disagree, neutral, agree, or completely agree). Candidates’ acceptability of web-based SOEs was defined as candidates’ perceptions of the adequacy of the web-based assessment process, overall fairness, and quality of examination material used. Parameters used to determine the adequacy of the assessment process included the following: adequate assessment of clinical reasoning, judgment, insight, and decision-making; appropriate complexity of case scenarios and questions; appropriate duration of examination; appropriate time allocation per case scenario; and preference for in-person patient encounter or in-person examiner. Fairness was explored in terms of perceived overall fairness and the use of more case scenarios than previously during in-person examinations. Quality of examination material referred to clarity of material presented during the Zoom call. Candidates’ acceptability of Zoom as the hosting platform was defined in terms of perceptions of (1) overall acceptability and fairness of the web-based assessment process, (2) audiovisual quality of Zoom, and (3) personal benefits of web-based SOEs to examination candidates (time and financial savings). The survey also included 5 open-ended questions, which required a typed text response. These questions explored candidates’ overall positive and negative experiences regarding the web-based examination process. The survey was administered immediately after the examination proceedings, and we chose to anonymize all the information so as to allay candidate concerns about possible bias when deciding whether to participate in the survey. They only reported about the examination venue attended and certification examination undertaken.

**Quantitative Data Analysis**

Quantitative data from the web-based questionnaire were exported into a Microsoft Excel spreadsheet before analysis. For questions using a Likert-scale response, answers were reported in 3 categories: agree (strongly agree and agree responses), neutral (neutral responses), and disagree (strongly disagree and disagree responses). Percentages were calculated and rounded to 1 decimal point.
The respective pass rates for the first 2 cycles of web-based certification examinations, 2020 and 2021, were compared with the overall pass rate for the preceding 6 cycles of in-person certification examinations conducted between 2017 and 2019 using the chi-square test for independence with a Yates correction. $P<.01$ was taken as the level for significance.

**Qualitative Data Analysis**

Qualitative data from the open-ended questions were captured on the web using Google Forms, exported into an Excel spreadsheet, and subjected to thematic analysis using the 6-step approach to thematic analysis by Braun and Clarke [26]. The qualitative responses were read with the stated question in mind, after which a set of themes was developed by members of the research team (FM and JKM). The responses were reread and assigned to themes, which were further refined as more themes emerged. The responses were reread a third time (JKM), and the themes were reviewed. Discrepancies were presented to a third author (VB) and discussed until consensus was reached.

**Ethical Considerations**

The study was approved by the human research ethics committee of the University of Cape Town (HREC 280/2020), CMSA, South African Committee of Medical Deans, and Health Professions Council of South Africa. Participation was voluntary, and informed consent was obtained before inclusion in the study. This study, which involved human participants, was performed in accordance with the Declaration of Helsinki. All examination candidates gave signed informed consent before participation in the study. All methods were conducted in accordance with relevant guidelines and regulations. Declared consent for publication is not applicable as no identifying images or information was used in the paper.

**Results**

**Participants**

Table 1 shows that during the first 12 months of the COVID-19 pandemic, from June 2020 to June 2021, a total of 3105 candidates registered for postgraduate certification examinations conducted by CMSA. After announcing a transition to web-based examinations, of the 3105 candidates, 351 (11.3%) candidates withdrew (written: 293/351, 83.5%; oral: 58/351, 16.5%); overall participation was 88.7% (2754/3105) during the pandemic. Of the 2754 entrants, 1912 (69.43%) passed the written components of the certification examinations, and 1525 (55.37%) were invited to a web-based SOE, of which 1467 (53.27%) attended the SOE (1467/1525, 96.2% participation).

$^a$Pass rate of virtual SOE: total=79% (1159/1467), year 2020=79.9% (497/622), year 2021=78.3% (662/845).

$^b$Overall pass rate: total=86.5% (2433/2812, year 2020=91% (1583/1739), year 2021=79.2% (850/1073).

$^c$SOE: structured oral examination.

$^d$Only exit-level certification examinations include virtual SOEs.

**Questionnaire Completion**

The web-based survey was administered to the first cohort of candidates who participated in web-based SOEs between June 1, 2020, and November 15, 2020. Of the 622 potential participants, 542 (87.1%) completed the web-based survey.

**Are Web-Based SOEs Acceptable to Candidates?**

**Candidates’ Perceptions of Web-Based SOEs**

Table 2 shows that, broadly speaking, candidates expressed a positive opinions about web-based SOEs. They considered web-based SOEs to be a fair method of examination (374/542, 69%), which tested their clinical reasoning and insight appropriately (346/542, 62.7%), more cases better displayed their knowledge (369/542, 68.1%). Less than one-third (173/542, 31.9%) felt that real patient encounters would have been preferred, and a small minority (152/542, 28%) would have preferred an in-person oral examination.

Candidates’ Perceptions of Zoom for Hosting Web-Based SOEs

The results in Table 3 show that most candidates found the Zoom platform to be acceptable for hosting web-based SOEs (434/542, 80.1%) and considered it to be a fair examination technique (396/542, 73.1%). Most reported that Zoom was technically adequate: 80.1% (434/542) could clearly see and hear examiners, and 69% (374/542) said that video and image quality was adequate. SOEs conducted via Zoom were associated with personal cost-saving (434/542, 80.1%) and time-saving (428/542, 78.9%) benefits because candidates were spared the trouble of traveling. Approximately two-thirds of the participants (336/542, 61.9%) indicated that CMSA examinations should be conducted in the same manner in the future.

\(^a\)CMSA: Colleges of Medicine of South Africa.
What Technical Challenges Did Candidates Encounter While Using Zoom?

The first 2 cycles of virtual SOEs required 6258 Zoom calls, all of which were successfully completed on the appointed examination day. All candidates were able to complete their web-based SOE using Zoom. Altogether, 173 technical challenges were reported during the first examination cycle (2020). All (173/173, 100%) were successfully resolved. Of the 173 challenges, a total of 164 (94.8%) were specifically described in the open-ended section of the survey. Overall, 3 major themes were identified: connectivity-related issues with poor-quality connection, disconnection, and laptop battery failure; poor audio quality of Zoom call with sound delay, poor quality or interruption, and low sound intensity from examiners sitting very far from the microphone; and poor image quality on Zoom call with video or photograph either very small or unclear:

Some issues with connectivity in one station. [It] was quickly resolved and another examiner took over [the] questions so I don’t feel disadvantaged due to it. [Candidate 383]

Electricity load-shedding occurred with the generator being switched on at the venue. The volume of the speaker was low and the invigilator increased the volume. [Candidate 263]

Sometimes it would appear as though an examiner had frozen on the screen where their broadband signal had become temporarily weak. This did not disturb the call entirely given that we had the buffer 5 minutes in case of technical glitches. [Candidate 128]

Some audio disturbance, and can hear the exam next door is a bit distraction. [Candidate 414]

On the Basis of Candidates’ Experiences, How Could We Enhance the SOE Experience?

Overview

Thematic analysis of the open-ended questions allowed us to better understand the positive and negative experiences of candidates undertaking web-based SOEs using Zoom. We identified 27 themes, which we categorized into 4 overarching themes, as shown in Table 4.

Table 4. Themes from qualitative analysis of candidates’ responses.

<table>
<thead>
<tr>
<th>Themes</th>
<th>Subthemes</th>
<th>Negative experiences</th>
</tr>
</thead>
</table>
| Examination design and content | • No home-ground advantage  
 | • Standardized scenarios and questions  
 | • Fair questions  
 | • Expanded case number  
 | • Less intimidating  
 | • Helpful mock examination  
 | • Less examiner-examiner interaction | • No preparation time  
 | • On-site IT support | • No station preview  
 | • Helpful and friendly proctoring staff  
 | • More examiner interaction without patients | • Limited media engagement  
 | • Travel convenience  
 | • Financial saving  
 | • Home comforts  
 | • Less interruption | • Limited case discussion  
 | • Variable audiovisual quality  
 | • Obtaining assistance  
 | • Lack of earphones  
 | • Lack of screen share control  
 | • No hard copies of case scenarios |

Examination Design and Content

Candidates endorsed the lack of a home-ground advantage:

The fact that all candidates are on the same footing. The home candidates have a clear advantage when it comes to clinical OSCE with patients. Those travelling to other provinces do so at great cost and emotional stress. The examination as it was done now should be the way forward. [Candidate 257]

Candidates appreciated the standardization of case scenarios and examination questions:

Excellent standardisation. All candidates had the same examiners, same questions, same experience. Removed all bias from exam. [Candidate 22]

A great number of case scenarios also contributed to a fair examination in the virtual context than in previous in-person oral examinations:
I really enjoyed that the number of cases in the examination was increased as I think that one is able to get a good impression of a candidate if they are examined over broader spectrum rather than to a certain extent as depicted by the examiners, so that if a candidate does badly in one case they still have a shot at redemption. [Candidate 238]

Mock examinations were also perceived favorably. However, the long waiting times before and after the examination were negatively received:

The Zoom Mock exam was reassuring, thank you for giving us clarity. Though it was unpleasant to wait for 2 hours before exams start, I did appreciate the session slots. It was very organized, I commend the team. [Candidate 487]

Unfortunately the duration of the examination process is tedious. If this platform goes ahead it would be preferable to have wrapped up the exams in a shorter time frame. [Candidate 485]

Negative experiences that candidates felt could be improved included an overview of the station before it begins:

Ask examiners to provide a brief overview of the length of the station/number of questions in order to plan answers/timing accordingly. [Candidate 167]

Participants also wanted to add preparation time to each station:

Inadequate time to review slides and prep, many stations required you time to grasp the concepts and integrate the information. It was difficult to do in the timeline provided. Difficult to read the slides and process information and feedback to examiners. [Candidate 63]

Candidates wanted better control of the media included in the case scenarios, for example, scrolling through computed tomography imaging studies:

Unable to interact with images and unavailability of dynamic acquisitions. [Candidate 222]

Unable to control imaging myself to make an assessment. [Candidate 386]

They also wanted the option of viewing video clips more than once:

For the video station, to have an option of watching the video twice if you would like to do so because in a real case scenario when examining a patient, you can repeatedly ask the person to do something. Some of the stations should be made realistic, like the emergency station, in a real-life situation, the patient comes in, you don’t get history first the ask to see the patient. [Candidate 481]

Although the candidates enjoyed the breadth of knowledge that was assessed, they wanted an additional way to portray their clinical maturity and insight:

Feeling unable to give a proper account of my knowledge. There is no room for clinical discussion or arguments when answering against a rubric all the time. Maybe one or two stations would be valuable where there’s no rubric and just a discussion around a topic or a case etc. [Candidate 90]

Other negative experiences included a reflection of case scenario design and highlighted the importance of designing appropriate questions for a virtual examination environment:

The examination should have either a model or a device with which the candidate could demonstrate their skills [if the candidate is being asked to demonstrate use of such device]. Adequate resolution of images is also a necessity. [Candidate 70]

Participants suggested administering the case scenarios in a more authentic way to better reflect a real patient encounter:

Because there are no real patients perhaps show pictures of not only the positive findings that the examiner needs to candidate to comment on, but also important negative clinical findings. For example, if the main pathology is in the external ear, it would be helpful to show a picture of a normal TM [tympanic membrane]. When the candidate now interprets the scan, it helps to know that the middle ear was normal. [Candidate 33]

Examination Environment

Candidates really appreciated the helpful, compassionate, on-site proctoring staff:

Invigilators were very supportive and accommodating, they gave us 5-star treatment, Thank you very much. Examiners were very empathetic. [Candidate 487]

Moreover, they specified that efficient troubleshooting and reliable technical support were important:

Well organized, flowed well with on-the-spot problem solving, excellently managed. [Candidate 421]

Having an efficient way to call for rapid technical assistance was identified as a possible improvement:

...Have a buzzer or bell in the exam room to enable you to ask for assistance if signal is lost. Or having
a technical person in the room while you are busy. [Candidate 505]

Clear instruction about the conduct of the examination was also considered important:

*Inform the candidates how the examination will be conducted.* [Candidate 443]

*...Explain the role of the technician prior to examination...* [Candidate 44]

Familiarity with the virtual platform was highlighted as an important positive finding. Candidates liked that the virtual platform offered an emotionally and professionally neutral venue. They also reported that the virtual examiner-candidate meeting was less anxiety provoking:

*I was comfortable having the oral in a Zoom meeting in a neutral venue that is outside the laboratory. I felt less anxiety than for face-to-face interactions.* [Candidate 166]

*The zoom meeting was less stressful, I am generally anxious, I was less anxious.* [Candidate 98]

*Less anxiety as examiners are not present with me.* [Candidate 78]

Sound quality issues included concerns about struggling to hear examiners:

*Not always being able to hear clearly.* [Candidate 241]

Concerns about not being heard by examiners were also mentioned:

*Worrying about not projecting well/being audible.* [Candidate 462]

Earphones to enhance sound quality were suggested:

*Using earphones might assist with sound quality...* [Candidate 505]

Candidates would have liked paper to write on:

*Allow you to have blank paper with you during the question session to better structure your thoughts.* [Candidate 349]

They also wanted hard copies of the case scenarios during the virtual SOEs:

*Provide a paper copy of the case scenario and questions. Increase the time allowed for answering.* [Candidate 60]

**Candidate-Examiner Interaction**

Examiners’ interaction with candidates was an important theme, and both positive and negative encounters were mentioned by candidates.

Candidates found the virtual encounters to be less intimidating:

*I found that having the examiners visible but not face-to-face made the exam less intimidating.* [Candidate 182]

They also reported that examiners’ engagement with candidates was improved because of the absence of patients:

*I felt that the examiners engaged with you more during the zoom meeting because there were no patients.* [Candidate 226]

However, the virtual environment required more examiner engagement with candidates to reassure them that they were being heard:

*Due to lack of in person examiners, examiners need to be engaging and acknowledge the participants response. Not guide or prompt, but make it clear to the participant that they could be heard.* [Candidate 123]

Furthermore, candidates did not approve of examiners being distracted during virtual examinations conducted in their homes:

*Examiners should have their phones off and not be distracted by other factors if examining from home.* [Candidate 130]

Examiners’ visibility on the screen was viewed both positively and negatively:

*I wasn’t actually told I had to have the examiners’ video visible, so I switched it off and found this a much more pleasant experience than what I had been expecting based on colleagues’ related experiences of previous examinations.* [Candidate 251]

*All examiners must be visible during the exam.* [Candidate 459]

The importance of examiners’ eye contact with the camera was specifically mentioned:

*Does lose some of the interpersonal contact. Can be distracting if the examiner doesn’t look at the camera/interact.* [Candidate 125]

Candidates noted that there was less “positive” examiner cueing because it was not possible to read the examiners’ body language:

*Lacking positive reassurance from visual cues given by examiner in a normal setting. Although it is not a given that you would receive that even in a face to face oral.* [Candidate 352]

*Not being able to read body language.* [Candidate 362]

*Less able to elicit nonverbal communication/feedback with mock patient and examiner, but this was not a major factor.* [Candidate 427]

**Personal Benefits for Candidates**

Candidates found the examination design to be overwhelmingly positive. It was associated with financial savings, reduced levels of anxiety, travel convenience, and availability of home comforts:

*No travel. No need to adjust to unknown environment and clinical setting. Costs saved.* [Candidate 349]

*To be based locally in a huge relief. It alleviates a lot of the stress during an already very stressful time.* [Candidate 365]
I liked that it started later, reduced anxiety of traffic and allowed me to sleep better. [Candidate 431]

Home, familiar surroundings, and staff very helpful. [Candidate 373]

Textbox 1. Suggestions from candidates for enhancing the web-based structured oral examination (SOE) experience.

Are Pass Rates of Web-Based and In-Person Certification Examinations Comparable?

Most candidates (1159/1467, 79%) who undertook web-based SOEs were ultimately successful in passing their certification examinations and gained admission to the respective member colleges of CMSA. The pass rates for 2020 and 2021 were 91.4% (1583/1732) and 79.7% (850/1067), respectively. The average pass rate for postgraduate in-person certification examinations conducted by CMSA 3 years before the pandemic (2017-2019) was 58.23% (4030/6921). This was significantly lower than the pass rate for the first 2 cycles that included web-based certification examinations (2020: N=8635; \( \chi^2 = 667 \); \( P < .001 \); 2021: N=7988; \( \chi^2 = 178 \); \( P < .001 \)).

Discussion

Principal Findings

This paper reports about >1500 candidates’ experiences of web-based SOEs conducted via Zoom as part of postgraduate specialty and subspecialty certification examinations hosted by CMSA during the early part of the COVID-19 pandemic. Despite the short time frame in which this transition to web-based examinations was executed, the initiative was well received by candidates. Overall, they perceived web-based SOEs to be a fair and appropriate assessment method, were generally satisfied with the use of Zoom for hosting the examination proceedings, and reported surprisingly few technical challenges. The qualitative data provided a rich analysis of their positive and negative experiences and provided constructive suggestions that could further improve the web-based SOE experience.

An important finding of our study was the observation that candidates undertaking web-based certification examinations performed better than candidates previously undertaking in-person certification examinations. This study did not set out to explore the possible reasons for this observation, but some qualitative observations from candidates may be of interest in this regard. First, candidates reported feeling less intimidated by examiners during web-based oral examinations. Second, improved standardization of the examination process using identical case scenarios and standardized questions with marking memoranda may have contributed to fair examination conditions supporting better overall candidate performance. Third, candidates found the overall web-based examination experience to be less stressful, and this may have positively influenced their performance. Fourth, examiners were required to score candidates’ performance independently without conferring before awarding a final score. This limited examiner-examiner interaction may have limited examiner coercion and had a positive impact on the final scores awarded.

Important Improvement Considerations

On the basis of our qualitative analysis of candidates’ experiences, we formulated 10 suggestions that could further enhance the web-based SOE experience for candidates. These suggestions may be helpful to others currently seeking to improve web-based SOE experiences for candidates. Clear, concise information should be delivered to the candidates ahead of the examination, informing them about the conduct of the examination and approaches to troubleshooting and dealing with technical problems when encountered, especially to ensure that technical issues do not have an impact on examination time. Specific preparation time should be allocated before each case scenario conversation commences. Candidates should have paper in each station to make brief notes during web-based SOEs, if needed. Case design and content should be carefully reviewed to ensure that it is appropriate for a web-based examination, for example, avoid demonstrating the use of equipment that is not present in the web-based examination setting. The screen share option on Zoom should be available to the candidate to review images and videos independently. Examiners should be briefed about the importance of visual and

https://formative.jmir.org/2024/1/e40868
verbal engagement with candidates to ensure a more authentic experience for candidates.

**Findings of Other Studies**

There are several prepandemic papers reporting favorably about the use of in-person SOEs in medical education [14-21]. Although these reports were encouraging and supported the use of SOEs for assessment, they did not speak in the context of web-based oral examinations for high-stakes postgraduate certification purposes, which is the topic of this paper. When looking specifically at this context, it is apparent that this is an emerging field that has gained momentum during the pandemic. Currently, there are a few recent reports directly relevant to the key findings of this study. Before the pandemic, McGrath et al [27] reported a study comparing web-based oral examinations with in-person oral examinations for anesthesia residents. The study randomized 35 residents to testing conditions using an immersive learning environment. Although an immersive learning environment is not the same as a web-based oral examination conducted via Zoom, the paper broadly contributes to the conversation about moving postgraduate oral examinations into a web-based setting. It is worth noting that the authors reported similar academic performance in both groups, which is consistent with our findings of the noninferior performance of candidates undertaking web-based oral examinations. In the study, as also seen in our study, most examination candidates preferred the web-based experience, found it to be less intimidating than in-person oral examinations, and commented about the cost saved by not traveling to testing sites.

Recently, Chaurasia et al [5] conducted a small pilot study of 8 radiation oncology postgraduate trainees and 8 examiners testing the use of web-based oral examinations conducted via Zoom. Candidates were engaged in 8 stations of 25 minutes each, using breakout rooms. Similar to us, they found Zoom to be easy to use, adequate for examination purposes, and free of serious technical difficulties and described it as a fairly seamless experience. They used screen share and annotate for anatomy review, contouring, and treatment plan evaluation for virtual radiation oncology cases. Users described the web-based experiences easier or the same for ease of understanding of the cases and reported preparation to be the same or less time consuming than for in-person oral exams. The authors concluded that a move to web-based oral examinations for postgraduate certification examinations in radiation oncology should be considered as a feasible alternative.

In 2021, a total of 44 senior vascular surgery postgraduate trainees from 17 US training institutions undertook web-based mock oral examinations with 2 remote examiners via Zoom [28]. For each candidate, examiners selected 4 cases from a book of 30 vascular scenarios, and candidate performance was assessed using a standardized scoring sheet. Consistent with our findings, the authors reported no difference in how well the knowledge base of candidates could be examined compared with in-person oral examinations. They also reported that candidates could adequately express their confidence in the web-based setting and concluded that web-based oral examinations are a viable option to consider for examination purposes. They also mentioned the cost saved by remote examinations. The most important considerations highlighted in that paper was the fairness of test grading achieved by using a standardized marking sheet and the equity of test questions achieved by using a standardized set of case scenarios. This speaks to factors that may contribute to favorable candidate performance as already mentioned by us.

In 2022, the Vascular Surgery Board reported about the successful implementation of web-based certification examinations [29]. They reported about the findings of 356 successful candidates who each undertook three 30-minute virtual oral examinations hosted via Zoom. Similar to the findings of our study, the examination process was well received by candidates and found to be technically adequate. Similar to our candidates, they raised concerns about image quality and time constraints to answer all questions but expressed appreciation for good planning and execution, convenience of local examination conditions, and avoidance of travel costs. Overall, candidates were significantly more in favor of continuing web-based examinations as compared with examiners (87% vs 32%; P < .001). The authors make a case for the feasibility and convenience of continuing web-based certification examinations beyond the COVID-19 pandemic. Questions about IT support costs and the cost of remote proctoring are also raised in the paper.

The American Board of Obstetrics and Gynecology also recently published the outcome of their web-based oral certification examinations that were also conducted via Zoom [30]. Between 2021 and 2022, a total of 1491 specialty and 830 subspecialty candidates undertook three 1-hour oral examinations using 3 pairs of examiners per candidate. They found that candidates performed similarly in the web-based certification examinations as compared with previous in-person oral certification examinations. Similar to our findings, they experienced few technical difficulties, and candidate satisfaction with the remote examination was high; however, they expressed anxiety about the use of technology (remotely at home or elsewhere). Despite the success of these remote oral examinations, the issues of remote proctoring and the technical burden placed on candidates being examined in their homes have resulted in a decision to return to testing center–based in-person examinations.

The American Board of Surgery also recently published the findings of their first web-based certification examination for general surgery candidates conducted in 2021 [31]. They report about 306 successful candidates who also completed a web-based satisfaction survey after the examination. They also found that the pass rates for web-based oral examinations were no different from those of in-person oral examinations and that the new examination format was well received by candidates. Audio and video quality were adequate, and 78% of the survey respondents indicated that web-based certification examinations were preferred. The authors argue that the findings support the expanded use of this method of assessment.

The American Board of Ophthalmology has also reported about their success in conducting web-based oral examinations via Zoom for >1000 candidates over the past 12 months. Similar to our study, they took the opportunity to improve the standardization of the examination process and used 2
independent examiners. They described the inordinate preparation and planning required to effect a rapid transition from in-person to web-based certification examinations. They also found that the examination was very well received by both candidates and examiners who felt that the ability to assess knowledge, insight, and judgment using web-based oral examinations was the same as in-person examinations. Positive opinions regarding the use of the assessment method after the pandemic were expressed by a range of stakeholders. However, they did express some ambivalence over the continued use of web-based oral examinations.

Strengths and Limitations
Most current reports in the literature focus on small numbers of candidates. At the time of writing, this was one of the largest published studies reporting about web-based SOEs for postgraduate certification purposes. There are, however, important limitations in this study. We only reported about the initial 12 months of implementation, and a follow-up report is needed. Candidates may have viewed web-based oral examinations more favorably during the pandemic, and this opinion needs to be reviewed. The most significant limitation of the study is that the opinion of examiners was not captured. This was not possible during the pandemic because examiners were overburdened with additional clinical responsibilities and were setting up a new examination method with very little preparation time before the web-based examinations process began. Clearly, their opinion is needed, and after 36 months of implementation, it will contain a wealth of important considerations. Finally, this is a single-country study, and reports from elsewhere are needed.

Future Directions
Internationally, the move from in-person to web-based oral examinations, as part of postgraduate specialty certification examination processes, has gathered momentum [2,3,29-32]. There are, however, lively debates about the ongoing use of web-based oral examinations in the postpandemic era, and it seems that opinions are currently divided on the matter [29-32]. Cost and time savings and convenience of arranging and attending are significant factors in favor of remote oral examinations. Major disadvantages of web-based oral examinations include the cost of IT support and remote proctoring [33] and the inability of examiners to assess bedside skills (history taking and physical examination). Increased uptake of workplace-based assessment in postgraduate training programs should effectively address the ongoing concerns about clinical competence. More cost-efficient delivery of IT support and the challenges of remote proctoring require further studies.

Conclusions
This study highlights the value of conducting formative research about the use of web-based SOEs as part of postgraduate certification processes. We found that this method of assessment was well received by examination candidates, could be conducted via Zoom with surprisingly few technical challenges, and did not have a negative impact on candidates’ academic performance. Our encouraging findings are consistent with early reports from elsewhere that provide positive preliminary evidence supporting the ongoing use of this novel web-based assessment method in postgraduate medical education.

Acknowledgments
The authors wish to thank the candidates for participating in the study, and they extend a special thank you to Bianca van der Westhuizen and Riefda Thomson for the time they spent in assisting the authors with data extraction. No funding was obtained for this study.

Abstract

Background: Patients with unmet social needs and social determinants of health (SDOH) challenges continue to face a disproportionate risk of increased prevalence of disease, health care use, higher health care costs, and worse outcomes. Some existing predictive models have used the available data on social needs and SDOH challenges to predict health-related social needs or the need for various social service referrals. Despite these one-off efforts, the work to date suggests that many technical and organizational challenges must be surmounted before SDOH-integrated solutions can be implemented on an ongoing, wide-scale basis within most US-based health care organizations.

Objective: We aimed to retrieve available information in the electronic health record (EHR) relevant to the identification of persons with social needs and to develop a social risk score for use within clinical practice to better identify patients at risk of having future social needs.

Methods: We conducted a retrospective study using EHR data (2016-2021) and data from the US Census American Community Survey. We developed a prospective model using current year-1 risk factors to predict future year-2 outcomes within four 2-year cohorts. Predictors of interest included demographics, previous health care use, comorbidity, previously identified social needs, and neighborhood characteristics as reflected by the area deprivation index. The outcome variable was a binary indicator reflecting the likelihood of the presence of a patient with social needs. We applied a generalized estimating equation approach, adjusting for patient-level risk factors, the possible effect of geographically clustered data, and the effect of multiple visits for each patient.

Results: The study population of 1,852,228 patients included middle-aged (mean age range 53.76-55.95 years), White (range 324,279/510,770, 63.49% to 290,688/488,666, 64.79%), and female (range 314,741/510,770, 61.62% to 278,488/448,666, 62.07%) patients from neighborhoods with high socioeconomic status (mean area deprivation index percentile range 28.76-30.31). Between 8.28% (37,137/448,666) and 11.55% (52,037/450,426) of patients across the study cohorts had at least 1 social need documented in their EHR, with safety issues and economic challenges (ie, financial resource strain, employment, and food insecurity) being the most common documented social needs (87,152/1,852,228, 4.71% and 58,242/1,852,228, 3.14% of overall patients, respectively). The model had an area under the curve of 0.702 (95% CI 0.699-0.705) in predicting prospective social needs in the overall study population. Previous social needs (odds ratio 3.285, 95% CI 3.237-3.335) and emergency department visits (odds ratio 1.659, 95% CI 1.634-1.684) were the strongest predictors of future social needs.

Conclusions: Our model provides an opportunity to make use of available EHR data to help identify patients with high social needs. Our proposed social risk score could help identify the subset of patients who would most benefit from further social needs...
screening and data collection to avoid potentially more burdensome primary data collection on all patients in a target population of interest.

Introduction

Addressing social needs and social determinants of health (SDOH) challenges in the health care system has emerged as a key component of addressing health disparities [1]. Patients with unmet social needs continue to face a disproportionate risk of increased prevalence of disease, health care use, higher health care costs, and worse outcomes across a range of health-related domains [2-5]. Thus, health disparities cannot be resolved through traditional clinical interventions in the health care system. Targeted interventions to address social needs and SDOH challenges, especially among minority populations, are necessary to overcome widespread disparities [6].

The use of coding systems such as International Classification of Diseases, Tenth Revision (ICD-10) codes for social needs (ie, Z-codes) has increased in recent years, suggesting that clinicians and provider organizations are increasingly aware of social needs and SDOH challenges and the importance of screening for and documenting such needs [7]. Social needs are also extensively documented in unstructured electronic health records (EHRs), such as free-text provider notes [8-12]. Moreover, the rapid adoption of EHRs nationwide and the creation of associated health information technology tools have made it possible to use this growing body of data on social needs and SDOH challenges in risk prediction and adjustment models [13-21].

Some existing predictive models use EHR and administrative claims data on social needs to predict patterns of health care use, cost, and health outcomes [16,18-20,22]. Population-level data on community characteristics is a key component of understanding and addressing SDOH challenges and their impact on health care use, cost, and outcomes [23,24]. Therefore, some EHR-based models have developed linkages to these population-level data to better account for community-level information in their risk predictions [17,21,25-27]. Some existing models have also used the available data on social needs and SDOH challenges to predict health-related social needs [14,15] or the need for various social service referrals [13].

Despite these one-off research and pilot efforts, the work to date suggests that many technical and organizational challenges must be surmounted before SDOH-integrated health information technology solutions can be implemented on an ongoing, wide-scale basis within most US-based health care organizations.

Using both patient- and population-level data, we sought to develop a social predictive risk score based entirely on electronic information readily available within most health care delivery systems. Predictive models such as this could help providers to systematically identify patients at risk of having future social needs, who represent likely targets for further in-depth assessment of their social needs and ultimately potential referral to community-based organizations to address such needs. Using a systematic electronic case-finding screening approach such as this would help the health care system avoid burdensome and inefficient social needs assessment (eg, primary data collection from every patient at every visit).

Methods

Data Sources

This was a retrospective study using the Johns Hopkins Health System (JHHS) Corporation’s EPIC-based EHR structured data from July 2016 to June 2021. Based on the patient’s home address during the in-scope study periods, we linked community-level data (at the census block group level) from the US Census American Community Survey, 2018 five-year cohort [28]. We developed a prospective model (using current year-1 risk factors to predict future year-2 outcomes) within four such 2-year cohorts (ie, 2016-2017, 2017-2018, 2018-2019, and 2019-2020). Each cohort contained model predictors in the first year (2016 in the first, 2017 in the second, 2018 in the third, and 2019 in the fourth cohort) and model outcomes in the second year (2017 in the first, 2018 in the second, 2019 in the third, and 2020 in the fourth cohort). The overall data were randomly split into training and validation data sets (80% of the data were used for model development while the remaining 20% were used for validation). The final model was applied to the 2020-2021 cohort to evaluate its accuracy.

Study Population

Adult patients aged 18 years or older at the time of entering the observation period who were alive at the end of the observation, had at least 1 eligible encounter in the first and second years of each study cohort, and had a valid address for linkage to population-level data were included in this study.

Variable Selection

We identified variables with the highest potential impact on the health and social well-being of minority populations through a review of the literature and consultation with minority health, population health, and social needs and SDOH experts at JHHS. We also sought input from primary care providers and frontline workers, such as social workers and care managers,
representatives of community-based organizations, and patients and their caregivers.

We identified a comprehensive list of predictors of interest available within the EHR’s structured data, including various patient- and community-level characteristics as well as health care use measures (Table 1) [29,30].

To develop the variable on previous social needs, we obtained any ICD-10 codes presenting social needs using the “Compendium of Medical Terminology Codes for Social Risk Factors” developed by the Social Interventions Research and Evaluation Network [31] or any information on social needs available in the JHHS-EHR Wellness Registry, a data mart table in EPIC storing information related to general patient health, consolidated from many subject areas including social history and risk scores. After reviewing the classification of the ICD-10 codes by Social Interventions Research and Evaluation Network, we developed 13 subdomains and 5 domains of social needs (Figure 1).

We reviewed the ICD-10 codes and mapped each to a unique social need subdomain. We also reviewed available information on social needs in the EPIC Wellness Registry and selected variables corresponding to one of the 13 subdomains of social needs. We collapsed the responses available for each variable to generate a binary variable (“yes” or “no” indicator), suggesting the presence or absence of a social need. We defined previous social needs as a binary variable (“yes” or “no” indicator), suggesting the presence or absence of any corresponding mapped ICD-10 codes or any corresponding social needs identified in the EPIC Wellness Registry to 1 or more of the 13 social needs subdomains. We defined the outcome as a binary indicator of having a social need in the second year of each cohort (using the same logic as for the development of the predictor of social needs).

Table 1. Predictors of interest available within the electronic health record (EHR) structured data for inclusion in the generalized estimating equation model predicting prospective social needs for patients at Johns Hopkins Health System between 2016 and 2021.

<sup>a</sup>N/A: not applicable.

<sup>b</sup>ICD-10: *International Classification of Diseases, Tenth Revision.*

<sup>c</sup>ACG: Adjusted Clinical Group.
**Figure 1.** The framework for classification of social needs identified in the electronic health record (EHR) structured data.

The Adjusted Clinical Group (ACG) System Resource Utilization Band represent a simplified population segmentation system based on the overall morbidity burden of each patient. Representing expected future use based on current morbidities, the measure is calculated using all available ICD-10 codes for a person in the EHR during year 1, ranked from low to high according to the expectations of resources used during year 2.

**Statistical Analysis**

We used a generalized estimating equation (GEE) model to predict prospective social needs, adjusting for the effect of the geographically clustered data as well as the effect of multiple visits for each patient (the records were clustered at the patient and 5-digit zip code level). The model selection was based on the goodness of fit test for GEE modeling, and the final risk score was composed using the variables identified as having the highest impact in the GEE model. We also validated the model using multiple denominators to ensure generalizability and retrained and tested the model for each subpopulation of interest (eg, individuals aged 65 years or older, racial and ethnic minority populations, and those living in the most and least disadvantaged neighborhoods).

**Ethical Considerations**

The institutional review board of the Johns Hopkins Bloomberg School of Public Health reviewed and approved this study as exempt. The board approved the EHR data extraction for the secondary analysis of deidentified data.

**Results**

**Demographics**

The final study population included 1,852,228 patients in total. To be included in the sample, the patients had to be in at least 1 of four 2-year study cohorts (Table 2). The characteristics of patients across the study cohorts were comparable. Study cohorts included mostly middle-aged (mean age range 53.76-55.95 years across study cohorts), White (range 324,279/510,770, 63.49% to 290,688/488,666, 64.79%), and female (range 314,741/510,770, 61.62% to 278,488/448,666, 62.07%) patients from neighborhoods with high socioeconomic status (mean area deprivation index [ADI] percentile range 28.76-30.31%).

Between 8.28% (37,137/448,666) and 11.55% (52,037/450,426) of patients across the study cohorts had at least 1 social need documented in the ICD-10 codes or EPIC Wellness Registry, with safety issues and economic challenges (ie, financial resource strain, employment, and food insecurity) being the most common documented social needs (87,152/1,852,228, 4.71% and 58,242/1,852,228, 3.14% of overall patients, respectively; Table S1 in Multimedia Appendix 1 provides details on the social needs domains across study cohorts). Between 18.67% (95,350/510,770) and 21.18% (95,393/450,426) of patients across the study cohorts had high or very high Resource Utilization Band, indicative of having a high disease burden, as reflected by many serious comorbidities.
Table 2. Characteristics of the study population for the development of the social risk score using electronic health record data at Johns Hopkins Health System between 2016 and 2021: overall and by 2-year enrollment cohorts (all characteristics are reported based on the first year of each cohort unless otherwise indicated).

<sup>a</sup>Neighborhood characteristics for the person’s residence of the longest duration are reported as a percentile of national rank [30].  
<sup>b</sup>ICD-10: International Classification of Diseases, Tenth Revision.  
<sup>c</sup>These clinical measures are derived from the Johns Hopkins Adjusted Clinical Group (ACG) System version 12.0. The Resource Utilization Band represents expected future use based on current morbidities [29].

GEE Modeling

Details of the GEE models are presented in Table 3. The GEE model had an area under the curve (AUC) of 0.702 (95% CI 0.699-0.705) in predicting prospective social needs in the overall study population. The strongest predictors of future social needs in the whole population in descending order were social needs documented in the EHR during the previous year period (odds ratio [OR] 3.285, 95% CI 3.237-3.335), ≥1 emergency department visit in the previous periods (OR 1.659, 95% CI 1.634-1.684), and a very high Resource Utilization Band measure indicative of a significant morbidity burden (OR 1.371, 95% CI 1.317-1.427).

^aOR: odds ratio.

^bNot available.

^cNeighborhood characteristics for the person’s residence of longest duration are reported as a percentile of national rank [30].

^dThese clinical measures are derived from the Johns Hopkins Adjusted Clinical Group (ACG) System version 12.0. The Resource Utilization Band represents expected future use based on current morbidities [29].

To help assess bias and applicability to various subpopulations, we identified comparable performance for models of select subgroups, with AUCs of 0.701 (95% CI 0.696-0.706), 0.711 (95% CI 0.706-0.716), and 0.711 (95% CI 0.708-0.714), respectively, for individuals aged 65 years or older, Black patients, and those living in the most disadvantaged neighborhoods.
neighboring. The strongest predictor of future social needs in the study subpopulations remained the previous social needs, with ORs of 3.043 (95% CI 2.96-3.128), 2.9 (95% CI 2.824-2.977), and 3.390 (95% CI 3.334-3.447) among individuals aged 65 years or older, Black patients, and those living in the most disadvantaged neighborhoods, respectively.

To ensure that the most common social needs (ie, safety and economic challenges) were not the main drivers of the model’s performance, we performed a sensitivity analysis and ran the model after excluding patients with any social needs in subdomains of safety and economic challenges. This resulted in a slightly better-performing model with an AUC of 0.768 (95% CI 0.763-0.773). In this instance, previous social needs were by far the most significant predictor (OR 11.857, 95% CI 11.521-12.202), followed by emergency department visits (OR 1.916, 95% CI 1.865-1.969), need for an interpreter (OR 1.528, 95% CI 1.397-1.672), and Black race (OR 1.307, 95% CI 1.273-1.342). Contrary to the analyses performed with all social needs included, patients with higher Resource Utilization Band had slightly less risk of increased social needs, and lower Resource Utilization Band had slightly greater protective value regarding social needs (Table S2 in Multimedia Appendix 1 provides details of the GEE model).

Discussion

Overview

Achieving a comprehensive assessment of a person’s health and addressing health disparities goes beyond just documenting clinical diseases and medical interventions. We must also capture, standardize, analyze, and report reliable information on social needs and SDOH challenges within operational clinical decision support systems that are built into EHRs. Moreover, the rapid change toward “value-based” health care models [32] in the United States has required the incorporation of social needs and SDOH contexts and frameworks to ensure that the health care systems and health plans equitably address the needs of minority and disadvantaged communities [33,34]. For these value-based models to perform well, it is critical that clinical and social interventions are aligned and that no financial disincentives are imposed on providers who disproportionately serve minority and disadvantaged patients [33,34].

To achieve these goals, applied research is needed to identify optimal solutions for the effective collection and application of social needs and SDOH information within EHRs, link provider-based data to community-level data describing the characteristics of patients’ neighborhoods, and anchor such information to the providers’ digital workflow. This approach will provide the vehicle for harnessing social needs and SDOH data to target interventions at the point of care (eg, referrals of an individual); the health delivery system level (eg, hiring a social worker in the clinic); or the community (eg, building or strengthening community-based initiatives) [35]. To avoid burdensome and inefficient social needs assessment and data collection, it is essential to develop automated screening tools using EHR or community-based data to help identify the subset of patients who would most benefit from social needs assessment and data collection.

Several EHR-based screening tools for social needs assessment have been piloted in recent years, and results have shown these tools to be effective in determining social needs and SDOH challenges [36,37]. However, the feasibility of such tools remains unclear, with health care systems needing to dedicate considerable time and budget to train and educate staff and manage workloads [21]. Our proposed social risk score aimed to reduce the burden of this process and increase its accuracy by identifying patients at high risk of having any social needs for more efficient screening.

Comparison With Previous Evidence

Our proposed model was based on a large and diverse data set of patients in the JHHS-EHR. The AUC of our model in predicting prospective social needs was 0.702 (95% CI 0.699-0.705) in the overall study population. This AUC may be the result of many instances of false negatives related to the documentation of social needs in structured EHR data. At the time of completing this study, social needs screening and referral were not common practices at our institutions. Thus, we expect many patients with social needs did not get a proper screening and documentation of such needs. The new mandate established by the Centers for Medicare and Medicaid Services requires hospitals to report to the Inpatient Quality Reporting Program 2 brand new measures of social needs (ie, the number of patients screened for social needs and the number of patients identified with selected social needs) [38]. We expect the health care system to establish more systematic and uniform processes for screening and documentation of social needs. This effort will increase the volume of data on social needs in the EHR, which will result in better performance of our models in the future.

Our findings were comparable with those in the study by Holcomb et al [14], where they predicted health-related social needs using EHR and community-level data and machine learning modeling for Medicare and Medicaid beneficiaries participating in the Accountable Health Communities project. Their models performed relatively well, with AUCs ranging from 0.59 to 0.68 for patients with different domains of social needs. Another notable mention was the study by Byrne et al [15], where they used EHR data, including responses to the Veterans Health Administration’s Homelessness Screening Clinical Reminder Survey, to develop and test predictive models of housing instability and homelessness. All their models performed well, with the random forest models performing better than the logistic regression models for both the housing instability (85.4 vs 78.3) and homeless (91.6 vs 87.1) outcomes. Lastly, Kasthuriratne et al [13] built random forest decision models to predict the need for social work referrals using clinical and population-level data on SDOH challenges. The performance of the model ranged from an AUC of 0.713 for the model using both clinical and SDOH data to 0.731 for the model using clinical data.

Moreover, our results demonstrated that the most significant predictive factor for having prospective social needs was the documentation of previous social needs. This study also found associations between prospective social needs with previous ED visits and morbidity-related high resource use presented in Resource Utilization Band. Lastly, our model showed a...
minimally increased risk of social needs in association with characteristics of the neighborhood of residence, presented as the ADI measure. This finding was similar to the results of the study by Nguyen et al [39], where they identified a small statistically significant association between the ADI and total score on social needs from the Health Leads Social Needs Survey among pediatric patients’ families receiving primary care at a large academic institution. A review by Chen et al [21] also indicated the low success of the integration of population-level data for predictive modeling and risk stratification purposes, including the prediction of social-related service referrals [13], in contrast to the performance of models using individual-level data in referrals to a social worker [40]. Overall, these findings indicated that individual characteristics played a more crucial role in predicting future social needs than neighborhood characteristics.

Clinical Implications
The implementation of an EHR-based social risk score such as the one we developed would have many implications for clinicians and practice organizations. At the point of care, our social risk score could be integrated directly with EHR-derived data warehouses; thus, the proposed risk score could be leveraged to allow clinicians to tailor more personalized care and modulate care coordination efforts. This personalized social risk score could also help support tools tailored to the needs of patients, which would empower the navigation of available social services [35]. At the health delivery system level, the linkages of geo-derived databases could improve the assessment of social needs and SDOH challenges for health systems and provide opportunities for longer-term plans to address those factors in current and future care management programs. Additionally, the merged clinical and nonclinical databases could enable providers to follow patients with social needs and SDOH challenges over time through their interaction with the health system. At the community level, the social risk score and the social needs or SDOH data could enhance care coordination efforts by integrating community-level data into clinical decision support tools and coordinated interventions [41].

Limitations
Several limitations existed for this study. First, EPIC Wellness Registry data were essentially nonexistent between the years 2016 and 2018, which, in addition to the possibility of ICD-10 codes being underused by providers, might lead to an underrepresentation of social needs in this study’s population. Second, Latino and Hispanic patients were underrepresented in this study’s population, which may have impacted the generalizability of the proposed model. Furthermore, data on racial and ethnic minority groups such as American Indian and Alaskan Native, Native Hawaiian, Other Pacific Islander, and multiracial individuals were limited in our data set. Another important factor that might have affected our results was the potentially more frequent screening of social needs in female individuals, ethnic and racial minority populations, those with higher disease burdens, and superusers of health care services [42], leading to biased results for these individuals. Misclassification and inconsistency in documenting social needs in the EHRs could influence our results.

Moreover, the use of EHR data as the sole source of information limited our data to services provided to patients across the JHHS facilities and did not include other services outside JHHS. Also, we used the patient’s home address to link the EHR data to the American Community Survey community-level data. Thus, we did not include patients with a missed or invalid home address. This may have resulted in missing some patients with social needs, such as residential instability. Finally, our final model was applied to the 2020–2021 cohort to evaluate its accuracy, which included patient encounters during the first peak of the COVID-19 pandemic. While some subpopulations of patients experienced more social needs during the pandemic, the challenges that the health care systems faced during this period impacted the screening and documentation of social needs and may have resulted in missed data on social needs for this cohort.

Conclusion
Screening for social needs and SDOH challenges using available secondary EHR data represents an important step toward addressing health disparities more efficiently and improving patient care and population health. Our proposed model integrates community-level data with patient-level data to arrive at a social risk score that can be used to systematically identify patients at increased risk of having future social needs and is thus appropriate for in-depth assessment of their social needs and potential referral to community-based organizations to address these needs. Our model identified previous social needs and high morbidity levels as the strongest predictors of future social needs. Missing data in the EHR reflecting past clinician documentation of social needs may have impacted the performance of our proposed model, and the predictive accuracy of models like ours will likely increase as the capture of such information becomes more commonplace. Future studies should focus on developing EHR-integrated clinical decision support tools to make this information available in the providers’ digital workflow and at the point of care.

Abstract

Background: Sexual pain is a common but neglected disorder that affects approximately 3% to 18% of women and an unmeasured number of gender-diverse people worldwide. Despite its wide prevalence, many people feel reluctant to visit conventional health care services or disclose their symptoms due to the fear of stigmatization. To alleviate this stigma, various web-based interventions have been developed to complement and, in some cases, replace conventional sexual health interventions. However, the way these web-based interventions are developed could inadvertently reproduce, perpetuate, or exacerbate stigma among end user patients.

Objective: The purpose of this study was to understand patients’ perspectives on how sexual pain–related web platforms can be designed to alleviate stigma or prevent the unintended effects of stigma among patients who use web-based interventions.

Methods: Individual semistructured interviews were conducted among 16 participants with lived experiences of painful sex in a large urban city in Western Canada. Participants were recruited via social media platforms, newsletters, and a provincial health volunteer website. Using a sample sexual pain website to provide context, participants were interviewed about their experiences of stigma and how they think web platforms could be designed to address stigma. The interviews were conducted via Zoom (Zoom Technologies Inc) and analyzed using thematic analysis.

Results: The findings revealed 4 overarching themes that represented participants’ perspectives on designing web platforms that may alleviate or prevent the unintended effects of stigma. These findings suggested the design of inclusive web platforms, having a nonprovocative and calming user interface, having features that facilitate connections among users and between users and providers, and displaying personal testimonials and experiences of sexual pain.

Conclusions: This study highlighted patient-centered design approaches that could serve as a reference guide in developing web platforms that alleviate or prevent the unintended effects of stigma, particularly among nonheterosexual and gender-diverse people. While this study was conducted in the context of sexual pain, the results might also apply to web platforms on other potentially stigmatizing health-related disorders or conditions.

(KEYWORDS: stigma; digital health; sexual pain; destigmatizing; end user patients)

Introduction

Sexual pain is a common but neglected problem, predominantly experienced by females, that is estimated to affect approximately 3% to 18% of women globally [1]. The disorder affects multiple aspects of one’s life including absenteeism from work, poor interpersonal relationships, and impaired social functioning with a profound impact on the quality of life [1]. Despite the
negative effects of sexual pain, many women feel reluctant to visit service providers or disclose their symptoms to family and friends due to the fear of stigma [2]. Stigma is defined as an attribute and dynamic social process characterized by widespread social disapproval, blame, rejection, devaluation, and segregation [3]. The extent to which people with sexual pain are affected by stigma depends on the nature of the disorder and whether it is concealed or exposed. According to Tyler and Slater [4], people with invisible conditions or disorders are more likely to be affected by internalized stigma, while those with visible conditions or disorders may be predisposed to public stigma. Public stigma refers to the overt discriminatory practices that are directed at someone, while internalized stigma refers to the acceptance of negative attributes and a reduced sense of self-worth as a result of possessing a supposedly stigmatizing attribute [2]. While hidden disorders like sexual pain may not immediately provoke public stigma, people with such disorders may still be concerned about an impending negative reaction from the public or even stigma from present and future intimate partners if their pain status is eventually revealed [4]. The fear of disclosing a condition can be classified as anticipated stigma, and this is quite common among people with sexual health–related disorders [5]. Therefore, people with sexual pain may face both internalized and public stigma of various proportions at the personal, interpersonal, and societal levels. As stigma becomes more of a dynamic social process [3], the modalities of managing this issue are becoming increasingly complex and challenging, especially for people with hidden disorders like sexual pain.

In response to the negative impact of stigma on people with sexual pain, various web-based platforms have been developed to complement, and in some cases, replace conventional care services [2,6,7]. Web-based platforms on painful sex could range from educational resources, decision support systems, web-based social support platforms, and therapy-based platforms [8-12]. Even though web-based platforms are increasingly used as resources inquiring about and managing sexual pain [13,14], available evidence suggests that sexual health–related web-based platforms could inadvertently foment stigma among end users [15]. Other studies revealed that merely using a sexual health platform in public spaces could be interpreted as having a disorder and could lead to stigma in what is termed stigma by association [6]. Notably, people who use sexual health–related web platforms may likely link the appearance of certain images and content to an existing social stigma, thereby resulting in technology-mediated experiences of stigma [7]. Furthermore, the replacement of face-to-face conversations with web-based tools may further emphasize the feeling of discomfort or stigma associated with in-person interactions as it gives an indication that sexual pain is not something to be discussed but self-discovered using web-based tools.

The likelihood of web-based platforms resulting in technology-mediated experiences of stigma may be attributed to the general lack of attention to the issues of stigma when developing sexual health–related digital platforms [16]. Even though patients’ views and opinions are usually sought when developing sexual health–related digital technologies [17,18], their perspectives on how web-based platforms can be designed to alleviate stigma are usually not considered when developing such interventions. The apparent lack of attention to stigma may not only lead to a mismatch between people’s expectations and web-based platforms but could inadvertently reproduce and perpetuate stigma among patients who may find such platforms undesirable [7]. We attempted to address this gap in our prior studies by developing a set of destigmatizing design guidelines to provide a reference guide for developers of sexual health–related web-based platforms [16,19]. However, these guidelines were based on expert opinions and did not address the salient concerns of patients regarding stigma. With a disorder like sexual pain, patients often withhold sharing their diagnosis publicly, and we believe that many of the stigma-related considerations for designing web-based platforms could only be obtained from people with lived experiences of the disorder. The purpose of this research was thus to examine the perspectives of people with sexual pain on how web platforms could be designed to alleviate stigma or prevent digital platforms from inadvertently fomenting stigma among end user patients. The findings of this study are expected to produce user-interface design recommendations not just for sexual pain digital platforms but for web-based platforms on other stigmatized conditions or disorders in sexual health and mental health.

**Methods**

**Study Design**

A semistructured interview was conducted among 16 people with lived experiences of sexual pain in a large urban city in Western Canada. Participants were recruited via (1) social media platforms, (2) newsletters, and (3) a provincial health volunteer research website. To be eligible, potential participants must have been at least 18 years old, experienced or self-reported sexual pain (alone or partnered), and reported previous or current use of a health-related web-based platform. Due to the limited involvement of male partners in prior sexual health–related studies [8], we decided to recruit people who also identify as biological males and report experiences of painful sex.

**Interview Guide**

A semistructured interview guide (Multimedia Appendix 1) was developed based on the person-centered care model by focusing on the participants’ emotional needs and preferences about how digital health technologies can be developed to be less stigmatizing and emotionally safe. The interview guide was developed to address key areas including demographic information, participants’ experiences with stigma, and their perspectives on how web-based platforms can be designed to alleviate stigma or prevent the unintended effects of stigma. The interview guide was reviewed by our patient advisory team, pretested on 3 patients outside of this study sample, and was revised accordingly.

**Data Collection**

The interviews were conducted by the first author (AFA), with assistance from the second author (HN). Since different web-based platforms exist, we decided to contextualize our study by providing participants with a sample website that we developed in a previous study [10]. A link to this website was
sent to participants at least 3 days before the interviews. Participants, particularly those who have never used a sexual pain web platform, were asked to explore the sample website before the interviews. The interviews were conducted via Zoom with participants’ videos turned off to protect their confidentiality. Participants were asked questions related to the design of web-based content, interactive features, images, colors, sex, gender, and class representations on digital platforms that can help alleviate the stigma of painful sex. Depending on participants’ backgrounds and prior experiences of stigma, probing questions were asked regarding how web platforms can be designed to address the experiences of stigma related to their identity. Data collection occurred from April to July 2023, and each interview lasted approximately 1 hour. All interviews were recorded onto the University of British Columbia’s accredited Zoom Cloud and transcribed using TEMI web-based transcription services (Temi Inc).

Data Analysis
The transcribed data were imported into the NVivo software (version 11; QSR International). Data were analyzed using a thematic analysis approach [20]. The data analysis occurred alongside data collection. The first and second authors familiarized themselves by reading over the first 4 transcripts multiple times. The 2 authors independently developed a coding framework inductively from the first 4 transcripts. We compared the 2 coding frameworks and arrived at a common coding scheme at the end of the fourth interview. Any differences between the coders were resolved by discussing with other members of the research team. We then applied the unified coding scheme to the rest of the data as they emerged from subsequent interviews. As the data analysis proceeded, the coding scheme was revised as new data emerged. The coded data were sorted and organized into categories, and themes were then generated from the categories depending on their overall importance to the research questions. We compared data from people in different age groups, sex, and gender identities to understand if such identities reflected specific preferences on how web platforms can be designed to alleviate stigma.

Ethical Considerations
The study was approved by the University of British Columbia behavioral research ethics board (REB # H23-00273). All participants provided written informed consent before the data collection. All data were anonymous because participants were not to state or mention any identifying information during the interview. Each participant was provided with CAD $50, which was equivalent to US $35 honoraria in appreciation of the time spent on the study.

Results

Demographic Characteristics
A total of 16 participants were interviewed. Data saturation occurred after the 14th participant, and we decided to interview an additional 2 participants. Regarding gender identity, 12 participants identified as women, 2 identified as men, and 2 identified as two-spirit. Regarding racial identity, 8 participants identified as White, 3 identified as a person of color, and 2 identified as Indigenous. Participants’ ages ranged from 25 to 63 years, with the majority of them younger than 30 years old. Even though all participants had used health-related websites, 6 of them had additional experiences using sexual pain-related websites. While we did not specifically ask people about their sexual identity, 3 of them openly stated their sexual identity as nonheterosexual. Seven participants stated they are marginalized by being identified as a woman, nonheterosexual, and Indigenous. On one hand, participants who indicated a marginalized identity also reported feeling stigmatized at some point in their lives or a feeling of impending stigma from their experiences of sexual pain. On the other hand, participants who did not express any marginalized identities were not very concerned about stigma, with 1 participant indicating that they do not associate sexual pain with stigma.

Participants’ Perspective on Design Approaches to Alleviate Stigma
The analysis generated 4 main overarching themes that reflected participants’ perspectives on how sexual pain-related web platforms can be designed to alleviate stigma or prevent such platforms from inadvertently fomenting stigma. Some of the broader thematic areas contain subthemes that come together to define each overarching theme.

Theme 1: Inclusive Design of User Interfaces

Overview
Inclusive design emerged as a major theme that reflected participants’ perspectives on how digital platforms could be developed to prevent the unintended effects of stigma. Participants recognized the diversity of people who may have direct or indirect experiences of sexual pain and the need to design digital platforms that satisfy the experiences of people with different racial or cultural backgrounds and sexual and gender identities. Three subthemes emerged under the overarching theme of inclusive design.

Subtheme 1: Design to Include Diverse Sexual Experiences
The participants indicated that web platforms on sexual pain should not just be limited to information on penis-vagina sex but include other forms of sexual experiences. According to the participants, other forms of sexual experiences like anal sex and the use of sex toys could equally elicit pain and therefore must be captured on web platforms. Participant 3 stated saying:

Sex is not just penis to vagina interaction. There's also sex toys and different ways in which people partake in sex. And so being very inclusive of that sense so that everyone feels safe in that website environment. And touching on the fact that there are different toys and people who are trans, for example, use dilators which can also bring pain.

The participants stated that these other forms of sexual experiences are already stigmatized by society and excluding them from digital platforms could worsen the stigma associated with such sexual experiences. The desire for inclusion of information on diverse sexual experiences was common among younger people. In fact, 2 participants who were older than 60
years were not open to the idea of other sexual experiences beyond penis-vagina sex.

**Subtheme 2: Design to Include Diverse Sexual and Gender Identities**

The participants also recognized that people may have different gender identities apart from being a woman and still experience painful sex. They specifically stated that not all people who identify as a woman may have a vagina and not all people that identify as a man may have a penis. To accommodate gender-diverse people in web-based platforms, participants suggested having inclusive pronouns by having drop-down menus or subsections on websites that account for people with different gender identities. Other participants argued that including pronouns of all gender-diverse people on web platforms may be difficult or impossible to achieve. Thus, they suggested the use of gender-neutral terms as a way of reducing the stigma associated with other stigmatized sexual identities. Participant 8 stated the need for gender-neutral terms by stating:

> Oh my god, my ovaries are partially removed because I had a tumor. And I think that using less gendered language would be very, very, very, destigmatizing for people like me and for people who are trans. Because I love when people actually think of us and it shows that we are not as bad as some people think. I would probably stick with non-gendered wording, like people with uteruses or just like talking about the specific parts that may show pains.

While participants argued for designs to include diverse gender identities, they agreed that painful sex may be more common among cisgendered people. In addition to the gender-diverse pronouns, participants suggested that web platforms on painful sex should include male partners who may not directly experience pain but may be part of the activity that produces sexual pain. Participant 6 noted the need to include male partners by stating:

> But honing in on the partners aspect, I think is really to make sure that there are resources for partners as well who aren't actively dealing with the pain. Okay. It's something that I've noticed is missing a lot.

**Subtheme 3: Design to Reflect Cultural, Religious, and Ethnic Diversities**

The participants also indicated their preference for designs that include people with different cultural, religious, and ethnic identities. This theme occurred across participants who identified as Indigenous or other marginalized identities. Participants expressed the need to see their culture or ethnicity represented when visiting web-based platforms regarding painful sex. Participant 14 specifically stated:

> I was talking to one of my friends and she’s a black woman and she said when she was looking up sexual pain, she only saw white women on the websites. And so, she didn't think the information applied to her. She didn't see anyone who looked like herself. So, I think if images are used, it has to be intersectional so people can see themselves on the website.

According to participants, these minority groups are already marginalized and stigmatized in society, and such stigma may only intensify if their cultural and racial identities are not represented on web platforms. Some participants with religious backgrounds also noted the importance of religious sensitivity and how that can alleviate stigma, particularly stigma relating to traumatic sexual experiences. Participant 7 stated:

> I think that having that cultural sensitivity aspect embodied in a digital platform is important. Whether that be having individuals who have religious trauma associated with sex and who have gone through this experience give a testimonial or talk about it on a video or having religious supports or access to resources on the website, whether it be clickable links, phone numbers, whatever it might be on there.

**Theme 2: Nonprovocative and Calming User Interfaces**

**Overview**

Participants also reiterated the use of nonprovocative and what they termed “calming user interfaces” as an approach to alleviating stigma via web interfaces. According to participants, people with experiences of painful sex may already be overwhelmed by some form of hidden trauma and stigmatized feelings associated with the disorder. Thus, they suggested that calming and uncluttered interfaces could be an appropriate design approach to alleviating such stigmatized feelings. They specifically argued for the content on the landing pages to provide comfort to website users before they dive into the actual content of the website. The use of (1) nonprovocative and nonexplicit images and (2) subtle and calming colors emerged as subthemes that together defined the overarching theme of uncluttered and calming user interfaces.

**Subtheme 1: Nonprovocative and Nonexplicit Images**

Many participants argued for the use of nonexplicit images. Participants with a health science background thought explicitly displaying anatomical images of sexual organs might help in educating patients on the specific location of pain. Participant 2 stated:

> For me personally, I feel like the more graphic and anatomical images, the better because when I was younger, I literally didn't know anything about sexual anatomy. It's probably not allowed on the internet, but I think having those images would be helpful.

However, the majority thought that such images could be uncomfortable and might inadvertently foment stigmatized feelings. Participant 1 stated her abhorrence for seeing explicit content on sexual health–related web platforms and indicated how that made her feel uncomfortable.

> I read on one medium where they have provocative pictures of people, you know, in the lovemaking act. It wasn't pornographic but certainly explicit and personally, I am uncomfortable with that.

**Subtheme 2: Subtle and Calming Colors**

Participants’ views on addressing stigma via web platforms extended beyond the use of nonexplicit images to include the
color of the images and the general color scheme of websites. There was unanimity in participants’ preference for colors like blue, green, dark, purple, soft greens, turquoise, and so forth. These colors were perceived to be calming and comforting for an already distressed user population of people with painful sex experiences. On the contrary, participants were generally unfavorable to bright colors like red and pink as such colors were thought to symbolize pain. Participant 9 indicated his desire for calming colors by stating:

so probably not like bright pink and that kind of thing. You know painful sex comes with its own trauma and having all these bright colors may be a put-off. I liked the one I saw in this interview, it was like really calm colors, and they weren't too noisy, so you really focused on the information on the site and it was like, I think calming colors are maybe a good idea too.

Apart from indicating how these calming colors may be comforting to the eyes, participants were not explicit on how these color schemes could help address stigma when probed further.

Theme 3: Interpersonal Connection via Web Platforms

Overview
As a way of addressing stigma, participants indicated a preference for integrating interactive features on web-based platforms that allow the creation of interpersonal connections among people with similar experiences or with health care professionals. According to participants, being connected to others will be crucial in addressing stigma for a hidden disorder like sexual pain. Two subthemes emerged under this overarching theme.

Subtheme 1: Creating Forums to Connect People With Similar Pain Experiences
There was a strong preference for forums, discussion boards, and messaging boards that would enable people with similar sexual disorders to connect, interact, and share experiences with each other while remaining anonymous. Participant 9 compared this to Reddit, and how a Reddit-like function on web platforms can offer a free, easy, and anonymous forum for people to discuss sensitive topics.

I think in that sense; the forums open up the isolation. The experiences and stories of strangers who have the same condition and you know such varied experiences will tell me that I am not alone in this and should not harbor any negative feelings. You know the internet gives us this fantastic gift of connection without obligation.

While participants acknowledged the importance of forum posts in addressing stigma, they also recognized the security and privacy risks associated with forum posts and how they can inadvertently perpetuate stigma. One participant noted how such forums can be used as avenues for harassment, bullying, and other risky behaviors. To prevent digital health platforms from inadvertently fomenting stigma, the participants suggested developing rules and regulations that govern forum posts, the use of pseudonyms and having designated professionals who would moderate web-based platforms.

Subtheme 2: Creating Avenues to Connect With Health Care Professionals
In addition to creating avenues on web platforms for people to connect, participants also reiterated the importance of creating avenues to connect with health care professionals, especially if it is a local website. According to participants, connecting with health care professionals via web platforms can “serve as a shield” from being exposed to the public stigma—a situation that participants found helpful during the COVID-19 pandemic. Participant 13 noted the importance of connecting to professionals by stating that:

speaking to a medical professional is more easily accessible and then having kind of the barrier of the screen in between, like not having to talk to someone face to face about it, but be able to type, I think could be helpful and, and perhaps start as a way to reduce the stigma.

According to participants, these forms of web-based interactions via web platforms can facilitate web-based consultations, thereby reducing the stigma people encounter by visiting onsite services.

Theme 4: Displaying Personal Accounts and Experiences of Painful Sex
The data revealed that displaying personal experiences on web platforms could help alleviate the stigma of painful sex among web users. The participants stated that seeing or hearing what others have gone through can help them relate to other people’s personal accounts of sexual pain while validating their own experiences. Participant 2 stated:

When you find websites like this sharing information, it makes you feel like, I’m really not that strange. I’m not weird. Like there are a lot of other people who experience this too and that’s why they’re putting forward this information on this platform. So, it kind of makes people realize that it’s more common than they think. And that also helps to alleviate fear surrounding it.

Some participants suggested the use of video testimonials to convey experiences, while others suggested a combination of text and video testimonials but from different sources. According to participants, reading about people’s stories; hearing their voices; and understanding what they went through, how they discovered their diagnosis, and how it was treated will help others learn and understand their situation and clarify myths and misconceptions that often fuel stigma. Some participants also suggested the use of comic images and videos to convey their experiences of painful sex as a way of addressing stigma. Participant 3 stated:

I like the comic thing. Like having people talking about these sorts of things in a comical style and that can make it less terrifying. By making it comical, you make it more entertaining, and people are more likely to pay attention to these sorts of things.
Discussion

Principal Findings
This study examined the perspectives of people with lived experiences of sexual pain on how web-based platforms can be designed to alleviate the unintended effects of stigma. While we acknowledge current practices of involving end users in developing sexual health–related digital interventions [21,22], no study has specifically investigated how such technologies can be designed to address the unintended effects of stigma. To the best of our knowledge, this is the first study that examined patients’ perspectives on how to address stigma through the design of digital health web platforms. Our study identified 4 broad categories that represented patient-centered strategies on how sexual health–related web platforms can be designed to address stigma. These categories include the design of inclusive web technologies, having a nonprovocative and calming user interface, having features that facilitate connections between users, and displaying personal accounts and experiences of sexual pain on web interfaces. Our sample revealed varying demographic information that ranged from marginalized populations including Indigenous, nonbinary, and people of color to White or Western populations. Participants’ indication of a marginalized identity suggests that the stigma of sexual pain may not exist in isolation but may intersect with multiple stigmatized identities to produce what is known as intersectional stigma [23].

These findings may help provide a conceptual or practical user-interface design guide for service providers to design digital health intervention that lessens or avoids the potential of fomenting stigma among people using sexual pain–related web platforms. We believe that these findings are not just applicable to sexual pain web platforms but could be applied to web-based platforms on other stigmatized conditions or disorders. By including male participants, this study also adds another dimension to sexual pain research in what is generally considered to be a woman’s health problem. The inclusion of people who identify as men male partners might have addressed the general lack of men’s involvement in sexual health research [24]. Even though participants who identified as men were not necessarily partners of those who identified as women as suggested in our prior study [10], they nevertheless illuminated the aspects of sexual pain that are specific to men yet often overlooked (eg, pain resulting from men who have sex with men).

Strategies to Addressing Stigma in Web Design
The themes identified from this study reflect patients’ perspectives on how web-based platforms can be designed to alleviate the stigma of sexual pain. The findings highlight the importance of inclusive user interfaces for people with diverse sexual pain experiences; gender-diverse people; and people with different cultural, ethnic, and religious identities. The findings of this study thus extend the idea of inclusive design beyond addressing the usual age, physical, mental, language, and accessibility limitations [25-27] to include specific stigma-related concerns that are often associated with people of diverse sexual and gender identities (two-spirit, lesbian, gay, bisexual, transgender, queer, and questioning, intersex, asexual) as well as diverse sexual preferences (anal sex and sex toys).

It is worthwhile to note that sexual pain is often discussed in relation to heterosexual encounters, people who engage in anal sex or sex using vibrators or sex toys may experience worse pain that, unfortunately, often ends up ignored in sexual pain–related platforms [28]. Designing to include these sexual perspectives is critical to foster inclusivity and may eventually help address some of the myths and misconceptions that often fuel stigma related to nonheterosexual forms of sexual encounters. On the contrary, user-interface design practices that exclude such groups from web platforms could be considered a form of marginalization through design [29]—a practice that may not only places people with nonheterosexual experiences into isolation but also amplifies the stigma associated with such sexual encounters.

The use of nonprovocative images was seen as a good design strategy for addressing stigma. We understand that intervention developers may want to display anatomical images of sexual organs on web platforms for enhanced comprehension and clarity of the information presented [30]. While useful, such practices may need to be reconsidered in sexual health web platforms as they may inadvertently reproduce, perpetuate, or exacerbate stigmatized feelings among people who find such explicit content undesirable. Participants’ suggestion for the display of nonprovocative images supports our previous assertion that provocative and explicit sexual images on web platforms could inadvertently foment stigma among end users [7,15,22]. It further confirms the assertion that the stigma of sexual health issues may be amplified through digital content, particularly digital images [31]. Furthermore, even though there was a general desire for inclusive images of nonheterosexual encounters and gender-diverse people, care should be taken to ensure that such images are not provocatively displayed on digital platforms that may end up stigmatizing an already stigmatized group. A possible solution may involve user testing of such content among the different user populations before they are displayed on web platforms.

Participants did not only recommend the use of nonprovocative images but also expressed a desire for the colors of such images, and the general color schemes of web platforms, to be calming and nondistressing to users. The differences in color preferences might be a reflection of the diverse cultural backgrounds of the participants. Participants’ position on the use of calming colors like green, yellow, and blue confirms Goethe’s theory of colors where he associated certain color categories (eg, yellow and green) with positive emotional responses of warmth and excitement, while other categories (eg, red) were associated with negative arousal [32,33]. Even though participants were not explicit on how the choice of colors can address stigma, the current theories on colors suggest that less distressful color schemes like green and yellow could have a healing effect on people who have experienced the trauma of painful sex [33]. While we identified what is considered as calming colors, the differences in these colors might also pose a new challenge in determining a unified color scheme that is considered calming to a significant majority of web users. Thus, further research is needed to examine how the visual effects and different
combinations of colors on user interfaces could alleviate the stigma of sexual pain.

Interpersonal communication features have been shown to provide informational support, instrumental support, belonging support, self-esteem, and emotional support to people with similar health conditions [34]. Participants’ recommendation for the integration of anonymous and interpersonal communication features (chat rooms, forum posts, and messaging boards) confirms the use of these interventions for people with other stigmatized conditions like HIV and AIDS [35]. The recommendations for networking functions in web platforms also support the use of social networking sites as an effective educational strategy for reaching out to people with diverse sexual experiences who often experience stigma [35]. With the increasing use of digital health technologies, such interpersonal connection features might move a significant part of sexual health services onto web-based platforms (eg, consultation, testing, and prescription). Beyond that, such interaction features could also foster new friendships for isolated individuals while providing opportunities for people to share and validate their personal experiences that are often internalized as negative feelings. These opportunities for interpersonal connection might not only make people feel less isolated but may also normalize their sexual pain experiences, thereby alleviating stigma [36].

Forums could have more effect on stigma reduction when people with internalized negative feelings can read personal accounts and testimonials from other people with the same disorder. Such testimonials may not just be limited to forums or messaging boards but could be displayed on landing pages, particularly if they are coming from popular personalities. Text or video testimonials from “famous” personalities have been shown to be very persuasive and might help elicit healthy emotions and memory [37]. Testimonials from famous personalities are especially important given the significant role of power and power dynamics in stigma formation [38]. Web-based video testimonials have shown effectiveness in alleviating explicit and implied stigma of mental illness among students [39], thus suggesting their usefulness for other stigmatized disorders in sexual health. Despite the importance of interpersonal connections on web platforms, it is important to be aware of the inherent security and privacy risks that could inadvertently expose people to further stigma or restigmatization [40]. The use of anonymous chat rooms and forum posts and moderation of web-based platforms by trained personnel is recommended to prevent the privacy risk associated with such platforms [41].

Strengths and Limitations

Our study relied on web-based data collection methods, which provided some degree of anonymity and might have boosted the confidence of participants to discuss a sensitive topic like painful sex. We believe that the diversity of our sample may have enriched our findings by bringing a nuanced perspective of gender-diverse and nonheterosexual experiences of painful sex and their associated stigmatized feelings. Males engaging in nonheterosexual sexual acts like anal sex or females using sex toys may experience worse forms of stigma and sexual pain, yet are often ignored on web platforms.

Despite these strengths, this study was not without limitations. Even though we included participants who identified as men, two-spirit, and nonheterosexual people, their involvement was limited to 2 and 3 participants, respectively. The relatively lower participation rate could not have allowed us to delve deeper into the unique perspective of two-spirit and people who identify as men on how to address stigma via web-based platforms. Thus, further studies are needed to examine sexual pain stigma specific to each minority group (men, two-spirit, and nonheterosexual people) and highlight ways to incorporate the findings into web-based platforms. By just showing participants only our sample website, we also believed their responses might have been limited to a single website. It is possible that participants’ responses might have differed if they had been shown other websites on sexual pain. Despite this limitation, using a single website helped participants, particularly those who might not have used sexual pain–related websites before to be more articulate on how to develop websites to alleviate stigma.

Conclusions

Web-based platforms on sexual pain have the potential to empower people, promote the development of new web-based friendships, and promote the sharing of personal experiences, thus reducing feelings of isolation. However, the manner in which these platforms are developed has implications by either alleviating or exacerbating the stigma of sexual pain. This study highlighted patient-centered design approaches that could serve as a reference guide in developing destigmatizing web platforms for people with sexual pain, particularly for those who feel stigmatized by their gender, racial, and sexual identity. While this study was conducted in the context of sexual pain, we believe that the results may also be applicable to web platforms on other stigmatized sexual health–related disorders or conditions and to stigmatized issues in mental health. As a next step, intervention studies may be needed to investigate how these guidelines might be applied in practice and whether web platforms resulting from these findings would indeed be less stigmatizing compared to websites that did not adopt such destigmatizing approaches.

Acknowledgments

Abstract

Background: There is great interest in using artificial intelligence (AI) to screen for skin cancer. This is fueled by a rising incidence of skin cancer and an increasing scarcity of trained dermatologists. AI systems capable of identifying melanoma could save lives, enable immediate access to screenings, and reduce unnecessary care and health care costs. While such AI-based systems are useful from a public health perspective, past research has shown that individual patients are very hesitant about being examined by an AI system.

Objective: The aim of this study was two-fold: (1) to determine the relative importance of the provider (in-person physician, physician via teledermatology, AI, personalized AI), costs of screening (free, 10€, 25€, 40€; 1€=US $1.09), and waiting time (immediate, 1 day, 1 week, 4 weeks) as attributes contributing to patients’ choices of a particular mode of skin cancer screening; and (2) to investigate whether sociodemographic characteristics, especially age, were systematically related to participants’ individual choices.

Methods: A choice-based conjoint analysis was used to examine the acceptance of medical AI for a skin cancer screening from the patient’s perspective. Participants responded to 12 choice sets, each containing three screening variants, where each variant was described through the attributes of provider, costs, and waiting time. Furthermore, the impacts of sociodemographic characteristics (age, gender, income, job status, and educational background) on the choices were assessed.

Results: Among the 383 clicks on the survey link, a total of 126 (32.9%) respondents completed the online survey. The conjoint analysis showed that the three attributes had more or less equal importance in contributing to the participants’ choices, with provider being the most important attribute. Inspecting the individual part-worths of conjoint attributes showed that treatment by a physician was the most preferred modality, followed by electronic consultation with a physician and personalized AI; the lowest scores were found for the three AI levels. Concerning the relationship between sociodemographic characteristics and relative importance, only age showed a significant positive association to the importance of the attribute provider (r=0.21, P=.02), in which younger participants put less importance on the provider than older participants. All other correlations were not significant.

Conclusions: This study adds to the growing body of research using choice-based experiments to investigate the acceptance of AI in health contexts. Future studies are needed to explore the reasons why AI is accepted or rejected and whether sociodemographic characteristics are associated with this decision.

Introduction

Skin cancers are the most common groups of cancers diagnosed worldwide, with more than 1.5 million new cases estimated in 2020 [1]. Melanoma is the deadliest form of skin cancer. Based on demographic changes, it is estimated that more than 500,000 new cases of melanoma and almost 100,000 deaths from melanoma should be expected worldwide by 2040 [1]. As melanoma case numbers are expected to increase in the future, high-cost treatments will continue to put a strain on the already overburdened health care budgets. To combat the rising mortality rate of melanoma, early detection is critical. Currently, the German national treatment guidelines [2] recommend skin cancer screening as a standardized full-body skin examination performed by dermatologists who have completed specialized training in the early detection of skin cancer. In addition, dermatologists should use dermoscopy to diagnose suspected skin cancer. Given the rising number of cases as well as increasing scarcity of trained dermatologists [3-5], there has been substantial research into the feasibility of artificial intelligence (AI) to augment or replace traditional skin cancer screening regimens [6].

AI describes machines (or computers) that mimic the cognitive functions associated with human thought, such as learning and problem-solving. These systems observe their surroundings and adopt action to reach their targets directly [7]. Further, AI has the ability to learn from images and subsequently provide an image-based diagnosis. Dermatology, as an image-based field of medicine, retains a dominant position in the AI evolution with the ability to classify skin lesions [8].

Research into the technical quality of AI-based skin cancer screening technologies has shown that these systems achieve detection rates that are on par or better than those of highly trained clinicians [9-13]. This highlights the great potential of AI for future skin cancer screening in the general population. As part of apps, AI systems offer immediate access to dermatological screening for all patients with mobile digital devices, enabling health care and treatment to be provided regardless of time and place and close to everyday life [6]. Thus, AI systems capable of detecting melanoma and nonmelanoma skin cancer could avoid unnecessary care, reduce health care costs, offer solutions to the increasing scarcity of clinicians, and reduce the waiting times for an appointment and for a diagnosis [3-5]. However, there is a risk that some melanomas will be missed and treatment delayed if the apps incorrectly reassure the user that their lesion is of low risk [14].

Although the technical quality has improved, there is also a growing awareness that patients do not generally accept the use of AI-based systems in health care settings. There is still no consistent definition of technology acceptance in the literature. Terms such as “acceptability,” “acceptance,” and “adoption” are often employed in this context, sometimes interchangeably. Dillon and Morris [15] defined user acceptance “as the demonstrable willingness within a user group to employ IT [information technology] for the tasks it is designed to support.”

Khullar et al [16] conducted an online survey to examine patients’ perspectives about applications of AI in health care, showing that 31% of respondents reported being very uncomfortable and 40.5% were somewhat uncomfortable with receiving a diagnosis from an AI algorithm that was accurate 90% of the time but incapable of explaining its rationale. Longoni et al [17] demonstrated that consumers are very hesitant about being examined by an AI system and consumers’ willingness to pay decreases when an equivalent service is performed by an AI system. Additionally, they concluded that patients’ perceived neglect of uniqueness leads to more resistance to medical AI [17].

Past research has also identified several factors that might impact patients’ preferences to use AI-based health care services. The European Commission [18] interviewed citizens of the 28 member states of the European Union (N=27,900) and concluded that younger participants with a high educational level are more likely to use online health care services. This finding was also replicated in oncology patients, where younger patients indicated higher acceptance of and a greater intention to use digital tools and apps to manage their cancer [19]. The European Commission [18] also found that the opinion on AI strongly depends on exposure to related information and knowledge. This relationship is also supported by a series of experiments showing that resistance to the utilization of medical AI is driven by the subjective difficulty of understanding algorithms [13].

Concerning skin cancer, previous research has shown that patients were generally reluctant to use AI-based systems in the field of dermatology. Snoswell et al [6] examined the consumer preference and willingness to pay for mobile teledermoscopy services in Australia using a discrete-choice experiment (N=199). They found that patients prefer a trained medical professional to be involved in their skin cancer screening and that patients are less willing to pay money for teledermatology [6]. However, Snoswell et al [6] did not take into account sociodemographic factors that may have had an impact on the patients’ decisions. In a multicenter clinical study assessing the performance of automated diagnosis of melanoma with a self-completion questionnaire (N=65), Fink et al [20] found that most patients agreed that computer-assisted diagnoses are trustworthy and may generally improve the diagnostic performance of physicians. However, participants rejected the idea of AI-based systems completely replacing physicians and instead strongly favored hybrid solutions in which diagnoses by a physician are supported by automated systems [20].

To date, only three studies have directly addressed the question of which factors are associated with patients’ preferences regarding AI-based skin cancer screening [21-23]. Ghanì et al [22] studied public interest in teledermatology, which was found to be positively associated with a younger age, higher educational attainment, and higher household income. Chang et al [21] examined sociodemographic differences in teledermatology acceptability with a cross-sectional survey (N=13,996), showing that respondents who were interested in teledermatology were more frequently 18–39 years of age, men, college graduates, and tablet or smartphone users. Similarly, young age, male gender, a previous history of melanoma, and higher educational level were significantly associated with a more positive attitude toward skin cancer–related apps [23]. However, it is unclear whether these results from questionnaires...
can be replicated in choice-based experiments that rely to a lesser degree on introspection and are thus one step closer to actual behavior [24].

As described above, provider and costs for a skin cancer screening have high relevance for the user [6,16,17,20]. For this choice-based conjoint analysis, we further added the attribute waiting time for a diagnosis, because studies have shown a strong negative correlation between patient satisfaction and waiting time [25,26]. AI provides the opportunity to get a skin cancer screening immediately, without any waiting time [3]. Due to the shortage of medical professionals, waiting time for a skin cancer diagnosis is also an important attribute for the user [5,7].

The aim of this study was two-fold based on the following two research questions: (1) How important are the attributes provider, costs for screening, and waiting time for diagnosis for participants’ preference for skin cancer screening? (2) Are sociodemographic characteristics, especially age, systematically related to the relative importance scores of participants to the various attributes?

Methods

Study Design

This cross-sectional study used a choice-based conjoint analysis to examine the acceptance of medical AI for a skin cancer screening from the user perspective. Conjoint analysis is a quantitative marketing research method that quantifies the value consumers place on the attributes of a product [27]. Respondents are asked to make a choice between 2 or more different choice sets, where each set is described in terms of several predefined attributes, each with different levels. Given a sufficient number of choices per respondent, it is then possible to statistically estimate the importance of each attribute and level for the choice in terms of part-worth utilities. This method offers a behavioral approach and is less susceptible to social desirability and other biases [28].

This study systematically manipulated three attributes (provider, cost, and waiting time) for a hypothetical skin cancer screening. Participants were presented with 12 different choice sets one after another, each consisting of three different modes of skin cancer screenings that were generated by combining different levels of the three attributes (see Figure 1 for an example). The choice sets were generated by the conjointly algorithm using default settings [29].

Survey

Before the survey was conducted, it was tested with the “think-aloud” method by three volunteers to find out if there were any comprehensibility problems. For this purpose, the pretest participants had to speak their thoughts aloud while completing the survey [30].

The questionnaire started with informed consent, where participants were informed about the nature and scope of the survey and about the protection of their data. Before starting the questionnaire, participants completed the consent form and agreed to participate in the anonymous study. The participants then moved on to the choice-based conjoint task, which consisted of 12 different choice sets. The participant’s task for each choice set was to indicate the skin cancer screening that they most prefer (ie, they selected one of the three options as their preferred choice). After responding to the choice sets, participants were asked whether they had undergone a skin cancer screening in the last year and at which type of provider.

Finally, the sociodemographic characteristics (age, gender, education, status, income) were assessed. Finally, the survey asked again whether the data could be used for analysis in anonymized form in case respondents changed their minds during the course of the survey and to filter out people who just wanted to “click through” without seriously answering the questions.

Participants

Recruitment was based on a convenience sample through the social environment; individuals were asked to participate in the open voluntary survey shared with contacts via WhatsApp and Instagram. Standard procedures for conducting and reporting online surveys [31] were followed. Furthermore, conjointly’s default methods were used to identify and bar potential duplicate entries from the same user. Data were collected during the time period of September 29, 2022, through October 20, 2022. The link to the survey was clicked 383 times by unique site visitors. Of these potential respondents, 126 (32.9%) people
filled out the conjoint survey completely and gave their agreement for processing their data. In total, 220 (57.4%) respondents opened the link but did not complete the survey and another 33 (8.6%) people were disqualified from the study because they answered the survey several times. Three people (0.8%) did not give their agreement to process their data and a single respondent (0.3%) was excluded because the survey was answered too quickly. Respondents took an average of 4.7 minutes to complete the survey. Table 1 provides an overview of the respondents’ sociodemographic characteristics. There was a relatively equal proportion of participants identifying as male and female. The average age of the participants was 37.6 years and the median age was 29 years.

Table 1. Sociodemographic characteristics of participants sampled from September 29, 2022, to October 20, 2022 in Germany (N=126).

Ethical Considerations

Our online study was conducted in accordance with the American Psychological Association’s Ethical Principles of Psychologists and Code of Conduct. In particular, data collection was anonymous; harmless to participants; and did not involve deception, injury, or place participants under high levels of physical or emotional stress. In line with 2023 guidelines of the German Research Foundation, formal ethical approval was not required because our study did not include aspects that would necessitate a statement, per subsection two of the "Information on proposals in the field of psychology" [32]. Informed consent was obtained from all participants after the purpose of the study and the data collection were outlined in the survey introduction. Participants indicated their consent by clicking a button. Study data and identifiers were anonymized during the data collection and data analysis to maintain confidentiality. No compensation was awarded to participants.

Results

Table 2 provides an overview of the relative importance values of the attributes and part-worth values of each level for each attribute as determined by conjointly to answer the first research question [29]. A treatment by a physician that is completely compensated by insurance and has no waiting time emerged as the most preferred mode of treatment. Overall, provider was the most important attribute, followed by costs and waiting time. For all attributes, we found two levels with part worths around zero and one positive and negative level. For provider, the physician had a positive part worth and the AI system had a negative part worth, while both the personalized AI and teledermatology had near-zero part worths. For waiting time, immediate results had a positive part worth and a 4-week wait had a negative part worth, while a 1-day and 1-week wait had similar near-zero part worths.

Figure 2 shows an overview of the relationships between sociodemographic characteristics and the relative importances to answer the second research question. We found a medium-sized positive relationship between age and provider. In addition, there were two nonsignificant trends. The first indicated an inverse relationship between age and the importance of costs and the second indicated an inverse relationship between income and the importance for costs. All other importances were not systematically related to sociodemographic variables (Table 3).

Discussion

The aim of this study was to determine how important the attributes provider, costs, and waiting time are for users’ preference for skin cancer screening and to investigate whether sociodemographic characteristics, especially age, are systematically related to participants’ individual importances. We found that provider was as equally important a factor for participants’ decisions as cost and waiting time. While a physician was the most preferred level of this attribute, AI-based treatment was disliked and a personalized AI had the same value for participants as teledermatology. Concerning the relationship between sociodemographic characteristics and relative importances, we found that only age showed a reliable positive association to provider, in which younger participants place less importance on the provider than older participants. In the following, we discuss these findings in turn before discussing the limitations of the study and providing a general outlook.

Regarding the role of the provider in users’ decisions, other studies underline our results that patients exhibit hesitant behavior toward medical AI. Patients would rather not have a treatment than be examined by an AI system, even if the AI system shows the same or better accuracy as a physician [17]. However, the same study also found that patients prefer personalized AI over nonpersonalized AI. Similarly, earlier discrete-choice experiments [6] as well as surveys [33] found that patients prefer a trained medical professional to be involved in their skin cancer screening; 41% of respondents were open to using AI as a standalone system for skin cancer screening and 94% were open to using it as a support system for physicians [33]. Together, existing studies indicate that personalized AI and teledermatology are generally more accepted than nonpersonalized AI for skin cancer screening, while the physician remains the most preferred option.

Concerning the impact of age differences on the acceptance of AI in dermatology, our findings also support some earlier results [21-23]. Higher interest in using teledermatology [21,22] and in using skin cancer–related apps [23] was associated with younger age. The results of cross-sectional studies back up our findings from the choice-based conjoint analysis. Based on these trends, it is possible to imagine that the acceptance of AI in skin cancer screening will rise in the future due to the aging of digital natives and their increased acceptance of AI.

Regarding income and educational factors, our findings do not align with those of previous studies. Ghani et al [22] concluded that higher education attainment and a higher household income increased the interest in using teledermatology. Chang et al [21] came to similar conclusions, indicating that college graduates showed the greatest interest in teledermatology. In addition, Steeb et al [23] showed that a high educational level was associated with a positive attitude toward skin cancer–related apps. While we were not able to show significant relationships to income and educational background, the smaller sample size in this study compared to those of earlier studies might explain this inconsistency.

Previous studies also identified gender differences in the acceptance of AI in skin cancer screening. Chang et al [21] came to the conclusion that men are more likely to use teledermatology than women. Steeb at al [23] found similar results in which male gender was significantly associated with a positive attitude toward skin cancer–related apps. However, the gender difference that was reported in earlier studies was not visible in our data. Again, this might be a factor of sample size and the smaller sample size in our study compared to earlier studies.
size, but it might also be that these gender differences reported in earlier questionnaire studies reflect differences in the technology self-concept [34] rather than actual preferences.

Several aspects must be considered in interpretation of our findings. First, the sample was not randomly selected but was based on a convenience sample. While a wide range of recruitment means were used, the results are likely not generalizable to the general public but rather more specific to highly educated young adults. Further research is needed with the target group. Although the sample size may not seem particularly large, sensitivity analysis showed that this sample size was in fact sufficient to detect a medium-sized correlation ($r=0.28$) with a power of 90% and error rate of 5%. Second, some participants contacted us about the meaning of the attribute waiting time because they were unsure whether this pertained to the waiting time for a diagnosis or the waiting time for an appointment. Future studies should make this distinction more explicit to study possible differential effects of these two types of waiting times.

Taken together, we believe that this study adds to the growing body of research using choice-based experiments to investigate the acceptance of AI in health contexts. This approach offers additional insights and is less susceptible to social desirability and other biases [35]. However, the choice-based conjoint analysis only allows studying a small number of potential attributes at a time [24]. Because we included personalized AI as a level for the attribute provider, our study adopted the findings of Longoni et al [17] that personalized AI increases patient acceptance. In addition, we examined factors that may have an impact on patients’ decision-making following the study of Snoswell et al [6].

For the future, it could be interesting to add “AI as a physician support system” to the choice set [33]. It might also be interesting to find out whether patients who perceived themselves as more individualized are less accepting of AI [17]. Additionally, it could be interesting to explore whether specialized knowledge about AI systems would increase patient acceptance [13] and which other factors might have an influence on patients’ acceptance. Ideally, this would not only rely on correlational evidence as used here but also on experimental evidence that shows how preferences and importance may be altered. The variables such as income and educational background cannot be manipulated easily. Nevertheless, we believe that the magnitude of these effects provides some benchmarks for future studies that aim to use experimental methods to alter preferences.

In summary, while there have been technological advances in the effectiveness of AI for supporting skin cancer screening and health care more generally, we believe that the true potential of AI systems can only be realized if patients’ needs and demands are taken into account.

Acknowledgments

This research was conducted within the framework of the project “SAIL: SustAInable Lifecycle of Intelligent Socio-Technical Systems,” funded by the Ministry of Culture and Science of the State of North Rhine-Westphalia under grant NW21-059B. Abstract

Background: Digital health is increasingly used to meet the needs of perinatal people, with estimates of pregnancy-related internet use ranging from 90% to 97% of pregnant people. As digital health takes on greater importance during the perinatal period, it is essential that providers and developers of digital health content understand why perinatal people use these resources and the features that enhance their experience. However, gaps remain in understanding the content that is most helpful and how the platforms are navigated. Learning directly from perinatal people about their needs will help ensure alignment between perinatal needs and available content.

Objective: This formative study aims to identify the reasons why perinatal people use digital health resources; the features of the digital health platforms that are of greatest importance to them; and how these differ by perinatal stage (pregnancy vs postpartum), mental health conditions, parity, and demographics (race and ethnicity).

Methods: This mixed methods study used interviews; surveys; and secondary data on demographic, health, and pregnancy characteristics to identify the digital health needs and preferences of pregnant and postpartum people who used the Maven digital health platform in the United States during their pregnancy or postpartum period. The interviews informed the content of the surveys and provided additional insights and examples for interpreting the survey results. The surveys were used to collect data from a sample of Maven users, and the results were linked to the secondary data set. The interviews were thematically analyzed, and survey data were analyzed using descriptive statistics and stratified by parity, race, and mental health status.

Results: Overall, 13 people were interviewed (including n=4, 31% pilot interviews), and 147 pregnancy and 110 postpartum survey respondents completed the surveys and had linkable secondary data. Top reasons for using digital health resources during pregnancy were to (1) know what is normal or typical during pregnancy, (2) have access to a health care provider when needed, and (3) know how the baby is developing. Top reasons for postpartum use were to (1) help with breastfeeding, (2) know what normal baby development is, and (3) help with the baby's health issues. Top platform features during pregnancy and the postpartum period were (1) credible and trustworthy information and providers, (2) nonjudgmental information and support, and (3) no cost to the user. In general, more reasons for using digital resources were identified as extremely important during pregnancy compared with postpartum. The results showed minor variations across strata.

Conclusions: This formative research found minor differences in digital resource needs and preferences across user characteristics among perinatal people in the United States. Future work should examine whether there are variations in interests within topics by user characteristics, which may provide additional opportunities to better meet user needs.

Introduction

Background

Digital health, which refers to digital health applications, ecosystems, and platforms [1-4], is increasingly used to meet the needs of perinatal people [5-8], with estimates of pregnancy-related internet use ranging from 90% to 97% of pregnant people [9-13]. Digital health is expected to have growing importance because of its potential to provide health prevention, consultation, treatment, and management while simultaneously providing an opportunity to reduce costs and improve access to care and patient satisfaction, which together may lead to better informed and more engaged patients [1,4,14,15].

To date, research on perinatal digital health needs falls into 2 categories: self-report via surveys or qualitative data collection (interviews and focus groups) and content analysis of perinatal digital forums. Previous research has shown that access to perinatal digital health information provides reassurance and support [5,16,17]. Both types of studies have found that most people use digital resources during pregnancy to access information on maternal health (eg, pregnancy ailments, pain and complications, and health and nutrition during pregnancy) and during the postpartum period to access information on baby-related topics such as infant sleep and feeding (especially breastfeeding) [18,19]. Self-report studies have also indicated interest in childbirth, fetal and infant development, and infant illnesses, and studies of web-based forums have revealed interest in people and relationships [5,10,11,18-21]. The relative interest in these topics and the specific content within them vary throughout the perinatal period [17,19,20]. Research has also found that a positive experience using digital health resources is characterized by being easy to access and navigate, providing trustworthy and unbiased information, and being customized (eg, trackers and localized information) [4,22,23]. Perinatal digital health users specifically value an experience that provides information that is proactively delivered; offers immediate access; and provides information that is practical and concise, entertaining, and reassuring [5,24,25].

As digital health takes on greater importance during the perinatal period, it is essential that providers and developers of digital health content understand why perinatal people use these resources and what contributes to a positive user experience [26]. The information sought by perinatal people differs from the information that health care providers prioritize and offer. For example, postpartum people seek information on sleep, emotional changes, and breastfeeding, whereas providers focus on medical issues such as bleeding and infection [27,28]. Although there is a growing body of literature, there remain gaps in understanding of the content that is most helpful and how the resources are navigated [5]. There is a demand for more detailed analyses, including which digital resources are most helpful [16], with a particular need to understand what is valued during the postpartum period [18]. Research is needed on digital health needs and experience among perinatal people with mental health conditions, especially pre- and postpartum anxiety [20], and more insights are needed on barriers to and facilitators of using digital health, especially with newer technologies such as apps [4,20]. Learning directly from perinatal people about their needs will help ensure alignment between perinatal needs and available content [18,29]. The design of digital health content should be directly informed by individuals and their experiences. However, the research on patients’ user experience of digital health is limited, especially during the perinatal period [4].

Objectives

This mixed methods study, which used formative interviews and surveys, investigated the reasons why pregnant and postpartum people use digital health resources and what contributes to a positive user experience. Using a national sample of pregnant and postpartum users of Maven [30], a comprehensive reproductive and family digital health platform that includes patient education, care coordination, and provider services, this formative study identified how needs and preferences differ by perinatal stage (ie, pregnancy vs postpartum), mental health conditions, parity, and demographics (race and ethnicity). The results from this study can be used to inform a user-centered approach to developing the content and design of digital health resources and improve the alignment between resources and users. In recognition of the fact that patients have diverse gender identities, we have used gender-inclusive language throughout this paper. If a participant described themselves using gendered language (ie, “as a working mother...”), we used their terminology. When describing the results of previous research, we used the terminology used by the study investigators.

Methods

Study Design

In this mixed methods study, we identified the digital health needs and preferences of pregnant and postpartum people who used the Maven digital health platform during their pregnancy or postpartum period. The study used formative interviews to inform the content of surveys and provide additional insights and examples for interpreting the survey results. Surveys were used to collect data from a sample of Maven users that could be linked to a secondary data set of demographic, pregnancy, and health characteristics in the Maven platform (Figure 1).
Digital Platform Background

Maven was developed in 2014 as a digital platform to support perinatal people and their families. Users have a primary point of contact called a care advocate, an allied health professional (eg, social worker or nurse) who works with the user to navigate the services and resources on the platform. Services and resources include web-based classes; educational materials; and internet-based appointments with a diverse team of health care providers, including obstetrician-gynecologists, mental health professionals, midwives, and doulas. Access to Maven is a sponsored benefit through an employer or the health plan of the user or their partner. The study investigators are Maven employees of the Maven clinical research team. When activating their Maven accounts, users consent to the use of their contact information by Maven for various reasons, including research. The investigators only have direct contact with Maven users or access to identifiable data within the scope of specific research projects, in accordance with institutional review board (IRB) approvals, and in concordance with Health Insurance Portability and Accountability Act regulations. Access to user data is minimized by requesting recruitment lists and platform-based data from the Maven product analytics team, which deidentifies the information before sharing it with the research team. To recruit Maven users for interviews and the survey, the recruitment parameters were sent to the product analytics team, which generated a list of deidentified IDs of users who met the parameters. This list of deidentified IDs was sent to the Maven team responsible for direct communication with users, which sent out recruitment emails (using email addresses linked to the deidentified IDs).

Formative Interviews

In September 2022 and October 2022, semistructured interviews with postpartum people were conducted virtually via Zoom (Zoom Video Communications) to identify the reasons why perinatal people use any digital health resources, not just Maven. To help encourage participants to think about digital use broadly, at the start of the interview, they were asked to list all the digital resources used during their pregnancy and the postpartum period, and throughout the interview, they were reminded to think about digital resources in general. The first part of the interview was open-ended, and participants were prompted not only to describe the reasons why they used digital resources but also to identify additional reasons for which they would like to use them. In the second part of the interview, participants were shown (via screen sharing on Zoom videoconferencing) a list of reasons why digital resources could be helpful during the perinatal period. Participants were asked whether they had used a digital resource for each individual reason or whether they would like to use a digital resource for each individual reason in the future. Finally, participants were asked about the importance of digital health resources being inclusive of their entire identity, which was explained as including anything that the participant considered part of their identity, such as race, gender, sexual identity, geography, social or economic status, and mental and physical health conditions, and to describe their experience with (lack of) inclusion.

Pilot interviews were conducted with 4 postpartum Maven staff members who had used Maven during pregnancy and the postpartum period and were post partum at the time of the interview. The interview guide was modified based on their feedback and the interviewer’s learnings from conducting the pilot interviews. Following piloting, interviews were conducted with 9 Maven users, all of whom were post partum so that they could speak to their digital needs and preferences throughout the perinatal period. Participants were recruited with an emphasis on including people from a range of ethnicities and races, health conditions, and parity. Participants were recruited via email. Interviews lasted approximately 1 hour, were conducted via Zoom, and were recorded. An interviewer and a notetaker were present, and transcripts were autogenerated on Zoom. Participants (Maven staff and nonstaff) consented to the interview, had the option of having the video on or off, and could decline to have the interview recorded (one participant...
declined, and we relied on detailed notes for that interview. The consent form was included in the recruitment email and reviewed at the start of the interview, and consent was provided verbally. Participants were given a US $50 Amazon gift card as a thank you for their participation.

The prevalence of each reason for using digital resources was calculated by counting the number of interviews (Maven staff and nonstaff) in which the reason was mentioned as important. The reasons that were mentioned as important in the most interviews were included in the survey.

Survey Development

In addition to the semistructured interviews, separate quantitative surveys were developed to inquire about digital resource use during pregnancy and the postpartum period. Through the qualitative analysis, it emerged that participants were describing 2 aspects of digital resource use: the information or support they were seeking and features of the digital health platforms. Consequently, the survey contained 2 sections, each addressing one of these aspects. To focus on common needs and remove outliers that were mentioned by only 1 or 2 participants, reasons for using digital resources and features affecting experience were excluded from the surveys if they were cited by less than one-third of the interview participants. In each section of the survey, participants indicated the importance of each item on a Likert scale that included a description of each option (a little important or doesn’t matter to me—I don’t care much about this, important—I would like to have this but I’m OK without it, very important—I care about this a lot but it’s not absolutely necessary, and extremely important—a “must have”) and subsequently picked the 5 most important items (not ranked). We opted to allow participants to select up to 5 items as a means to balance the tension between the high number of reasons why pregnant and postpartum people are turning to digital resources and the need to prioritize to inform actionable decisions about what content to provide in these resources. To reduce the potential bias of basing responses on their use of Maven, the instructions in the survey reminded respondents to think holistically about digital health resources. The following is an example of the instructions from a section of the pregnancy version of the survey: “Thinking about the reasons you might use any digital resource during pregnancy, rate how much each of these reasons matter to you. Digital resources include websites, apps, videos, blogs, search engines, etc.”

The surveys were piloted with 4 Maven staff members who had used Maven during pregnancy and the postpartum period and were post partum at the time of piloting. The wording and format were modified based on their feedback. The revised surveys were piloted with 4 Maven nonstaff users. During piloting, we identified that nearly all items were selected as very important. To minimize ceiling effects, the response options were revised to provide more response options that reflected higher levels of importance and add definitions (eg, extremely important: a must have). We also opted to reverse the order of the options (with a little important or not important to me as the first option rather than the last). In addition, we included a section for selecting the 5 most important reasons for use and platform features, which would provide information on the relative importance of the items if we continued to have a ceiling effect.

On the basis of feedback from the staff and nonstaff member pilots, we added 2 items that had not emerged in the interviews: using digital resources to help with formula feeding and feeding solid foods. These were added as participants felt that the survey was not inclusive or relevant to the entire postpartum period if it only asked about breastfeeding.

The survey was built in SurveyMonkey (SurveyMonkey Inc) using a Health Insurance Portability and Accountability Act–compliant account.

Survey Administration

Survey respondents were recruited from current Maven users. To be eligible for the pregnancy survey, users had to be between 0 and 6 months post partum and have had a Maven account during pregnancy. To be eligible for the postpartum survey, users had to be 3 to 12 months post partum and have a Maven account during the postpartum period. Recruitment was via email, which included a link to the survey. Each survey link was associated with the user’s unique Maven identifier to link the survey responses to user demographic characteristics previously recorded on the Maven platform (described in the Secondary Data section). A reminder email was sent 1 week after the initial email to anyone who had not clicked through to the survey. The survey remained open for 2 weeks from the time of the initial email. A consent form appeared before the start of the survey, and consent had to be provided digitally to access the survey. Participants were entered into a draw for a chance to win 1 of 5 US $100 Amazon gift cards per survey (5 for the pregnancy survey and 5 for the postpartum survey). Data were collected from January 18 to 29, 2023.

Secondary Data

Maven users are encouraged but not required to fill out a questionnaire when they activate their account. The Maven pregnancy questionnaire collects data on physical and mental health, pregnancy conditions, demographics, and parity. The Maven postpartum questionnaire collects information on demographics, mode of delivery, and previous pregnancy conditions. For survey participants who completed the Maven questionnaires, we linked their survey responses with their Maven questionnaire data using their unique Maven identifier. Maven users consent to the use of their Maven questionnaires for research when they activate their accounts, and the research team does not have access to any identifying information.

Analyses

Survey Analysis

Respondents who completed the survey and a Maven questionnaire were included in the survey analysis. Figure 2 shows the pathway for inclusion in the analysis, from eligibility to be recruited to starting and completing the survey and completing a Maven questionnaire. The quantitative data from both the pregnancy and postpartum surveys were assessed primarily through the evaluation of descriptive statistics. Chi-square and Fisher exact tests were used to assess differences among pregnancy items, postpartum items, and user experience.
features by parity, presence of any mental health conditions, and race and ethnicity. A user was considered to have a mental health condition if they reported any of the following: a history of anxiety, depression, perinatal mood disorder, or high pregnancy-related anxiety. A history of anxiety or depression was assessed in the Maven questionnaires using the following question—“Do any of these conditions apply to you or did they in the past?”—with the selection of Anxiety or depression from a list of conditions. Experience of perinatal mood disorder was assessed using the following question—“Have you experienced any of the following during this pregnancy?”—with a selection of Perinatal mood disorder. Pregnancy-related anxiety was assessed on a 5-item Likert scale in response to the following question—“On a scale of 1-5, how anxious are you feeling about your pregnancy?”—with responses of 4 (very) or 5 (extremely) indicating the presence of pregnancy-related anxiety. For analyses stratified by race and ethnicity, we recategorized individuals who identified as Hispanic, Black, Asian or Pacific Islander, or multiracial into 1 category labeled non-White because of our small sample of people of racial and ethnic minorities. Consistent with the study’s aim of identifying differences in needs and preferences between respondents with these characteristics, P values were calculated to determine whether the differences were statistically significant (with results considered to be statistically significant if the P value was <.05). Statistical analyses were conducted using RStudio (Posit Software, PBC).

**Figure 2.** Flowchart of the pregnancy survey respondents (A) and postpartum survey respondents (B) included in the survey analysis.

### Interview Analysis

The interviews were analyzed thematically using a framework analysis [31-36]. Themes were identified deductively based on the interview guide and inductively based on the messages that emerged from the interviews. Themes and their definitions were reviewed by all team members who participated in the interviews (as interviewers or notetakers) and were modified based on group discussion and consensus. The analysis table was populated based on the notes taken during the interviews and subsequent analysis discussions. Audio recordings and transcripts were referenced if the notes were unclear or lacked sufficient details to populate the analysis table. All entries in the analysis table were reviewed by NH, who attended all but one of the interviews. Any information that was missing or potentially miscategorized in the table was flagged for review by the person who entered the information and, if necessary, discussed to reach a consensus. To better understand the experiences and perspectives associated with the topic of each of the items in the quantitative surveys, the corresponding interview themes were summarized, and representative anecdotes or quotes were selected. All quotes were verified using the audio recordings. Quotes and anecdotes are cited using the interview participant number (eg, P1 refers to participant 1), and it is specified whether the participant was from the pilot interviews (eg, Pilot P1 refers to the first interview among the pilot participants).

### Ethics Approval

The study protocol was approved by the WCG IRB (study 1338443). The use of secondary data was deemed exempt by the WCG IRB under 45 Code of Federal Regulations § 46.104(d)(4).

**Results**

### Survey Sample Characteristics

In total, we had 147 pregnancy survey respondents and 110 postpartum survey respondents with complete Maven questionnaires (Table 1 and Figure 2). All survey responses
were collected within 48 hours of sending the initial recruitment email. The average age of the respondents was 32.8 (SD 4.6) years and 32.7 (SD 3.5) years for pregnancy and postpartum survey respondents, respectively. On the basis of those who reported their race and ethnicity, our sample was comparable with the overall US population in terms of the percentage of people identifying as non-Hispanic White (134/257, 52.1%) and multiracial (5/257, 1.9%), with an overrepresentation of people identifying as Asian (31/257, 12.1%) and an underrepresentation of people identifying as Black (4/257, 1.6%) or Hispanic (16/257, 6.2%) [37]. A total of 44.9% (66/147; pregnancy survey) and 51.8% (57/110; postpartum survey) of the respondents had household incomes of >US $100,000. Approximately 28% (72/257) of the sample reported a history of a mental health condition (Table 1).

\(^a\)Variables with <15% of missing data: age, race, social vulnerability, BMI (pregnancy survey respondents), mental health history (pregnancy survey respondents), and parity (pregnancy survey respondents). Variables with 15% to 30% of missing data: household income and BMI (postpartum survey respondents). Variables with 30% to 40% of missing data: parity (postpartum survey respondents) and mental health history (postpartum survey respondents).

\(^b\)Measured using the Centers for Disease Control and Prevention Social Vulnerability Index.

\(^c\)A total of 65.5% (72/110) of postpartum survey respondents provided parity or mental health data. Therefore, the sample size for those variables is 72.

**Reasons for Use of Digital Resources During Pregnancy**

On the basis of the survey responses, the most important reasons for using digital resources during pregnancy were to know what is normal or typical during pregnancy, have access to a health care provider when needed, and know how the baby is changing and developing during pregnancy (Table 2).
Table 2. Reasons identified as extremely important when using digital health resources during pregnancy by parity, mental health status, and race and ethnicity (N=147).

Respondents who selected I prefer not to say for race and ethnicity were not included in this comparison.

In interviews, participants described the role that digital resources play in meeting these needs (Table 3), and they emphasized the importance of these resources during their first pregnancy (Pilot P1 and P2). Among the information they sought about what is normal, participants wanted to know what they would encounter during each phase of labor and delivery and were looking for information such as how long to expect to push. A participant described learning about the phases during a digital birth-planning appointment:

[The digital appointment with the birth planning specialist] was very helpful to know what to expect at the hospital during birth, and actually I feel like they were more helpful than the in person doula that I hired...I remember them stepping through the birth process. You know, active labor and transition, the pushing and talking about the ring of fire. [P5]

<td>To become more empowered to speak up for myself during pregnancy and labor</td>
<td>“I read a ton of articles [online] because I felt like otherwise it was like the blind leading the blind. My husband had never done that before. I’m an only child like my mom was going to be there, but she hadn’t done it in thirty years. So it was kind of like, Okay, Who in this room knows what they’re doing? The answer was going to be nobody...So I read a lot just to know these are all the possible outcomes. This is how it might go. These are the things that I’m going to be asked, and I wanted to know, while I’m in a calm and sound state of mind, like is my answer Yes? Is my answer No? What are the implications if I say yes or no. And then I can communicate that to my partner and my mother. So if they needed to advocate for me [they could]” (P4).</td>
</tr>
<tr>
<td>To explore my options for labor and delivery</td>
<td>“[Exploring my labor and delivery options] I would say [getting support on Maven] helped a little but that was more so because of me, and I didn’t look into it as much as I should have...Because, I thought I would have a natural birth. But I ended up having a C section, but just not knowing what to expect, and more so it was on the process of like what an induction is, and like how your body would look like afterwards, because I didn’t get to in my entire pregnancy. But all the drugs they pumped into you to induce you caused me to blow up after, and I just didn’t expect that, no one tells you, right? They just tell you to consent, and you say yes, so like all that, I wish I knew. But I don’t think that I looked into it as much, because I just didn’t know” (P8).</td>

<tr>
<td>To help me with feeding my baby breast milk</td>
<td>I didn’t see lactation consulting in person until after birth, which was at the pediatricians office. So it’s nice to have that, to be able to talk to one [online] beforehand, to know what to prepare for. And then also I talked to one after as well, after giving birth. That was super helpful” (P5).</td>
</tr>
<tr>
<td>To help me with my baby’s health issues</td>
<td>“[My baby] was very colicky, I took an [online] appointment and showed the doctor what was happening, so they also gave me a hint she might have a milk allergy, [and said to] check with your doctor and check the stools and all” (P2).</td>
</tr>
<tr>
<td><strong>During pregnancy or the postpartum period</strong></td>
<td></td>
</tr>
<tr>
<td>To know what is normal or typical during pregnancy or postpartum</td>
<td>“[Getting digital help on my baby’s sleep] helped a lot, because I had a lot of questions about what’s normal, what’s not normal and they answered everything. It made me feel like I wasn’t doing something bad” (P8).</td>
</tr>
<tr>
<td>To know how my baby is changing and developing during or after pregnancy</td>
<td>“I had like three apps on my phone to track [how my baby was changing] like every week” (P4).</td>
</tr>
<tr>
<td>To have access to a health care provider when I need them</td>
<td>“It wasn’t just 8 to 5 that I could access someone...The sleep consultant was like you can just message me any time, and I’ll respond and help you real time with what you need. That’s something that you can’t get with any in person care provider” (P3).</td>
</tr>
<tr>
<td>To help me with being physically active during pregnancy or the postpartum period</td>
<td>“I was trying to be physically active during pregnancy but then there were times where I stopped because of the spotting. They didn’t know what was going on. Then I found out it was okay. But then the last trimester it got tougher since I was tired a lot and having pain...It would have been nice to see what I could do, like modifications and exercises I could do around the pain I was having” (P5).</td>
</tr>
<tr>
<td>To help me with healthy eating during pregnancy or the postpartum period</td>
<td>“Just offering ideas of foods, more nutritious foods to eat, healthier options, because you can look around on the Internet but just talking to a person who is, you know, that’s their specialty, and you can give them personal information about yourself so they can help you” (P9).</td>
</tr>
<tr>
<td>To help me manage anxiety or depression</td>
<td>“I was in so much pain and I thought maybe [the baby will be also in pain, or somehow it will affect the baby, because I’m not happy. So then I talked to [an online] doctor, and one of the doctors was very good and she talked to me more than the time of appointment, and she was very kind, and she said, I know how you are feeling, but she gave me so much support, emotional support, and she said, ‘You can come to talk to me anytime.’...So she then she assured me, ‘Everything is fine, and you don’t need to worry’” (P2).</td>
</tr>
<tr>
<td>To help me manage my health problems (chronic, ongoing, or related to pregnancy or postpartum)</td>
<td>“I have arthritis and Hashimoto. So two autoimmune diseases. So when I got pregnant, I had a lot of concerns about that, and how that would affect my pregnancy, or vice versa” (P8).</td>
</tr>
<tr>
<td>To get recommendations of things to buy to care for my baby or myself</td>
<td>“I’m a working mother. At the time, you know, working while pregnant, and so I didn’t have time to spend hours and hours going down the rabbit hole of like, this stroller versus that stroller. Like just like, tell me what you recommend, and we’re moving on. So it felt like the research had been done for you” (P4).</td>

Reasons for using digital health resources | Illustrative quote
---|---
To connect with a community of people who are in the same stage of pregnancy as me or who have a baby the same age as mine | “I used Reddit honestly before I was telling people I was pregnant...I really kind of used Reddit to ask people different questions early on in my pregnancy like ‘Oh, this happened to me. Is this normal?’ Like I said, it was in the very early stages of before we were talking to anybody, so I didn’t really have anyone to talk to” (P7).

To get additional information or clarification on things my physician or pediatrician tells me | “The pediatrician’s really good for, like, is the baby’s body healthy, but they’re not necessarily specifically trained in infant nutrition and infant sleep. They kind of know enough to be dangerous. You know, I would ask some questions like, ‘How do I get my baby sleeping through the night longer?’ And they would say something really old school like ‘Put rice cereal in their bottle,’ and I’m like well, one I’m not even giving a bottle, I’m breastfeeding and two, that’s like not really even something people say anymore. So it’s just like our pediatrician wasn’t super helpful. I totally trust him for everything else. But just not those services” (P3).

In interviews, participants talked about being able “to count on” accessing health care providers on the internet for urgent situations, such as a participant (P1) who used a digital health care provider when she did not feel her baby kick for a while and wanted to know whether she should go to the emergency room.

Almost all the participants talked about the importance of knowing how their baby was growing and developing during pregnancy. They described wanting to know about the development week by week and found that digital resources could easily provide this information.

In the survey, nulliparous respondents were more likely than parous respondents to find knowing what was normal (P=.004) and how their baby was developing (P=.06) to be extremely important (Table 2). Compared with non-Hispanic White respondents, respondents identifying as Hispanic or people of racial and ethnic minorities were more likely to report that digital health resources were extremely important for the management of anxiety or depression (P=.003) and chronic health problems (P=.002). Compared with respondents without a mental health history, respondents with a mental health history were more likely to find it important to receive web-based help with healthy eating during pregnancy (P=.04; Table 2).

**Reasons for Use of Digital Resources During the Postpartum Period**

On the basis of survey responses, during the postpartum period, the most important reasons for using digital resources were to help with feeding the baby breast milk, know what is normal baby development (eg, developmental milestones), help with the baby’s health issues, and help with feeding the baby solid foods (Table 4).

The reasons for using digital resources during the postpartum period were described in interviews (Table 3). When asked specifically about the use of digital health resources for help with feeding, interview participants primarily spoke about support for breastfeeding. In particular, participants found it valuable to connect with a lactation consultant during pregnancy to prepare for breastfeeding and during the postpartum period for tips that facilitated feeding:

*I didn’t see lactation consulting in person until after birth, which was at the pediatrician’s office. So it’s nice to have that, to be able to talk to one [online] beforehand, to know what to prepare for. And then also I talked to one after as well, after giving birth. That was super helpful. Just things I could do for milk supply. And then the one major helpful thing that I learned is about the pump parts where I can just store them in the fridge, and I don’t have to wash it after every time, because it was a hassle, too. [P5]*

In interviews, participants described using digital resources to know what to expect about life with a baby and to find out whether the things they encountered were normal, such as struggling with the baby’s sleep schedule, and what it is really like to breastfeed. Participants voiced frustration that this type of information was not provided by in-person providers, so they looked for answers on the internet:

*They don’t tell you anything [at the hospital]. A big one for me was breastfeeding, like just how complex it is. There’s just so many things in the hospital they don’t tell you anything, either. They just ask you like, “Are you going to breastfeed, yes or no,” and you have to decide on the spot, and, like you don’t know anything about this. After that, coming home, I definitely did research on [a digital platform] and the resources that they had for help. [P8]*

Participants also wanted digital resources to provide information on what is normal for babies as they grow, including what developmental milestones to expect at each age. A participant described using an app to know what to expect as her baby changed:

*[There] is an app that when you put in the baby’s due date, this helps you to see your baby’s development, like milestone-wise. So week by week, you know some of the things to look for. And mainly I use it to see like, when are one of the cranky times coming up because they’re going through a milestone leap where they’re learning, you know lots of new things. [P9]*

In interviews, participants provided anecdotes about the value of digital resources for helping with the baby’s health issues, especially the ability to access support when it is needed. A new parent described meeting with a digital sleep coach in the middle of the night when her baby would not sleep, a service she said she could not obtain from her in-person providers as they only handled emergencies after hours:

*It wasn’t just 8 to 5 that I could access someone...The sleep consultant was like you can just message me any time, and I’ll respond and help you real time with... [P9]*
what you need. That’s something that you can’t get with any in person care provider. If you call their after hours number it’s because it’s an emergency right? Not because you are just, like, wondering why your baby is fussy, or awake window, or; you know whatever. [P3]

In the survey, nulliparous respondents were more likely than parous respondents to find it extremely important that digital resources help with feeding their baby solid food ($P=0.01$) and with their own health problems ($P=0.06$; Table 4). Respondents identifying as Hispanic or people of racial and ethnic minorities were more likely than non-Hispanic White respondents to report that it is extremely important that digital resources can be used to connect them with a community of people who have a baby of the same age ($P=0.02$) and to obtain recommendations of things to buy to care for their baby or themselves ($P=0.08$). Respondents with a mental health history were more likely than those without a mental health history to find it important to obtain web-based help with breastfeeding their baby ($P=0.01$; Table 4).

aA total of 65.5% (72/110) of postpartum survey respondents provided parity or mental health data.

bRespondents who selected “I prefer not to say” for race and ethnicity were not included in this comparison.
The reasons for using digital resources that the fewest survey respondents selected as extremely important during the perinatal period were uses related to general wellness (ie, healthy eating, exercise, and losing weight), connecting with a community in the same perinatal stage, and obtaining recommendations of things to buy to care for their baby or themselves. Notably, these lowest-ranked reasons were still selected by 8.2% (9/110) to 22% (32/147) of the respondents (Tables 2 and 4).

In contrast to the surveys, help with healthy eating was one of the topics that the most interview participants identified as a reason for using digital resources, although it was usually in response to specifically being asked about it in the structured part of the interview. When discussing the use of digital resources for healthy eating, participants tended to refer to access to personalized information such as food recommendations that fit with their dietary restrictions. A participant described why tailored information would be helpful to her on a digital health platform:

> Because if I had dietary restrictions I’m going to have to go searching more for that information on my own. [P9]

Interview participants described why the features of digital health resources were important (Textbox 1). When looking to interact with content that was trustworthy, participants mentioned a range of ways in which they determined whether digital content was credible. A couple of participants explained that they trusted the content if it was consistent with the information they received from their in-person providers. This was done by taking the information from the digital content to the in-person provider for verification or by seeing that the content was consistent with what they had already been told:

> Whatever I heard from the [web-based] doctor, it was matching with my experience and my other doctor as well...it builds trust since my doctor is saying the same thing. [P2]

> So it was like things that the [web-based] practitioner might have suggested or recommended that I would then mention at my doctor’s appointment...kind of to get a check box from my regular doctor, but it was always like, she agreed with what had been communicated. [P4]

Importance of Digital Health Platform Features During Pregnancy and the Postpartum Period

The 3 most important features of digital health platforms identified through both the pregnancy and postpartum surveys were credible and trustworthy information and providers, digital resources that are free to the user, and nonjudgmental information and support. Although access to appointments (ie, fast access and access at convenient times) was not among the top 3 most important features, approximately half of the respondents felt that it was extremely important (Table 5). See Multimedia Appendices 1 and 2 for digital health platform features identified as extremely important by parity, mental health status, and race and ethnicity during pregnancy and the postpartum period, respectively.
Credible and trustworthy information and providers
- “Sleep schedules, again, with so much information online, you get really caught up in, like, ‘Am I doing the right thing?’ especially in the beginning. I remember one thing, I was struggling with my baby’s sleep schedule. And so I went to this sleep expert from [my digital platform], and they said that’s normal, like, a baby shouldn’t really have a sleep schedule until six months. They’ll never have one, and it’s like everything online, says the opposite! So just like having information that is accurate and like coming from experts [really helped]” (P8).

Digital resources that are free to me
- “But because this service was free to me I felt like ‘well, it’s there, and I might as well use it,’ so I’ve taken advantage of it” (P3).

Nonjudgmental information and support
- “And these platforms really help because, one, you’re able to speak to someone different that may not even have your medical history. They don’t have your medical history in front of you. So maybe it’s the medical system, health care system thinking or judging you based on your history, right, rather than just listening to this specific one time incident. So maybe they’re less biased ‘cause they just have the one thing they’re looking at” (P8).

Fast access to appointments
- “If I’m struggling with a situation that I think is super important with the baby like the baby has a cold and has a runny nose, fever, I’m gonna want whoever is available next” (P9).

Easy to find information; easy to navigate
- “[My app] did not help [for finding information on baby’s development] because the information, I guess I didn’t seek it out, but I also didn’t see it readily available” (P9).

Access to appointments at convenient times
- “Especially for a new mom, if you’re trying to work around is my baby napping or not, and that’s not always predictable, just to be able to quickly touch base with someone. I used it during pregnancy as well, so I feel it kind of rounds out the care you are receiving from your in person doctor” (P4).

Information that is actionable (specific recommendations for what to do)
- “In my state it is legal to end the pregnancy, right? So [the online provider] gave me the support that if you want to go for this, this will happen, or if you go, these are the steps you need to follow, and all...She was telling me all the steps, what I need to do, and what I not to do, and she gave me a support for keeping this pregnancy” (P2).

Receive fast responses to my digital messages
- “When I messaged, it wasn’t always [the same person] that responded, it was someone else. But it’s nice to have that, too. Like, someone quickly getting back to me. So I didn’t mind that” (P5).

Resources that are specific to my needs (personalized)
- “Because if I had dietary restrictions I’m going to have to go searching more for that information on my own. [And it would be helpful to] come up with a list of foods that would be specific to me, because we didn’t do that. I realized that may be asking a lot of someone. But that’s just what I see would be super helpful” (P9).

Access to a lot of information on each topic (depth of information)
- “I like the options when I went in, and I would read through an article. It’s like, Oh, here’s some other related stuff to this. If you’re still interested, I really like that because there was a couple of times with a few articles where, like I want to know more about this, and so I would keep clicking and read a little bit more” (P6).

Access to information on a lot of topics (breadth of topics)
- “[It would help if the platform had], like, a more robust portfolio of different like classes and articles” (P4).

Consistent care or support from the same people over time on the digital platform
- “The sleep coach that I am talking to now. She’s the same one I’ve talked to every single time...[It’s important to have continuity], especially just like to not have to answer the same questions over and over again, like they just kind of know who I am, looking for me, my style, and just more get to the care rather than have to do the basic information each session” (P3).

Proactive outreach from the digital resource (pushes content to me; provider reaches out to me)
- “One thing I like about the Baby Center or a lot of the articles I get from other providers is that they’re just in the email, and I don’t have to go anywhere” (P7).
Care or content that fits with my culture and identity

- “The [online doctor] knew Indian culture. So they knew Indian body like how our body reacts after [giving birth]. We are different than other people. So by giving specific things or a suggestion to Indians that is specific to my body, like after delivery, Indians don’t drink too much water. They understand, but my [in-person] doctor will say, drink four litre five litre today. I know so but one of the doctor on Maven when I talk, she said, I know the Indian people don’t drink too much water just after delivery, so I understand that. So if you want to have less water, so you can have a coconut water instead of normal water that will increase the hydration. So that kind of suggestion I don’t get from normal doctor” (P2).

Others said that they trusted digital content that was reviewed by medical professionals (Pilot P3) or had a “provider stamp of approval” (P9). A couple of participants were looking for digital resources that provided information from the people who conducted the research (P8) and that included “the latest research and peer reviewed evaluation” (P3).

In interviews, participants explained that access to free digital health services enables users to consume more health resources and spend more time interacting with health care providers than during in-person appointments:

[When there are] no limit on appointments...suppose I forgot something and I want another appointment and I can do it today. I don’t have to wait for another appointment. [P2]

They also accessed types of resources that they valued but would not use if there was an out-of-pocket cost:

So I think I just wouldn’t have gotten what I needed [in-person] because I have two other children, and I didn’t [get what I needed] with them. Just, like you know, Google things or Pinterest, or talk to friends, and that’s it. But because this service was free to me I felt like “well, it’s there, and I might as well use it,” so I’ve taken advantage of it. And so things like a sleep consultant I probably wouldn’t have paid for. But it was just so nice to have a sounding board...So yeah, I think just having services there that I wouldn’t have made the effort to use before, but because they’re just sitting there on my phone, I might as well, and it’s free to me. [P3]

Participants highlighted that free digital resources are particularly important as the cost of in-person services is very high and they were looking for a cheaper alternative:

Free resources—that’s big, since in person visits are very expensive. [P5]

Interview participants also wanted to interact with digital health content and people who provided information and support without judgment. A participant explained that it is easier to receive nonjudgmental care from a digital health care provider as the person only knows the information that is being shared in the moment and cannot be biased by previous interactions or conditions. Another participant explained that she did not want to discuss her baby’s sleep issues with her in-person pediatrician as she was worried that the physician would judge her as a bad mother. It felt safer to explore the problem with the web-based provider, with whom she did not have an ongoing relationship (Pilot P4).

Interview participants shared anecdotes illustrating the accessibility of web-based providers and described connecting with these providers at night and on weekends or around their work or family schedules:

Whereas in person, they’re always busy. So there’s some waiting time...If I had concerns, I want to consult with somebody...[it’s] very helpful where I can just find someone to talk to within the week, sometimes even the same day...Being able to get in touch with someone quickly during pregnancy and even postpartum has been super helpful. [P5]

There was one time where I had a concern and it was 2AM and I reached out to a practitioner over the phone, it might have been with Maven or it might have been with Telehealth, and [I had] flexibility with getting help at abnormal times of day. [P8]

In general, the importance of digital health platform features was consistent by race, parity, and mental health. Differences emerged for free resources, which were more important to respondents without a mental health history compared with those with a mental health history (P=0.02), and consistent care from the same people over time on the digital platform (P=0.01) and access to information on a lot of topics (P=0.02) were more important for Hispanic and people of racial and ethnic minorities respondents than for non-Hispanic White respondents.

For both pregnant and postpartum survey respondents, the 2 least important features were care or content that fit with their culture and identity and proactive outreach from the digital resources. These features were selected as extremely important by less than 20% of respondents. In interviews, participants described experiences on digital health platforms that were enhanced by resources and support that were respectful of and relevant to their culture or identity. When specifically asked about the importance of digital health resources that “take their whole identity into account,” participants consistently interpreted this to be about race, ethnicity, and gender or sexual identity, and participants from non–historically marginalized populations tended to report that inclusion was not relevant for them. This emerged in comments such as “Personally, I’m a woman, heterosexual, so I fit in fine, more than fine” (Pilot P1) and “[Health care is] not hard for me to navigate as a straight, White woman” (Pilot P3). However, as they shared anecdotes about their use of digital health platforms, they described experiences that were meaningfully inclusive (or noninclusive) related to other characteristics, such as their lifestyle (eg, family structure, work choices, and how they cared for their child) or religious practices. A participant appreciated that a nutritionist took the time to accommodate the fact that she kept kosher and “went above and beyond to research kosher supplements and make sure they were appropriate” for her to take (Pilot P2), and a working mother described her appreciation for resources that recognized her more limited availability to be with her children.
I’m probably in the majority, for most of the like, you know, bubbles you would fill in of race, gender, like I’m not a minority in any of those, but I think that everyone was just very respectful...maybe because they got to just like learn a little bit about me. [P3]

People of racial and ethnic minorities participants appreciated when there were racially diverse providers on the platform. Even though the participants did not necessarily choose to interact with a member of their ethnicity or race, they valued the presence of diversity:

I felt included throughout the process. I think even seeing the diversity of the people you can choose for a specific topic also helps just, like, feel more included, like just her background. I am Mexican American. So I was born in the US but Mexican background. And so just seeing the diversity on the team was important to me. [P8]

Discussion

Principal Findings in Relation to Prior Research

This mixed methods study found that the reasons why perinatal people use digital resources are consistent with previous research. During pregnancy, our survey and interview participants were highly interested in fetal development [10,11,16,18,20,21], reassurance about what is normal [5,16,17,38], and childbirth [10,11,20,21,39], although in our study, the latter topic was not among the top reasons for use. Unlike other studies, we found less interest in health and nutrition during pregnancy. During the postpartum period, our results were concordant with those of previous research with regard to users having a high interest in feeding, especially breastfeeding; developmental milestones; and the baby’s health [18,19,21]. Although interest in infant sleep is also common in the literature [18,19], we did not explicitly ask about this. However, this need is consistent with our overall finding that respondents were looking for information about caring for their baby and with anecdotes in our interviews that centered on infant sleep when participants discussed wanting to know what is normal, reaching out to digital providers at night, and receiving nonjudgmental support. We found an especially high interest in using digital resources for breastfeeding help among respondents with a mental health history (17/20, 85%), which is consistent with studies showing an association between maternal anxiety and breastfeeding outcomes [40-42]. Aligning with findings from content analyses of perinatal forums, top interests included baby-related topics and pain during pregnancy [17,19], but we found less interest in using digital resources for the health of the birthing person, and we did not ask about relationships (a common topic in web-based perinatal forums [17,19]) as this did not emerge as a key interest during the formative interviews. In addition to finding many of the same known reasons for using digital resources, we found that using these resources to help manage anxiety or depression was commonly selected as extremely important (55/147, 37.4% during pregnancy and 45/110, 40.9% during the postpartum period), especially for people of racial and ethnic minorities during pregnancy (21/35, 60%).

Our survey identified that, during the postpartum period, reasons for using digital resources related to the health of the birthing person were ranked lower than reasons related to obtaining information or help about the baby. This aligns with findings that mothers tend to focus on their babies and deprioritize their own needs [43]. However, there are physical and emotional challenges during the fourth trimester that often go unaddressed and can negatively affect maternal and child outcomes [44,45]. Contributing to underuse is a misalignment between the issues being addressed by providers and the birthing person’s needs, discomfort with discussing “embarrassing” issues with providers and feeling judged by them, and not knowing where to access information [43,46,47]. Digital health resources provide an opportunity for birthing people to be more in control of when, how, and for which needs they access self-care resources. Even though self-care may not be the primary priority for using digital health resources, making these supports available is valuable for those times when the birthing person is ready and interested in using them.

Emerging from both our surveys and interviews was the preference for using digital health resources to access providers. The characteristics that make digitally based providers helpful are differentiators from in-person care, with providers on platforms being reported as spending more time, focusing on issues and questions that matter to the user, and providing support quickly and conveniently [48-50]. Although study participants were explicitly asked about what is important to them when using digital health resources in general, they all had access to Maven, which offers access to a wide range of provider services. Study participants may have been more likely to express the importance of digitally based providers as they had the opportunity to use them during their perinatal stage. Users of digital health services who do not have access to digitally based providers may not identify them as important as they have not had the opportunity to experience their value. Although our results may not replicate those among digital health users who have not had access to these providers, this does not mean that digitally based providers are not an important part of what should be offered in digital health. Rather, it is an opportunity to meet a need that people may not realize they have.

Generally, the needs and preferences for perinatal digital resource use did not show much variation by perinatal phase (pregnancy vs postpartum), parity, demographics, or health characteristics. The least important reasons for use were the same during pregnancy and the postpartum period: help with healthy eating and being physically active (and, for the postpartum period, help with losing weight), connecting with a community of people in the same perinatal stage, and obtaining recommendations of things to buy to care for the birthing person or baby. Platform features were ranked in generally the same order during pregnancy and the postpartum period. However, there seems to be a difference in the overall importance of information during pregnancy versus the postpartum period, with reasons for using digital resources being selected as extremely important by a greater percentage of respondents during pregnancy than post partum. During pregnancy, the only reasons for using digital resources that differed by race were...
non–pregnancy-related (help with managing mental health and physical health problems), which may reflect gaps in in-person care for people of racial and ethnic minorities [51,52]. In interviews, we found a difference in participants who said that care or content that fits with their cultural, racial, or ethnic identity was important to them, with people of racial and ethnic minorities describing the value of being able to access providers with a shared identity or who provided culturally relevant support, whereas non-Hispanic White participants tended to say that this was not relevant to them. We were surprised that we did not find this difference in the surveys. A possible reason for this discrepancy is that our survey analysis focused on “extremely important” responses, and it may be that culturally relevant support is important but not extremely important. This would align with comments in the interviews about liking that providers of the same race were available even if they did not choose to use these providers.

This study included a national sample from the United States. Although our sample underrepresented people who identify as Black and Hispanic and lower-income people, it includes a significant portion of sustained users of digital resources (based on their completion of questionnaires on the Maven platform at multiple time points throughout pregnancy and the postpartum period), which is valuable as they represent people who will often use digital resources and have the potential to be significantly helped and supported by them. However, future research should also explore these topics among lower-frequency users to identify and understand barriers or deficiencies in the resources that may be contributing to reduced use.

This study adds to existing research by linking survey responses to other pregnancy, health, and demographic data about the respondents. Psychological states and mental health, especially perinatal anxiety, in relation to digital use are understudied [20], as are race and ethnicity. This formative research found only minor differences in digital resource needs and preferences across several user characteristics, including perinatal phase, parity, demographics, and mental and chronic health conditions. If this finding holds up in additional research, it has implications for the design of digital resources as it suggests that it may be appropriate to cover the same high-level perinatal topics for users across these groups. However, additional research is needed to better understand whether the content within these topics needs to be tailored to different populations. For example, future research could find that, although it is appropriate to include resources on childbirth for all users, there may be a need for more information about birthing centers in resources targeting Black pregnant people. Additional insights that are needed to improve the relevance and impact of these resources include understanding the use of the internet by nonbirthing partners [20] and the impact of use on clinical outcomes and user satisfaction [51]. There is also an opportunity to develop a standardized set of methods and metrics for assessing perinatal digital resources [4].

Limitations

This study has some limitations. First, the generalizability of these results is limited as all survey and interview participants had access to private insurance, the sample had a relatively high income, and Hispanic and Black respondents were underrepresented. Second, there was a high amount of missingness within our race and ethnicity data from respondents selecting that they prefer not to provide this information (17/110, 15.5% and 35/147, 23.8% for postpartum and pregnancy survey respondents, respectively). This missingness may limit the reliability of our results regarding differences in digital needs by race. Finally, not all survey respondents completed the Maven questionnaires, and those who did not complete at least one Maven questionnaire were excluded from the analyses of the survey. This potentially biased the sample toward heavier users of digital resources, although this creates an opportunity to understand use needs among this segment of users.

Data Availability

Owing to the sensitive nature of the questions asked in this study, respondents were assured that raw data would remain confidential but may be shared upon request.

Conflicts of Interest

NH, AB, AA, and HRJ are employed by Maven Clinic. NH, AA, and HRJ have equity in Maven Clinic.

Abstract

Background: Suicide rates in the United States have increased recently among Black men. To address this public health crisis, smartphone-based ecological momentary assessment (EMA) platforms are a promising way to collect dynamic, real-time data that can help improve suicide prevention efforts. Despite the promise of this methodology, little is known about its suitability in detecting experiences related to suicidal thoughts and behavior (STB) among Black men.

Objective: This study aims to clarify the acceptability and feasibility of using smartphone-based EMA through a pilot study that assesses the user experience among Black men.

Methods: We recruited Black men aged 18 years and older using the MyChart patient portal messaging (the patient-facing side of the Epic electronic medical record system) or outpatient provider referrals. Eligible participants self-identified as Black men with a previous history of STB and ownership of an Android or iOS smartphone. Eligible participants completed a 7-day smartphone-based EMA study. They received a prompt 4 times per day to complete a brief survey detailing their STB, as well as proximal risk factors, such as depression, social isolation, and feeling like a burden to others. At the conclusion of each day, participants also received a daily diary survey detailing their sleep quality and their daily experiences of everyday discrimination. Participants completed a semistructured exit interview of 60-90 minutes at the study’s conclusion.

Results: In total, 10 participants completed 166 EMA surveys and 39 daily diary entries. A total of 4 of the 10 participants completed 75% (21/28) or more of the EMA surveys, while 9 (90%) out of 10 completed 25% (7/28) or more. The average completion rate of all surveys was 58% (20.3/35), with a minimum of 17% (6/35) and maximum of 100% (35/35). A total of 4 (40%) out of 10 participants completed daily diary entries for the full pilot study. No safety-related incidents were reported. On average, participants took 2.08 minutes to complete EMA prompts and 2.72 minutes for daily diary surveys. Our qualitative results generally affirm the acceptability and feasibility of the study procedures, but the participants noted difficulties with the technology and the redundancy of the survey questions. Emerging themes also addressed issues such as reduced EMA survey compliance and diminished mood related to deficit-framed questions related to suicide.
Conclusions: Findings from this study will be used to clarify the suitability of EMA for Black men. Overall, our EMA pilot study demonstrated mixed feasibility and acceptability when delivered through smartphone-based apps to Black men. Specific recommendations are provided for managing safety within these study designs and for refinements in future intervention and implementation science research.

Introduction
Suicide among Black Americans is a critical public health priority that requires immediate attention. Studies have shown that suicide rates among this population are increasing and that Black men, in particular, are at a higher risk of suicide-related mortality [1,2]. It is crucial for public health efforts to prioritize suicide prevention in the Black community and address the systemic issues that contribute to mental health disparities [1,2]. Epidemiological data reveal that Black men die by suicide at rates 4 to 6 times greater than Black women and that suicide is the third leading cause of death for young Black men [2,3]. While nationwide suicide rates provide a broader perspective on this alarming public health issue, delving into state-specific data, such as in Maryland between 2016 and 2020, reveal a localized increase in suicide death for Black Americans, compared to their White counterparts and highlights the urgent need for tailored research priorities [4]. The COVID-19 pandemic further exacerbated these alarming trends, with Black Marylanders experiencing an uptick in suicide deaths during the initial lockdown periods in the United States [5]. These national and state-specific trends highlight the pressing need to address more robust approaches to suicide prevention, emphasizing the importance of ensuring equitable access to support and resources for all communities.

Mental health disorders, such as depression and substance use, are known risk factors for suicide among Black Americans [6,7], but recent research also highlights racism and associated contextual stressors as important, but underresearched, explanatory risk factors for suicidal thoughts and behaviors (STB) among Black adults [8-10]. Previous studies have demonstrated the significant impact of racism and associated daily stressors on mental health outcomes, including depression, anxiety, sleep disturbances, and posttraumatic stress disorder (PTSD), among Black individuals [11-15]. However, the emerging research highlights the need to examine the specific ways in which racism contributes to STB among this population. Further research in this area is crucial to identify effective prevention strategies that can reduce the impact of racism and mitigate the rising trend of suicide completion among Black adults.

Black Americans also face significant barriers in accessing mental health care due to stigma, systemic lack of access to services, and cultural mistrust [16-19]. Although Black men are approximately 30% more likely to report having a mental health condition compared to non-Hispanic White individuals [20], they also have significantly lower percentages of mental health-related visits prior to a suicide attempt than men of other racial and ethnic backgrounds and Black women [21,22]. In addition, traditional clinical records used to assess suicide risk and prevention often rely on distal and static measures of risk, such as prior diagnoses and family history, which may overlook the dynamic interplay of proximal factors that contribute to STB and patient-provider synergy. Consequentially, while Black Americans face considerable obstacles in accessing mental health care, these disparities are particularly pronounced among Black men, highlighting the urgency of addressing these disparities and adopting approaches to assess more proximal aspects of suicide risk and prevention.

Suicide among Black Americans is a critical public health issue, delving into state-specific data, such as in Maryland between 2016 and 2020, reveal a localized increase in suicide death for Black Americans, compared to their White counterparts and highlights the urgent need for tailored research priorities [4]. Consequentially, while Black Americans face considerable obstacles in accessing mental health care, these disparities are particularly pronounced among Black men, highlighting the urgency of addressing these disparities and adopting approaches to assess more proximal aspects of suicide risk and prevention.
intervention [26]. Black men face daily societal and cultural stressors that may contribute to their heightened risk of suicide, including but not limited to, systemic and interpersonal racism, economic disparities, and limited access to mental health resources [8,33,34]. To address this gap, additional research is needed to clarify the efficacy of EMA monitoring as a suicide prevention tool for this at-risk population.

Methods

Eligibility and Recruitment Procedures

We recruited adult Black or African American men (18 years of age or older) with a lifetime history of suicidal ideation or attempt residing in Maryland counties where mobile crisis support was available. To be eligible, participants had to (1) own a smartphone and (2) not be present with active psychosis or cognitive deficits. We used two recruitment approaches: (1) providing recruitment information to eligible, active patients via the Johns Hopkins Health MyChart, the web-based patient portal of the Epic electronic medical record system that allows for health communication between patients and health care providers and (2) clinician referral. Participants who met the eligibility criteria through either of these approaches were referred to the study coordinator and were required to complete a screening survey to confirm their interest and eligibility.

Ethical Considerations

The study was approved by the institutional review boards of Johns Hopkins Bloomberg School of Public Health (IRB 00013672). All participants were provided detailed information about the study procedures and expectations, risks, and benefits as part of the informed consent process conducted by a research coordinator.

Baseline Survey

We asked enrolled participants to complete a brief baseline assessment including demographics and psychosocial measures associated with affective, gender, and race-specific factors associated with STB, such as anger, sadness, attributional style, and racial identity. A complete list of baseline measures is described elsewhere. During the informed consent process, participants received an overview of the MetricWire smartphone app from the study coordinator. The study coordinator also determined the county in which the participant resided, in order to align our safety protocol with mobile health crisis units in their area. After completion of the baseline survey, we asked participants to download the MetricWire app onto their personal smartphones for the duration of the study. The MetricWire app is available for both iOS and Android smartphone platforms at no cost in the Apple App Store (Apple Inc) or Google Play Store (Google), respectively. Examples of the user interface of the MetricWire app are presented in Figure 1.

Figure 1. Screenshot of suicidal ideation and intensity questions on the ecological momentary assessment user interface. CSSR: Columbia Suicide Severity Rating Scale.

EMA and Daily Diary Data Collection Procedures

This study used the MetricWire app to deliver daily EMA surveys to participants at 4 time points between 10 AM and 6 PM. Each of the prompts was designed to occur at least 2 hours after the previous prompt and included 3 push notification reminders at 20, 40, and 55 minutes after the initial prompt. If the participant did not complete the EMA survey within 60 minutes, it was marked as incomplete. The EMA surveys were designed to be brief and take no more than 3 minutes to complete to reduce respondent burden. To capture instances of racism-related stressors occurring outside of the random EMA survey prompts, participants were allowed to record event-driven entries detailing their daily experiences (see Figure 2).
We administered a brief daily diary survey via the MetricWire app once per day to assess participants’ everyday experiences, including sleep-related impairment and quality, as well as their daily experiences with racism-related stress. The daily diary was prompted each day at 8 PM. This survey was not designed to capture momentary instances but rather to provide a more comprehensive picture of participants’ daily experiences.

**Safety Protocols**

Upon enrollment, we provided participants with a document containing information about local and national mental health resources, including suicide crisis hotlines, to support their well-being throughout the study. To ensure participant safety during the data collection period, we implemented a 3-tiered safety protocol. Moderate risk, which is defined as any suicidal ideations (“Have you had thoughts of killing yourself?”), since the last assessment, but without any plan or intent, resulted in a notification to the participant guiding them to the online support groups and community-based mental health services and urging them to seek support. Elevated risk, defined as suicidal ideation with intent or a plan within the last 24 hours (“Have you planned out how you would do it?” or “When you thought about making yourself not alive anymore, did you think that this was something you might actually do?”), resulted in the same notification that was given to participants with moderate risk and participants will be asked if they would like to handle the matter themselves or if they would like us to contact a mobile crisis response unit in their area on their behalf. Acute risk, defined as suicidal ideation with an action since the last assessment (“Did you do anything to make yourself not alive anymore or kill yourself?”), resulted in a call to the participant’s closest mobile crisis response unit made by a member of the study team on the participant’s behalf. To protect participant privacy, data were not stored on their smartphones. Instead, survey response data were automatically synced to the MetricWire servers when participants were connected to the internet.

**Exit Interview**

After the 7-day data collection period, each participant underwent a qualitative semistructured exit interview conducted by the study team. The interviews probed participants on issues such as question difficulty and clarity, potential revisions to question prompts, and overall satisfaction with the study protocol and EMA surveys. Verbatim transcripts of the recorded interviews were produced and analyzed to evaluate the feasibility and effectiveness of the study protocol.

**Participant Incentives**

To encourage higher EMA survey completion rates, participants were eligible to receive up to US $110 throughout the study duration. The incentive was incrementally phased, with participants receiving US $10 after completing the baseline survey, US $20 for completing 20% (7/35) of all surveys, US $50 for completing 50% (17.5/35) of all surveys, and US $80 for completing 80% (28/35) of all surveys. We offered an additional US $20 for the completion of the exit interview.
internet, and encrypted response data were stored until the next
connection. These servers were continuously backed up.

To provide additional support, all research personnel interacting
with participants received training in psychological first aid to
assist with identifying any mental health needs. EMA responses
were closely monitored by the study coordinator and regular
updates were provided during biweekly research team meetings
between January 2022 and May 2023.

Quantitative and Qualitative Data Analysis

To measure the acceptability and feasibility of the EMA method,
we tracked four key metrics using Excel (Microsoft): (1) the
proportion of eligible patients who enrolled in the study, (2) the
percentage of completed EMA sessions out of the total number
of scheduled sessions, (3) the number of safety-related incidents
reported to mobile health crisis support teams, and (4) the
average time taken to complete the EMA surveys.

Semistructured exit interviews were audio recorded and
transcribed verbatim by the research team. The transcripts were
then imported into Dedoose (version 8; Sociocultural Research
Consultants, LLC) qualitative data analysis software for analysis.
A deductive coding framework was used based on previous
contceptual definitions related to implementation science. The
research team independently reviewed the transcripts and
generated a preliminary codebook based on a priori concepts.
These concepts focused on prevailing definitions of
acceptability, feasibility, adoption, and fidelity to the EMA
methodology.

Results

Demographics

Participants ranged from 18 to 34 years of age, with an average
age of 27 (SD 5.31) years. The majority (4/10, 40%) of our
sample had completed a high school degree, followed by an
associate or bachelor’s degree (n=2, 20%), while some
completed high school (n=1, 10%), college (n=2, 20%), and a
master’s degree (n=1, 10%). Participants lived across 3 counties
in Maryland, including Baltimore, Anne Arundel, and Howard.
Furthermore, participants identified as a spectrum of sexual
orientations, including heterosexual (n=3, 30%), gay (n=2,
20%), bisexual (n=1, 10%), pansexual (n=2, 20%), and
questioning (n=1, 10%). One participant chose not to disclose
his sexual orientation.

Feasibility of EMA and Daily Diary

The MyChart recruitment service identified and sent study
information to 744 active patients residing in Maryland. A total
of 58 individuals completed our interest survey. Of those, 53
(91%) were attributed to the MyChart recruitment service. Three
submissions were from clinician referrals and 2 were from
community outreach events. Out of the 58 individuals
completing the interest survey, 10 (17%) participants were
enrolled in the EMA study. The primary reasons for exclusion
after completing the interest survey were active psychosis (n=19)
and no history of suicidal thoughts or behavior (n=10). A total
of 7 individuals were excluded because they reported having
no mental health care provider.

The 10 enrolled participants completed 166 EMA surveys and
39 daily diary entries. A total of 4 (40%) out of 10 participants
completed 75% (21/28) or more of the EMA surveys. The
average completion rate of all surveys was 58% (20.3/35), with
a minimum of 17% (6/35), and maximum of 100% (35/35). A
total of 4 (40%) out of 10 participants completed at least 5 out
of 7 daily diary entries. The response rate for each day of the
week ranged from 64% (3.2 surveys submitted on average; day
1) to 54% (2.7 surveys submitted on average; days 6 and 7).
All 10 participants completed qualitative exit interviews at the
conclusion of the study. There were no safety-related incidents
that required mobile health crisis service response teams. On
average, participants took 2 minutes and 5 seconds to complete
EMA surveys and 2 minutes and 43 seconds to complete daily
diary surveys.

Qualitative Findings From Exit Interviews

After coding, several key themes arose, including the study
implementation, the iatrogenic effects of repeated suicidality
assessments, and strategies to improve usability and
effectiveness in suicide-related smartphone app development
for Black men. We present key details and findings on these
themes as follows.

Study Implementation

Table 1 shows representative quotes that illustrate participant
perspectives on adoption, acceptability, and feasibility to the
study protocol.

<tr>
<td>Acceptability</td>
<td>“They're good questions. It makes sense. It's exactly the information that you'd be looking for.” [Participant 1]</td>
<td>“The only thing that I can really think of as far as that is the hours...Maybe they're asleep, maybe they're working etc., etc.” [Participant 1]</td>
</tr>
<tr>
<td></td>
<td>“I like how it did call my therapist, because I finally set up a meeting with her. But she, you know, was like, 'Hey, um, you know, come in contact with me, because I know you're not doing well.' And I was like, 'Yeah, that's fair.'” [Participant 2]</td>
<td>“I thought it shouldn't have been the same questions. It got boring and repetitive and seemed like more of a hassle than something that was going to help me, because it's annoying now, because it's the same questions.” [Participant 5]</td>
</tr>
<tr>
<td></td>
<td>“I thought the questions were pretty straightforward.” [Participant 4]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>“I think for the most part, it was good, it was self-explanatory. It was easy to get to.” [Participant 5]</td>
<td></td>
</tr>
<tr>
<td>Feasibility</td>
<td>“What were your opinions regarding you know, how many surveys you got per day?” [Moderator]</td>
<td>“The wording was, yeah, as I was saying before, it was very, extremely clinical, which I mean, you're not really supposed to be beating around the bush as far as the stuff is concerned.” [Participant 1]</td>
</tr>
<tr>
<td></td>
<td>“Um, that was fine. I was. I'm not sure if you remember, but I was a bit wary beforehand. I was worried that it might be a little bit too many, but no, it was fine. The amount was perfectly okay. The timing was fine too. Yeah, the timing was definitely fine as well.” [Participant 1]</td>
<td>“Regarding racial stress record: ‘I really don't like the sound of my voice...like, ugh, don't like that, and eventually just stopped doing them. Because it's just like, it's easier to like, write things down. I guess.” [Participant 2]</td>
</tr>
<tr>
<td></td>
<td>“The only thing that I can really think of as far as that is the hours but as I had mentioned, before we even started this, anyone who's downloading this resource is probably doing it with the intention on actually utilizing it. So I can't really see someone actively like disregarding the surveys, unless they either don't notice them or, well, yeah, unless they don't notice them or somehow it slips past their schedule. Maybe they're asleep, maybe they're working etc., etc.” [Participant 1]</td>
<td>“Sometimes you miss an alert and yeah and that would be like, all day, that was my main focus, like oh my God, I got to remember my survey or whatever.” [Participant 5]</td>
</tr>
<tr>
<td>Fidelity</td>
<td>Prompts to complete surveys: “It was good, because some days I will remember, I have to take the survey so such and such time but other days, I wouldn’t to remember. I’m glad they, the prompts you know, were there.” [Participant 6]</td>
<td>“One of the things that was a little annoying was like oh, it would crash on me a lot. So I would have to re-open it, but when I would re-open it, it would take me right back to the question that it crashed on me on. So, I was like, ‘Oh, okay, that was convenient.’” [Participant 4]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>“it seemed like every time I tried to open the app, it wouldn't even open, like sometimes it...ugh like it was so frustrating, so I just wouldn’t try to do it for a while.” [Participant 6]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>“Lack of use due to app issues: ‘I didn't always have like issues as far as that's concerned, I didn't really use it very often, explicitly, because around the time that I was doing the, well, around the time that I was, you know, taking part in this study, it was out of work.” [Participant 1]</td>
</tr>
<tr>
<td>Appropriateness</td>
<td>Timing of prompts: “I'm not sure if you remember, but I was a bit wary beforehand. I was worried that it might be a little bit too many, but no, it was fine. The amount was perfectly okay. The timing was fine too. Yeah, the timing was definitely fine as well.” [Participant 1]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Completing racial stress record in a predominantly Black neighborhood: “I normally don't go through racial stuff, like I'm in a neighborhood is predominantly Black. I see one White person a day, maybe.” [Participant 6]</td>
<td>N/A²</td>
</tr>
<tr>
<td>Adoption</td>

</table>

²N/A: not applicable.
Overall, participants found the frequency and timing of the EMA survey prompts to be appropriate. One participant commented that the questions provided “exactly the information needed,” while another appreciated the reminder to contact their therapist. Participants generally found the questions straightforward and easy to understand, and the survey itself was considered self-explanatory and easy to access. Participant 1 noted that they were initially concerned about the number of prompts, but ultimately found them to be manageable:

I’m not sure if you remember, but I was a bit wary beforehand. I was worried that it might be a little bit too many, but no, it was fine. The amount was perfectly okay. The timing was fine too.

However, some participants reported feeling that the racial stress record and daily diary questions regarding discrimination may not have been relevant to their daily experiences.

I normally don’t go through racial stuff, like I’m in a neighborhood that is predominately Black. I see one White person a day, maybe. [Participant 5]

Our study identified some challenges related to technology issues that impacted the fidelity of our study implementation and, ultimately, participants’ ability to complete the surveys in a timely manner. Participants identified app crashes as a significant issue, which led to frustration and difficulty in completing the surveys.

One of the things that was a little annoying was like oh, it would crash on me a lot. So I would have to re-open it, but when I would re-open it, it would take me right back to the question that it crashed on me on. So, I was like, “Oh, okay, that was convenient.” [Participant 4]

This issue not only caused inconvenience but also resulted in participants potentially losing progress on their survey responses. Consequently, this problem may have discouraged some participants from continuing with the study.

Influence of Mood on EMA Compliance

The narratives shared by the participants highlighted the possibility of diminished effect resulting from frequent evaluations of suicidality, which could potentially exacerbate negative mental health outcomes. Participants’ accounts of their study experience suggest that depressed mood prior to a notification to complete a survey may impact compliance with suicide-related assessments. Overall, as stated by 1 participant, “during moments where I already wasn’t feeling too great, it exacerbated things a bit.” Further, another participant in the study described how their survey compliance can be influenced by their mood:

It’s sort of like a reflex for like, whenever something buzzes on my phone, and I’m like, not in a good mood, I immediately, like, swipe it [get rid of the notification]

Participant 2 noted that repeated assessments of suicidality could increase their awareness of passive suicidal thoughts, stating, “Not really trigger me, but be like, oh, yeah, I am, like, passively suicidal 99% of the time.” Another participant noted in his interview that he did not complete the last day of the trial due to an anniversary of a loved one’s death:

It was an emotional day and I didn’t want to continue because my responses would have changed drastically. I didn’t want nobody to look at me differently...I didn’t want to put myself in an uncomfortable position.

This response further cements the idea that response rates may be influenced by low mood. Several participants provided feedback on the survey questions, suggesting that shorter surveys may be more effective in assessing suicidality. They noted that if they responded with a positive mood score, assessed by the Patient Health Questionnaire-2 item measure (PHQ-2), it likely indicated they were doing well and not feeling suicidal. Multiple participants suggested that gauging mood before asking directly about suicide may improve the effectiveness of the survey.

Those questions are pretty good. But I would probably, like I’d probably try and, like keep the survey shorter...So maybe like gauge the mood before asking like, “Hey, are you going to kill yourself?” Because if I’m at like, 3, then the answer is like, it’s no, it’s, it’s gonna be no, you know, because I’m in like, a pretty good place. [Participant 2]

Given our study’s focus on suicide risk assessment, a significant portion of the survey questions pertained to assessing proximal or momentary risk for self-harm. Unfortunately, these questions were predominantly framed from a negative or deficit-oriented perspective, such as “Have you thought about killing yourself since the last prompt?” Several participants pointed out that this focus on negative experiences was contributing to their mood states and recommended that the survey be balanced with more positive questions.

It seems like everything was about if I have a terrible day...there should have been some questions that show record of your good days, too. [Participant 5]

Recommendations to Improve Usability and Effectiveness

As part of the qualitative exit interview, participants were asked to provide feedback and suggestions for the future use of the app. In relation to the app’s accessibility, several participants suggested incorporating features that would promote ease of use. Specifically, participants mentioned that a dark mode would be beneficial, as the bright white background of the app was uncomfortable for some. In addition, participants suggested incorporating a text-to-speech feature that would read the survey questions aloud to make it easier for individuals with visual impairments or reading difficulties.

To encourage better participation and compliance, some participants suggested that a more flexible schedule would better align with their daily routines and lifestyles. Some participants pointed out that they are less inclined to fill out surveys when they are occupied with other social activities. As a result, participants suggested a schedule that can be customized according to their personal needs and circumstances.
I guess, maybe if I could like, sort of choose my own schedule...like put it at times where I know that I'm going to be like, on my phone, or like, in my bed...I'm probably going to be in my bed not doing anything else, like probably playing a game on my phone. So I'll tell myself, “Hey, you have no excuse, fill this out so that they know you haven’t, like died.” But, if it’s like, in the middle of me, like going to the mall with my friends, I'm most definitely not going to stop and be like, “Hold on everybody, I have to fill this out” I’m just gonna forget about it. [Participant 2]

Participants provided various suggestions for enhancing the interactivity of the smartphone-based app, including incorporating a journaling component to allow them to document their thoughts in written form. Participant 2 described the potential benefit of such a feature, stating that it could provide a private space for them to express their emotions and thoughts more freely, without the fear of judgment or negative consequences.

I was thinking, maybe something where, you know, if you're not feeling that bad, you can just write down something...And knowing that it's going to medical professionals, I probably will be as kind of open as I am in my journal.

Additionally, other participants expressed interest in in-app features that would allow for personalized coping strategies, such as guided breathing exercises or links to mental health resources. These in-app features were seen as potential tools to promote engagement with the app and ultimately improve mental health outcomes. Finally, participants recommended that the survey include questions that allow for a more comprehensive and nuanced picture of their mood and well-being, and that these questions should be presented before questions pertaining to suicide risk to “ease into the heavier stuff,” as suggested by participant 1.

Discussion

Principal Findings

Our study aimed to assess the feasibility of using smartphone-based EMA to evaluate suicidality in real time among individuals in a high-risk sample of Black men. During the interviews, most participants generally reported that the frequency and timing of the prompts and reminders were suitable for the project and their daily lives. The results indicate that this approach shows promise for future research in this population. The results also suggested that while suicide-related smartphone apps have the potential to be effective tools for suicide prevention, they need to be developed and implemented with care. Even though the completion rate for EMA surveys was not optimal, we are encouraged by the high level of compliance with the daily diary entries. The study also did not pose any safety concerns, and the completion time for the surveys was found to be relatively short. Participants reported that the questions were generally relevant to their daily experiences and easy to understand. Additionally, the user feature that allowed for open-ended audio recordings was found to be useful in capturing daily experiences of racism, which is an important factor that could contribute to suicidality in this population. Finally, the qualitative findings from exit interviews suggest that the study procedures were perceived by participants to be acceptable and feasible.

Despite the promising results, the study revealed that the compliance rate was lower than in other studies not focused on Black men that leveraged EMA approaches to assess suicide risk [25,28]. One possible reason for this finding is that participants encountered technological issues and cited them as reasons for disengagement from the study. Participants noted redundancy in survey questions, which can lead to survey fatigue and reduced engagement. This redundancy might have contributed to the lower completion rates observed in the study. Moreover, the frequency of prompts may have contributed to the overall low compliance rate. The participants recommended fewer prompts and more flexibility in timing to enhance compliance.

Our findings also highlight the need for careful consideration of the potential harms of repeated assessments of suicidality, which focuses on a negative framing of mental well-being, and the need for the development of personalized interventions to mitigate any negative effects. Specifically, participant narratives from our qualitative exit interviews suggest that individuals experiencing negative moods may be less likely to engage with suicide-related assessments delivered via smartphone app notifications. Additionally, respondents felt that the EMA survey questionnaire could be more balanced by including both questions that assessed suicide risk and positive emotions as protective factors. One such measure, the Reasons for Living Inventory (RLI), was developed to identify factors that serve as deterrents against suicidal behavior. This inventory assesses positive emotions that support an individual’s decision to avoid death by suicide, should such thoughts emerge. Including measures, such as the RLI, that ground Black men to life is vital for addressing mental health challenges and fostering well-being for this demographic. By understanding how to balance the benefits of suicide-related assessments with their potentially harmful impact, scholars will be more equipped to identify protective factors and develop tailored interventions that are more likely to be used by Black men.

Our findings have important implications for the use of EMA among Black men. Smartphone-based methods, such as EMA and daily diaries, offer a unique opportunity to assess and evaluate suicide risk in real time. This approach represents a significant advancement in capturing momentary phenomena that could aid in suicide prevention, such as (1) characterizing dynamic mood changes over a short time span, (2) untangling stressful and racialized daily experiences, and (3) transmitting critical health information to health care providers to support care management. By using this approach, researchers can gain a more nuanced understanding of the experiences of high-risk populations and provide timely culturally relevant interventions to prevent suicide [23,24,32,33].

Moreover, researchers should be aware of certain populations that may be cautious to participate in research, such as Black men, particularly when it involves the explicit tracking and reporting of their daily experiences. This hesitancy can be
rational, given the history of systemic exploitation of Black communities in biomedical research [36]. Therefore, it is important for researchers to acknowledge and address these historical injustices to build trust and facilitate participation among these populations. Only by taking these steps can researchers ensure that their work is ethical, respectful, and ultimately beneficial to the communities they seek to serve [19,37,38].

Smartphone-based suicide prevention is also increasingly becoming a viable approach for combating rising suicide rates, especially among young adults. The prevalence of health-related internet searches via smartphones, as evidenced by the high percentage of people who are 18-29 and 30-49 years of age and who use their phones for medical information, suggests that smartphones can be effective tools for suicide prevention. Additionally, the fact that Black and Hispanic Americans use their phones for medical information more frequently than White non-Hispanic Americans suggests that smartphone-based interventions may be especially important in addressing suicide risk in communities that experience higher levels of stigma and barriers to accessing traditional health care resources [39]. By leveraging the widespread use of smartphones, suicide prevention efforts can reach a larger and more diverse population, potentially reducing the burden of suicide on individuals, families, and communities.

Limitations
There are several potential limitations to our study that should be noted. First, our primary recruitment method was through MyChart messaging, which may have limited the pool of potential participants to those who are more likely to have additional physical comorbidities. The recruitment approach may have influenced the response rate, since participants may not have had the same motivation to respond to an interest survey, compared to a direct referral from a medical professional. Second, all participants were required to own a smartphone, which may have excluded individuals who did not have access to this technology. Additionally, we excluded Black men with active psychosis, which may have further limited the diversity of our sample. Given the potential for overdiagnosis of psychosis in underserved communities [40], it is possible that we also excluded potentially eligible individuals. Our study was also geographically restricted to Black men receiving health care in Baltimore, Maryland, and its surrounding counties. Future studies should consider additional venues and settings to recruit Black men who are not engaged in psychiatric care, including but not limited to social media, advocacy groups, and peer-led and community-based organizations. Finally, our study involved a relatively small number of participants, with 9 eligible participants completing the EMA surveys. This limited sample size may not fully represent the diversity and complexity of experiences among Black men and can affect the generalizability of findings to a larger population. Future studies should expand from our preliminary findings with a sufficient sample size to statistically investigate predictors of low compliance and user uptake.

Conclusions
This study is the first to our knowledge to address critical gaps in suicide research by incorporating EMA to improve the care for Black men who are at risk of suicide. Using EMA may be an important tool to help stem challenges to the timely assessment of suicide among Black men, who comprise the largest percentage of deaths by suicide (81%) within the Black community [4]. Our findings highlight how acceptable and feasible this method is for this high-priority population, as well as potential approaches to improve its fit. Our study provides critical insights into the use of smartphones to capture real-time data for assessing the mental and emotional health of individuals in high-risk clinical samples of Black men. Our results highlight the suitability of EMA using smartphone-based approaches for studying sensitive topics related to suicide in vulnerable populations. Furthermore, the findings shed light on the next steps for creating more equitable suicide prevention approaches, including identifying areas of missing data and the cultural acceptability of smartphone-based tools for health promotion. However, further research is necessary to expand these tools to assess structural racism and other racialized factors that influence Black men's daily lives.

Abstract

Background: Approximately 80% of primary school children in the United States and Europe experience glue ear, which may impair hearing at a critical time for speech acquisition and social development. A web-based app, DigiBel, has been developed primarily to identify individuals with conductive hearing impairment who may benefit from the temporary use of bone-conduction assistive technology in the community.

Objective: This preliminary study aims to determine the screening accuracy and usability of DigiBel self-assessed air-conduction (AC) pure tone audiometry in adult volunteers with simulated hearing impairment prior to formal clinical validation.

Methods: Healthy adults, each with 1 ear plugged, underwent automated AC pure tone audiometry (reference test) and DigiBel audiometry in quiet community settings. Threshold measurements were compared across 6 tone frequencies and DigiBel test-retest reliability was calculated. The accuracy of DigiBel for detecting more than 20 dB of hearing impairment was assessed. A total of 30 adults (30 unplugged ears and 30 plugged ears) completed both audiometry tests.

Results: DigiBel had 100% sensitivity (95% CI 87.23-100) and 72.73% (95% CI 54.48-86.70) specificity in detecting hearing impairment. Threshold mean bias was insignificant except at 4000 and 8000 Hz where a small but significant overestimation of threshold measurement was identified. All 24 participants completing feedback rated the DigiBel test as good or excellent and 21 (88%) participants agreed or strongly agreed that they would be able to do the test at home without help.

Conclusions: This study supports the potential use of DigiBel as a screening tool for hearing impairment. The findings will be used to improve the software further prior to undertaking a formal clinical trial of AC and bone-conduction audiometry in individuals with suspected conductive hearing impairment.

Introduction

Over 5% of the world’s population, approximately 430 million people worldwide, have disabling hearing loss; 34 million of these are children [1]. The main causes of hearing loss in adulthood are age-related hearing loss, noise-related hearing loss, and hearing loss due to chronic otitis media. In children, the most common cause of hearing impairment is otitis media with effusion, also known as “glue ear”. Approximately 80% of primary school children in the United States and Europe experience glue ear [2]. In contrast to most forms of adult hearing loss, hearing impairment in children with glue ear fluctuates. Serial testing is often required to detect and manage the condition to mitigate its adverse impact on social development. Children in low- and middle-income countries, families experiencing socioeconomic deprivation, and disadvantaged populations are disproportionately affected by conductive hearing loss caused by glue ear and its complications, or from damage to the eardrum as seen in chronic tympanic perforations or chronic serous otitis media [3,4]. Since delayed recognition and management of childhood hearing impairment have long-term consequences for socialization and educational attainment, screening audiometry is recommended in primary school [5]. However, population screening programs are hindered by cost, standardization, requirement for staff training, false-positive referrals, and poor data capture [6,7]. Even where available, school screening may miss children with fluctuating hearing loss due to glue ears. Additionally, several year groups have missed screening during the COVID pandemic [8]. These children may face months of impaired hearing before diagnosis and management due to backlogs in audiology and specialist services.

Hearing thresholds are assessed using pure tone audiometry (PTA) with air-conduction (AC) headphones and bone-conduction (BC) transducers. This usually requires specialist equipment and trained clinicians. Automated audiometry and, more recently, validated self-testing hearing software apps, may improve the accessibility of screening and threshold audiometry testing, particularly in rural areas. The DigiBel web app is a recently developed Class I CE marked medical device that enables self-testing of AC and BC hearing levels. Like some other audiometry apps, it is suitable for community use in adults and children without clinical support. DigiBel has the novel facility to undertake BC audiometry with the same transducer used in a BC hearing assistance kit (BC headphones with Bluetooth-connected microphone, Raspberry Pi, Cambridge, United Kingdom). This could identify children who may benefit from this assistive technology while waiting for diagnosis, spontaneous resolution, or definitive management of their glue ear [9].

The purpose of this study of DigiBel audiometry is to determine the app’s sensitivity and specificity for detecting simulated conductive hearing impairment of more than 20 dB and to identify software modifications required prior to formal trials in a clinical population. Given the long protocol of testing or retesting and the requirement for usability feedback to inform improvement in the app design, this preliminary study involved healthy adult volunteers rather than children.

Methods

Overview

Healthy adult volunteers from the community without a previous history of hearing impairment were invited to participate in this comparative study of automated PTA and DigiBel audiometry. After receiving an explanation of the study, participants provided verbal consent to proceed to audiometry testing. Each participant was assigned a unique study identification number; no personal identifiable information was recorded.

Testing was undertaken in community settings such as participants’ homes and classrooms by nonaudiologist technicians. Prior to testing, each volunteer was instructed to place a foam earplug firmly into their left auditory canal and requested not to adjust it until testing was complete. This simulated a conductive hearing loss in the plugged ear, making each ear an independent entity for the purpose of statistical analysis and providing a range of hearing levels.

The reference automated AC PTA and the index DigiBel audiometry test were undertaken sequentially in random order. DigiBel audiometry for 4 frequencies was repeated immediately after the initial test, to assess within-session test-retest (TRT) reliability. After completing both audiometry tests, each volunteer was asked to complete a feedback questionnaire covering test preference and usability (Multimedia Appendix 1).

Automated Pure Tone Audiometry—The Gold-Standard Reference Test

Automated PTA was undertaken using an Oscilla (Oscilla A/S Aarhus Denmark) USB300 audiometer with TDH-39 headphones. The modified Hughson-Westlake algorithm was used for determining the reference AC audiometric threshold [10]. After an initial explanation by the technician and a conditioning test at 1000 Hz, thresholds were recorded at 2000, 4000, 8000, 1000, 500, and 250 Hz in accordance with British Society of Audiology recommendations [11]. The hearing threshold criterion for each frequency was determined as the lowest intensity at which participants accurately signaled 2 confirmations out of 3 presentations. The number of false positive responses was manually recorded.

The DigiBel Index Test

DigiBel has been laboratory and biologically calibrated (Institute of Sound and Vibration Research, University of Southampton, United Kingdom; and Cheer-audiology, Royston, United Kingdom) to run specifically on any model iPad tablet (Apple) with Sennheiser HD 400S AC headphones (Wedemark, Germany).

A pretest embedded video provides instructions for use and a checklist ensures that the iPad volume is on maximum and the headphones are fitted correctly. Noise sampling, using the built-in Sennheiser headphone microphone, ensures that the ambient noise level is less than 40 dB prior to testing. Testing can be paused and restarted at any stage if the ambient noise level changes unexpectedly or interruptions occur. Configurable...
settings include a choice of warble or pure tone, test frequencies, ambient noise setting, and child or adult version of the test.

The user taps a central animated button on the iPad display when they hear the tone (Figure 1A). A conditioning step requires the user to accurately tap the button on hearing a random onset suprathreshold tone at 1000 Hz before testing can begin. During testing, the onset of the tone is randomized from 0 to 3 seconds after the appearance of the response button to avoid a predictable response pattern. The tone stops in response to the tap and a psychophysical staircase algorithm starting from 60 dB (10 dB down, 5 dB up) is followed in a 2 down, 1 up rule, requiring 5 reversals dependent on the user’s input. The final threshold is calculated as the mean of the final 3 reversal thresholds. Once completed, a standard audiometry graph and the number of false positive responses are displayed (Figure 1B). The user can choose to repeat testing or undertake BC testing to determine the functional effect on hearing levels.

Figure 1. (A) DigiBel test interface and (B) DigiBel audiometry graph.

For this study, DigiBel AC PTA was undertaken in the sequence 2000, 4000, 8000, 1000, 500, and 250 Hz and retested in the sequence 2000, 4000, 8000, and 500 Hz using the adult test version.

Statistics
Data were analyzed in R (version 4.1.2; R Foundation for Statistical Computing) [12,13]. Accuracy and TRT reliability were assessed through Bland-Altman analysis, a statistical approach enabling analysis of the agreement between 2 measurement methods by assessing their mean differences (mean bias) and upper and lower limits of agreement (SD 1.96). Qualitative appraisal of mixed effects model 2-way intraclass correlation coefficients (ICCs) between the threshold measurements from each device was based on conventional standards with moderate, good, and excellent agreement indicated by an ICC of ≥0.50, ≥0.75, and ≥0.90, respectively [14]. The correlation between calculated bias and mean threshold values was analyzed using Pearson correlation coefficients (PCCs). The percentages of DigiBel threshold measurements lying within 10 dB of both the reference test and the repeated DigiBel test were calculated [15,16]. Statistical significance was calculated for the mean bias where confidence intervals did not cross zero, and for ICC and PCCs where P<.05. To assess diagnostic efficacy, sensitivity and specificity for detection of hearing thresholds above 20 Hz were calculated, using automated PTA as the reference. The Student t test was used to compare the number of false positive responses for each test. Throughout, magnitudes were reported as the mean (SD) unless otherwise stated.

Ethical Considerations
The study adhered to the tenets of the Declaration of Helsinki and the protocol was approved by the Quality and Safety Committee of Cambridge University Hospitals National Health Service Foundation Trust as part of a service improvement project. The Quality and Safety Committee at Cambridge University Hospitals considered that formal ethics committee approval was not required for this no-risk service improvement study in a healthy, adult population and opined that verbal consent was sufficient in these circumstances to prevent the collection of patient identifiable information (approval for
Service Evaluation Project – PRN9288; dated April 11, 2023. No other demographic information other than age was recorded to maintain anonymity for this service improvement study. No compensation was offered for participating in the study.

Results

Participant Characteristics

A total of 32 healthy participants agreed to take part, but 2 participants were excluded due to malfunction of the reference automated PTA test. The 30 participants who completed both the reference and index tests were 21-66 (mean 27.9, SD 10.3) years. TRT data were collected from 29 participants (one volunteer left early due to time constraints). Feedback forms were completed by 24 participants (Figure 2).

Figure 2. Participant flow diagram.

Accuracy and Reliability of DigiBel

Across the 6 tested frequencies, threshold hearing levels of DigiBel compared with automated PTA gave an ICC of above 0.75 (good or excellent agreement) and \( P < .001 \) in every trial (Table 1; Multimedia Appendices 2 and 3). The mean lower limit of agreement (LOA) was \(-17.04 \) dB (SD 2.12 dB) and the mean upper LOA was \(20.39 \) dB (SD 3.41 dB). No significant bias was apparent except at 4000 and 8000 Hz where a small but statistically significant bias was apparent (2.62 and 4.60 dB, respectively), with DigiBel providing systematically higher threshold results at those frequencies (Figure 3). An agreeable level of threshold difference in audiometry assessments has previously been defined as 10 dB; 263 out of 360 (73%) of DigiBel threshold measurements were within this standard [16]. There was a significant positive PCC between the measurement bias and mean at 500 (\( P < .001 \)), 1000 (\( P = .005 \)), 2000 (\( P < .001 \)), and 4000 Hz (\( P < .001 \)) test frequencies.

\(^a\)LLoA: lower limit of agreement.
\(^b\)ULoA: upper limit of agreement.
\(^c\)ICC: intraclass correlation coefficient.
\(^d\)PCC: Pearson correlation coefficient (calculated for the relationship between measurement bias and mean for each frequency).
\(^e\)Comparison of threshold values (in dB) using Bland-Altman statistics and ICCs between DigiBel and standard automated PTA and DigiBel test and retest.
\(^f\)N/A: not applicable.

Figure 3. Comparison of DigiBel and automated pure tone audiometry using Bland-Altman plots at 6 frequencies. Bland-Altman plots comparing mean and difference in threshold measurements (in dB) for DigiBel and standard automated pure tone audiometry at 6 frequencies (in Hz). The 95% CIs are shaded for the bias (red) and 95% limits of agreement (blue).

In TRT comparisons, ICC was above 0.90 (excellent) at all tested frequencies: 500, 2000, 4000, and 8000 Hz (Table 1). No statistically significant mean bias was exhibited at any frequency. The mean lower LOA was –13.99 dB (SD 2.34 dB); the mean upper LOA was 15.76 dB (SD 2.20 dB). Overall, 85% of TRT thresholds were within 10 dB of each other.
Sensitivity and Specificity

The sensitivity and specificity of DigiBel for detecting 20 dB hearing loss at each frequency are shown in Table 2. When applied to the 4 frequencies used for screening (250, 1000, 2000, and 4000 Hz), DigiBel had 100% sensitivity (95% CI 87.23-100) and 72.73% (95% CI 54.48-86.70) specificity for detecting 20 dB hearing loss in adults in a quiet setting.

Table 2. Screening accuracy of DigiBel for hearing threshold >20 dB identified by automated pure tone audiometry.

Usability

Out of the 24 participants, 21 (88%) participants, while completing the questionnaire, did not regularly use digital health apps. All 24 participants rated DigiBel either good (15/24, 63% of participants) or excellent (9/24, 38% of participants); 7/24, 29% participants preferred the DigiBel test; 6/24, 25% participants preferred the standard test; and 11/24, 46% participants gave no test preference. A total of 21 (88%) participants agreed or strongly agreed that they would be confident to use DigiBel at home without help. The most common qualitative feedback given to the question “what is the best thing about the app?” was that it was easy or intuitive to use (17/24, 71% of participants). Answering “what is the worst thing about the app?” the commonest complaint was that the test was too long or boring (10/24, 42% of participants). One participant commented on environmental noise leaks through the headphones (Multimedia Appendix 1).

Discussion

Principal Findings

In 30 healthy adults with simulated unilateral conductive hearing impairment, DigiBel’s screening sensitivity and specificity were 100% (95% CI 87.2-100) and 72.73% (95% CI 54.45-86.7), respectively. The hearing threshold measurement mean bias between DigiBel and automated AC PTA was not significant except at 4000 and 8000 Hz, where it reached statistical significance (2.62 and 4.60 dB higher than the reference, respectively).

At least 5 validated downloadable apps enable automated AC audiometry, several of which support self-testing without clinician involvement [17]. Two apps, uHear (Unitron Ltd) and ShoeBOX (SHOEBOX Ltd) for iOS, include a BC audiometry facility [18,19]. uHear has been calibrated for use with commercial in-ear Apple headphones and ShoeBOX uses purpose-built audiometry headphones. DigiBel is not yet commercialized but its potential advantage is its calibration to purpose-built audiometry headphones. DigiBel is not yet commercial in-ear Apple headphones and ShoeBOX uses facility [18,19]. uHear has been calibrated for use with ShoeBOX (SHOEBOX Ltd) for iOS, include a BC audiometry clinician involvement [17]. Two apps, uHear (Unitron Ltd) and audiometry, several of which support self-testing without participation commented on environmental noise leaks through the headphones (Multimedia Appendix 1).
DigiBel than standard testing. This may be due to the higher number of stimulus presentations compared with the ascending method used in standard automated PTA. The sensitivity of the iPad screen to a tap compared with the standard audiometer’s hand-held responder may be an additional factor. There was no evidence in this study that the higher false positive rate translated into a systematic overestimation of hearing ability.

All participants rated DigiBel as good or excellent, but 42% (n=10) of participants complained that the test took too long or was boring. Test duration was not measured during this study, but threshold testing for 6 frequencies is expected to take approximately 13 minutes with DigiBel, several minutes longer than standard automated PTA, primarily due to its staircase-reversal algorithm. Study participants had performed retesting which may have contributed to the perceived length of testing. The children’s version of the app has cartoons designed to increase interest but, even so, the test duration of threshold audiometry may limit its usability in young children. The DigiBel screening test of 4 frequencies takes approximately 3 minutes and may prove more feasible in this, its target population.

To simulate a range of hearing thresholds in the participant cohort, an earplug was used. This is a major limitation of the study because the effectiveness of the earplug may have altered during testing and earplugs may not accurately mimic genuine hearing impairment. Although this study indicates that DigiBel has acceptable accuracy for detecting simulated hearing impairment in healthy adult volunteers, these results are not generalizable and software corrections are required prior to clinical use.

This preliminary study confirms that the DigiBel app is an acceptable and easy-to-use self-testing web-based tool that accurately detects more than 20 dB of simulated hearing impairment in adults. Minor modifications to the 1000, 2000, and 4000 Hz frequency-specific normalization factors used in the software algorithm which converts sound pressure levels to hearing level are required to ensure uniformity of sound output and accuracy across the range of hearing abilities. A study, conducted in primary school children attending a hospital audiology clinic, is underway to assess the accuracy of DigiBel in identifying conductive hearing impairment. Additionally, the innovative concept behind DigiBel will be tested: its ability to identify those children who could benefit from the temporary use of a BC hearing assistance kit for use at school and home, and the impact this has on quality of life (using a parent- or patient-reported outcome measure questionnaire) while waiting for specialist care.

Conclusions

The World Health Organization identifies hearing loss as a major global health issue, with two-thirds of people with severe hearing loss living in low and middle countries with poor access both to hearing testing (audiometry) or conventional hearing aids. It can affect many aspects of life such as education, employment, and communication, and result in social isolation. Several software apps like DigiBel, studied here, have been developed to enable individuals to test their own hearing in the community. Uniquely, DigiBel has the additional potential to identify individuals with hearing loss who could derive immediate hearing support from an affordable and rechargeable bone-conduction hearing assistance kit while waiting for specialist care.

This initial study of DigiBel provides confirmation that the app is easy to use and accurate at detecting simulated hearing impairment. It identifies some software corrections that may improve its accuracy and lays the groundwork for future clinical studies to assess DigiBel’s performance in children and adults with hearing impairment.

Acknowledgments

The authors thank Josephine Marriage and Martha Mann at Chears-audiology, Royston, Cambridge for their support with the biologic calibration of the DigiBel app and Tamsin Holland-Brown for improving the manuscript. This research was supported by the National Institute for Health and Care Research (NIHR) Cambridge Biomedical Research Centre (NIHR203312). The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care.

Conflicts of Interest

AS, AJT, and TK have declared that no competing interests exist. LA declares nonfinancial competing interests as the inventor of DigiBel, which was developed with funding from a Medical Research Council Confidence in Concepts Grant.

Abstract

Background: Poor sleep hygiene persists in college students today, despite its heavy implications on adolescent development and academic performance. Although sleep patterns in undergraduates have been broadly investigated, no study has exclusively assessed the sleep patterns of premedical undergraduate students. A gap also exists in the knowledge of how students perceive their sleep patterns compared to their actual sleep patterns.

Objective: This study aims to address 2 research questions: What are the sleep patterns of premedical undergraduate students? Would the proposed study protocol be feasible to examine the perception of sleep quality and promote sleep behavioral changes in premedical undergraduate students?

Methods: An anonymous survey was conducted with premedical students in the Medical Science Baccalaureate program at an R1: doctoral university in the Midwest United States to investigate their sleep habits and understand their demographics. The survey consisted of both Pittsburgh Sleep Quality Index (PSQI) questionnaire items (1-9) and participant demographic questions. To examine the proposed protocol feasibility, we recruited 5 students from the survey pool for addressing the perception of sleep quality and changes. These participants followed a 2-week protocol wearing Fitbit Inspire 2 watches and underwent preassessments, midassessments, and postassessments. Participants completed daily reflections and semistructured interviews along with PSQI questionnaires during assessments.

Results: According to 103 survey responses, premedical students slept an average of 7.1 hours per night. Only a quarter (26/103) of the participants experienced good sleep quality (PSQI<5), although there was no significant difference (P=.11) in the proportions of good (PSQI<5) versus poor sleepers (PSQI≥5) across cohorts. When students perceived no problem at all in their sleep quality, 50% (14/28) of them actually had poor sleep quality. Among the larger proportion of students who perceived sleep quality as only a slight problem, 26% (11/43) of them presented poor sleep quality. High stress levels were associated with poor sleep quality. This study reveals Fitbit as a beneficial tool in raising sleep awareness. Participants highlighted Fitbit elements that aid in comprehension such as being able to visualize their sleep stage breakdown and receive an overview of their sleep pattern by simply looking at their Fitbit sleep scores. In terms of protocol evaluation, participants believed that assessments were conducted within the expected duration, and they did not have a strong opinion about the frequency of survey administration. However, Fitbit was found to provide notable variation daily, leading to missing data. Moreover, the Fitbit app’s feature description was vague and could lead to confusion.
Conclusions: Poor sleep quality experienced by unaware premedical students points to a need for raising sleep awareness and developing effective interventions. Future work should refine our study protocol based on lessons learned and health behavior theories and use Fitbit as an informatics solution to promote healthy sleep behaviors.

Introduction
Sleep health has been recognized as an unresolved public health concern since 2006 [1]. Although sleep plays a vital role in adolescent health and development, poor sleep patterns continue to be associated with college students. A 2015 study showed that 70%-96% of college students sleep less than the recommended 8 hours on weeknights [2,3]. With the heavy prevalence of sleep deprivation, it is important to recognize the detrimental effects it can have. Starting with cognitive processing, poor sleep has been shown to have negative effects on working memory, attention span, and speed of processing [4]. With poor sleep, our bodies can also experience impaired immune function, more susceptibility to illnesses, increased risk of stress, and decreased physical functions [5]. In addition, emotional dysregulation and lower levels of subjective well-being can be observed [6]. As a result, students experience a consequential effect on their academic performance [7]. It is therefore imperative to understand and discuss the sleep patterns of adolescents, especially college students, in order to aid them with tools that can help avoid these consequences.

Additionally, it is possible that students who may appear to receive an adequate amount of sleep can experience poor sleep due to bad sleep quality. Sleep quality refers to both quantitative aspects of sleep such as duration, sleep latency, and number of arousals, and qualitative aspects such as depth and restfulness of sleep according to a 1998 Psychiatry and Research publication [8]. Poor sleep quality refers to the struggle of falling asleep or maintaining sleep. A recent 2022 study clarifies this definition by adding the component of individuals’ self-satisfaction with their sleep as another part of sleep quality [9]. A previous survey on college undergraduates found that only 34.1% of students displayed good sleep quality based on Pittsburg Sleep Quality Index (PSQI) scores [10]. The PSQI is a self-rated questionnaire that serves as a standard tool for measuring sleep quality [8]. The responses to questionnaire items allow researchers to determine a global PSQI score, which helps distinguish between good-quality and poor-quality sleepers. A PSQI score smaller than 5 (<5) signifies good sleep quality, whereas a PSQI score equal to or larger than 5 (≥5) indicates poor sleep quality. However, to diagnostically study sleep, polysomnography (PSG) can be conducted, which involves recording brainwaves, oxygen level in the blood, respiration rate, and physical movements to diagnose sleep disorders [11]. PSG is used to understand the sleep patterns of patients and why there might be disruptions [12].

A recent study on the sleep quality of college students explored the determinants of sleep quality [13], interventions for improving sleep quality, overall demographics of sleep patterns, and associations of poor sleep quality with health problems. Some studies [7,14] have approached the understanding of sleep through a comparison of different college majors. One such major or a group of students that is of interest to us are students who are premedicine (premedical) majors or undergraduate students on the prehealth track. However, there is limited exploration looking specifically at the sleep patterns of premedical undergraduate students (premedical students hereafter). Previous research in this area has largely been centered on the sleep quality of students who are in a medical school or graduate medical education program and focused on sleep-related disorders among them [15-19]. Numerous studies have measured the sleep patterns of medical students but have not focused on understanding the patterns [20-33]. To date, only 1 study has tested medical students on their sleep knowledge and has found a disconnect between their understanding of sleep facts and actual sleep quality [34]. This led to the focus of our study on the sleep quality perception of premedical students.

A student’s perception of his or her sleep habits can give us insights into whether perception influences sleep behaviors and quality. Many prior studies [35-38] have looked at sleep state misperception. This concept discusses how there is a disconnect between the amount of sleep people think they get versus their actual duration of sleep. Research on sleep state misperception has primarily been conducted on people dealing with varying mental health conditions or sleep disorders [35-38]. In this manner, our research focused on the effect of sleep quality perception on sleep patterns, which considers overall sleep quality rather than just duration, in a relatively healthy population comprised of premedical students. Literature shows that in medical students, perception of stress can have an impact on their well-being [39], while another study has confirmed that there is a positive effect of education on sleep in undergraduates [40]. However, there is a gap in the literature in terms of understanding how premedical students perceive their sleep versus their actual sleep patterns. Although one study comes close to answering this question by examining the beliefs of sleep hygiene in medical students compared to their actual sleep practices [41], the behavior of premedical undergraduates is yet to be explored and understood.

Current validation studies suggest that while PSG remains the gold standard, Fitbit is capable of monitoring various sleep parameters that do not significantly deviate from PSG measurements [42-44]. The overall objective of our research was to understand the sleep patterns of premedical students and create interventions to promote positive behavioral changes. Our pilot study focuses on answering the following 2 research questions:

1. How do premedical students perceive their sleep habits and knowledge of sleep hygiene compared to actual sleep patterns?
2. How do premedical students perceive sleep hygiene and its relationship with academic performance?
questions (RQs). What are the sleep patterns of premedical undergraduate students (RQ1)? Would the study protocol be feasible to examine the perception of sleep quality and promote sleep behavioral changes in premedical undergraduate students (RQ2)?

**Methods**

**Setting**

This study was conducted with premedical students from a Medical Sciences Baccalaureate Program (MSBP) at the University of Cincinnati, an R1: doctoral university and an undergraduate College of Medicine in the Midwest United States. The MSBP is a program designed to help premedical students prepare for professional graduate schools in the health care field. The 4-year program consists of 376 students as of October 2022.

**Study Design**

To address RQ1, a “Well-being and Sleep Survey” (the well-being survey hereafter) was distributed to collect subjective sleep patterns. To address RQ2, a small group of participants (MSBP premedical students) were recruited to evaluate whether the study protocol (Figure 1) was feasible and could generate valid data for analysis. Specifically, the participants put on the Fitbit Inspire 2 wearable watch to monitor their sleep patterns. These participants were then invited to a semistructured interview to understand their Fitbit app experience. As shown in Figure 1, during the 2-week pilot study period, participants progressed through preassessment (week 0), midassessment (week 1), and postassessment (week 2) periods. The well-being survey was filled out by participants at all 3 fixed time points. During week 0, a semistructured interview was conducted assessing participants about their typical sleep habits and their previous experience with wearable devices. Participants at this point were also prompted to fill out a form daily, reflecting their thoughts regarding the Fitbit sleep score they received the night before. On week 1, a midassessment was performed in which the participants were asked to speak about their previous week’s experience with the aid of the daily reflections they had previously filled for days 1-7. In order to prompt the participants, researchers displayed a line chart of the 7 responses gathered from participants’ daily forms to project their sleep score trends over the week. Researchers also listed all participants’ free-text responses so that they could elaborate specifically about their sleep corresponding to certain dates. Lastly, in week 2, participants reviewed the daily reflections for days 8-14, which was followed by a semistructured interview.
**Figure 1.** Flowchart of the study protocol tested on 5 premedical participants during the 2-week pilot study with Fitbit Inspire 2. Week 0 started with preassessment, conducted in person at the University of Cincinnati Medical Sciences building. Week 1 midassessment and Week 2 postassessment were conducted virtually through Microsoft Teams meeting. The data collection was conducted in 2 cycles. Participants 1, 2, and 3 began the 2-week protocol in the last week of July 2022 and finished in the second week of August 2022. Participants 4 and 5 began the 2-week protocol in the first week of September 2022 and finished in the third week of September 2022. All of the participants had varying start dates during this time frame, but each participant was available for 10 weekdays and 4 weekend days during the duration of the 2-week data collection. PGHD: patient-generated health data; PSQI: Pittsburg Sleep Quality Index.

**Ethics Approval**

This study was reviewed and approved by the University of Cincinnati Institutional Review Board (approval 2021-1119) and determined as not human subject research due to its collection on de-identified data and the focus on quality improvement. This institutional review board determination resulted in the avoidance of collecting detailed student demographics such as sex and age and the deidentification of all participant information in the data.
Participant Recruitment
The survey participants were recruited on a voluntary basis via email and GroupMe messages through the research team’s professional and personal network. The small group of participants for the protocol evaluation was selected from the survey participants as a convenience sample. This study was expected to target 100 survey participants and 5 protocol evaluation participants.

Data Collection
The well-being survey was distributed among all cohorts (years 1, 2, 3, and 4 students) of the MSBP program (N=376). The survey consisted of PSQI items (1-9) adjusted to items (1-11) to accommodate the web-based survey format due to some combined line items in the original paper format, requiring different lines in the web-based survey. The response components combined to calculate a global PSQI score (with a Cronbach $\alpha$ of .83) [8], which suggests a high degree of internal consistency. These items were followed by a few questions assessing students’ demographics and their perception of their sleep quality. The well-being survey was created in Microsoft forms with survey questions as listed in Table 1. For the protocol evaluation, 5 students were selected from the well-being survey pool. In addition to the sleep patterns collected from the self-reported PSQI survey and the objective Fitbit wearables, these 5 participants’ feedback on the protocol was collected through semistructured interviews. The interview was recorded and conducted on a virtual platform and further analyzed thematically [45]. For the Fitbit data collection, 5 Fitbit Inspire 2 watches were deployed—one for each participant. Fitbit data were collected by linking the watch to the participant’s Fitbit web account. During the semistructured interview in the midassessment, the participants were instructed to log into their account on Fitbit.com. Next, they were asked to navigate to “Settings,” select “Data Export,” and then click on “Request Data.” This generated an email request to the participant to “Confirm Export Request.” Finally, after confirmation, the participant received a downloaded data zip file with JSON files containing complete archive data. The participants were then prompted to email the zip file to the researcher. This process was again repeated during the postassessment. Table 1 identifies each question sequentially, as it was presented in the web-based Microsoft form, as well as categorizes it as either a PSQI question or a demographic question. PSQI questions are directly derived from PSQI questionnaire items (1-9), which are adjusted to items 1-11 in our survey to accommodate the web-based format as compared to the original PSQI questionnaire paper format. The description lists exactly how the questions were asked to premedical MSBP students. The response type specifies whether survey participants responded to the question by inputting free text or selecting their answers on the Likert scale or multiple choice.
Table 1. Well-being survey questions that were administered to 376 students in the Medical Sciences Baccalaureate program at the University of Cincinnati.

aPSQI: Pittsburg Sleep Quality Index.
bMSBP: Medical Sciences Baccalaureate Program.

Survey Data Analysis

After MSBP premedical students completed the well-being survey, the responses were analyzed as follows. First, the PSQI items (questions 1-11) were scored based on PSQI scoring guidelines. Then, a global PSQI score was assigned to each survey participant. Next, 3 analyses were made: (1) comparing student distributions with good PSQI scores (<5) versus poor PSQI scores (≥5) categorized by each cohort, (2) detecting the consistency between the perception of sleep quality and the PSQI score levels, and (3) finding the PSQI score differences on the perception of stress effect levels. Statistical analyses were performed to test the distribution homogeneity of each cohort using the chi-square test. The consistency between the perception of sleep quality and PSQI score will be tested using Cohen κ by grouping PSQI scores into corresponding sleep quality levels. For comparing the global PSQI score differences between stress effect levels, global PSQI scores were first treated as a continuous variable and the equality of medians on each group was tested using the Kruskal-Wallis test (nonparametric equivalent test of 1-way analysis of variance) to show any statistical difference. Furthermore, the post hoc Dwass-Steel-Critchlow-Fligner multiple comparisons test was applied to show the pairwise comparisons if at least one group median was significantly different from others.
Protocol Evaluation

The protocol evaluation was 2-fold. First, each assessment had an expected duration to avoid overwhelming the participants. The expected durations of the preassessments, midassessments, and postassessments were 30 minutes, 30 minutes, and 60 minutes, respectively. The postassessment was longer due to the semistructured interview. Second, the semistructured interview collected the participants’ feedback on the study protocol in 4 areas: (1) duration of the 3 (pre, mid, and post) assessments, (2) frequency of administering the well-being surveys, (3) completeness of Fitbit data, and (4) other suggestions. An additional analysis was conducted to assess the degree to which Fitbit data aligns with the self-reported data obtained through surveys by using Pearson correlation coefficients where >|0.7| is strong correlation, |0.3|-|0.7| is moderate correlation, and <|0.7| is poor correlation (of note, the vertical lines present the absolute value sign).

Results

Survey Responses and Analysis Results

The survey responses (n=103) demonstrated that premedical MSBP students sleep an average of 7.1 hours each night with 81.3% habitual sleep efficiency (average hours slept versus hours spent in bed, as defined in PSQI). Those who experienced trouble sleeping commonly expressed reasons such as not being able to sleep within 30 minutes, waking up in the middle of the night or early morning, anxiety, stress, and a restless mind. Among the cohorts (Figure 2), no significant difference was found in the median PSQI scores as indicated by the Kruskal-Wallis test at a .05 significant level (P=.11). Similarly, the proportion of students who had good versus poor sleep was not significantly different as indicated by the chi-square test (P=.48). This concludes that the distributions have no significant differences in the good or bad PSQI scores among the student cohorts. It is worth noting that the response rates of the survey for the first-, second-, third-, and fourth-year cohorts were 38% (33/88), 23.4% (25/107), 23% (20/86), and 26% (25/95), respectively. Further, the same analysis was applied to the categorical variables collected in the survey data (Multimedia Appendix 1), including 2 non-PSQI variables (perceived sleep quality and perceived stress). The only significant difference was that the first-year students tended to take medicines to help themselves to sleep unlike the other cohorts (P=.03). However, there was no significant difference between the low frequency group (less than once a week and no medicine) and the high frequency group (once a week or more). To demonstrate the consistency between the perceived sleep quality and the PSQI scores, we assumed that students who perceived “no problem at all” will receive PSQI global scores <5, those who perceived “only a very slight problem” will receive PSQI global scores of 5-7, those who perceived “somewhat of a problem” will receive PSQI global scores of 8-10, and those who perceived “a very big problem” will receive PSQI global scores ≥11. The Cohen κ (with 1 being a perfect consistency) showed that participants’ perceived sleep quality only had a slight consistency with the PSQI scores (κ=0.19). Table 2 shows the contingency of these 2 variables with an overpositive tendency from participants, that is, the bigger the problem the participants perceived in their sleep quality, the poorer the PSQI score they would receive. However, the table shows some inconsistencies. When participants perceived no problem at all in their sleep quality, 50% (14/28) of them actually had a nonoptimal PSQI score. When the participants thought there was only a very slight problem in their sleep, about a quarter of them (11/43, 26%) had a poor PSQI score. When the participants appeared to recognize that they had somewhat of a problem (or a big one) in their sleep, the majority of them had nonoptimal PSQI scores.

Finally, the comparisons between perceived stress impact and median global PSQI scores in each perceived stress level were analyzed (Figure 3). The Kruskal-Wallis test shows there is at least one median that is significantly different (P<.001) from others at the .05 significant level. The post hoc Dwass-Steel-Critchlow-Fligner multiple comparisons was applied and showed that the students who perceived “a very big problem” on the stress effect had significantly greater PSQI scores than the students who perceived “no problem at all” (P=.048) and “only a very slight problem” (P<.001). Similarly, for the students who perceived “somewhat of a problem,” the stress effect was significantly greater than that in students who perceived “only a very slight problem” (P=.001) but not significantly different from the “no problem at all” stress level (Table 3). This indicates that participants’ perceived stress effects have high correlation with their PSQI scores, but it may not be the only effect at play.

**Process Evaluation and Participant Feedback**

Overall, the participants reported the Fitbit app as a helpful tool in understanding their sleep. They were especially excited to visualize their sleep stage breakdown and obtain an overview of their sleep by simply looking at their Fitbit sleep score. The participants’ feedback on the study protocol was summarized in the following 4 areas.

First, all assessments were conducted in the expected duration, that is, 30 minutes for the preassessment and midassessment and 60 minutes for the postassessment. The web-based mode of midassessments and postassessments did not create any barriers to the data collection. The feedback also revealed that the interview component in all 3 assessments was effective and served different purposes. Specifically, the interview in the preassessment made the participants think about their previous experiences regarding sleep and patient-generated health data devices. The midassessment interview, which reviewed daily reflections at a glance, invoked awareness among participants. The interview in the postassessment was the most comprehensive as it gathered thoughts on daily reflections and assessed Fitbit data comprehension. The administered questionnaires in preassessments, midassessments, and postassessments, as shown in Figure 1, had a 100% response rate because participants were required to complete it during the semistructured interview. The global PSQI scores for 5 participants across the 2 weeks are shown in Figure S1 in Multimedia Appendix 2. The daily reflections also had a 100% response rate, as several reminder emails were sent out to ensure data collection.

Second, the participants did not have a strong opinion about the frequency of the well-being survey administration (3 times over a 2-week period in this study). However, the survey scores did not display much variation or clear trends. Although this can be due to the small group of participants (n=5), it may be more ideal to conduct the survey with more spaced durations.

Third, the Fitbit data provided notable variation daily and was able to grasp all 14 days well for the most part. Some participants experienced cases during which Fitbit would sense bed and wake time but would not be able to provide detailed analytics on the sleep stages or on the sleep score. For these participants, some of the issues included wearing the Fitbit too snug or loose or wearing the Fitbit only right before going to bed. In other cases, participants simply appeared to forget to put on their Fitbit watch after removing it for charging, leading to a void of data points. The participants were fairly adherent to completing daily reflections on time and found that a daily email reminder from the research team helped greatly with this task.

Lastly, the participants identified that the Fitbit app tends to provide vague descriptions. For example, the biggest concern raised was not being able to understand how the sleep score was calculated. This made participants question the score’s reliability and accuracy. Similarly, some participants highlighted redundancy of information (sleep stage condensed cycling), whereas others suggested presenting information in a more visually appealing manner (pie chart to see sleep stage breakdown), individualized manner (suggesting sleep recommendations based on score trends), and sleep score explainability (being specific to why a score may have dropped/raised on a day-by-day basis).

Finally, the degree to which Fitbit data aligns with the PSQI self-reported data obtained through surveys was assessed. Overall, across the 2-week period, there was a moderately negative correlation (r=−0.598) calculated from the data shown in Table S1 of Multimedia Appendix 2. In context, this means high Fitbit scores, indicating good sleep, were correlated with low global PSQI scores, also indicating good quality of sleep. Week 1 had a strong negative correlation (r=−0.87) compared to Week 2, which had a moderate negative correlation (r=−0.648).

**Discussion**

**Principal Findings**

This study presents the sleep patterns of premedical students through a sleep and well-being survey and evaluates a study protocol in preparation for a large-scale study. The survey showed that although the participants did have an average of 7 hours of sleep in general, only a quarter of them had good sleep quality. There was no difference in sleep quality among the student cohorts. Furthermore, there was an inconsistency between the perceived sleep quality by the students versus what their PSQI scores reflected. The poor sleep quality experienced by unaware students points to the need for self-monitoring through wearables such as Fitbit devices to increase sleep quality awareness. Lastly, a comparison of stress effect on sleep with PSQI scores establishes that sleep is not the only dominant factor in PSQI. The participants who perceived stress to play no role in their sleep still displayed a wide range of PSQI scores. Our findings show that the study protocol is highly feasible in terms of assessment durations and interview effectiveness. The usage of Fitbit devices did increase participants’ awareness to completing daily reflections on time and found that a daily email reminder from the research team helped greatly with this task.

Lastly, the participants identified that the Fitbit app tends to provide vague descriptions. For example, the biggest concern raised was not being able to understand how the sleep score was calculated. This made participants question the score’s reliability and accuracy. Finally, the degree to which Fitbit data aligns with the PSQI self-reported data obtained through surveys was assessed. Overall, across the 2-week period, there was a moderately negative correlation (r=−0.598) calculated from the data shown in Table S1 of Multimedia Appendix 2. In context, this means high Fitbit scores, indicating good sleep, were correlated with low global PSQI scores, also indicating good quality of sleep. Week 1 had a strong negative correlation (r=−0.87) compared to Week 2, which had a moderate negative correlation (r=−0.648).
regarding their sleep based on the qualitative feedback, along with their overall understanding of sleep factors. Participants keeping track of their sleep via daily reflections also aided in their cognizance. Based on the feedback, the study protocol can be improved by extending the duration, educating individuals about the Fitbit-wearing behaviors, and increasing the sleep score interpretability.

In assessing how the Fitbit sleep score data align with the global PSQI scores, we found a moderate negative correlation. This makes sense because higher Fitbit scores, suggesting good sleep, aligned with lower global PSQI scores, which indicates good sleep quality. Therefore, achieving moderate to high correlation displays a good potential for Fitbit sleep scores to serve as a proxy for PSQI global scores. Although week 1 gathered a stronger correlation than week 2, we believe that this result may be due to greater missing data in week 2, either from fatigue or nonadherence.

Implications

Our study shows that only 25.2% (26/103) of the participating premedical students had good sleep quality, as indicated by the PSQI scores. This proportion is lower than that (34.1%) previously reported among college students in general [10]. This leads us to a possible inference that premedical students may have sleep patterns different from those of college students overall. Our study also introduces a new direction, in which sleep patterns are not only measured but further analyzed to determine discrepancies between perception versus actual sleep quality. Prior studies [17,46] looking at sleep patterns in medical school students or undergraduate college students in general could also benefit from this approach and take their sleep analysis to the next step. For example, a 2016 study conducted on undergraduates at the University of California explored relations between sleep and mental health in individuals with healthy sleep habits [17]. Hence, further understanding the sleep perceptions of these healthy students could be used to create a benchmark to which other types of sleepers can be measured relatively. Another application could include a longitudinal study, similar to the one proposed by the University of South Wales in Australia [46]. This 5-year study provides insights into the mental health of medical students, with sleep being one of the factors measured via Fitbit. By incorporating the concept of sleep and well-being perceptions, the longitudinal approach may provide a better understanding of whether perceptions stay consistent or change over time.

The increase in awareness regarding sleep due to Fitbit usage mentioned by the participants also opens an area for possible interventions. As previous literature has reported, when individuals are educated in a personally relevant manner, their awareness leads to behavior change [47-49]. An important component of behavior change is self-efficacy, which is the perception of one’s ability to achieve certain outcomes [50-52]. Hence, interventions can begin with Fitbit usage to increase participant awareness regarding why they need to make a change, establish how certain health behaviors will lead to expected outcomes, and then provide ways for participants to reach those outcomes [53,54]. Conversely, I study has tested a habit loop model, which is based on cue, routine, and reward [55]. The Fitbit usage behavior in terms of the habit loop model can be as follows: trust in Fitbit accuracy of physical and sleep data (cue), intensity of Fitbit use (routine), and adjustment of physical and sleep behaviors (reward). Although this study shows that trust in Fitbit produced little changes in sleep and health behaviors, future studies should be built upon this foundation to examine the potential behavioral change through the supplementation of educational information to participants.

In the evaluation of the protocol itself, there were inconsistencies in obtaining sleep scores from Fitbit at times. A pre-existing measure during this study was placing instructions in the daily reflection reminder email to contact the research team immediately if they received no score in order for the research team to troubleshoot. Some other troubleshooting measures could help ensure participants wear their Fitbit at all times. For example, the study team can propose a standardized charging time that prompts participants to remove and charge their Fitbits during our week 1 midassessment session and wear the Fitbit again at the conclusion of the meeting. This can prevent participants from forgetting to wear their Fitbits during the study period. Not all participants explored all the features of Fitbit’s sleep interface. This points to the need to give participants a tutorial about the various types of analytical information available that participants can browse through to understand their sleep patterns. Finally, for the Fitbit data retrieval process, researchers asked the participants to download their data from the Fitbit.com website in week 1 and week 2 assessments. This proved to be a time-consuming process; therefore, the protocol was updated to begin data download at the beginning of the assessment meeting, which allowed the download to be finished by the end of the meeting. These lessons learned help to refine our study protocol and will lead to higher data quality in our large-scale study.

Limitations

This study is limited in several ways. First, the assessment was conducted with premedical students from a single program in a single institution. Hence, it is possible that the findings were limited to the student demographics in our institution. Additionally, the well-being survey administered in this study did not ask for their sex, race, or age due to the constraints in the institutional review board protocol. Thus, this analysis does not demonstrate whether demographic factors are linked with certain sleep patterns. Moreover, this study did not consider the academic performance of the participants and its relationship with sleep patterns. Demographic information and academic performance will be collected in our future studies with an updated institutional review board protocol. Next, we only recruited 5 students via convenience sampling for protocol evaluation. Small sample sizes introduce the possibility of skewed opinions. However, it should be noted that the goal of this study was to test the protocol rather than any hypothesis. Additionally, the Fitbit usage habits demonstrated by the pilot study group point to the need to improve the Fitbit usage protocol. For example, participants were advised to always wear their Fitbits except while charging. However, some students after charging their Fitbit forgot to wear it overnight, thereby leading to nonadherence. Another instance involved a participant using the “sleep now” function offered by the watch to track
sleep, even though the participants were not instructed on that feature’s use. Using that function did dysregulate the visualization data, which returned to normal once the participant was asked to terminate the function’s usage.

Future Work
With the findings gathered from this pilot study, we hope to expand to a larger experiment within the MSBP and expand to premedical programs at other institutions. We hope to address sleep quality discrepancies and determine a feasible solution for sleep hygiene improvement in premedical students. Another future work involves the calculation of Fitbit sleep scores especially when the sleep data are collected but the sleep score is missing. In this study, we tried to explore how the Fitbit score was calculated and attempted to assess trends. Fitbit informs everyone that their sleep score is devised from 3 pieces of information: time asleep and awake, deep and rapid eye movement sleep, and sleeping heart rate and restlessness.

However, it is unclear how exactly the sleep score values are formed. Therefore, it was difficult to generate actionable information. Hence, this topic should be further explored to determine whether sleep scores are indeed valid measures of sleep.

Conclusions
We conducted a pilot study to understand the sleep patterns of premedical undergraduate students and evaluated the study protocol. The survey results showed a generally lower sleep quality for this student population and posited a gap between the perceived sleep quality versus PSQI-measured sleep quality. This gap may be solved by the awareness raised by Fitbit usage. We will revise the study protocol based on the lessons learned and health behavior theories and conduct a large-scale experiment to use Fitbit as an informatics solution to promote healthy sleep behaviors.

Acknowledgments
This research did not receive any funding. We thank Dr Anil Menon, Director of the Medical Sciences Baccalaureate Program at the University of Cincinnati College of Medicine, for supporting the implementation of this study along with the student tribunal for the recruitment efforts. In addition, we thank Dr Claudia Rebola, Co-Principal Investigator of the WorkWell project, for providing Fitbit watches for data collection.

Abstract

Background: Perinatal depression (depression during pregnancy or the first year postpartum) affects 10%–25% of perinatal individuals, with a higher risk among youths aged <25 years. The Mothers and Babies Course (MB) is an evidence-based intervention for the prevention of perinatal depression, grounded in cognitive behavioral therapy, attachment theory, and psychosocial education.

Objective: We developed a digital adaptation of MB (Interactive Maternal Group for Information and Emotional Support [IMAGINE]) and evaluated it in a pre-post mixed methods pilot among young perinatal people in the United States.

Methods: IMAGINE was a structured digital group of up to 7 participants, with scheduled MB content and open discussion for 12 weeks, facilitated by a social worker. Scheduled content included asynchronous SMS text messages, graphics, prerecorded videos, mood polls, and optional weekly synchronous video calls. Eligible participants were pregnant or ≤80 days postpartum, aged 16 to 24 years, had access to a smartphone, spoke English, and had a Patient Health Questionnaire score <10. Participants were recruited throughout the United States from August 2020 to January 2021 through paid social media ads, in-person outreach at clinics, and respondent-driven sampling. Participants completed quantitative questionnaires at enrollment and 3 months, and qualitative interviews at 3 months. We determined uptake, acceptability (by Acceptability of Intervention Measure score), and utility (by use of cognitive behavioral therapy skills). We compared depression symptoms (by Patient Health Questionnaire score), social support (by abbreviated Social Support Behavior score), and perceived stress (by Perceived Stress Score) between enrollment and follow-up by paired 2-tailed t test.

Results: Among 68 individuals who contacted this study, 22 were screened, 13 were eligible, and 10 enrolled, for an uptake of 76.9%. Furthermore, 4 (40%) participants were pregnant at enrollment. Participants had a median age of 17.9 (IQR 17.4-21.7) years, 6 (67%) identified as Black, 5 (56%) Latinx, and 6 (67%) using Medicaid health insurance. Further, 9 (90%) participants completed follow-up. Among these, the mean acceptability score was 4.3 out of 5 (SD 0.6) and all participants said they would recommend IMAGINE to a friend. Participants reported using a median of 7 of 11 skills (IQR 5-7 skills) at least half the days. We found no significant changes in depression symptoms, perceived stress, or social support. Qualitatively, participants reported one-to-one support from the facilitator, connection with other parents, and regular mood reflection were especially helpful aspects.
of the intervention. Additionally, participants reported that the intervention normalized their mental health challenges, improved their ability to manage their mood, and increased their openness to mental health care.

**Conclusions:** This pilot study provides promising evidence of the acceptability and utility of IMAGINE among perinatal youths. Our study’s small sample size did not detect changes in clinical outcomes; our findings suggest IMAGINE warrants larger-scale evaluation.

**Introduction**

Perinatal depression, defined as depression during pregnancy or up to 1 year after childbirth, affects an estimated 10%-25% of birthing people in the United States [1,2]. Untreated, perinatal depression can have long-term negative impacts on birthing parents and newborns, including elevated risk of suicide [3], preterm birth [4], low birth weight [5], and impaired infant attachment [6]. Young parents (aged 15 to 24 years), those with low income, and people of color experience elevated risks of perinatal depression [7,8].

Despite many programs aimed at reducing the incidence of adolescent pregnancy in the United States, nearly 23% of all pregnancies occurred in people aged 15 to 24 years in 2020 [9]. Young parents are more likely to have risk factors that place them at greater risk for perinatal depression, including unplanned pregnancy, social isolation, and intersecting social determinants of health [10,11]. Many barriers to mental health care exist for perinatal youths, including lack of financial resources to pay for treatment, lack of access to or money for transportation, and difficulty finding childcare and missing work to attend appointments [8]. Young parents are therefore a key group needing innovative and tailored perinatal mental health support.

Evidence-based interventions have been developed to prevent and treat perinatal depression. The Mothers and Babies Course (MB) is a cognitive behavioral therapy (CBT) program developed for low-income racial minority women in the United States [12]. MB can be delivered to individuals or groups and is focused on building participants’ skills in modifying their thoughts, social contact, and pleasant activities. Further, 4 randomized controlled trials of the MB program found it reduced depressive symptoms in the perinatal period, and it has been rolled out at scale in the United States through home visiting programs [13-18]. MB has been recognized by the US Preventive Services Task Force as an evidence-based intervention that should be recommended for individuals at high risk of perinatal depression [19]. Despite these advances, there are barriers to accessing interventions such as MB, due to regional provider shortages, lack of transportation and childcare, clients’ difficulty committing to a prespecified time to attend sessions, and experienced or internalized stigma of seeking mental health care [20]. These barriers may be higher among those at the highest risk of perinatal depression, and barriers were further exacerbated by the COVID-19 pandemic and consequent physical distancing protocols [21-24].

Mobile phones can be used to offer more accessible mental health support to young parents (known as mobile health [mHealth]). mHealth interventions have shown promising results in improving perinatal mental health [25-30], and young people in the United States are an ideal audience for such programs: nearly all Americans aged 18 to 29 years own a phone, and 96% own a smartphone [31]. mHealth can eliminate the need to travel to appointments, and asynchronous mHealth programs allow patients to access care within their schedules, which can be especially helpful to parents [32]. Group mHealth interventions allow new parents to connect with and share ideas with peers, which can lower feelings of social isolation and increase social support and mental well-being [33].

We developed a digital adaptation of MB for the prevention of perinatal depression in youths, named Interactive Maternal Group for Information and Emotional Support (IMAGINE) [34]. In this paper, we present a mixed methods evaluation of a pilot study of the IMAGINE intervention, assessing the uptake, acceptability, and utility of IMAGINE.

**Methods**

**Study Design**
We conducted a single-arm pilot study with pre-post mixed methods evaluation.

**Study Population and Recruitment**
Participants were eligible to participate in the IMAGINE pilot if they were: pregnant or ≤180 days postpartum, aged 16 to 24 years during pregnancy, had daily access to a smartphone, and were comfortable conducting study visits and reading and responding to social media messages in English. Individuals who exhibited elevated depression symptoms at screening (Patient Health Questionnaire [PHQ-9] score ≥10 [35]) were excluded and referred to individual clinical care.

Participants were recruited between August 2020 and January 2021, through 3 main methods. First, study information was shared through paid, targeted advertisements on Instagram and Facebook throughout the United States. Specific parameters used to target participants were: female sex, aged 16 to 25 years, located anywhere in the United States. Second, this study’s team identified health care providers and community-based organizations in several cities in the United States (Seattle, WA; Olympia, WA; Philadelphia, PA; and Temple, TX) and provided materials for staff at these organizations to promote this study by distributing flyers. Finally, we used respondent-driven...
sampling [36] to encourage participants who enrolled in this study to invite their peers to participate; a financial incentive of US $20 was offered to the referring participant if their referred peer enrolled.

Potential participants who learned about this study through any method contacted this study by phone call, text message, email, Instagram message, or by sending a message through this study’s website. Study staff then contacted potential participants to conduct eligibility screening by phone or video call. If participants were ineligible due to elevated depression symptoms at screening, study staff shared the National Crisis Line phone number and offered support to find treatment near their location. This study’s team psychiatrist was available to support linkage with resources.

**Informed Consent**

Informed consent was obtained by study staff for screening and enrollment. Participants provided verbal consent to participate in eligibility screening. Eligible participants provided written consent for study enrollment, using a web-based consent form on REDCap (Research Electronic Data Capture; Vanderbilt University) [37].

**Study Visit Schedule**

Participants enrolling in the IMAGINE pilot attended 2 study visits by video call: enrollment and 3-month follow-up after completion of the intervention. Quantitative data were collected at enrollment and follow-up using a REDCap web-based questionnaire. Qualitative interviews were additionally conducted at follow-up.

**Intervention**

The IMAGINE intervention was a facilitated digital group adaptation of the evidence-based MB program [12], developed through a human-centered design process described elsewhere [34]. MB content focuses on engagement in pleasant activities, healthy thinking, and social support, and is grounded in CBT, attachment theory, and psychoeducation. IMAGINE was delivered using the messaging platform, Slack (Slack Technologies, Salesforce Inc), to groups of up to 10 participants, facilitated by a member of this study’s team with Master’s-level training as a social worker. Groups ran for approximately 12 weeks. Participants were grouped based on the timing of enrollment: groups were filled sequentially as participants enrolled. Guided by our formative work [34], the intervention consisted of multimedia adaptation of MB content, delivered through 5 components. First, MB session content was delivered asynchronously, through short SMS text messages, summary graphics, and prerecorded videos sent approximately 4 times per week. Messages were designed to promote group discussion or personal reflection. Participants were encouraged, but not required, to participate in group discussions by sending messages and reacting to other participants’ messages, at a time that was convenient for them. Second, an automated “mood poll” was sent to each participant individually 3 times per week, prompting the participant to reflect on their mood, activities, thoughts, and social contacts. Third, the facilitator was available for individual messaging through Slack. This was used for the facilitator to answer questions and send messages when a participant showed low engagement in other parts of the intervention. Fourth, participants could send messages on topics beyond the MB curriculum, through separate Slack “channels” (parallel conversations all members had access to): “ask an expert,” where participants could send questions for members of this study’s team with expertise in obstetrics and psychiatry; “random,” where participants could share any content; and “references,” where the facilitator posted graphics summarizing intervention content and links to resources. Fifth, in addition to asynchronous messaging content, the facilitator held a weekly 1-hour synchronous group video call, using the videoconferencing platform, Zoom (Zoom Video Communications, Qumu Corporation). Participation in the call was optional, to reduce barriers to participation due to scheduling and attendance challenges. No new content was delivered on the call, but participants could ask questions, share experiences, and receive support from the facilitator and other group members. Intervention content was developed in advance of the intervention and manually sent by the facilitator, except for mood polls, which were automatically scheduled within Slack. The facilitator could exercise discretion in message pacing based on participant feedback and questions during the intervention period. All 5 elements of the intervention were considered to be active components in engaging MB’s mechanism of action.

**Quantitative Data Collection**

**Recruitment Log**

A spreadsheet was used by study staff to record participants who contacted the IMAGINE study and their completion of eligibility screening.

**Screening Questionnaire**

Screening was completed verbally by phone or video call and responses were entered by study staff into an electronic questionnaire using REDCap, hosted at the University of Washington [37]. The screening questionnaire ascertained pregnancy status, age, access to a smartphone, comfort in English, and depression symptoms by PHQ9.

**Enrollment Questionnaire**

Enrollment of eligible participants was conducted either immediately following consent or at a separate scheduled visit, based on participant preference. The enrollment questionnaire was administered using REDCap by study staff through Zoom or phone calls. If conducted by video call, study staff screen-shared the REDCap questionnaire and read each question aloud so the participant could see and hear the questions and responses; data were entered by study staff. The enrollment questionnaire ascertained demographic characteristics and technology access. It also included an abbreviated 12-item version of the Social Support Behavior (SSB) instrument [38] to ascertain social support (score range 5-60). We used an abbreviated version of SSB to reduce the burden of data collection on participants. This version of the SSB has not been psychometrically validated. We used the Perceived Stress Score (PSS-4) instrument [39] to ascertain perceived stress (score range of 0-16). This instrument has previously been used in MB studies and is recommended for comparability [40,41].
Instrument reliability was previously reported as Cronbach $\alpha$ .72 [39].

Follow-Up Questionnaire
A follow-up visit was conducted at 3 months. The week after the completion of the IMAGINE intervention, a member of this study’s team other than the group facilitator contacted participants and arranged a follow-up study visit, conducted via Zoom video conference. The follow-up electronic questionnaire was administered using REDCap and assessed pregnancy status, PHQ9, abbreviated 12-item SSB, PSS-4, and acceptability of IMAGINE via the Acceptability of Intervention Measure (AIM) [42]. The AIM scale is 4 Likert scale questions with possible responses scored 1-5: completely disagree, disagree, neither agree nor disagree, agree, and strongly agree. The score is calculated as the mean numerical value of the responses across the 4 items. Instrument internal consistency and validity were previously reported as Cronbach $\alpha$ .85 and confirmatory factor analysis loadings 0.75-0.89 [42]. Participants were also asked how often they had used key CBT skills over the past month, using a Likert scale with possible responses: not at all, a few times, half the days, most of the days, and every day. The following questions were asked about mood tracking, engaging in pleasant activities, overcoming obstacles to engage in pleasant activities, thought interruption to reduce harmful thoughts, designated worry time to reduce harmful thoughts, time projection to imagine a better time in the future, self-instruction, positive contact with others, soliciting positive support from others, and using assertive communication. These questions were modeled on the core CBT components of the MB program [17]. If a participant reported the use of a skill, they were asked how helpful the skill was, using a Likert scale with possible responses: not helpful at all, somewhat helpful, or very helpful. Study staff screen-shared the REDCap questionnaire, as in the enrollment visit.

Engagement data
We quantitatively assessed engagement in the different components of IMAGINE. Messaging data from all Slack channels was exported as an HTML file. Message counts for each group member were determined by searching for each member’s username and counting the number of occurrences in the file. Completion of automated mood polls was determined based on reports from the Polly tool within Slack that was used to send polls. Attendance of each group member in Zoom calls was recorded by the facilitator.

Quantitative Data Analysis
We calculated descriptive measures of uptake, acceptability, and utility. Uptake was defined as the percentage of screened, eligible participants who enrolled in the intervention. Acceptability was determined based on self-report responses to the AIM. Utility was defined as the percentage of participants who reported using each CBT skill discussed in MB at least half the time. Additionally, among those who used each skill at least half the time, the percentage of participants who found it to be helpful was calculated.

We determined pre-post change in indicators of mental wellness. Depression symptoms were determined by PHQ9 score, calculated according to instrument guidelines, with a possible range of 0-27. Social support was calculated using the abbreviated SSB, as the sum score over all questions referring to family support and separately those referring to friend support. The mean and SD for each score were summarized for each time point. Scores at the 2 time-points were compared by paired 2-tailed $t$ test. RStudio (version 2023.06.0+421; Posit) was used for all data analysis.

Qualitative Data Collection
Qualitative In-Depth Interviews (IDIs) were conducted with all study participants at the 3-month follow-up visit. IDIs were conducted virtually over Zoom using a semistructured interview guide designed by this study’s team. The guide explored participants’ experience in the intervention, utility and potential improvements to each component of the intervention, level of engagement with intervention content, barriers to participation, and recommended improvements for future intervention implementations.

Qualitative Data Analysis
We conducted a thematic analysis of IDIs using a mixture of inductive coding driven by themes emerging from the transcripts and deductive coding based on themes from the interview guide. Qualitative analysis focused on the perceived acceptability and mental health impact of the IMAGINE intervention as well as recommendations for future iterations. First, 3 members of this study’s team (KR, EW, and AG) read all transcripts and separately developed initial codebooks based on themes that emerged from the transcripts and were explored in the interview guide. Initial codebooks were compared and discussed to create an agreed-upon combined codebook. Transcripts were then coded by 2 analysts (EW and AG) using Dedoose (Sociocultural Research Consultants, LLC) software [43]. Disagreements between analysts were resolved through discussion.

Ethical Considerations
The IMAGINE study was approved by the University of Washington Institutional Review Board (STUDY00008278). All participants provided informed consent for eligibility screening, exposure to the intervention, and data collection. Waivers were obtained for written documentation of informed consent and parental consent for adolescents younger than 18 years.

Results

Participant Flow and Intervention Uptake
Figure 1 summarizes participant flow from contacting this study to completing screening, enrolling in this study, and completing follow-up. In total, 68 individuals contacted this study between October 16, 2020, and January 29, 2021. Of these, 22 were assessed for eligibility, while 46 individuals did not complete screening due to challenges scheduling screening calls or participants declining to complete screening. Of the 22 who were assessed, 13 were eligible and 9 were ineligible, most (n=7, 77.8%) due to elevated depression scores warranting referral to individual care. In total, 3 eligible participants declined participation and 10 eligible participants were enrolled.
in the pilot, for an uptake of 76.9% (10/13 eligible participants). Participants were divided into 2 intervention groups: 7 in group 1 (active December 2020 to February 2021) and 3 in group 2 (active February to May 2021). While groups could be up to 10 participants, we elected to initiate the first group when 7 participants had been enrolled to minimize participants’ wait, while recruitment of the remaining participants continued. Of the 10 study participants, 9 completed the 3-month follow-up questionnaire and IDI.

**Figure 1.** Participant flow. PHQ-9: Patient Health Questionnaire.

### Participant Demographic Characteristics

Demographic characteristics of enrolled participants are summarized in **Table 1**. All participants identified as female, and the median age was 17.9 (IQR 17.4-21.7) years. Of 9 participants who provided their race or ethnicity, 6 (67%) identified as Black, 5 (56%) identified as Latinx, 1 identified as an unlisted category, and 2 (22%) identified as White. Further, 4 (40%) participants were bilingual and 5 (50%) had completed at least a high school diploma or general education development. In total, 4 (40%) participants were pregnant at the time of this study and 6 (67%) used Medicaid health insurance. All but one of the participants reported that they were stably housed.

Intervention Acceptability and Utility

Quantitative Assessment

Among the 9 participants who completed follow-up, we found a mean acceptability score of 4.3 out of 5 (SD 0.6) on the AIM questionnaire. All participants reported that they would recommend IMAGINE to a friend. When asked about the use of core CBT skills covered in MB, all participants reported engaging in “playing with baby,” “contact with others,” and “talking to/contacting someone who has been a positive support for self and baby” skills during at least half the days in the prior month (Table 2). The majority reported using the following skills at least half the days: “mood tracking” (n=6, 66.7%), “engaging in pleasant activities” (n=6, 66.7%), “overcoming obstacles to doing pleasant activities” (n=6, 66.7%), “thought interruption to reduce harmful thoughts” (n=5, 55.6%), “using time projection to imagine a better time in the future” (n=6, 66.7%), and “using self-instruction to give oneself helpful directions” (n=7, 77.8%). When asked about the helpfulness of each skill, 100% of participants who used them (n=9) reported they were helpful (Table 2). Of the 11 skills we asked about, participants reported using a median of 7 (IQR 5-7) skills at least half the days.

We also analyzed participant engagement in the intervention. Figure 2 summarizes 3 measures of engagement: the number of SMS text messages sent on all Slack channels over the course of the intervention, the proportion of video calls attended, and the proportion of mood polls completed. Participants sent a median of 12 (IQR 11-15.8) messages during the 12-week intervention period, attended a median of 9.7% (IQR 0%-45.8%)...
of the weekly video calls, and responded to a median of 32% (IQR 14.5%-47%) of the mood polls. Levels of engagement, particularly messaging, generally decreased over time but increased at intervention close (Multimedia Appendix 1).

This n represents the number of those who met at least 1 new support person.

Figure 2. Participant engagement in the intervention.

Qualitative Assessment

IDIs explored the acceptability and perceived utility of IMAGINE. Participants highlighted several aspects of the intervention that were especially well-received (Textbox 1). Support from both the facilitator and other participants was viewed as beneficial. Most participants (n=8) reported valuing the connection with the facilitator and feeling that they could go to them for guidance and support. Participants (n=7) highlighted that support from other young parents in the program normalized and validated their experiences; several participants spoke about the value of connecting with others in similar situations to them. Mood polls were mentioned by all 9 participants as an impactful component of the intervention, with participants valuing the opportunity to reflect on their emotional state. In total, 2 participants highlighted the value of the intervention’s flexibility, both that the asynchronous design allowed them to access content at a time and pace that worked best for them, and that the facilitator made adaptations to respond to participant needs during intervention delivery.
Textbox 1. In-Depth Interview themes related to intervention acceptability.

<table>
<thead>
<tr>
<th>Support from the study facilitator</th>
</tr>
</thead>
<tbody>
<tr>
<td>• When I had something come up or just anything, like, I would just talk to her, or if I had a question, I would talk to her. I asked her the question, and she would like answer the best way that she could or stuff. And I was just like, that's really helpful.</td>
</tr>
<tr>
<td>[Participant 5, aged 21 y, postpartum]</td>
</tr>
<tr>
<td>• I had a kind of Facetime with her one time, just us, because the other girls weren’t able to make it. But that was very - I really appreciated that. It was kind of something that I didn't know that I needed, but she willing to like, hear me out and ask the right questions for me. So I think that was pretty awesome of her.</td>
</tr>
<tr>
<td>[Participant 7, aged 23 y, pregnant]</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Connection with other participants</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Seeing other women, not necessarily the facilitator, but being around the women that are going through the same things that you're going through, like that are also pregnant and just had babies, that makes a difference. That allows the connections that you form are a lot stronger and a lot tighter</td>
</tr>
<tr>
<td>[Participant 9, aged 23 y, postpartum]</td>
</tr>
<tr>
<td>• We all went through this together and I felt like we all kind of grew together and, you know, they could, we could all relate to each other. And I didn't really have many mom friends I guess before this.</td>
</tr>
<tr>
<td>[Participant 17, aged 17 y, pregnant]</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Mood polls</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Normally you don't really reflect on your day unless you have a bad day. So I just like the way how it got me thinking, ‘Oh, well, I did have a good day but I didn't notice it because it wasn't a bad day’ if that makes sense.</td>
</tr>
<tr>
<td>[Participant 12, aged 23 y, postpartum]</td>
</tr>
<tr>
<td>• I think they were helpful just because it was like a second to self-reflect, maybe look in the real world. Sometimes they ask you how you doing but it's kind of difficult to explain to someone, but when you're doing it for yourself, I think it can be a little bit more honest.</td>
</tr>
<tr>
<td>[Participant 7, aged 23 y, pregnant]</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Intervention flexibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>• At the beginning I think it started off slow and then she was sending a lot of messages, every day, so I wouldn't get time to read them. I'd have to go back a lot, and then that's something that I told her, and so she slowed down on the number of messages, so she sent them every other day, instead of every single day.</td>
</tr>
<tr>
<td>[Participant 17, aged 17 y, pregnant]</td>
</tr>
<tr>
<td>• Having lots of interactions in written form gave everyone an opportunity to share their perspective and their experiences and what works for them, and we didn't all have to be right then and there, like I could look at it at two o'clock in the morning and another girl could look at it at two o'clock in the afternoon.</td>
</tr>
<tr>
<td>[Participant 9, aged 23 y, postpartum]</td>

Mental Wellness

Quantitative Assessment

Summary statistics for mental wellness outcomes are presented in Table 3 and individual participant trajectories are displayed in Multimedia Appendix 2. We compared depression symptoms (by PHQ-9), perceived stress (by PSS-4), and social support (by abbreviated SSB) between enrollment and follow-up. No significant changes in scores were found. At enrollment, the median PHQ-9 score was 4.0 out of 27 (IQR 2.0-5.0), compared with 2.0 (IQR 2.0-3.0) at follow-up (P=.25); 6 of 9 participants demonstrated reductions in PHQ-9 scores from baseline to follow-up. Median PSS-4 at enrollment was 8.0 out of 16 (IQR 8.0-10.0) and 9.0 out of 16 (IQR 8.0-10.0) at follow-up (P=.46). The median social support score related to participants’ family was 50.0 out of 100 (IQR 42.0-53.0) at enrollment, and 48.5 out of 100 (IQR 47.5-50.5) at follow-up (P=.11). The median social support score for friends was 51.0 out of 100 (IQR 47.0-54.0) at enrollment and 50.0 out of 100 (IQR 46.0-53.0) at follow up (P=.88).

$^a$PHQ-9: Patient Health Questionnaire.

**Qualitative Assessment**

In IDIs, participants highlighted 3 ways they perceived participating in IMAGINE benefited their mental health (Textbox 2). First, participants (n=5) expressed that being in a group with other young parents normalized and validated their experiences, which helped them feel more connected with others and strengthened their belief that they could make changes to improve their mood. Second, several participants (n=5) noted that they had gained skills in regulating their emotions. Some stated that they still used some of the mood monitoring and management techniques discussed in the program after it had ended. Participants highlighted that they had few opportunities in their day-to-day lives to reflect on their mood and that there was value and ease in reflecting “for yourself” through the digital platform, rather than to another person who may not understand their feelings. Participants also commented that they learned to pay closer attention to emotions in the middle of the spectrum (ie, not crisis or elation), and that helped them monitor when and why their mood changed. Third, several participants (n=6) stated that they would be more open to mental health services in the future after they completed IMAGINE. Some common feedback from participants related to this was that it helped them realize they needed to return to psychotherapy if they had sought it in the past, or for those without prior experience, IMAGINE helped normalize some of the unknown or off-putting aspects of mental health care. It became more familiar to discuss moods and feelings with others, which increased their openness to seeking care.
**Textbox 2. In-Depth Interview themes related to mental health impact.**

### Normalized experiences
- It helped me, like, open up a little more, and realize that I’m not the only person suffering, and that there’s more people like me that I can talk about it with. I don't have to, you know, suffer by myself.
  - [Participant 17, aged 17 y, pregnant]
- [IMAGINE helped me] understand… my emotions right now were normal… Before, I felt like I was broken or I needed to be fixed or there’s something wrong with me and now… there’s nothing wrong with me. [I’m] normal.
  - [Participant 9, aged 23 y, postpartum]

### Gained emotional regulation tools
- I had a pregnancy before that and it was also a preterm birth. And so, that baby passed away. And so it was really hard for me. I was really depressed, and so I know that if I would have had had like the Imagine group it like it would help it would have helped me to manage my, my emotions and stuff.
  - [Participant 5, aged 21 y, postpartum]
- I definitely added a handful more tools to my arsenal to be able to calm myself down, stay calm, or not become overwhelmed with everything that's going on… I've been using these - to me they're like lower tier ways of coping. So it's like when I'm not at a ten, I'm at like a five, I can use these.
  - [Participant 9, aged 23 y, postpartum]
- Reading the mood tree1… identifying the stressors… how to regulate it, different forms of communication, just all these different things for your mood and focusing on that. It just helped me to realize taking myself is a priority. And not just my baby and making sure she’s okay but making sure I'm okay as well.
  - [Participant 17, aged 17 y, pregnant]

### Opened to mental health services in the future
- I like to bottle up my anger or my problems and they explode on the wrong person at the wrong time so that being in a group kind of made me realize like I need to go back to counseling. I was already in counseling but I don't feel like I was taking it as serious but when I sat back and realized… No, I do need to get it together, that's when I was like, I'mma just go back to counseling.
  - [Participant 14, aged 18 y, pregnant]
- When you talk to [my family] about… feeling depressed and you're not mentally okay they're, like, "oh that's not real, it's fake, it's all in your head"... And so, [IMAGINE] just helped me to think that there is help, and it is real, and that it's not just in your head.
  - [Participant 5, aged 20 y, postpartum]

### Recommended Improvements
IDI's explored participants’ barriers to intervention participation and recommended improvements to IMAGINE. Frequently identified barriers to participation included being too busy, introversion, and low engagement from other members (Textbox 3). Participants (n=7) mentioned being unable to read all the messages or join Zoom meetings because they were working, in school, or busy with parenting responsibilities. Introversion was mentioned by a few participants (n=3), and 1 participant stated that a reason she did not participate in more Zoom calls was the thought that she was expected to be on camera, which she found uncomfortable. Limited engagement from other group members was discussed as a deterrent to engagement: participants (n=6) felt they would have engaged more and benefited more if synchronous and asynchronous conversations had included more voices. In total, 2 participants also reported technology challenges, both of which were resolved.

Participants shared recommendations to address their barriers to engagement (Textbox 3). Several participants (n=8) recommended changes to the frequency and timing of the synchronous Zoom calls to facilitate their attendance. Calls were scheduled each week based on polls with the group to identify the optimal time. Participants suggested that offering calls in the evenings, during the weekends, or announcing the schedule for all calls at the start of the program rather than scheduling them week-by-week could improve attendance. A few participants suggested offering multiple call times each week. Some participants (n=3) also requested more onboarding at the start of the group, including more orientation to the Slack platform and more icebreakers and rapport-building activities with other group members to encourage greater comfort and collective engagement in the group. While IMAGINE was designed to be virtual and COVID-19 restrictions meant in-person contact was not possible at the time, a common piece of feedback (n=7 participants) was to have at least one in-person meeting or offer a hybrid version of IMAGINE to deepen relationship-building with other group members.
### Barriers

### Discussion

**Principal Results**

In this mixed methods pilot study, we found that IMAGINE, a novel digital adaptation of the evidence-based MB course, had high acceptability and perceived utility. Uptake of IMAGINE, defined as the proportion of eligible participants who enrolled, was high. However, many individuals who initially contacted this study did not complete the screening process, suggesting these screening procedures presented barriers. These barriers may include the need to arrange a call with study staff to...
complete screening; it is possible the reach would be higher in a lower-barrier delivery model where clients could self-register in the group without arranging a screening call. We also found that a substantial proportion of screened participants were ineligible, most commonly due to elevated PHQ-9 scores. While our study’s focus was on the prevention of perinatal depression, this observation suggests that IMAGINE may also be appealing to individuals who are already experiencing elevated symptoms of depression; this observation is important in considering potential future applications of IMAGINE.

Acceptability scores were high and all participants stated they would recommend IMAGINE to a friend. Quantitative measures of engagement in the intervention, such as frequency of messaging and attendance of video calls, demonstrated low-moderate engagement. Nevertheless, most CBT approaches discussed in the IMAGINE intervention were used frequently and reported to be useful by the majority of participants. Qualitatively, participants reported one-to-one support from the facilitator, connection with other parents, and regular opportunities to reflect on their mood through mood polls were especially helpful aspects of the intervention. Additionally, participants reported that the intervention normalized their mental health challenges, improved their ability to manage their mood, and increased their openness to mental health care. We found no significant changes in depression scores, perceived stress, or perceived social support, although our study’s small sample size was not powered to detect changes in these outcomes.

Participants also made recommendations for improvements to the IMAGINE intervention in future iterations, including more opportunities for synchronous connection with other group members, additional rapport-building activities, and further simplification of message content.

**Comparison With Prior Work**

Our findings add to a small but growing body of literature on the use of digital interventions to prevent perinatal depression. While several studies have found that internet-delivered CBT is effective in the treatment of depression, including in the perinatal period [28,44-49], digital interventions for the prevention of perinatal depression have been less well studied [30,50].

Our findings are consistent with data from in-person MB. The levels of CBT skill use that IMAGINE participants reported were similar to that reported in a cluster randomized trial of in-person MB [51]: 66% (n=6) of IMAGINE participants reported that they engaged in pleasant activities and 100% (N=9) talked to or contacted someone who has been a positive support, compared with 78% and 80% respectively in Tandon et al’s [51] study previously adapted MB to a self-guided web-based format with informational pages, audio and video clips, and worksheets that follow MB modules in English and Spanish. A pilot randomized trial of the intervention, named Mothers and Babies Online Course, found nonsignificant improvement in depression symptoms; this study’s power was limited by sample size and the authors commented that facilitator guidance may improve uptake and efficacy [25,52]. The IMAGINE intervention differs from the Mothers and Babies Online Course in its inclusion of a facilitator and group delivery format, both of which were viewed as helpful components by participants in our pilot. Our findings of high acceptability, low-moderate engagement in intervention content, and high perceived utility are consistent with those of Barrera et al [25], suggesting digital delivery of MB with and without facilitation is a promising strategy that warrants further evaluation.

**Strengths and Limitations**

Our study has several strengths. The IMAGINE intervention was developed through systematic adaptation of the evidence-based MB course that prioritized fidelity to core MB components while adapting to participants’ design recommendations [34]. Our recruitment strategy feasibly reached potential participants across the country. Our evaluation is strengthened by including measures of CBT skill use that align with the mechanism of MB and were used in previous MB studies, allowing comparison of our findings with other MB studies. Furthermore, our study explored the experiences of young perinatal people, whose often marginalized perspectives are critical to developing responsive interventions. Guided by the principles of human-centered design [53], we collected in-depth insights from users before and after our pilot to drive future iteration and improvement of the intervention.

The primary limitations of our study are its small sample size and nonrandomized design. This study was not powered to evaluate the intervention’s effect on mental health outcomes, and pre-post comparisons are susceptible to confounding by changes over time that are not attributable to the intervention. Additionally, recruitment was primarily through Facebook and Instagram, which were selected for participants who were already using social media platforms and may be more open to a digital intervention. Due to resource constraints for this pilot study, our eligibility criteria included the ability to read and write in English, which systematically excluded non-English speakers, whose needs may differ. Future evaluations should address the limitations of this study by achieving a larger sample size, employing a randomized design, recruiting from nonsocial media sources, and developing translations in additional languages, particularly Spanish, in which MB materials already exist.

**Conclusions**

This pilot study provides promising evidence of the acceptability and utility of a digital group adaptation of MB among perinatal youths. These findings support further development and evaluation of the IMAGINE intervention to increase access to evidence-based interventions for the prevention of perinatal depression. Future iterations of IMAGINE will incorporate user recommendations from this study and use randomized powered evaluations to test clinical impact.
Acknowledgments

The authors gratefully acknowledge IMAGINE study participants and recruitment partners. This study was funded by a grant from the Technology and Adolescent Mental Wellness program at the University of Wisconsin-Madison. This study was also supported by the National Institutes of Health (grant K18MH122978) and the University of Washington Behavioral Research Center for HIV (BIRCH), a National Institute of Mental Health–funded program (P30 MH123248). Abstract

Background: Patients undergoing spinal surgery report high levels of insecurity, pain, stress, and anxiety before and after surgery. Unfortunately, there is no guarantee that surgery will resolve all issues; postsurgical recovery often entails moderate to severe postoperative pain, and some patients undergoing spinal surgery do not experience (long-term) pain relief after surgery. Therefore, focusing on sustainable coping skills and resilience is crucial for these patients. A digital health intervention based on acceptance and commitment therapy (ACT) and positive psychology (PP) was developed to enhance psychological flexibility and well-being and reduce postsurgical pain.

Objective: The objective of this study was 3-fold: to explore the potential benefits for patients undergoing spinal surgery of the digital ACT and PP intervention Strength Back (research question [RQ] 1), explore the feasibility of a future randomized controlled trial in terms of recruitment and dropout (RQ 2), and assess the acceptability of Strength Back by patients undergoing spinal surgery (RQ 3).

Methods: We used a nonrandomized experimental design with an intervention group (n=17) and a control group (n=20). To explore the potential benefits of the intervention, participants in both groups filled out questionnaires before and after surgery. These questionnaires included measurements of pain intensity (Numeric Pain Rating Scale), pain interference (Multidimensional Pain Inventory), anxiety and depression (Hospital Anxiety and Depression Scale), valued living (Engaged Living Scale), psychological flexibility (Psychological Inflexibility in Pain Scale), and mental well-being (Mental Health Continuum–Short Form). Semistructured interviews combined with log data and scores on the Twente Engagement With eHealth Technologies Scale were used to assess the acceptability of the intervention.

Results: A significant improvement over time in emotional (V=99; P=.03) and overall (V=55; P=.004) well-being (Mental Health Continuum–Short Form) was observed only in the intervention group. In addition, the intervention group showed a significantly larger decline in pain intensity (Numeric Pain Rating Scale) than did the control group (U=75; P=.003). Of the available weekly modules on average 80% (12/15) was completed by patients undergoing spinal fusion and 67% (6/9) was completed by patients undergoing decompression surgery. A total of 68% (17/25) of the participants used the intervention until the final interview. Most participants (15/17, 88%) in the intervention group would recommend the intervention to future patients.
Conclusions: This pilot feasibility study showed that combining ACT and PP in a digital health intervention is promising for patients undergoing spinal surgery as the content was accepted by most of the participants and (larger) improvements in pain intensity and well-being were observed in the intervention group. A digital intervention for patients undergoing (spinal) surgery can use teachable moments, when patients are open to learning more about the surgery and rehabilitation afterward. A larger randomized controlled trial is now warranted.

Introduction

Background

Patients undergoing spinal surgery report high levels of physical complaints as well as insecurity, pain, low well-being, stress, and anxiety before and after surgery [1-3]. Postsurgical recovery often entails moderate to severe postoperative pain, and approximately 20% to 30% of patients undergoing spinal surgery do not experience (long-term) pain relief after surgery [3,4]. This results in a longer hospital stay, higher health care costs, longer physical and mental recovery, delayed return to work, and the potential development of chronic pain. The potential transition from postoperative pain to chronic pain is a major issue as chronic pain affects many aspects of a patient’s life, such as work; physical, emotional, and social well-being; and quality of life [5,6]. Mental factors such as cognition, emotions, and expectations play a significant role in the experience of pain [7]. The fear-avoidance model explains the trajectory from acute to chronic pain through fear and catastrophizing, which is the tendency to enlarge the threat of pain and a feeling of helplessness, leading to an increase in pain avoidance as a dominant coping strategy [8]. Pain avoidance then leads to a less active lifestyle, thereby worsening rather than relieving pain. High levels of catastrophizing and fear have been found to predict higher levels of (postoperative) pain and pain chronicity and a lower quality of life in patients who undergo surgery [4,9-11]. In addition, realistic expectation management is key as unrealistic or unfulfilled expectations about surgery and preoperative stress may lead to the experience of higher levels of postoperative pain [12-18]. This link between mental factors and expectation management with postoperative outcomes shows that psychological preparation before surgery is essential to improve recovery after surgery.

Although the potential benefits of psychological preparation before surgery have long been known [19], a more recent meta-analysis of psychological preparation techniques before surgery could not find strong evidence from high-quality research to verify these claims [20]. Potentially, interventions that focus on promoting adaptive coping skills and reducing maladaptive emotion regulation skills are more promising. Smith and Zautra [21] and Sturgeon and Zautra [22] found, for example, evidence that coping strategies such as (pain) acceptance, engaging in beneficial social interactions, and experiencing a value-based purpose in life have the potential to improve mental well-being and promote resilience in the face of (chronic) pain. Sustainable resilience to (chronic) pain requires skills promoting adaptation and mental health in the long term [22]. In other words, adaptation to different contexts and circumstances requires (psychological) flexibility and a long-term focus. In the context of pain, psychological flexibility implies that painful sensations, feelings, and thoughts are accepted as opposed to avoided and that attention shifts toward personally valued goals [23]. For patients undergoing spinal surgery, psychological flexibility enables them to cope with the fluctuating circumstances surrounding surgery (eg, insecurity, fear, and pain) in a flexible rather than rigid manner. Being able to accept negative emotions or sensations such as pain and insecurity in the face of surgery might prevent catastrophizing, fear, and avoidance behavior.

Psychological flexibility is the aim of acceptance and commitment therapy (ACT) [24]. ACT is based on the relational frame theory and focuses on performing value-based activities in life even in the face of insecurity and adversity [24]. In a similar way, positive psychology (PP) is the scientific study of well-being and optimal functioning, focusing on human flourishing instead of reducing the risk factors for psychopathology and malfunctioning. PP involves topics such as strengths, virtues, meaning, happiness, gratitude, compassion, resilience, and flourishing [25]. ACT and PP can help experience a value-based purpose in life, promote resilience, and improve mental well-being. Mental well-being comprises positive emotional, psychological, and social functioning [26]. The presence of higher levels of these 3 dimensions of well-being is an indicator of flourishing [26-28]. Promoting positive resources and skills that contribute to successful adaptation and (mental) health are the aims of PP interventions (PPIs) [25,29]. PPIs and ACT have been found to be effective in the treatment of chronic pain [30-35], improving affect and functional ability after knee surgery [21], and quicker cessation of pain and opioid use in veterans after orthopedic surgery [36]. In summary, PP and ACT could potentially benefit patients undergoing spinal surgery in terms of physical (eg, pain) and psychological (eg, well-being) factors.

In the context of surgery, digital health interventions can be used to aid patients during their recovery process [37]. These interventions can be used to improve postoperative outcomes by supporting healthy lifestyle behavior change before and after surgery [38,39] and to improve medication adherence [40,41]. Digital health interventions can also better prepare patients for surgery or shorten postoperative recovery through behavioral modification, patient monitoring, or protocol adherence [42-45].
Behavioral modification can also be applied to promote a healthy lifestyle. This is important as healthy lifestyle behavior changes before and after orthopedic surgery, such as increased preoperative physical activity or smoking cessation, have been associated with improved postoperative bone healing [46] and wound healing [47], quicker recovery times, and reduced pain scores [48]. Moreover, patients undergoing surgery who engage with digital health interventions show better medication adherence, better adherence to discharge instructions, greater patient satisfaction, improved clinic attendance, lower readmission, and less emergency department visits after surgery [49]. van der Meij et al [50] found in their review that, in most studies, perioperative digital health interventions improved clinical patient-related outcomes compared with face-to-face perioperative care alone for patients who had undergone various forms of surgery. This shows the potential of digital health interventions to improve perioperative care in addition to face-to-face meetings with professionals.

Despite the clear potential of ACT and PPIs for mental well-being and long-term resilience, they have not yet been used to develop interventions targeting psychological flexibility in patients undergoing spinal surgery. In addition, seeing the potential of digital health interventions in the context of surgery, this form also seems promising for patients undergoing spinal surgery. For this reason, a digital health intervention called Strength Back [51] was developed. Strength Back aims to increase psychological flexibility and well-being and improve postoperative recovery in patients undergoing spinal surgery. This intervention, developed through cocreation with different stakeholders, contains procedural information, pain education, and PPI and ACT exercises.

**Objectives**

Although the intervention is based on a scientific, theoretical framework, the effects and impact of the intervention need to be proven to be able to implement it in an evidence-based health care setting. This requires a collection of evidence, such as through a randomized controlled trial (RCT). As an RCT is complex and expensive, preparation and insights in advance into the required parameters, such as measures, recruitment, and dropout numbers, are essential to perform a thorough RCT. In light of the aforementioned research on PP and ACT in other target populations, several outcome measures covering physical and psychological factors need to be explored as potential benefits of this intervention. In addition, in an RCT, the best possible version of the intervention needs to be tested. This is in line with the recommendation of the Medical Research Council of first testing and refining an intervention to ensure it is acceptable to successfully evaluate whether it is effective [52]. In addition, to reduce psychological and practical barriers and maximize acceptability, it is important to understand and accommodate patients’ views [53]. As of yet, it is unknown how patients undergoing spinal surgery value the intervention Strength Back in terms of acceptability, potential benefits, and feasibility in a real-life setting and what the required parameters for a future RCT would be. Therefore, the objective of this study was 3-fold: to explore the potential benefits for patients undergoing spinal surgery of the digital ACT and PPI Strength Back (research question [RQ] 1), explore the feasibility of a future RCT in terms of recruitment and dropout (RQ 2), and assess the acceptability of Strength Back by patients undergoing spinal surgery (RQ 3).

**Methods**

**Study Design**

This was a nonrandomized pilot study, a subset of feasibility studies as described by Eldridge et al [54]. Our study design included an intervention group and a historic control group (Figure 1). We used a historic control group as the development of the intervention was still ongoing and the target population was small. The participants in the control group received care as usual. In addition to receiving care as usual, the participants in the intervention group were given access to the digital health intervention Strength Back. To test the acceptability of the intervention, individual interviews were conducted with the participants in the intervention group. Both groups filled out a questionnaire before (pretest time point) and after (posttest time point) surgery.

![Figure 1. Study design and timeline for individual participants (patients undergoing spinal surgery) in the control and intervention groups of this pilot feasibility study.](https://formative.jmir.org/2024/1/e54600)
As suggested by Orsmond and Cohn [55], we used a combination of qualitative and quantitative measures in this feasibility study. We aimed to include 20 participants in our control group and 20 participants in our intervention group, which is in line with the study by Billingham et al [56], who found a median sample size of 36 in their review of feasibility studies.

Participants
Patients undergoing decompression or spinal fusion surgery were eligible for inclusion in either the control or intervention group of this study. Patients undergoing spinal surgery other than decompression or spinal fusion surgery (eg, patients with hernias or patients of oncology) were excluded. Other inclusion criteria were age of >18 years, proficiency in Dutch, and an email address. Participants in the intervention group needed an Android or iOS smartphone or tablet at home and had to be willing to use a digital health intervention both before and after surgery.

All participants in this study were recruited through purposive sampling at an orthopedic center in the Netherlands. The participants in the historic control group were recruited between February 2020 and July 2020. The participants in the intervention group were recruited between September 2020 and February 2021.

Conditions

Care as Usual
The historic control group received care as usual. They were provided with brochures containing information about their diagnosis, surgical procedure, surgery preparation, physical guidelines during recovery, contact information, and possible complications. In addition, usual care consisted of several appointments besides the surgery itself: an intake and a preoperative screening before surgery, a consultation by phone 10 days after surgery, and a physical checkup at the orthopedic center 6 weeks (both surgery types) and 12 weeks (spinal fusion surgery) after surgery.

Strength Back Digital Health Intervention
In addition to care as usual, participants in the intervention group were given access to the Strength Back digital health intervention (see Figure 2 for screenshots). The content of this app was developed through a process of cocreation. The stakeholders involved in this process were patients who had undergone spinal surgery, orthopedic surgeons, a physical therapist, a nurse practitioner, a research coordinator, and several nurses. The content of the intervention was based on the results of interviews and focus group sessions with the aforementioned stakeholders (patients and health care professionals) combined with ACT and PP exercises. Multimedia Appendices 1 to 3 of this publication and our previous publication on the cocreation of Strength Back [51] provide more details on the developmental process.
Figure 2. Screenshots of the Strength Back intervention (in Dutch, Kracht TeRUG) for patients undergoing spinal surgery. (A) The information on the spinal condition, the animation on pain education, and the video of the nursing ward. (B) The “wish question,” text about acceptance of pain, and “mindful breathing” exercise.

The intervention consisted of 13 information modules, which were continuously available, and 6 to 12 weekly modules. Participants did not receive personal messages from a health care professional. The contact information of the orthopedic clinic was provided in the intervention, making sure participants could contact a health care professional in case of any questions.
