Beyond the ECHO framework, the findings of the research study have further shown the perceived importance of cybersecurity standards, guidance, and tools for health care organizations. While there are several internationally recognized standards, guidance, and tools, their lack of focus on the health sector specifically neglects the unique aspect of cybersecurity as a critical element of patient safety and its implications for health care organizations in reducing avoidable harm. Existing standards, guidance, and tools are also often complex and technical language-heavy, which impacts their usability in low-resource health settings, often within LMIC health systems, where the level of knowledge of cybersecurity may be less advanced. As such, there is an urgent need for policy makers to fill the gap in providing targeted resources, such as standards to follow, to enable health care organizations to comply with international best practices. Policy makers must also enable an improved understanding of the unique challenges faced by health care organizations in developing more secure systems and how cyber resilience in this critical sector must feature as a priority as part of a national security agenda.

Acknowledgments

The development of the Essentials of Cybersecurity for Health Care Organizations (ECHO) resource was funded by the Qatar Foundation.

Authors’ Contributions

NO and SG conceptualized the manuscript and developed the data collection instruments. NO managed recruitment and oversaw the data collection. NO, RFC, MP, and FO completed the data analysis. NO and RFC wrote the original draft with support from SG. All authors equally contributed to the writing, reviewing, and editing. AD and SG supervised the work.

Conflicts of Interest

None declared.

Abstract

Background: For almost two decades, researchers and clinicians have argued that certain aspects of mental health treatment can be removed from clinicians’ responsibilities and allocated to technology, preserving valuable clinician time and alleviating the burden on the behavioral health care system. The service delivery tasks that could arguably be allocated to technology without negatively impacting patient outcomes include screening, triage, and referral.

Objective: We pilot-tested a chatbot for mental health screening and referral to understand the relationship between potential users’ demographics and chatbot use; the completion rate of mental health screening when delivered by a chatbot; and the acceptability of a prototype chatbot designed for mental health screening and referral. This chatbot not only screened participants for psychological distress but also referred them to appropriate resources that matched their level of distress and preferences. The goal of this study was to determine whether a mental health screening and referral chatbot would be feasible and acceptable to users.

Methods: We conducted an internet-based survey among a sample of US-based adults. Our survey collected demographic data along with a battery of measures assessing behavioral health and symptoms, stigma (label avoidance and perceived stigma), attitudes toward treatment-seeking, readiness for change, and technology readiness and acceptance. Participants were then offered to engage with our chatbot. Those who engaged with the chatbot completed a mental health screening, received a distress score based on this screening, were referred to resources appropriate for their current level of distress, and were asked to rate the acceptability of the chatbot.

Results: We found that mental health screening using a chatbot was feasible, with 168 (75.7%) of our 222 participants completing mental health screening within the chatbot sessions. Various demographic characteristics were associated with a willingness to use the chatbot. The participants who used the chatbot found it to be acceptable. Logistic regression produced a significant model with perceived usefulness and symptoms as significant positive predictors of chatbot use for the overall sample, and label avoidance as the only significant predictor of chatbot use for those currently experiencing distress.

Conclusions: Label avoidance, the desire to avoid mental health services to avoid the stigmatized label of mental illness, is a significant negative predictor of care seeking. Therefore, our finding regarding label avoidance and chatbot use has significant public health implications in terms of facilitating access to mental health resources. Those who are high on label avoidance are not likely to seek care in a community mental health clinic, yet they are likely willing to engage with a mental health chatbot, participate in mental health screening, and receive mental health resources within the chatbot session. Chatbot technology may prove to be a way to engage those in care who have previously avoided treatment due to stigma.

(JMIR Form Res 2024;8:e45959) doi:10.2196/45959
Introduction

Over 10 years ago, the Annapolis Coalition for Behavioral Health Workforce Development declared a behavioral health workforce crisis in a report summarizing the key resource challenges in the field [1]. Some of the key challenges noted in this report included the observation that behavioral health care workers are too few and poorly distributed throughout the country, leaving many communities without a trained behavioral health workforce. National projections for 2013-2025 suggest that behavioral health provider supply has not kept pace with demand [2]. Simply training more professionals will not be enough to address these issues of supply and demand [3].

In total, 5 key characteristics have been proposed for service delivery models that might effectively meet the demands placed on the behavioral health care system: (1) the capacity to reach individuals not usually served, (2) scalability (the ability to implement an intervention on a large scale), (3) affordability, (4) expansion of the nonlicensed (ie, peer and paraprofessional workforce via task shifting), and (5) expansion of settings (bringing interventions to locales where those in need are likely to participate) [4]. To a great extent, these 5 key characteristics can be addressed using technology [5-7].

One specific form of technology that holds great promise for addressing behavioral health care workforce demands is chatbot technology. Chatbots are conversational interfaces (eg, Amazon Alexa and customer service chatbots used by banks or insurance companies) that use text or speech in a conversational, human-like manner to deliver information. A major strength of bots is their centralized programming (ie, its “brains”) on secure, cloud-based computing servers, which permits users to interact with the chatbot via multiple, existing platforms like SMS texts, WhatsApp, and Facebook messenger without the need to install special software or apps. Chatbots are heavily used in consumer settings because of their ability to quickly provide tailored information and increase purchasing probability. In the health sector, chatbot use is less prevalent but has been applied to mental health intervention delivery [8,9].

Researchers and clinicians have argued for almost two decades that certain aspects of treatment can be removed from clinicians’ responsibilities and allocated to technology. Research suggests, for example, that some aspects of treatment, such as exposure for panic disorders or cognitive restructuring for depression can be delivered via technology with comparable outcomes to delivery by a clinician [10,11]. Such reallocations of clinical tasks can preserve valuable clinician time and should alleviate the burden on the behavioral health care system by only requiring that services tasks where efficacy is dependent on human interaction are delivered by a human. The most recent comprehensive review of the literature summarizing existing research on blended models of service delivery—models combining some aspects of face-to-face intervention with technology-based intervention [12]—categorized blending according to both the ratio of services delivered via technology versus face-to-face and the order in which the technology or face-to-face components were delivered. One type of sequential model presents internet intervention before face-to-face intervention to engage patients during wait times and uses stepped care to reduce clinician burden. Further, 2 of the studies included in the review showed significant differences in positive outcomes (ie, symptom reduction) between those individuals engaged via technology during waiting times versus those not engaged [13,14]. However, 1 study failed to show any difference between wait-list patients engaged via the internet before face-to-face intervention and patients engaged via a self-help booklet [15]. Unfortunately, none of the studies available at the time of this review examined the cost-effectiveness of this sequential blended service delivery model, though 1 published protocol describes plans to examine the cost savings of a stepped care model [16].

Several technology-based tools exist that deliver interventions using digital therapeutics. Examples of such tools include reSET-O (Digital Therapeutics Alliance) [17], a digital therapeutic for treating opioid use disorder, and Woebot (Woebot Health) [8] and Wysa (Wysa Ltd) [9], cognitive behavioral therapy–based conversational agents for addressing a range of clinical concerns among various populations. To our knowledge, less attention has been given to developing, testing, and using conversational agents (chatbots) for other clinical tasks. In addition to aspects of treatment, other service delivery tasks that could arguably be allocated to technology to alleviate clinician burden without negatively impacting patient outcomes include screening, triage to services of appropriate intensity (as in a stepped care model), and referral. This has been attempted in the field of substance abuse via the Substance Abuse and Mental Health Services Administration’s Screening, Brief Intervention, and Referral (SBIRT) program, which applies the principles of stepped care to substance abuse and aims to funnel people in need into substance use treatment [18]. Woudles and colleagues [18] argue that technology-based delivery of SBIRT may be equally effective to human-delivered SBIRT and that technology-based delivery would increase the accessibility of this intervention and reduce the impact of stigma as a barrier to care for certain populations (eg, pregnant women using substances).

Here, we describe the results of a national survey. This survey was exploratory, designed to understand the relationship between potential mental health chatbot users’ demographics and actual chatbot use and uptake of mental health resources provided by a chatbot; the rate of completion of mental health screening when delivered by a chatbot; and the acceptability of a prototype chatbot designed for mental health screening and referral. This chatbot not only screened participants for psychological distress, but also referred them to appropriate resources (breathing exercises, self-help, peer resources, and crisis lines) that matched their level of distress and preferences. The goal of this study was to determine whether a mental health...
screening and referral chatbot would be feasible and acceptable to users. If indeed this type of technology is feasible and acceptable, it may hold promise to be tested in further research to help ease the strain on the behavioral health care system by assuming the role of screening and referral and delivering low-intensity interventions (eg, breathing exercises and self-help interventions) to those who are experiencing less distress, reserving referral to higher-intensity resources (eg, crisis lines and care from licensed clinicians) for those in greater distress. Additionally, conducting screening via chatbot technology may provide an opportunity to engage those who are currently experiencing significant distress, but are not yet willing to seek the help of a licensed clinician due to environmental barriers such as stigma, with some resources (eg, self-help or stigma reduction interventions) when otherwise they may receive no support.

Methods

Study Overview

During May and June 2021, we conducted a national, hybrid, cross-sectional, internet-based survey among a sample of US-based, English-speaking persons aged 18 years or older registered with the Amazon Mechanical Turk (MTurk) system; a subset of all survey users continued beyond the initial survey to interact with a prototype mental health chatbot and completed a second survey. Though not specifically designed as a research panel, MTurk has been increasingly used to recruit for research studies across social science disciplines [19] and is both more diverse and more attentive than college student samples [20]. Further, MTurk is largely representative of a broader population, skewing toward younger women of minority status [21].

Figure 1 displays this study’s design. MTurk’s recruitment parameters were set to offer study participation only to users meeting the above inclusion criteria. Users interested in participating completed informed consent and then completed a web-based survey collecting demographic data and mental health history (from the PhenX toolkit) [22], along with a battery of measures assessing behavioral health and symptoms, stigma (label avoidance and perceived stigma), attitudes toward treatment-seeking, readiness for change, and technology readiness and acceptance (see Measures).

Next, participants were provided a brief description of chatbots (ie, what they are, common examples of chatbots, and their utility) and invited to either connect to a prototype chatbot (called “Tabatha”) designed to screen users for psychological distress and provide mental health resources and referrals, or end study participation; compensation was not linked to chatbot use. For participants declining to use the chatbot, the reason for their decision was solicited by the choices: “I have no interest in chatbots,” “I do not have the time to use a chatbot,” “I do not know what a chatbot is,” “I do not need mental health services,” “I prefer speaking to a human about my mental health.” An “other” option was also available so participants could provide additional reasons.

Participants agreeing to use the chatbot clicked on a link in this study’s questionnaire that opened a separate internet browser window in which the Tabatha chatbot appeared with text reading, “Hello, my name is Tabatha… What name would you like to go by for our conversation today?” (Figure 2). Users could provide any name by which they wished to be identified. Tabatha then greeted the participant using their name and stated that its purpose was to provide mental health screening and resource navigation, making clear that—despite the human-like nature of the text messages—it was a computer program and not a human responding. Further, Tabatha provided users with phone numbers for emergency services if they were experiencing a crisis. Next, Tabatha administered the Patient Health Questionnaire-9 (PHQ-9), a widely used, 9-question depression screener that scores the severity of depressive symptoms on a score of 0 (none) to 27 (severe) [23]. Participants were then provided with their PHQ-9 score and an explanation of its meaning (see screenshot of PHQ-9 screener and results presentation in Figure 3 [24-27]) and provided mental health resources commensurate to their level of distress based upon mental health professional feedback. Table 1 provides the interpretation of PHQ-9 scores in terms of the level of distress, the chatbot’s response based on the PHQ-9 scores, and resources provided based on distress levels.

Participants who chose to use the chatbot were asked to respond to four acceptability statements adapted from the Acceptability of Intervention Measure [28,29]. The acceptability statements included, “this mental health chatbot is appealing to me,” “this mental health chatbot meets my approval,” “I welcome mental health screening using a chatbot,” “I like this mental health chatbot,” and “I will use a chatbot like this in the future.” Finally, Tabatha asked participants if they would like to receive a single follow-up message 2 weeks later asking whether the referrals provided were used. For participants declining Tabatha’s follow-up message, study participation ended, while participants accepting the follow-up message were asked to provide a mobile telephone number capable of receiving SMS messages (this was necessary because, up until this point, the use of Tabatha was anonymous; a telephone number allowed for direct communication with the participant’s mobile phone). Further, 2 weeks later, Tabatha contacted participants who provided a mobile number, asking whether mental health resources were used.

\textsuperscript{a}PHQ-9: Patient Health Questionnaire.

Ethical Considerations

This study was reviewed and approved by the University of South Florida’s Institutional Review Board (IRB; STUDY002142). The IRB determined that this research was exempt from IRB oversight. Before completing the survey, participants were presented with an informed consent document. This study was granted a waiver of signed informed consent and participants were asked to acknowledge consent to participate in this study by clicking a radial box within the survey. All participants were compensated US $5.00 (the standard rate for MTurk users) for study participation regardless of chatbot use per Figure 1. The US $5.00 compensation was paid to the MTurk user through the MTurk platform. Study data were deidentified and stored in a password-protected [30] folder that could only be accessed by members of this study’s team.

Measures

Symptoms

Symptoms were measured within the chatbot session using the PHQ-9, a 9-item depression symptom checklist [23]. The 9 items are scored from 0 to 3 on a Likert scale of “not at all” to “nearly every day.” The PHQ-9 internal reliability and test-retest reliability are high [23]. The PHQ-9 is meant to be self-administered, making the chatbot administration of this screening tool a reasonable adaptation. In the survey completed before initiating the chatbot session, symptoms were assessed using the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) Level 1 Cross-Cutting Symptom Measure [31], a self-rated measure assessing mental health domains that are important across psychiatric diagnoses. This adult version of the measure contains 23 questions assessing 13 psychiatric domains, including depression, anger, mania, anxiety, somatic symptoms, suicidal ideation, psychosis, sleep problems, memory, repetitive thoughts and behaviors, dissociation, personality functioning, and substance use. Each item asks how much or how often the individual has been bothered by the specific symptom during the past 2 weeks. The measure was found to be clinically useful and to have good test-retest reliability in the DSM-5 field trials that were conducted in adult clinical samples across the United States and Canada [31].

Readiness for Change

The URICA (University of Rhode Island Change Assessment) was used to measure the stage of change (precontemplation,
contemplation, action, and maintenance) of a user of Tabatha. This 32-item scale uses a Likert scale from 1 (strongly disagree) to 5 (strongly agree) to answer statements describing how a person might feel toward treatment or approaching problems [32]. The URICA has good reliability with $\alpha$ from .79 to .89 and good construct validity supported through factor analyses [32].

**Attitudes Toward Treatment-Seeking**

Attitudes toward treatment-seeking were measured using an adapted version of the ATMHT (Attitudes Toward Mental Health Treatment) scale [33]. The scale was adapted from Fischer and Turner's Attitudes Toward Seeking Professional Psychological Help scale [34] to update language and culturally meaningful items. This 2-factor scale (beneficial attitudes and pessimistic attitudes toward mental health services) has demonstrated adequate internal consistency (beneficial attitudes toward mental health services $\alpha=.84$; pessimistic attitudes toward mental health services $\alpha=.79$), reliability, and validity. The ATMHT scale contains 20 items assessed on a 4-point Likert scale (4=strongly agree).

**Perceived Stigma**

We measured perceived stigma using the perceived devaluation-discrimination scale, a 12-item instrument asking participants to indicate the extent to which they agree with statements indicating that most people devalue individuals with mental illness (eg, most people feel that entering a psychiatric hospital is a sign of a personal failure) [35]. Participants respond using a 6-point Likert scale (6=strongly disagree). Higher scores on the perceived devaluation-discrimination scale represent greater perceived stigma. The scale has demonstrated good reliability, with $\alpha$ ranging from .86 to .88 [35] and validity [36].

**Label Avoidance**

The Self-Stigma of Seeking Help (SSOSH) scale measured label avoidance [37]. The SSOSH is a 10-item measure asking participants to answer on a 5-point Likert scale (5=strongly agree). The SSOSH has been found to have good internal consistency ($\alpha=.91$), and test-retest reliability ($r=.72$) [37].

**Technology Readiness and Acceptance**

The TRAM (Technology Readiness and Acceptance Model) is a questionnaire that incorporates both the Technology Readiness Index and the Technology Acceptance Model for a deeper understanding of the use of technology and an individual’s readiness and acceptance [38,39]. All items are measured on a 7-point Likert scale (7=strongly agree). The TRAM has good reliability for each of the subscales (optimism, $\alpha=.95$; innovativeness, $\alpha=.95$; discomfort, $\alpha=.90$; insecurity, $\alpha=.92$; perceived usefulness, $\alpha=.95$; perceived ease of use and use intention, $\alpha=.92$) [38]. The TRAM has been found to have adequate model fit.

**Acceptability**

Acceptability of the chatbot following use was measured using four items adapted from the Acceptability of Intervention Measure.

**Analytic Approach**

Feasibility was modeled descriptively based on willingness to use the chatbot. We used $\chi^2$ tests to examine the relationship between categorical demographic variables and the dichotomous outcome variable, willingness to use chatbot (yes or no). Continuous variables were examined as predictors of willingness to use the chatbot via correlations and logistic regression. Acceptability data were examined using descriptive statistics.

**Results**

**Overview**

Guidelines for Transparent Reporting of Evaluations with Nonrandomized Designs were followed. This study enrolled 640 individuals; 329 individuals were included in the analyses. Correlations between all variables for the total sample can be found in Table S1 of Multimedia Appendix 1. Further, 80 participants were excluded from analyses as they answered 1 of the 3 attention check questions dispersed throughout the survey incorrectly. These questions were included to ensure that participants were paying attention to this study and not just selecting random responses and that the participant was not a bot. These 3 items consisted of a question asking the participant to spell the word “horse” backward, a question asking the participant to describe a picture of a picnic scene, and a question asking the participant to respond with “somewhat agree.” In total, 71 participants were excluded because they responded to the survey more than once, even given explicit instructions that they could only respond to the survey 1 time. Further, 160 individuals were excluded from analyses as they had taken less than 10 minutes to complete the survey. Table 2 presents the demographic characteristics of participants.
Table 2. Demographic characteristics of a sample of US adults from a cross-sectional survey examining the feasibility and acceptability of a mental health screening and referral chatbot.

GED: General Educational Development.

**Feasibility**

Table 2 provides the proportions of participants willing to use the chatbot by demographic characteristics. Of the 329 individuals included in the analyses, 222 (67.4%) agreed to use the chatbot. In terms of racial and ethnic variables, we found a significantly greater proportion of Black and White versus Asian participants (n=319, χ² =11.82; P<.05) and a greater proportion of Hispanic versus non-Hispanic participants agreed to use the chatbot (n=328, χ² =13.16; P<.001). We found that other demographic variables also contributed, with a significantly larger proportion of participants who had dependents versus no dependents (n=325, χ² =10.94; P<.01), those with insurance versus without insurance (n=322, χ² =12.49; P<.01), and those who were employed versus unemployed (n=326, χ² =9.82; P<.01) agreeing to use the chatbot.

Table 3 presents the mental health characteristics of participants and the proportions of participants willing to use the chatbot by mental health characteristics. Current mental health variables were related to agreeing to use the chatbot with a significantly greater proportion of those who were currently receiving treatment versus not currently receiving treatment (n=325, χ² =15.13; P=.001), those with a diagnosis versus no diagnosis (n=322, χ² =9.89; P<.01), and those currently distressed versus not currently distressed (n=312, χ² =21.69; P<.001) agreeing to use the chatbot. All effect sizes for these findings were small, with Cramér V ranging between 0.17 and 0.26. For individual effect sizes, refer to Table 3.

---

https://formative.jmir.org/2024/1/e45959
Correlations between continuous variables and willingness to use the chatbot for the entire sample and for those individuals who indicated that they were currently experiencing distress can be found in Multimedia Appendix 1. Table 4 displays the results of forward stepwise logistic regressions with willingness to use the chatbot as the outcome variable for the overall sample as well as for those individuals who indicated that they were currently experiencing distress. Significant correlates of chatbot use were included as predictor variables in the regression models. For the overall sample, the perceived usefulness of the chatbot and symptoms significantly predicted chatbot use, with greater perceived usefulness and greater symptoms predicting the likelihood that the participant agreed to use the chatbot. For the distressed sample, higher levels of label avoidance significantly predicted a greater likelihood of agreeing to use the chatbot.

Acceptability
Of the 222 participants who agreed to use the chatbot, 168 (75.7%) completed the PHQ-9 screening questions in the chatbot, and 164 (73.9%) answered all of the acceptability items. The average depression score was 8.6 (SD 7.2), which constitutes mild depression among the sample of respondents who chose to complete the PHQ-9 screening within the chatbot session. Overall, participants agreed with the acceptability of the chatbot. The mean acceptability score was 19.8 (SD 4.2).

Participants who chose not to use the chatbot (n=107) indicated that they chose not to do so because they did not believe they needed mental health services (n=40), they had no interest in chatbots (n=36), they preferred to speak to a human about their mental health (n=33), they did not have time to use a chatbot (n=20), they did not know what a chatbot is (n=8), or they indicated some other reason (n=3). Frequencies of the reasons participants selected for not using the chatbot can be found in Table S2 of Multimedia Appendix 1. If they agreed to use the chatbot, participants were asked if they would be willing to provide their phone numbers within the chatbot session so that the chatbot could follow up with them in 2 weeks to see if any resources they received were used and whether they were helpful. Further, 63 (28.4% of those participants who agreed to use the chatbot) individuals agreed to provide their phone numbers. Furthermore, 56 (25.2% of those who agreed to use the chatbot) individuals agreed to allow the chatbot to follow up with them in 2 weeks; however, not all of these individuals provided a phone number for follow-up purposes. The reasons participants provided for not wanting to provide their phone numbers can be found in Table S3 of Multimedia Appendix 1, along with frequencies for each reason. Reasons provided for not wanting to provide one’s phone number included “my contact information is private” (n=61), “I do not give my number to strangers” (n=34), “I do not want unsolicited calls” (n=32), “it does not feel confidential” (n=20), “I do not want to give my number to a robot” (n=20), “I do not trust chatbots” (n=3), or “another reason not listed” (n=8).

Of the 56 individuals who received a follow-up text at 2 weeks, 9 (16.1%) individuals clicked on the link in the follow-up text to engage with the follow-up chatbot. Further, 4 (7.1%) individuals stated that they did not use the resources. Reasons included “I didn’t have time to look them over” (N=2) and “I didn’t feel like I needed them” (N=1). Of the 5 people who reported using the resources, all stated they were helpful. Further, 1 participant reported that the resources they received “…really helped me to move on to the next stage.” Another stated, “it was good advice.”

Discussion
Principal Findings
We found in this exploratory study that a chatbot designed to screen for mental distress and refer to appropriate resources matching one’s distress level was feasible and acceptable among a convenience sample of US adults. Moreover, label avoidance was the single significant, positive predictor of chatbot use among distressed participants. Most participants (n=222, 67.4%) were willing to try the chatbot, indicating that using a chatbot to screen for mental distress and connect patients or participants to resources is feasible. Of the 222 individuals who agreed to use the chatbot, 168 (75.7%) completed the PHQ-9 screening within the chatbot session, and 164 (73.9%) persisted in completing the acceptability questionnaire at the end of the chatbot interaction. Again, these findings speak to the feasibility of using chatbot technology to facilitate mental health screening and referral.

A small number of participants agreed to provide their phone number within the chatbot session for follow-up purposes and a small subgroup of these participants clicked on the link within the follow-up text they received 1 month after completing the initial survey and chatbot session. Understanding the reasons for not using the chatbot and not providing one’s phone number are important to modify the chatbot and develop messaging and marketing around the chatbot that will address potential user concerns. The most cited reasons for not using the chatbot included a perception that one did not need mental health screening and referral chatbot.
services, did not have an interest in chatbots, and preferred to speak with a human about one’s mental health. To address some of these points, future iterations of the chatbot might include attention to the marketing of the chatbot, incorporating messaging around the need for mental health screening for preventative care as well as helping potential users to understand that the chatbot is not meant to replace human interaction and screening may result in referral to a human such as a peer or a licensed mental health professional. The top reasons for not providing one’s phone number to enable follow-up included a desire to keep one’s contact information private, a policy that one does not share one’s number with strangers, and not wanting solicited calls. Future iterations of this chatbot may entertain other possible mechanisms for follow-up as an alternative to providing a phone number and more clear messaging about how a phone number would be used (ie, only for a follow-up text as opposed to a call).

Overall, the participants who did agree to try the chatbot found it acceptable. The feasibility and acceptability findings of this study are in line with recent work by Shah and colleagues [40] to develop and iteratively test a chatbot to screen users for eating disorders and refer them to care. Demographic predictors of chatbot use included being White or Black or African American, identifying as Hispanic or Latino, having dependents, having insurance coverage, being employed, having used mental health services in the past, having received a diagnosis of a mental health condition, and reporting current distress. Taking these demographic characteristics into consideration when designing future iterations of the chatbot will be crucial to making sure the chatbot is available to those who need it, is culturally relevant and responsive, and is marketed appropriately. Positive correlates of chatbot use among the full sample included technology discomfort and insecurity, symptoms, beneficial and pessimistic attitudes toward treatment-seeking, perceived usefulness of the chatbot, and reported intentions to use the chatbot. Among the full sample, the only significant predictors of chatbot use were perceived stigma and DSM-5 cross-cutting symptoms. Among those participants who endorsed current psychological distress, the only significant predictor of chatbot use was label avoidance.

Limitations

This feasibility and acceptability study had limitations. First, we recruited participants through Amazon’s MTurk, which limits the generalizability of these findings. Second, we did lose a substantial portion of our sample due to either inattention to or an unreasonably short time taken to complete the survey. On the one hand, this may lead one to question the integrity of the data provided by participants of MTurk. On the other hand, we have greater confidence in the quality of the data that we did include in our analyses due to the data-cleaning procedures that we applied. Finally, the effect sizes for our statistical tests ($\chi^2$ tests in particular) are small. A replication of this study with a larger sample is called for to confirm these findings.

Conclusions

This study found that label avoidance was the single significant, positive predictor of chatbot use among distressed participants. The existing research literature suggests that label avoidance, the desire to avoid mental health services to avoid the stigmatized label of mental illness, is a significant negative predictor of care-seeking [41,42]. Therefore, our finding regarding label avoidance and chatbot use has significant public health implications in terms of facilitating access to mental health resources and stigma reduction programs and messaging. Those who are high on label avoidance are not likely to seek care in a community mental health clinic, yet they are likely willing to engage with a mental health chatbot, participate in mental health screening, and receive mental health resources within the chatbot session.

In 2020, among the 52.9 million adults living in the United States with any mental illness, less than half (46.2%) received mental health services in the past year [43]. This technology-facilitated approach to connecting people with mental health resources holds promise to reach the nearly 54% of US adults living with a mental illness who are currently going without care and presents an opportunity for intervention as well. Research suggests that many adults in the United States living with the most common mental health condition, major depressive disorder, are receiving treatment from their primary care provider [44]. This is an important consideration for future work with this chatbot for a couple of reasons. First, primary care offices may be a deployment site for a chatbot like the one we tested. This could help ensure behavioral health screening and referral and minimize demand on primary care providers. Second, the use of technology for screening and referral in primary care settings may help to eliminate the possible effects of clinician bias on behavioral health screening and referral [45].

Stigma reduction interventions (ie, videos of people sharing their stories of mental health challenges, service usage, and recovery) might be delivered via the chatbot to support those who need it to seek mental health services from a licensed clinician. Research suggests that video-based contact is an effective means of reducing the stigma surrounding mental illness [46]. Additionally, motivational interviewing strategies might be used within the chatbot session to move users through the transtheoretical model of health behavior change [47], toward a decision to seek evidence-based treatments. Others have demonstrated the possibility of deploying motivational interviewing conversational sequencing using chatbot technology for stress management [48] and smoking cessation [49]. Chatbot technology may prove to be a way to engage those in care who have previously avoided treatment due to stigma, which could have a significant public health impact by way of shrinking the mental health treatment gap.

The future vision for Tabatha, given the feasibility and acceptability of the prototype chatbot, is as a conversational agent aimed at assuming the service delivery tasks of screening, referral, and stigma reduction. Tabatha might be deployed in various settings with diverse populations, and refer to a plethora of existing resources, including other conversational agents designed to deliver digital therapy (ie, reSET-O, Woebot, and Wysa). Future research should focus on examining Tabatha’s effectiveness in reducing stigma and navigating users to existing behavioral health resources of various intensities. The current Tabatha prototype is a rule-based chatbot, as opposed to a
machine-learning chatbot [50]. Future research might consider how machine learning might be used to facilitate screening, referral, and stigma reduction through Tabatha.

Abstract

Background: Acute mental health services report high levels of safety incidents that involve both patients and staff. The potential for patients to be involved in interventions to improve safety within a mental health setting is acknowledged, and there is a need for interventions that proactively seek the patient perspective of safety. Digital technologies may offer opportunities to address this need.

Objective: This research sought to design and develop a digital real-time monitoring tool (WardSonar) to collect and collate daily information from patients in acute mental health wards about their perceptions of safety. We present the design and development process and underpinning logic model and programme theory.

Methods: The first stage involved a synthesis of the findings from a systematic review and evidence scan, interviews with patients (n=8) and health professionals (n=17), and stakeholder engagement. Cycles of design activities and discussion followed with patients, staff, and stakeholder groups, to design and develop the prototype tool.

Results: We drew on patient safety theory and the concepts of contagion and milieu. The data synthesis, design, and development process resulted in three prototype components of the digital monitoring tool (WardSonar): (1) a patient recording interface that asks patients to input their perceptions into a tablet computer, to assess how the ward feels and whether the direction is changing, that is, “getting worse” or “getting better”; (2) a staff dashboard and functionality to interrogate the data at different levels; and (3) a public-facing ward interface. The technology is available as open-source code.

Conclusions: Recent patient safety policy and research priorities encourage innovative approaches to measuring and monitoring safety. We developed a digital real-time monitoring tool to collect information from patients in acute mental health wards about perceived safety, to support staff to respond and intervene to changes in the clinical environment more proactively.

Introduction

Overview

High levels of patient safety incidents are reported within mental health services. Between April 2020 and March 2021, a total of 300,703 incidents were reported in England, often involving self-harming behavior and disruptive, aggressive behavior [1]. Patient safety within mental health services is recognized as a priority within the National Health Service (NHS) Patient Safety Strategy 2021 update [2] and is a key research priority within the extant literature [3–6].

Supporting patients and families to be partners in care safety can be viewed as both a logical and moral imperative [7]. Furthermore, understanding the patient perspective is an important patient safety priority in the mental health field [4]. Recognizing the limitations of patient safety incident reporting systems, research evidence suggests that patients and families are a valuable source of safety intelligence that can inform service improvement in acute [8–10] and primary care settings [11–13]. Indeed, our previous research directly addressed this priority for mental health patient safety research, by evidencing that patients acknowledge the value of their potential involvement in interventions to improve safety and the need to develop interventions that proactively seek the patient perspective of safety [14,15].

In addition to understanding the patient perspective, there is also policy and research impetus to understand safety in real time, to shift from a reliance on retrospective patient safety measures [6,16], and a push toward embracing innovative approaches and digital solutions to safety challenges [6,17].

Considered together, these policy and research priorities provide the rationale for the development of a digital monitoring tool that captures the patient perspective of safety in real time, in an acute mental health ward setting.

Theoretical and Conceptual Underpinning of the Digital Monitoring Tool

The theoretical foundation for the development of a digital real-time monitoring tool is embedded within the measurement and monitoring of safety (MMS) framework [16]. Previous research exploring the framework in practice acknowledged its potential to support a broader and richer approach to organizational safety [18,19]. Specifically, we focus on 1 domain of the framework—sensitivity to operations. This domain describes the need for a collective awareness by staff of the workings of the service and their ability to be sensitive and responsive to subtle changes and disturbances. This domain highlights the crucial but often overlooked activity of “monitoring” the safety of care as it is delivered in real time, and it is a domain where patients and families are recognized as potential key sources of information. Within the wider patient safety literature, the importance of safety “monitoring” as opposed to solely “measurement” and the potential of prospective clinical surveillance as a means of promoting safety within organizations have gained traction [20,21]. Supporting the idea of prospective clinical surveillance as a means of promoting safety is particularly important within the acute mental health care context, where fluctuations in the dynamic of the inpatient group and the interplay between patients, staff, and the environment can occur rapidly, with individual patient needs creating immediate knock-on effects for other patients, their quality of care, and their safety.

Two further concepts that informed our thinking and the development of the real-time digital monitoring tool are milieu and contagion. The concept of milieu is often aligned with the notion of ward atmosphere, which involves the interplay between the physical environment, social structures, and social interactions [22]. In this work, we conceptualize the milieu as being akin to the ward atmosphere. Safety may be related to tensions in the milieu of the ward [23], and improving the milieu may improve safety [24]. There is research to support the notion of a “contagion effect” of safety incidents (violence and self-harm behaviors) within an inpatient mental health ward setting [25], with evidence to suggest that patient aggression and self-harm behaviors do not occur at random intervals, but cluster temporally. Therefore, a key safety issue is the potential for 1 incident to increase the likelihood of further incidents occurring as a result of disturbed ward milieu and contagion.

Considering contagion and milieu alongside the domain sensitivity to operations of the MMS framework [16] underpinned our operationalization of how we might capture perceptions of safety in real time. A digital monitoring tool capturing how the ward is perceived by patients (ie, the milieu) at any given time may provide intelligence that supports staff to respond proactively to emerging safety issues and intervene earlier, which may prevent future incidents from occurring via disturbed ward milieu and contagion.

Aim

The aim of this study is to design and develop a digital real-time monitoring tool that collects and collates information from patients in acute mental health wards about their perceptions of safety, in order to support staff in monitoring and improving the safety of the clinical environment.

Approach

This paper focuses on the design and development of the digital monitoring tool. Two stages are presented: stage 1—a synthesis of exploratory research, existing research, and stakeholder engagement and stage 2—design and development. The methods and results are presented for each stage separately. The findings relating to the implementation and evaluation (qualitative) of the tool are reported elsewhere [26] and include further information about how the tool was operationalized in the implementation phase.
Methods

Stage 1: Exploratory Research, Existing Research, and Stakeholder Engagement Synthesis

Objective

This stage focused on bringing together and synthesizing key findings from our exploratory research, previous research, and early stakeholder engagement discussions. The purpose of this synthesis was to generate themes, preliminary ideas, and needs for the monitoring tool from multiple perspectives.

Activities and Analysis

We conducted (1) a systematic review [27] and evidence scan, (2) semistructured interviews with health professionals [28] and patients, and (3) stakeholder engagement sessions (see Textbox 1).

Textbox 1. Overview of activities contributing to data synthesis.

Ethical Considerations

The interview study with health professionals received ethical approval from the University of Leeds, School of Healthcare Ethics Committee (HREC 19-028), and the interview study with patients received ethical approval from South Central—Berkshire B Research Ethics Committee (20/SC/0360). Prior to the interviews, researchers explained the purpose and process of the interview to the participant, read the consent form out loud, and recorded consent verbally. Interviews were audio recorded, anonymized, and transcribed professionally. Patients who were interviewed received a £10 (US $12.79) shopping voucher as a thank you for their time.

Data Synthesis

We produced summary documents for the systematic review and evidence scan, ongoing interviews with patients and health professionals, and stakeholder engagement sessions. The findings were organized and reviewed through the lens of implications for the design and development phase and discussed on an ongoing basis between the core research team (including 2 co-investigators with lived experience), the project Steering Group, digital partners (Ayup Digital), and co-design partners (Thrive by Design).

Stage 2: Design and Development

Objective

This stage was informed by stage 1 and focused on the design and development of a digital monitoring tool to enable a real-time understanding of the patient perspective of safety in acute mental health wards.

Activities and Analysis

This stage was significantly affected by the COVID-19 pandemic [31]; pragmatic adjustments were made to the original
co-design plan to produce a feasible alternative in which a single NHS Trust permitted limited visits from a clinical member of the co-design team who was familiar with the local protocols.

At the outset of this stage, members of the core research team, digital partners, and co-design partners drew from the ongoing stage-1 synthesis to inform the basis of the subsequent activities. The reworked co-design activities included face-to-face discussions and opportunistic feedback from patients and staff during ward visits in 2 wards in the North of England. This stage also involved further stakeholder engagement sessions with the same 2 stakeholder groups described in stage 1. We used a collaborative, human-centered, and sprint-based or agile approach [32,33], incorporating techniques such as “personas” (typical users with specific characteristics including experience of disability and different levels of digital skills), storyboards (to elicit user goals), patient journey mapping (the path of an individual patient and health care staff member in a ward), user stories (to elicit specific user requirements), and prototyping (rapid creation of paper prototypes of a digital tool). The first cycle of activities generated requirements for the digital tool; subsequent activities tested and refined the tool as it developed and considered its use within the clinical workflow of the ward environment.

Ward-Based Activities

Visit 1 (December 2020)

Draft ideas for the digital products were discussed, for example, wording, format, color, and how they would work in relation to existing systems. People wrote comments and provided feedback on all aspects of the design. From the staff perspective, we explored whether the visuals looked like anything already in use, to avoid unintended consequences arising from confusion.

- Ward A (adult acute ward caring for male patients aged 18-65 years): opportunistic feedback and discussion with 3 patients and 3 members of staff (clinical and administrative).
- Ward B (adult acute ward caring for female patients aged 18-65 years): opportunistic feedback and discussion with 5 patients and 12 members of staff (clinical and administrative); a total of 3 members of staff and 5 patients participated in a co-design workshop (approximately 40 minutes duration).

Once activities commenced in the wards, members of the core research team, digital partners, and co-design partners continued to meet fortnightly to interrogate and interpret the feedback on the digital product ideas in more detail, focusing on who would benefit, considering the “must haves,” and recording when there was consensus on what not to include. Discussions centered on how many of the “must haves” were realistic to implement, and alongside input from the project Steering Group fed into the development of the second iteration of the digital products.

Visit 2 (January 2021)

Discussions and activities focused on the refined prototype ideas for the digital products. For both Ward A and Ward B, multiple versions of the latest iteration of products were presented and feedback elicited, in addition to revisiting discussions from visit 1. People provided feedback on the wording, icons, colors, and representations, that is, was it what they imagined? From the staff perspective, the requirements of the staff dashboard were revisited, and from the patient and staff perspective, the acceptability of a public-facing ward interface was explored. As there was a high turnover of patients, many new patients were involved, although many of the same staff contributed, which enabled discussions from the first visits to be revisited.

- Ward A: opportunistic feedback and discussion with 5 patients and 3 members of staff (clinical and administrative).
- Ward B: opportunistic feedback and discussion with 6 patients and 5 members of staff (clinical and administrative).

Feedback from the ward-based discussions and activities was collated and prioritized using the Must Have; Should Have; Could Have; Won’t Have this time (MoSCoW) method [34], which then guided conceptual and technical development. Prototype ideas were refined following the prioritization exercise.

Stakeholder Engagement

Sessions followed via video conferencing software with the same 2 stakeholder groups described previously in stage 1 (July 2021). The most recent prototype ideas were presented and discussed, focusing on (1) the design of the patient interface: Would you feel comfortable completing it? (2) Could you say why you would feel more or less comfortable? (3) Do you think completing a report on the ward atmosphere on a digital tablet would make you feel less or more distressed? and (4) public-facing ward interface: How would you feel about this being displayed in a ward?

Results

Stage 1: Exploratory Research, Existing Research, and Stakeholder Engagement Synthesis

The findings from the synthesis are organized around 7 themes with associated implications for the subsequent design and development phase (see Textbox 2). Supporting information for each theme is outlined in Tables S1-S7 in Multimedia Appendix 2.
**Textbox 2.** Themes and design and development implications.

### Conceptualization of safety
- Allow for a multifaceted conceptualization of safety.
- Consider how the word “safety” may be misinterpreted—provide a clear description.

### Anonymity
- Anonymity essential.
- Reinforce feedback is anonymous and that everyone’s experience is important—all feedback valued.
- Give clear information about the use and purpose of collecting information via digital technology.

### Milieu (ward atmosphere), contagion, and incidents
- The technology needs to be sensitive to subtle changes in a negative direction in order to anticipate the potential for an incident occurring.
- Explore whether the technology can be sensitive to context, for example, highlight when a safety incident has recently occurred.
- Location: potential for the technology to be sensitive to location within the ward, for example, increased anxiety or input activity by patients into the technology (prior to and after an incident).
- Night and day: the technology needs to recognize night and day as different contexts.
- The technology may need to account for or recognize ward profiles (eg, all male, all female, and mixed wards).
- The technology may need to account for or recognize differences between individual patients.

### Digital technology in the ward
- Ensure the purpose of the monitoring tool is clearly described to patients and staff.
- The technology needs to be inclusive across a wide range of patients and digital abilities.
- Staff may need support with using the technology and with data interpretation.
- Consider multiple mechanisms for data collection other than a single device or reporting “point.”
- Consider other relevant systems in place for staff.

### Involving patients in understanding safety
- Technology needs to incorporate the input of quantitative and qualitative data to give patients choice about the level of detail they provide.
- Explore using language or imagery that is universal and include a free text option to expand.
- Consider different levels of providing feedback, for example, level 1 reporting—a color or smiley face and level 2—more detailed information.
- Explore whether thresholds need to be built into the system to trigger alerts or action.
- Consider how the phrases used to describe safety converge with those used by other relevant organizations.
- Consider the location of data collection and timings.
- Consider the implications of the type of ward.

### Feeding data back
- The technology and mechanism of feeding data back needs to work within existing trust and ward infrastructure.
- Explore frequency or timing of monitoring the data to ensure staff can be responsive.
- Consider approaches to displaying the data.
- Consider who can see the data and when.
- Staff may need support with data interpretation and action.

### Unintended consequences
- Important to provide choice and freedom on when to provide feedback.
- May need to offer different levels of providing feedback.
- Consider how the technology sits alongside verbal information and feedback.
Stage 2: Design and Development

Intervention Design and Description

Overview
The latest version of the digital monitoring tool, WardSonar (prototype 3), includes 3 components—a patient recording interface, a health professional dashboard, and a public-facing ward interface. Further information about the prioritization process and conceptual and technical development is provided in Multimedia Appendix 3.

Patient Recording Interface
The recording interface is an app accessed on a tablet device (see Figure 1). The interface provides brief background information and prompts patients to answer a series of questions. No patient data are collected, and all data collected on the interface are anonymized at the point of entry. The interface uses a weather analogy with questions, such as “How does the ward atmosphere feel right now?” (very calm to very stormy), as the co-design phase identified the need to provide different ways for people to be able to express how the ward was feeling, such as pictures and text. Therefore, free-text options were also included. The design and development phase highlighted that more options for how the ward was feeling would be beneficial to reflect that this is often more than “good, bad and okay” and that the feeling is more of a spectrum. Therefore, the interface includes 5 options to describe how the ward is feeling, and an additional question to indicate the direction things are moving in (ie, getting better, getting worse, or staying the same). Attention was paid to understanding the contextual constraints and pressures that patients may be experiencing (eg, location when entering data and current mental state at the time of data entry), and feedback from the design and development phase suggested that a reporting “point” could create negativity toward the area it is placed and prevent people from using it.
The idea of patients using their own mobile phones to provide feedback was also considered in the design and development phase. This was not progressed at this initial stage as not all patients have a smartphone or access to data, and from a technological development perspective, in the subsequent implementation phase, each ward required a secure login to access the app. Organizing this for each patient on either their own or a study-bought device would have required technological support in the wards, which would not have been feasible during the COVID-19 pandemic, and we were aiming for the approach to be implemented with minimal support. Therefore, in the subsequent implementation phase, it was decided that staff would supply patients with the tablet device (provided by the research study) optimally 3 times per day so patients could enter real-time safety perspectives. Staff supplying the tablet device to patients also addressed staff concerns about the security of the tablet devices and who would have responsibility for them.

**Staff Dashboard**

The staff dashboard is the main interface used by staff to view data submitted by patients on a tablet device or desktop computer (see Figure 2). It is accessed in specific, authorized locations, such as the ward office, and provides real-time snapshot data and greater informational insights through the use of data visualizations. The co-design phase with staff,
statisticians, and researchers resulted in the dashboard including barometer-style visualization of “How is the ward feeling,” statistical process control charts, graphs, and statistical metrics, and the functionality for monthly, weekly, daily, or shift aggregate data to be comparable to historic time periods.

**Figure 2.** Prototype-3 staff dashboard.

**Public-Facing Ward Interface**

The public-facing ward interface displays the average ward atmosphere rating for the current shift on, for example, a television screen, desktop computer monitor, or tablet device (see Figure 3). The outcome measure is displayed in the form of a barometer.
Stakeholder Engagement

The 2 groups were positive about the prototype-3 patient recording interface, in particular, the simplicity of the interface and the anonymity it provides. Overall, people felt the patient interface would be a safe space to report concerns. However, it was emphasized that this system should not replace reporting in person to staff. Regarding the question of factors affecting how the ward feels, there was consensus that it was important to be able to select more than 1 factor and this change was subsequently implemented. A number of potential unintended consequences were emphasized such as people being concerned that others were making reports about them; that the technology might trigger people’s symptoms; and that the ward interface could be confusing, as patients may think it referred to the weather outside. Of particular note were discussions around the potential for a poor ward atmosphere when a ward is understaffed, meaning there may be limited support from staff to circulate the device at these times. There were concerns raised around the accessibility and inclusivity of the patient recording interface which would need to be addressed in future iterations, for example, people who may experience barriers related to language or literacy, people with learning disabilities, and people with visual impairments. As potential unintended consequences were highlighted regarding the public-facing ward interface, this component of the tool did not progress to the subsequent implementation phase [26].

Technical Specifications

The digital products were built using open web standard technologies (eg, HTML5, CSS3, JavaScript, and PHP) in a componentized and scalable way, to allow modifications and future developments, and were based on the Government Digital Service Agile Delivery methodology framework and NHS standards. All digital products are hosted in a custom cloud environment built on top of the Amazon Web Services infrastructure. Data are recorded in real time and sent to an application programming interface. The interface was built to Web Content Accessibility Guidelines (WCAG) 2.1 AA [35] standards and is device agnostic.

Patients are able to input data via a device supplied by ward staff. Patient data are monitored through the staff dashboard by authorized members of staff with access via a tablet device or desktop computer. Any data input by patients are recorded via the app and is automatically sent back in real time to the central database. If Wi-Fi is temporarily unavailable in the ward, then the data that are input are stored locally on the device in offline mode. When the device comes back into the Wi-Fi range the data are automatically submitted to the central database. Further information about the technologies used and infrastructure is provided in Multimedia Appendix 4.

Logic Model and Program Theory

A logic model was generated to articulate how the various components of WardSonar related to each other (see Figure 4). In conjunction with the logic model, Multimedia Appendix 5 provides a narrative description of the program theory explaining how WardSonar might facilitate change in proximal and distal outcomes.
**Figure 4.** The logic model for the WardSonar monitoring tool. *For example, gender, ethnicity, disorder, and digital literacy; **for example, qualification and gender; ***for example, skill mix and staffing levels.

**Discussion**

**Principal Findings**

We successfully developed WardSonar, a theory-informed, patient-centered, real-time digital safety monitoring tool for acute mental health wards. The WardSonar monitoring tool aims to collect daily information from patients in acute mental health wards about perceived safety to support health professionals in monitoring and improving the safety of the clinical environment.

The process of design and development included synthesizing findings from a systematic review, evidence scan, interviews with patients and health professionals, and stakeholder engagement, to inform a cycle of design activities. The synthesis highlighted broad themes and potential unintended consequences to be explored further within the subsequent design phase. For instance, the importance of the tool allowing for a multifaceted conceptualization of safety, ensuring patient anonymity, being sensitive to subtle changes, and being inclusive across a wide range of patients and digital abilities.

The design and development process resulted in 3 components of the monitoring tool. First, a patient recording interface to assess how the ward feels. Patients were keen to have different ways to be able to express how the ward was feeling, including pictures, text, and being able to write in free text. The need to capture whether the direction is changing, that is, “getting worse” or “getting better” was felt to be really important from a health professional perspective. The second component was a staff dashboard with functionality to interrogate the data at different levels, and the third component was a public-facing ward interface. Potential unintended consequences and challenges were highlighted, for example, the public-facing ward interface being potentially triggering if displaying a negative ward atmosphere. Embedding the principles of WardSonar within the MMS framework [16], and within the domain sensitivity to operations specifically, has produced a safety monitoring tool that recognizes patients as a key source of safety information and facilitates health professionals being aware of subtle changes and disturbances.

**Implications for Research and Practice**

The next step is for the WardSonar monitoring tool and its components to be implemented in practice, and for this to be accompanied by a robust evaluation. This will generate evidence around key questions pertaining to feasibility and acceptability, for example, is it feasible and acceptable to collect safety data from patients in mental health wards? and, how do staff use the data collected from patients? Such an evaluation may support further refinement of WardSonar, and over the longer term, would explore the assumptions articulated in the WardSonar logic model, for instance, our hypothesized distal outcomes, leading to a refined logic model and program theory in line with Medical Research Council guidance on developing and evaluating complex interventions [36].
A key feature of the design and development phase was the need for WardSonar to be accessible for people with different language and literacy needs and for it to be accessible for a range of digital abilities. Our most recent stakeholder engagement identified concerns around accessibility and inclusivity of the patient interface. Therefore, it will be essential for these concerns to be examined further in subsequent evaluation work to ensure future iterations of the WardSonar tool can be accessed equitably.

**Strengths and Limitations**

To our knowledge, the WardSonar monitoring tool is the first system that actively seeks the perspective of safety from patients in real time for use within acute mental health wards. A key strength of this work is our theory-based approach and the multiple data sources brought into the design and development phase. A limitation of our work is the level of co-design and stakeholder engagement activity we were able to undertake, as our original plans had to be amended considerably due to the impact of the COVID-19 pandemic on the project.

**Conclusions**

Recent patient safety policy and research priorities encourage innovative approaches to measuring and monitoring safety, and there is a need for a patient-centered understanding of safety in an acute mental health setting. At present, no interventions or tools exist to address this need. We developed a digital real-time monitoring tool to collect information from patients in acute mental health wards about perceived safety, to support health professionals to respond, and intervene to changes in the clinical environment more proactively. Further research is required to evaluate the implementation of WardSonar to further refine and improve this innovative approach.

**Acknowledgments**

This project was funded by the National Institute for Health and Care Research (NIHR) Health and Social Care Delivery Research program (HSDR, NIHR 12/80/70) and was supported by the NIHR Yorkshire and Humber Patient Safety Translational Research Centre. The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care. We would like to express our thanks to everyone who participated in interviews and discussions, which informed the development of WardSonar, and to the stakeholder groups and research staff involved in the WardSonar project. We would also like to thank Steven Taylor from Ayup Digital and the WardSonar Steering Group for their contributions, support, and steer. The project was supported by 2 coinvestigators with lived experience of mental health services and mental health services and digital expertise. Stakeholder engagement fed into the development of the monitoring tool.

**Data Availability**

The data sets generated and analyzed during this study data are available from the Principal Investigator (JB) on reasonable request.

Abstract

Background: Subjective cognitive concerns (SCCs) entail perceived difficulties in thinking or memory, often reported without substantial objective evidence of cognitive impairment. These concerns are prevalent among individuals with a history of brain injuries, neurological conditions, or chronic illnesses, contributing to both psychological distress and functional limitations. They are increasingly considered to be a risk factor for future objective decline. A considerable number of individuals reporting SCCs also exhibit mental health symptoms, such as a history of trauma, depression, or anxiety. Interventions that address modifiable emotional and cognitive factors related to SCC could improve functioning and quality of life. Therefore, the use of emotion regulation strategies, especially those directed at minimizing rumination, could serve as a promising focus for interventions aimed at mitigating subjective cognitive concerns in veteran populations.

Objective: This pilot study explored the feasibility, acceptability, and preliminary efficacy of a brief, 1-session emotion regulation intervention called “Worry Less, Remember More.” The Worry Less, Remember More intervention was designed to reduce rumination and improve subjective cognitive functioning in veterans with subjective cognitive changes (N=15).

Methods: We randomized 15 veterans to either the active telehealth condition or waitlist control and completed the intervention. Participants were aged between 31 and 67 (mean 49.5, SD 10.1) years, and the sample was primarily male (12/15, 83%) and White (10/15, 67%). The most common diagnoses were posttraumatic stress disorder and depression. Following the intervention, veteran input was sought through semistructured interviews with a subset of 12 participants, examining feasibility, acceptability, and perceived efficacy. Preliminary efficacy was also measured using pre- and postintervention self-report measures.

Results: Veterans reported that this intervention was acceptable, with 92% (11/12) of the sample reporting that they benefited from the intervention and would recommend the intervention to others with similar difficulties. Semistructured interviews revealed difficulties with feasibility, including problems with the remote consenting process, forgetting appointments, and needing additional strategies to remember to consistently use the interventions. The intervention improved self-reported cognitive symptoms on quantitative measures but did not improve self-reported rumination.
Conclusions: This pilot study establishes the preliminary feasibility, acceptability, and efficacy of the Worry Less, Remember More intervention for veterans with subjective cognitive symptoms. Future iterations of the intervention may benefit from simplifying the electronic consent process, providing reminders for appointments, and incorporating compensatory cognitive strategies to assist with using the telehealth system, as well as applying the strategies learned in the intervention. While future research is needed with larger samples, including nonveteran populations, the intervention may also be a useful clinical tool to bridge care between neuropsychology clinics and mental health treatment.

Introduction
Subjective cognitive concerns (SCCs) refer to perceived challenges in thinking or memory reported with either no evidence or only minimal objective evidence of cognitive impairment [1]. SCCs are common in people with histories of brain injuries, neurological illnesses, and other chronic illnesses and contribute to psychological distress and functional impairment [2-5]. More than 10% of US veterans aged 45 years or older report subjective cognitive symptoms [6]. Interest in SCCs has increased due to cognitive symptoms, such as “brain fog,” following the COVID-19 infection [7]. Research has found that SCCs are often related to potentially modifiable factors that influence cognition, such as mood, and many individuals with SCCs have mental health symptoms, including a history of trauma, depression, or anxiety [8-11]. A recent study in a neuropsychology clinic found that childhood trauma predicted SCCs and that this relationship was mediated by a ruminative thought style [12]. Emotion dysregulation, including rumination, contributes to and maintains psychopathology as well as cognitive dysfunction, particularly in those with affective illnesses [13] and has been implicated in the maintenance of neuropsychiatric illness [14,15]. Rumination, or the tendency to passively and persistently dwell on negative or problematic aspects of life, and the ruminative thought process, which includes the act of focusing on the potential causes and outcomes of the negative or problematic aspects of life, are forms of emotional dysregulation, which are patterns of emotional experience or expression that interfere with goal-directed activity [14]. Ineffective coping strategies perpetuate emotion dysregulation and, thereby, depression and other psychological disorders [16,17].

Emotion regulation approaches vary in their impact on both emotional health (eg, depression relapse and severity) and cognitive functioning. Less effective regulation strategies, such as rumination (eg, perseverative thought processes focusing on negative content) [18] and suppression (inhibiting the outward signs of inner feelings), are suggested to be cognitively taxing, thus diminishing cognitive resources [19]. Rumination and suppression have been associated with poor health and negative psychological outcomes in the general population as well as in veteran populations [20]. In veterans, rumination has been found to moderate the association between posttraumatic stress disorder (PTSD) or depression and risky behavior [21] and between moral injury and negative mental health symptoms [22]. Rumination is also associated with sleep problems in veterans with PTSD and depression [22]. There is also preliminary evidence that rumination may moderate the relationship between attentional difficulties and PTSD symptoms [23].

As such, emotion regulation strategy use, particularly strategies aimed at reducing rumination, may be a good target for intervention to reduce SCCs in veteran populations. In order to address these difficulties, we created a 1-session treatment called “Worry Less, Remember More,” integrating elements from Watkins’s [24] rumination-focused cognitive-behavioral therapy for depression and Gilbert’s [25] compassion-focused therapy (Multimedia Appendix 1 [24,26,27]). The psychoeducation portion consisted of concepts from evolutionary psychology as described by Gilbert [25], including an evolutionarily adapted attentional bias toward negative information, information about emotional regulation systems and their responses to trauma and stress, and attention as a limited resource that can be redirected. We used Watkins’s [24] 12-session rumination-focused cognitive-behavioral therapy for depression to provide specific examples of rumination, purposes of rumination, and 3 short intervention exercises. The session was designed to be delivered through telehealth, as there is evidence that telehealth and web-based interventions are feasible, acceptable, and efficacious in bridging care and supplementing existing mental health treatment [28,29], including in populations with cognitive difficulties [30].

In addition to establishing the feasibility and efficacy of emotion regulation interventions to improve subjective cognitive functioning, it is also important to establish the acceptability of the intervention to individuals with SCCs to increase treatment engagement, compliance, and completion [31]. For this study, we operationalized feasibility (including demand, implementation, practicality, and integration into existing systems) and acceptability according to Bowen et al [32], Pearson et al [33], and Sekhon et al [34]. The goal of this study was to establish the feasibility, acceptability, and preliminary efficacy of a 1-session, rumination-focused intervention for veterans with SCCs compared to a waitlist control condition.

Methods

Ethical Considerations
This study was approved by the Central Texas Veterans Healthcare System Institutional Review Board (IRB number...
00697). All participants were informed of the purpose of the study, as well as the possibility of dropping out at any time, and signed written informed consent before participation. All included study data are deidentified, and all quotes are anonymous and have been carefully reviewed to have all potentially identifiable data removed. Participants were paid US $40 per visit (US $120 in total).

**Recruitment**

Veterans were recruited from the Veterans Administration (VA) neuropsychology specialty clinics, primary care clinics, and mental health clinics. The majority of veterans who participated were referred by mental health providers, though some veterans self-referred through flyers placed on the medical campus.

Inclusion criteria included verbal endorsement of cognitive difficulties and veteran status. Exclusion criteria included (1) a score of <23 on the Montreal Cognitive Assessment (MoCA); (2) current substance abuse; or (3) a diagnosis of serious mental illness, such as schizophrenia or psychotic disorders. We screened 49 veterans for eligibility, of whom 9 were self-referred and 40 were referred by mental health providers. Of the 49 veterans referred, 23 did not return to complete informed consent, 4 declined to participate, 2 had MoCA scores <23, another 2 were ineligible due to substance use, and 1 was ineligible due to a diagnosis of severe mental illness. Thus, a total of 17 veterans were enrolled and randomized to either the intervention or waitlist control condition before baseline testing. Of the veterans randomized, 15 attended the first visit (baseline testing and intervention for the intervention group; baseline testing only for the waitlist control group), and 12 attended both the initial assessment and follow-up testing. The 12 participants who completed the intervention also completed quantitative assessments and qualitative interviews at the 8-week follow-up. All study procedures (including screening, consenting, assessment, and intervention) were delivered remotely using VA video telehealth software.

**Sample Characteristics**

Participants' were aged between 31 and 67 (mean 49.5, SD 10.1) years (Table 1), and the sample was primarily male (12/15, 83%) and White (10/15, 67%). The most common diagnoses were PTSD and depression. There were no significant differences between the full sample and the qualitative interview participant subset on age, gender, race or ethnicity, rates of PTSD or sleep difficulties, or the percentage of participants who completed all study visits. The qualitative interview group had a higher percentage of brain injuries and lower rates of depression.

**Study Procedure**

The pilot study was a 1-visit randomized controlled trial with 2 follow-up visits to gather outcome data. All study visits were conducted remotely, using the VA telehealth system. Before the start of the study, participants were randomized to either an intervention or waitlist control condition. At the first visit, participants in both conditions completed a comprehensive preintervention self-report battery. Immediately following the initial baseline measures, those randomized to the intervention condition then participated in a 30-minute psychoeducation and rumination-focused intervention, whereas those in the waitlist control condition were excused. Then, 8 weeks later, both groups completed follow-up behavioral measures, and the waitlist control group received the intervention. Both groups completed follow-up behavioral measures at the third visit, approximately 8 weeks after the second visit.

**Measures**

Measures administered included the Beck Depression Inventory-Second Edition (BDI-II) [35], the Beck Anxiety Inventory (BAI) [36], the Ruminative Response Scale and Perseverative Thinking Questionnaire-Short Form (RRS-SF) to assess rumination [37], the Behavior Rating Inventory of Executive Functioning-Adult (BRIEF-A) self-report [38], the Neurobehavioral Symptom Inventory (NSI) [39], and the
Rivermead Post-Concussion Symptoms Questionnaire [40]. Raw scores from the BRIEF-A and cognitive items from the Rivermead and NSI were summed into a cognitive index score for each participant.

**Statistical Analysis**

Quantitative analyses were performed in R (R Core Team) using statistical packages and the original code [41]. The data were checked for normality and outlier values; no corrections were needed. When <10% of data were missing at random, missing values were estimated and imputed using a random forest–based imputation, which has been shown to be appropriate for imputing mixed continuous or categorical data even in the presence of potential interactions and nonlinearity [42]. Differences in pre-post outcome measures (rumination and cognitive composite score) were assessed using repeated measures ANOVA with group as a between subject factor and time point (pre or post) and test as within-subject factors. Significant ANOVAs were followed up with 2-tailed t tests. Post hoc power analysis showed that with our sample size, we were only 15% powered to find an effect similar to previous single-session studies, which found small effects on emotional functioning (d=0.10-0.30). Based on the effect sizes in these studies, 139 participants per group would be needed for an α=.05 and a power of 0.80. As such, the purpose of this study is only to determine preliminary efficacy.

**Qualitative Data Collection and Analysis**

We created an interview guide based on acceptability and feasibility concepts from Sekhon et al [34] and Bowen et al [32]. One portion of the interview guide consisted of 2 questions asked of all participants (“would you recommend this intervention to others with thinking difficulties?” and “did you feel you benefited from this intervention?”). The second portion of the interview guide contained flexible questions and prompts related to intervention cohesiveness, perceived effectiveness, usability, feasibility, and preferences. Example prompts from the interview guides are included in Table 2.

Interviews were conducted by 2 researchers at least 1 month after the second visit, and each interview was conducted by a researcher not involved in intervention delivery for each participant. Interviews lasted 20–45 minutes and were recorded and transcribed verbatim by the primary researcher (TA). Following each interview, a memo was written describing the conversation, themes observed, and experience of the interviewer. During the interview and transcription, responses were put under the construct addressed. If a response did not appear to address a construct, it was written at the bottom of the interview form. Following transcription, these responses were read and coded according to pre-established codes. Pre-established codes and themes were identified through discussions with participants before initiating the formal qualitative portion of the project. Additionally, themes that appeared in both the data memos before the transcription process and after all interviews were completed were coded. All interviews were read and coded for evidence of emerging codes. A secondary coder met to review and discuss the assigned codes. Discrepancies between coders were resolved by discussion.

Results

Quantitative Findings
There were no significant differences between groups on preintervention measures of rumination, perseverative thinking, or mood. There was a significant difference on one measure of neuropsychiatric symptoms, with higher reported cognitive difficulties on the NSI in the treatment group (Table 1). Both groups reported high levels of neuropsychiatric symptoms, rumination, and perseverative thinking, as well as severe symptoms of depression and moderate symptoms of anxiety.

Acceptability
A total of 92% (11/12) of participants reported they benefited from the intervention and would recommend the intervention to other veterans with similar difficulties. The 1 veteran who reported they did not benefit directly from the program reported benefiting somewhat from the intervention, as it was able to provide a referral to more intensive cognitive rehabilitation treatment.

Efficacy
When examining the postintervention outcome measures (rumination and the cognitive composite index), there was a significant interaction between time and group for the cognitive composite index ($F_{1,13}=5.97; P=.03$), with significant improvement in the intervention group and not the control group (small effect $d=0.10$). There was not a significant interaction between time and group on measures of self-reported rumination.

Qualitative Findings
Preintervention Expectations and the Motivation to Participate
Veterans reported few, if any, expectations for the intervention, with comments like “I didn’t really know what to expect” or reported general expectations about improving cognition, such as “It was supposed to help with my memory, correct?” (Table 2 contains participant responses). A total of 92% (11/12) veterans reported that their primary motivation to start the intervention was to have tools to help with their daily difficulties with cognition. One veteran reported that his primary motivation to participate was to improve future treatments for other veterans experiencing cognitive problems.

Acceptability
When asked about recommending the intervention to others with similar difficulties, several veterans (n=4 with similar comments) reported that the intervention “would be helpful to do postdeployment” and should be given to all “combat veterans for sure” before the development of cognitive difficulties. The feedback on perceived effectiveness was generally positive, with most veterans reporting improvement in daily functioning. Notably, more veterans reported their spouse or partner had noticed improvement (n=6) compared to those who stated they had noticed improvement themselves (n=4).

Feasibility
A barrier to participation in the study was the required remote consenting procedures. A total of 23 veterans expressed interest but did not return the consent form. Those who participated in the intervention reported that the remote consenting process was more difficult compared to previous in-person consenting for research participation. Another barrier to participation was forgetting appointments, and many participants had to be rescheduled multiple times due to forgetting appointments. Veterans were called the week of their appointment to remind them of their appointment; however, they requested additional reminders and reminders in digital modalities, such as “email appointment reminders, like a hard copy, just as a physical reminder.” Retention rates improved when the telehealth system started to send out SMS text message reminders of the appointment along with the email reminder.

Even though 92% (11/12) of participants said they recommended the intervention, only 2 out of the 12 veterans were able to describe and recall an exercise from the study, and several indicated that they forgot what the exercises were. Of the 10 veterans who did not remember the specifics of the intervention, 2 reported it was helpful to learn more about additional resources for both cognitive skills and treatments for mood, which they were able to pursue after the intervention. A veteran reported it was helpful as “this helped me put things into words and helps me understand. Sometimes you don’t know how to put things into words.” He reported that being able to explain both his cognitive difficulties and mood symptoms had improved communication with his family and members of his health care team. In contrast to the intervention exercises, the psychoeducation portion was noted as helpful in interviews with 10 veterans.

Discussion
Overview
We found the preliminary efficacy of a 1-session rumination-focused intervention to improve cognitive symptoms; however, there was no change in rumination, which was the proposed treatment target and mechanism. In qualitative interviews, veterans reported this intervention was acceptable and beneficial, as evidenced by over 92% (11/12) stating they benefited from the intervention and would recommend the intervention to others with similar difficulties. In addition to being acceptable to veterans, there was a high level of perceived effectiveness and intervention cohesiveness. Due to the discrepancy between self-reported improvement and the scores on the RRS-SF, further research may benefit from exploring the use of other rumination or perseverative thought measures.

The psychoeducation and brief intervention modules have potential utility in bridging care after neuropsychological or neurological evaluations and subsequent referrals to mental health treatment. Brief, internet-administered interventions have been shown to be effective in bridging care for mental health symptoms [28]. The brief interventions described in the module and handouts can then be used to build awareness while waiting to be seen by mental health clinicians or for existing mental health patients to understand how their treatment may improve...
their cognitive functioning. In these cases, the intervention can be incorporated into the feedback session and may yield additional “buy-in” from veterans to fully participate in mental health treatment. Due to the large number of veterans reporting SCC, telehealth-based intervention is an efficient and cost-effective way to meet these needs [43].

There are several limitations in this study, including the small sample size, which limited statistical analyses. Our pilot work suggests that veterans with subjective cognitive changes are amenable to psychological treatment and perceive benefit from a short, 1-session intervention. Further work with a larger sample size is needed to fully evaluate efficacy and whether the intervention described here should be implemented more broadly. Additionally, a larger sample size will allow further exploration of how changes in rumination may or may not mediate the relationship between SCCs and cognition. Further studies can then evaluate whether the psychoeducation about rumination is sufficient to fulfill the long-term goals of the intervention, namely, to bridge care following referral to mental health services and increase veteran buy-in for participation in psychological treatments to improve cognition. Further research in this area could also explore the use of a longer intervention as a standalone treatment.

**Conclusion**

In conclusion, we found preliminary evidence for the feasibility, acceptability, and efficacy of a 1-session rumination-focused intervention for veterans with SCCs, which will benefit from continued evaluation of this intervention as well as comparison to routine clinical practice.

Abstract

Background: Respiratory syncytial virus (RSV) affects children, causing serious infections, particularly in high-risk groups. Given the seasonality of RSV and the importance of rapid isolation of infected individuals, there is an urgent need for more efficient diagnostic methods to expedite this process.

Objective: This study aimed to investigate the performance of a machine learning model that leverages the temporal diversity of symptom onset for detecting RSV infections and elucidate its discriminatory ability.

Methods: The study was conducted in pediatric and emergency outpatient settings in Japan. We developed a detection model that remotely confirms RSV infection based on patient-reported symptom information obtained using a structured electronic template incorporating the differential points of skilled pediatricians. An extreme gradient boosting–based machine learning model was developed using the data of 4174 patients aged ≤24 months who underwent RSV rapid antigen testing. These patients visited either the pediatric or emergency department of Yokohama City Municipal Hospital between January 1, 2009, and December 31, 2015. The primary outcome was the diagnostic accuracy of the machine learning model for RSV infection, as determined by rapid antigen testing, measured using the area under the receiver operating characteristic curve. The clinical efficacy was evaluated by calculating the discriminative performance based on the number of days elapsed since the onset of the first symptom and exclusion rates based on thresholds of reasonable sensitivity and specificity.

Results: Our model demonstrated an area under the receiver operating characteristic curve of 0.811 (95% CI 0.784-0.833) with good calibration and 0.746 (95% CI 0.694-0.794) for patients within 3 days of onset. It accurately captured the temporal evolution of symptoms; based on adjusted thresholds equivalent to those of a rapid antigen test, our model predicted that 6.9% (95% CI 5.4%-8.5%) of patients in the entire cohort would be positive and 68.7% (95% CI 65.4%-71.9%) would be negative. Our model could eliminate the need for additional testing in approximately three-quarters of all patients.

Conclusions: Our model may facilitate the immediate detection of RSV infection in outpatient settings and, potentially, in home environments. This approach could streamline the diagnostic process, reduce discomfort caused by invasive tests in children, and allow rapid implementation of appropriate treatments and isolation at home. The findings underscore the potential of machine learning in augmenting clinical decision-making in the early detection of RSV infection.

Introduction

Every winter, respiratory syncytial virus (RSV) causes acute lower respiratory tract infections in approximately 33.8 million children younger than 5 years worldwide [1]. Approximately all children are infected at least once, and half are infected twice or more by the age of 24 months [2]. Newborns and children with underlying medical conditions are particularly susceptible to severe infection [3-5]. Therefore, reducing the number of RSV-infected patients is paramount for reducing the number of associated deaths. Consequently, there is an urgent need to develop a quick and accurate detection system for RSV infection [6].

Laboratory testing of RSV, including rapid antigen testing and polymerase chain reaction tests, provides reasonably accurate infection-related information [7]. However, the collection of nasopharyngeal secretions, a necessary step for these tests, can cause discomfort in children. Furthermore, given that RSV test results rarely influence treatment decisions, these tests are not routinely conducted [8,9]. On a positive note, RSV infections are not serious in most cases, and there is no active treatment, indicating that most patients can be treated at home under the constant supervision of parents or caregivers while taking precautions [10,11]. Thus, remote identification of RSV infection allows patients to be cared for at home, preventing infection spread [12]. This approach could also ease the burden on health care workers during epidemics by providing remotely procured information. Nonetheless, a home-based detection method that matches the accuracy of a rapid antigen test has yet to be recognized.

The symptoms and signs of RSV infection may help establish remote detection strategies. Studies that focused on the detection of RSV infection based on symptoms either lacked discriminatory accuracy or highlighted difficulties because of the diverse clinical manifestations of RSV infection [13-18]. However, symptom onset of RSV infection may not appear as a cross-sectionally typical pattern at a specific time point but rather as a pattern that is diverse in characteristics, including the longitudinal aspects of symptoms. Particularly, the symptoms of RSV infection peak 4-5 days after infection and change with the increase or decrease in viral load [19,20]. Dyspnea and other lower respiratory symptoms, including wheezing, moaning, and tachypnea, which are typical symptoms of severe RSV infection, occur when infected ciliated bronchial epithelial cells drop into the lower respiratory tract, thereby delaying the manifestation of upper respiratory symptoms [21-23]. Contrarily, most studies linking RSV infection to overt symptoms used cross-sectional data based on symptoms at specific time points and did not consider the time course of symptom onset in the longitudinal profile of individual children.

Therefore, we propose that cross-sectional studies based on specific time points of signs and symptoms expressed with RSV infection appear to be unrelated to RSV infection, but this may not represent the unique disease trajectory of RSV infection in individual patients infected with RSV. Therefore, machine learning models based on symptom data structured to include longitudinal characteristics may enable highly accurate identification of viral infection. As the progression of symptoms can exhibit multiple patterns in each individual, considering aspects such as the size of patient bronchi and machine learning algorithms, which are already widely used to diagnose and classify diseases based on symptom characteristics, are equally suitable for identifying RSV infection [24-27]. Here, we sought to leverage the longitudinal diversity of symptoms using machine learning based on patient-reported information, aiming to confirm the presence of RSV infection remotely at home with sensitivity and specificity comparable to those of rapid antigen testing [28]. If this strategy is recognized, it will contribute to reducing the physical burden on children, saving medical costs, and preventing nosocomial infections. The purpose of this study is to develop and validate a machine learning–based RSV infection identification model using patient self-reported symptom information for outpatients. This study is also valuable as it is one of the few studies conducted in a cohort of outpatients with mild infections.

Methods

Overview

The results are presented according to the TRIPOD (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis) statement [29].

Ethical Considerations

The study was conducted according to the Declaration of Helsinki and Japan’s ethical guidelines. The institutional review board of Yokohama City Municipal Hospital approved the protocol (18-05-04), and we obtained informed consent from the patients’ parents in the form of an opt-out clause. In this study, analysis was conducted using data that had been anonymized to ensure the privacy and confidentiality of participants. No compensation was provided to the participants.

Data Collection Setting

This observational retrospective cohort study involved patients aged ≤24 months who visited the pediatric or emergency department of Yokohama City Municipal Hospital between January 2009 and December 2015 and had RSV rapid antigen test results. According to the facility policy, all outpatients were required to fill an electronic template, and those who exhibited test results. According to the facility policy, all outpatients were required to fill an electronic template, and those who exhibited cold symptoms were subjected to RSV rapid antigen testing. These patients were extracted from a prospectively curated database and enrolled in this study. In this study, we used the immunochromatographic Quick-Navi RSV test (Denka Seiken Co Ltd) for nasopharyngeal swab fluid testing as the gold standard. Patients who presented weakly positive results in the rapid antigen test were excluded.

Data Preparation

An automated medical interview system with an electronic template was introduced to standardize the entry of clinical symptoms, and the patient’s parents completed the form before the hospital visit. A group of highly trained general pediatric attending physicians with over 15 years of clinical experience created the template for entering symptoms and signs, allowing parents to select up to 3 symptoms per entry. Once a symptom
was selected, the system presented additional questions based on the selection, with all responses except temperature being optional. Therefore, the status of each symptom, along with the number of elapsed days since symptom onset, was recorded as a categorical variable. Additional questions for each symptom were presented differently for each age group; all questions and options used are listed in Multimedia Appendix 1. The feature set was solely based on information from the electronic template and did not include any additional data from the examination or treatment. Based on medical insights, the symptoms introduced to the models were limited to cough, runny nose or nasal congestion, and wheezing, using only baseline characteristics and overall health status features. Statistical feature selection was not performed.

**Experimental Process**

We developed and evaluated a machine learning model that outputs binary information on RSV infection based on symptom and sign information. Users can obtain information about RSV infection status by entering symptoms to determine whether to seek medical attention.

**Models**

Random forest, extreme gradient boosting (XGBoost), and support vector machine models were used to determine appropriate machine learning algorithms. We used grid search in a hyperparameter space for all classifiers, optimizing the hyperparameters based on 10-fold cross-validation. The area under the receiver operating characteristic curve (AUC-ROC) was calculated for each model using the optimized hyperparameters. Finally, we selected the machine learning algorithm and its corresponding hyperparameters that performed best.

**Model Performance Evaluation**

Model performance was assessed through calibration and discrimination. Calibration was evaluated graphically using a calibration plot and Hosmer-Lemeshow test with 10 groups, where \( P < 0.05 \) indicated a poor model fit. The AUC-ROC sensitivity, and specificity were used to evaluate model discrimination ability. Sensitivity and specificity were calculated using the Youden index, and performance was calculated under conditions, where 1 parameter was fixed to be equivalent to that of the rapid antigen test. Additionally, we calculated model discriminatory power based on the number of elapsed days since the onset of illness to assess the use of rapid patient isolation. The performance of a valid model should not be considerably worse even in short periods after disease onset. The discrimination metrics of the final model were evaluated to estimate stability using the 1000 times bootstrap method. This resampling technique, which involves generating multiple bootstrap samples and using them to train and test the model, offers a robust estimate of evaluation indices even with small samples by correcting for optimism in the model’s performance [30].

To further assess the effect of additional symptom information on detection accuracy, we constructed a baseline model that classified patients based solely on the presence or absence of symptoms. As RSV infection is seasonal and its prevalence varies by season, a model excluding only the month of hospital visit was also created for comparison.

**Interpretability Evaluation**

We evaluated the interpretability of the final model using Shapley additive explanations (SHAP), calculated using an algorithm that mimics the Shapley value used in game theory to evaluate the relative importance of each feature on discrimination performance while considering interactions. Therefore, it was used to corroborate the presence of essential variables and interactions. R (version 4.2.0; R Foundation for Statistical Computing) was used for all analyses.

**Results**

**Patient Characteristics**

Between January 2, 2009, and December 31, 2015, a total of 7362 patients underwent rapid antigen tests, and their parents provided the necessary information through an electronic template. Of these, 4182 patients who were aged 24 months or younger were included in the analysis. One patient with weak positive test results and 7 with inaccurate age information were excluded. Figure 1 depicts the process of patient exclusion, data selection, and missing value completion. Of the remaining 4174 patients, 619 (14.8%) were positive and 3555 (85.2%) were negative for RSV infection. Table 1 presents the demographic and clinical characteristics of patients. The details of the features used in the model are provided in Multimedia Appendix 1.

Machine Learning Algorithm Selection

During the algorithm selection process, XGBoost demonstrated the highest AUC-ROC at 0.825 (95% CI 0.772-0.875), outperforming other algorithms such as support vector machine and random forest, which showed AUC-ROCs of 0.704 (95% CI 0.665-0.740) and 0.798 (95% CI 0.756-0.857), respectively. Therefore, we adopted XGBoost for the proposed and baseline models.

Calibration and Discrimination Ability of the Differential Models

The model with the XGBoost algorithm fit well visually, with good calibration in the Hosmer-Lemeshow goodness-of-fit test ($P=.27$). For discrimination ability, the AUC-ROC of the estimated model calculated with 1000 times bootstrap was 0.811 (95% CI 0.784-0.833). The sensitivity and specificity were 73.5% (95% CI 66.8%-79.4%) and 73.9% (95% CI 70.3%-77.2%), respectively. To validate the exclusion performance of the proposed model, the threshold was adjusted according to the discrimination performance of the rapid antigen test [28]. When the sensitivity was set to 71.6% (95% CI 64.8%-77.8%), approximately 68.7% (95% CI 65.4%-71.9%) of the total patients were predicted to be negative for RSV infection. Patient samples were predicted to be positive (6.9%, 95% CI 5.4%-8.5%) when the specificity was set to 96.6% (95% CI 95.3%-97.7%). For the baseline model, which was considered to determine the effect of additional symptom information on performance improvement, the AUC-ROC was 0.766 (95% CI 0.739-0.792) for the model that excluded the month of visit (model 2), 0.703 (95% CI 0.677-0.731) for the model that considered only the presence of symptoms (model 3), and 0.521 (95% CI 0.484-0.556) for the null model that relied solely on age (model 4). The discrimination performance of the proposed model is summarized in Table 2.

Model prediction performance is calculated by adjusting thresholds under different conditions. The scores are based on 1000 times bootstrap, with means and 95% CIs of each sample.

*AUC-ROC: area under the receiver operating characteristic curve.

Discrimination Based on Days Since Onset

Elapsed time was measured by counting the number of days since the initial onset of symptoms. A total of 46.8% (n=1952) of patients reported that symptoms such as cough, nasal discharge, or wheezing began within 3 days, and 77.4% (n=3231) of RSV-positive patients developed these symptoms within 8 days. The AUC-ROC was 0.721 (95% CI 0.628-0.815) for patients on the day of symptom onset and 0.746 (95% CI 0.694-0.794) and 0.779 (95% CI 0.749-0.808) for patients within 3 and 8 days of onset, respectively. To assess the robustness of these AUC-ROC values, 1000 bootstrap samples were used for computation, as depicted in the box and whisker plot in Figure 2. This figure illustrates the distribution of AUC-ROC values across the elapsed days since symptom onset, highlighting that the variance in AUC-ROC values diminishes as the sample size increases with more elapsed days.
Interpretability of the Final Model

Variables contributing to the prediction were examined using SHAP. The variable that primarily contributed to the relative prediction performance was the month of visit, followed by the number of days from the onset of cough and maximum body temperature. Based on the Beeswarm plot, the number of days from the onset of the cough variable exhibited bifurcation along the x-axis, indicating variability in its impact on the model’s output. However, age or current body temperature did not show a clear trend between the feature value and SHAP (Figure 3).

Figure 2. Area under the receiver operating characteristic curve (AUC-ROC) for elapsed days in the proposed model.
Figure 3. Average Shapley additive explanations (SHAP) value for each feature from the top in order of importance.

Discussion

Principal Results

We developed a machine learning tool that leverages longitudinal diversity of symptoms for the remote detection of RSV infection at home. The model that incorporated the time course of the onset of symptoms and their evolution (model 2) exhibited enhanced discriminative performance. However, our final model, including information on onset days and month of visit (model 1), performed effectively in terms of sensitivity and specificity. By adjusting the threshold based on 2 exclusion criteria set at the same level as the rapid antigen test, this model applied thresholds of 0.152 or 0.463, thereby performing an exclusion accuracy comparable to the standard RSV detection method and successfully identifying 75.6% of infected patients for exclusion. This approach could potentially reduce the need for further confirmatory testing—most positive cases comprised samples with values above the threshold based on high sensitivity. Samples with values below the threshold had almost no positives and could be considered negatives. Samples with values below the threshold based on high specificity comprised mostly of negatives, indicating that samples with values above the threshold could be considered as positives. Nevertheless, rapid testing should be continued for patients who fall within the defined thresholds. The consistency between the estimated positive probability and the actual percentage was confirmed using calibration. Hence, there is no reason to perform additional testing on samples labeled based on the 2 thresholds.

When considering the number of days since disease onset, our proposed model demonstrated an AUC-ROC of approximately 0.721 for patients who began to experience symptoms on day 1, which is the visiting day, showing particularly high accuracy when including patients with symptoms that emerged within 5 days. The results indicate that discriminatory ability improved within approximately 6 days; however, it was high even on the day of onset.

Comparison With Previous Studies

The model used here showed a higher discriminative performance than those used in other studies on symptom-based RSV infection detection. For children, a model with 80% sensitivity, 68% specificity, and an AUC-ROC of 0.66 has been reported [15]. A model with 72.8% sensitivity and 73.2% specificity has also been reported; however, this model included x-ray and laboratory test results as features, which differed from the variables we used, where patients even outside the hospital could ascertain RSV infection by themselves [16]. Therefore, the results are considered noteworthy in terms of identification accuracy. To the best of our knowledge, this is the first study to include outpatients and obtain symptom information through nonmedical personnel, which is in contrast to previous studies that involved inpatients or data obtained by health care professionals [13-18].
Our results indicate that adequately accurate predictions can be acquired using machine learning and symptom information. The detection of RSV infection based solely on patient-reported symptoms is still in its early stages; however, our tool shows robust capabilities in distinguishing positive and negative results. The tool estimates RSV infection based on symptom data and progression entered by the patient’s caregivers at home, indicating that the intervention of medical personnel is not required. This remote detection strategy could potentially reduce the risk of nosocomial infections and physical burden on children. Moreover, by applying this tool, isolation measures can be implemented before visiting a medical facility. This will allow RSV infections to be detected at home, reducing the need to visit hospitals, thereby preventing secondary and nosocomial infections and reducing the burden on health care providers, especially during an epidemic, and protect them from coinfection with RSV and severe acute respiratory syndrome coronavirus 2 [32]. In addition, it may limit the spread of the virus in the community.

Another unique feature of this study is that the model was developed based on 3 primary symptoms: cough, nasal discharge, and wheezing, which were selected and extracted from the system based on the clinical manifestations of RSV infection. Therefore, although other symptoms were recorded in the electronic template, they were not used here based on clinical rationale.

**Limitations**

There are several limitations to this study. First, participant demographics were limited as this study was conducted at a single institution. However, it is worth noting that Japan’s insurance system, which allows for free access, may mitigate potential economic-related biases in our findings. Additionally, the rapid antigen test may yield false positives when there is a low disease incidence [33,34]. Thus, the final diagnostic result, used as the gold standard here, may vary. The RSV prevalence pattern may already be changing and combining this with a surveillance system would further improve accuracy. Furthermore, model calibration must be confirmed based on race to assess performance differences between races when introduced to populations with widely varying demographics. In this study, we used a single cohort for internal validation and did not perform external validation, necessitating further testing on additional data sets to confirm generalizability.

**Future Research Directions**

Future prospective studies are required to assess the generalizability of this algorithm to all patients because they may differ from the retrospective cohort used in this study. The model developed in this study is specific for RSV infection; however, similar methods may be used to construct models to detect infections with other viruses using their respective symptoms.

**Conclusions**

Our detection tool was based on patient-reported symptoms and basic attribute information; nevertheless, it effectively detected RSV infection. Furthermore, our findings highlight the necessity to develop machine learning models and support the use of structural data for capturing complex patterns for symptom-based detection of RSV infection. The presented model leverages the distinct temporal patterns of RSV symptoms, allowing accurate identification of the infection even at early stages and with symptom evolution. Health care providers can perform model analysis before an outpatient visit to direct infected patients to home treatment or an appropriate isolation cohort. Applying this model to other settings can validate a standardized and comprehensive approach to improve RSV infection detection at home, and it could then be applied to other viruses.

**Data Availability**

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

**Authors' Contributions**

SK analyzed the patient-reported data. YM interpreted the patient data and results and substantially contributed to manuscript writing. NY led and supervised the study. All authors read and approved the final manuscript.

**Conflicts of Interest**

None declared.

Abstract

Background: Although comprehensive lifestyle habits are crucial for healthy aging, their adherence tends to decline as individuals grow older. Sustaining a healthy life over time poses a motivational challenge. Some digital tools, such as smartphone apps aimed at promoting healthy habits, have been used to counteract this decline. However, a more profound investigation is necessary into the diverse experiences of users, particularly when it concerns older adults or those who are unfamiliar with information and communications technologies.

Objective: We aimed to develop a mobile app focused on promoting the health of older adults based on the principles of software engineering and a user-centered design. The project respected all ethical guidelines and involved the participation of older adults at various stages of the development of the app.

Methods: This study used a mixed methods approach, combining both quantitative and qualitative methodologies for data collection. The study was conducted in Ribeirão Prêto, São Paulo, Brazil, and involved 20 older adults of both genders who were aged ≥60 years and enrolled in the Physical Education Program for the Elderly at the University of São Paulo. The research unfolded in multiple phases, encompassing the development and refinement of the app with active engagement from the participants.

Results: A total of 20 participants used a mobile health app with an average age of 64.8 (SD 2.7) years. Most participants had a high school education, middle-class status, and varying health literacy (mean score 73.55, SD 26.70). Overall, 90% (18/20) of the participants owned smartphones. However, 20% (4/20) of the participants faced installation challenges and 30% (6/20) struggled with web-based searches. The focus groups assessed app usability and satisfaction. Adjustments increased satisfaction scores significantly (Suitability Assessment of Materials: 34.89% to 70.65%; System Usability Scale: 71.23 to 87.14). Participant feedback emphasized font size, navigation, visual feedback, and personalization, and suggestions included health device integration, social interaction, and in-app communication support.

Conclusions: This study contributes to the development of health care technologies tailored to the older adult population, considering their specific needs. It is anticipated that the resulting app will serve as a valuable tool for promoting healthy habits and enhancing the quality of life for older adults.

Introduction

The older adult population in Brazil is continuously growing [1]. As this demographic expands, critical questions arise regarding how to support older adults in their quest for independence and vitality during the aging process. Furthermore, it becomes essential to identify effective strategies to promote...
In the contemporary scenario, marked by constant technological changes, digital products have become an integral part of the context and social life [3,4]. Therefore, there is an urgent need to develop mechanisms that not only enable older adults to comprehend these tools and their potential but also enable older adults to have access to digital products that cater to their specific needs. As Mansell and Tremblay [5] pointed out, knowledge plays a fundamental role in achieving social, economic, and cultural goals, being essential for cultural integration, political participation, and market inclusion.

In this context, information and communications technologies have emerged as vital instruments for developing digital tools that offer numerous benefits to society while contributing to the autonomy and well-being of older adults [6]. These benefits span from the realm of entertainment to the professional sphere and, critically, the field of health, where technology can enhance the well-being of older adults, improve their quality of life, and keep them healthier [7,8].

Tidd and Bessant [8] emphasized that innovation not only is limited to opening new markets but also involves creating meaning and developing new ways of serving. To achieve this goal, it is fundamental to engage all stakeholders in the knowledge-building process, promoting the dissemination of information through interactions such as initiatives coordinated by coalitions of interested professionals and research projects that consider local opinions and choices [5].

Involving the end user is a crucial goal during the development of innovative solutions, not only for evaluation but also in co-design, following a user-centered strategy. Indeed, it is a significant asset of research to base the work on a user-centered approach because it allows building a platform that will address the real needs of the users [3,4].

Digital inclusion emerges as the primary gateway to the use of information and communications technology, enabling individuals to develop the capacity to seek, understand, and apply information according to their needs, acquiring information literacy and digital literacy [9,10]. However, older adults often face obstacles when dealing with these tools as many of them are developed without considering the limitations of users with limited or no digital knowledge and without addressing age-specific issues [3,4]. This mismatch between the condition of older adults and their effective inclusion in the digital environment demonstrates the need for tools that facilitate learning and interaction.

Therefore, this study aims to address the urgent need for research and the search for solutions that can mitigate existing gaps and effectively bring older adults closer to the technological environment. In this context, the central question to be addressed in this research is how to develop a multiprofessional mobile app aimed at promoting health habits in older adults, integrating the perspective of older adults themselves through focus groups to optimize the design and ensure the effective usability of this technological tool for an older adult population.

**Methods**

**Ethical Considerations and Trial Design**

This research was conducted by the lead researcher CRBJ (associate professor), GAAO (associate professor and research assistant), and ACSS with a degree in health sciences (Faculdade de Medicina de Ribeirão Preto da Universidade de São Paulo [USP]). This project followed the ethical guidelines established by Resolution 466/2012 of the National Health Council and the basic principles of bioethics. All individuals involved in the research received the informed consent form and were informed of confidentiality, with all information disclosed only in scientific events or academic publications. The protocols for this randomized crossover, triple-blind, and placebo-controlled trial were approved by the Ribeirão Preto School of Physical Education and Sport Research Ethics Committee (Process: 58433922.0.0000.5659, on October 26, 2022).

The study details were registered on The Brazilian Clinical Trials Registry (RBR-6wgkszS8: development of an application to improve health in older people). All participants read and signed an informed consent form with detailed information about the experimental protocols.

**Study Type**

This study is part of a larger project and describes one of the initial steps. This study consists of technological production research for the development of a mobile app. The approach involves both quantitative and qualitative aspects, with a cross-sectional design. Data were collected from older adults in 3 focus group meetings. In this case, the specific topic was the design of apps for older adults. Data collected in focus group studies are typically used to gain insight into people’s perspectives and experiences. In this study, the data can be used to inform the design of apps that are easier to use and accessible for older adults.

**Study Location and Period**

The study was conducted in the city of Ribeirão Preto, São Paulo, Brazil, with the participation of older adults recruited from the convenience sample of participants in the Physical Education Program for the Elderly (PEFI) at Escola de Educação Física e Esporte de Ribeirão Preto (EEFERP; EEFERP-USP). This study was conducted between January and July 2023.

**Participants**

The study included older adults aged ≥60 years who had participated at some point in the physical training program offered at the EEFERP-USP through the culture and extension project. This PEFI program includes a WhatsApp group that facilitates recruitment through media and technology for all older adults who have already participated in the program. For a focus group testing the app design, it is essential to have a variety of participants with different demographic profiles, interests, and needs [11]. Therefore, for this focus group, we included 10 men and 10 women. A flowchart regarding the recruitment of participants is described in Figure 1.
The inclusion criteria included individuals aged \( \geq 60 \) years who possessed a mobile device capable of supporting the use of the app and its features—the criterion of having a mobile device is fundamental as the 3 stages of the focus group use this equipment. The exclusion criteria included limitations in performing the assessments outlined in the research, such as visual impairments, hearing impairments, and severe cognitive impairments. The Montreal Cognitive Assessment (MoCA) [12] instrument was used to assess cognitive function and screen for dementia. It was used to analyze whether the difficulty in using the app was related to cognitive performance or the design of the app.

Research Development

The project was divided into phases to meet the proposed objectives (Figure 2).

Figure 1. Flowchart for the recruitment of participants.
Development and Adjustment of the App With the Involvement of Older Adults

In this phase, the goal was to provide information for the development of a mobile app prototype that tracks and promotes health habits in older adults. Initially, the objectives were established in accordance with the documents and processes recommended by Serviço Brasileiro de Apoio às Micro e Pequenas Empresas for business and technology development. The following documents were created to align project understanding and initiate system modeling:

- **Phase 1: business plan**: describes the business objectives and the necessary steps to achieve them and identifies the market, product, and existing tools.
- **Phase 2: scope**: defines the initial project idea and goals and serves as a guide for project production and control.
- **Phase 3: Supplier, Input, Process, Output and Customer**: a tool from the Six Sigma methodology that manages and optimizes the flow of inputs and products.
- **Phase 4: use case diagram**: documents the main system functionalities from the user’s perspective.
- **Phase 5: flowchart**: graphically represents the sequence of screens and their access paths, providing an overall view of the product.
- **Phase 6: wireframing**: an Agile technique to create a first impression of the project and visualize the layout and flow. We used Figma (Figma, Inc), a cloud-based graphic design and user interface prototyping software. After the initial documents were prepared, wireframing was performed using Figma. The Agile methodology was adopted for communication with the lead researcher. Usability testing was conducted with 20 participants aged ≥59 years who were part of the PEFI at the EEFERP-USP. The testing was conducted using the design thinking method, allowing for feedback collection and app adjustments based on user needs.
- The app was developed with Vue and TypeScript for the frontend as a progressive web app and distributed through a Kubernetes cluster with backend communication via an application programming interface developed in Node.js, also using TypeScript. MongoDB was used as the database, hosted within Atlas to facilitate data cross-referencing and subsequent analysis (Figure 3).

These technologies were chosen for their performance and because they are native web technologies, allowing for broader distribution across various scenarios compared with a more complex framework such as Django, for example. Development time is also crucial, as changes can be made with a short build time afterward.

- **Phase 7: execution of focus groups**
Focus Group Objectives
The meetings were conducted at the EEFERP-USP, in a reserved room, a quiet location free of distractions, with audio recording for a duration of 60 to 80 minutes. In addition to the participants, there was a mediator, represented by the lead researcher, and an observer who took notes during the focus groups.

Open-ended questions about the user experience with the system were used during the meetings. In the first and last meetings, the study questionnaires were administered. Closed-ended questions were used in the meetings with caregivers to focus on the system evaluation. Video and audio recordings were used for recording and transcribing the participants’ comments on data security [11]. The layout of the room where the focus group was conducted is illustrated in Figure 4, showing the positions of participants, mediators, and recording equipment.

Focus group 1 comprised a total of 20 participants, equally divided between men and women, with 10 men and 10 women. The primary aim of the first focus group was to comprehend the perceptions of older adults regarding the purpose of the app. The tasks undertaken during this focus group included exploring the health and well-being needs of the older adults, identifying health habits deemed significant by them, gathering suggestions and tips from the older adults for the functionality and practicality of the app, and understanding the expectations of older adults regarding the design and usability of the app.

During the execution of focus group 2, some participants could not attend owing to unforeseen circumstances, medical appointments, and other events, resulting in a total of 13 participants, including 6 men and 7 women. The objective of the second meeting was to assess the early-stage mobile app and gather feedback for adjustments. The tasks carried out during the second focus group meeting included collecting opinions on the appearance, navigability, and features of the app; recording suggestions for improvements and specific adjustments desired by the participants; and exploring the willingness and readiness of older adults to use the app in the future.

In the third focus group, it was possible to bring together all 20 participants with the goal of conducting practical tests with the app, collecting feedback on its usability, and refining the ideal script for future focus group sessions. To achieve this objective, the conduct of the focus group revolved around tasks such as allowing participants to use the app in a controlled environment, documenting observations on how the older adults interacted with the app, gathering feedback on any difficulties or issues encountered during use, and identifying specific aspects of the app that needed improvement.

Questionnaires Applied
Before the development phase, various questionnaires were applied to gather comprehensive data crucial for the study.
objectives. These questionnaires covered a range of aspects including participant characterization, cognitive functioning, usability assessment, material suitability, socioeconomic classification, digital competencies, and health literacy.

1. Anamnesis: an initial questionnaire was developed to gather participant characterization for the study. This questionnaire included questions on gender, age, occupation, marital status, profession, and mobile phone brand and model.

2. MoCA: the MoCA is a cognitive screening questionnaire designed to assess cognitive functioning in older adults. The questionnaire consists of 11 items that evaluate attention, memory, reasoning, language, calculation, and orientation. Each MoCA item is scored from 0 to 3, with a maximum score of 30 [12]. A score of ≥26 is considered normal, whereas a score of ≤25 may indicate cognitive decline. However, it is important to note that the MoCA is only a screening test, and a more precise diagnosis should be obtained by consulting a health care professional [12].

3. System Usability Scale (SUS): this is a 10-item questionnaire that measures the usability of a system. It was developed by John Brooke in 1986 [13] and is one of the most widely used usability assessment tools [14]. SUS is a self-administered questionnaire used to evaluate the usability of various systems, including mobile apps, websites, software, and hardware [14]. The questionnaire comprises 10 items that assess system usability on a scale of 1 to 5, with 1 representing “strongly disagree” and 5 representing “strongly agree.” The SUS items evaluate usability in dimensions such as ease of learning, ease of use, efficiency, satisfaction, and memorability [14].

4. Suitability Assessment of Materials (SAM) questionnaire: SAM is a 10-item questionnaire that assesses the suitability of materials for specific applications. It was translated and adapted into Portuguese by Souza et al [15] and is a widely used material assessment tool. SAM is a self-administered questionnaire used to evaluate material suitability for a variety of applications, including medical products, consumer goods, and industrial products. The questionnaire comprises 10 items that assess material suitability on a scale of 1 to 5, with 1 representing “inadequate” and 5 representing “adequate.” SAM items evaluate material suitability based on physical properties, compliance with application requirements, and material safety [15].

5. Brazilian Socioeconomic Classification (CSEB): CSEB is a socioeconomic classification system developed by the Brazilian Institute of Geography and Statistics in 2010 [16]. It is based on a combination of factors, including income, education, and occupation. CSEB is used for research and social planning purposes and is an essential tool for understanding socioeconomic inequalities in Brazil. It can also be used to develop more equitable public policies [16].

6. Digital Competencies and Skills Questionnaire: digital competencies and skills were assessed through a questionnaire created by the researchers based on the Mobile Learning Competence Model for Seniors, specifically designed for older adults [17]. This questionnaire used a 3-point assessment scale: “Yes,” indicating full competence or skill in the evaluated area; “Yes, but with some difficulty,” indicating competence or skill with some challenges; and “No,” indicating the absence of competence or skill in the individual being assessed [18]. The questionnaire covered 6 fundamental categories of digital competencies and skills, including basic technology knowledge, internet navigation skills, mobile app use, digital communication, and digital resource use. The Mobile Learning Competence Model for Seniors provides a solid conceptual framework for measuring the digital competencies of older adults, allowing for a precise and contextualized analysis of their digital skills [17,18].

7. Health Literacy Test (TLS): TLS, validated from the Test of Functional Health Literacy in Adults, was developed by the Federal University of Rio Grande do Sul in 2019 [19]. It is a widely used health literacy assessment tool in Brazil. TLS for Seniors is a 20-item questionnaire that evaluates health literacy in individuals aged ≥60 years [19]. The questionnaire consists of 20 items that assess health literacy on a scale of 0 to 4, with 0 indicating “doesn’t know” and 4 indicating “knows very well.” TLS for Seniors assesses health literacy in dimensions such as understanding medical information, the ability to make health decisions, and the capacity to use health resources effectively [19]. This process will ensure the development of a mobile app that meets the needs and expectations of older adults, promoting greater adherence and effectiveness in health promotion within this population.

Data Analysis

Data analysis plays a fundamental role in understanding the perceptions, expectations, and needs of older adult participants regarding the mobile app developed in this study. The information collected through specific questionnaires was recorded in a Microsoft Excel software database. Descriptive analyses, such as mean, SD, and percentages, were conducted to characterize the sample in terms of age, gender, education, MoCA, occupational status, marital status, and economic classification. These variables were subjected to a detailed analysis using SPSS statistical software (IBM Corp), with a 2-tailed t test to check for potential differences between men and women.

Subsequently, the results of the focus groups were subjected to a qualitative content analysis. The transcriptions of the discussions were coded to identify emerging themes and patterns related to older adult participants’ perception of the app. This qualitative analysis allowed for an in-depth understanding of the participants’ opinions and suggestions presented during the focus groups. Content analysis was carried out according to Bardin [20]. A set of communication analysis techniques was used to obtain, through systematic and objective procedures for describing the content of messages, indicators that allow inferences about the production or reception conditions (inferred variables) of these message points. This analysis was divided into (1) preanalysis, (2) material exploration, and (3) data processing and interpretation.

To validate the questionnaires as a whole, the content validity index was calculated, with the result needing to be >0.90 (>90%) to be considered validated. The purpose was to measure the percentage of older adults who agreed on certain aspects of the
instrument and its items. A Likert scale was used with scores ranging from 1 to 4, where 4=entirely appropriate, 3=appropriate, 2=partially appropriate, and 1=inappropriate. The content validity index score was calculated by summing the agreement of the items marked “4” or “3” by 20 older adults.

Results

Participant Characterization

In the Results section, we provide a description of our sample based on various key variables. These data are essential for understanding the profile of the study participants. Table 1 displays the means and SDs of age and MoCA scores for both men and women.

Table 1. Sample characterization through mean, SD, and percentage of study participants (N=20).

\(^a\)MoCA: Montreal Cognitive Assessment.

We observed that, men had an average age of 64.8 (SD 2.7) years, whereas women had an average age of 65.1 (SD 4.3) years. The mean scores on the MoCA test were similar for men (mean 23.3, SD 4.4) and women (mean 23.5, SD 4.8). These variables did not show any statistical differences. Furthermore, we analyzed the distribution of participants according to other important variables. Regarding education, we noticed that most participants (6/10, 60% of men and 8/10, 80% of women) had completed high school. In contrast, a college degree was more common among men (2/10, 20%) than among women (1/10, 10%).

Regarding marital status, 60% (6/10) of the men were married, whereas none of the women in the sample were married. Furthermore, both groups had a similar number of single individuals (2/10, 20%), whereas the number of divorced individuals was higher among women (3/10, 30%) compared with men (2/10, 20%). A significant proportion of women were widowed (4/10, 40%), whereas none of the men in the sample fell into this category.

The occupation of the participants varied, with some groups represented in only one of the genders. For example, all retirees were men, whereas the categories “Homemaker” and the professions such as nurse, teacher, secretary, cook, psychologist, and receptionist were exclusive to women in the sample.

Finally, we explored the socioeconomic class of the participants. The middle-class status was more prevalent among women (6/10, 60%), whereas the upper-class status was more common among men (4/10, 40%). The lower class was relatively uniform among both sexes, with 30% (3/10) of men and 20% (2/10) of women belonging to this category.

These pieces of information provide a comprehensive overview of the demographic and socioeconomic profile of our participants, offering a solid foundation for the analysis and interpretation of the subsequent study results.

Characterization of Mobile Devices

Participants were also asked to provide the brand and model of their mobile device. There were 4 Samsung smartphones, 2 Motorola smartphones, 2 Redmi smartphones, and 2 iPhones. Of the 20 participants, 18 (90%) reported that the app worked on their mobile models, resulting in a functioning rate of 90% (equivalent to 9 mobile devices). The mobile model that did not work with the app was the Samsung Galaxy A02s model.

Health Literacy

A variation in scores was observed, ranging from 37 to 98. The average score of the sample was 73.55 (SD 26.70), indicating that most individuals had a good understanding of health information. Some scores stood out, such as 45% (9/20) of the participants who missed only 1 question, achieving 98 points.

- Low health literacy (20-40): Four participants scored in this range, indicating a low level of health understanding, which may affect their ability to make informed decisions about medical care.
- Moderate health literacy (40-60): Four participants scored in this range, suggesting a moderate level of health understanding. They can probably understand basic information, but may have difficulty with more complex material.
- High health literacy (60-100): Twelve participants scored in this range, indicating a high level of health understanding. They are likely to be able to understand and use health information effectively to make informed decisions about their care.

Participant classification was based on the results of the TLS. Of the 20 participants, 12 (60%) were classified as having “adequate” health literacy, with scores above 71; a total of 4 (20%) had “inadequate” health literacy, scoring below 40; and 4 (20%) had “marginal” health literacy, with scores ranging from 40 to 70. This suggests that most participants exhibited an adequate level of health literacy, although there was variation in the results.

Digital Competencies and Skills

This study addressed various categories related to participants’ knowledge and skills concerning technology and the use of mobile devices. The results provide a comprehensive overview of the technological competencies of the sample, as well as areas where improvements may be considered.

In category 1, which assessed basic technology knowledge, it was observed that all participants owned mobile devices, which is a positive indicator of the penetration of these technologies. However, 10% (2/20) of the participants reported difficulties in turning on and off these devices, suggesting the need for additional guidance in this aspect. In addition, 20% (4/20) of the participants encountered challenges in installing apps, highlighting an area for potential improvement.

In category 2, which investigated internet navigation skills, it was noted that all participants knew how to open a web browser. However, 30% (6/20) of the participants reported difficulties in typing website addresses or conducting web-based searches. Nevertheless, most participants possessed this fundamental knowledge, which was encouraging.

Category 3 addressed the use of mobile apps for learning. Most participants had already used mobile apps to learn something new, demonstrating an interest in leveraging these educational tools. However, 20% (4/20) of the participants had never used them, suggesting an opportunity to promote the use of these resources. Moreover, 40% (8/20) of the participants reported difficulties in searching for and downloading relevant apps, indicating a need for assistance in this area.

In category 4, which analyzed the ability to conduct web-based research, the vast majority of participants had already conducted web-based research to obtain information. However, 30% (6/20) of the participants faced challenges in selecting appropriate keywords, and some struggled to assess the quality of the information found. This underscores the importance of promoting effective search skills and critical content evaluation.

In category 5, which explored digital communication, most participants used emails and instant messaging apps. However, 30% (6/20) of the participants encountered difficulties with messaging apps, indicating an area where training could be beneficial. In addition, most participants demonstrated an awareness of proper digital communication etiquette, which is essential for effective web-based interaction.

Finally, in category 6, which assessed the use of digital resources, most participants exhibited satisfactory skills in handling cameras and media sharing features. Nevertheless, some researchers have encountered challenges in attaching images, photos, and videos in digital communications.

The results of this study indicate that participants have a basic understanding of technology and a general willingness to adopt mobile devices and apps in their lives. However, areas were identified in which some participants faced challenges and
difficulties. These insights are valuable in guiding the development of digital empowerment programs and ongoing education to enhance technological skills and promote digital inclusion.

**Satisfaction and App Usability**

Table 2 presents the results obtained at 2 points in the focus group, the first interaction with the app (focus group 1) and after adjustments with the users (focus group 3), regarding 2 evaluation metrics: the SUS Validation Index and the SAM Validation Index. These focus groups were conducted to assess user satisfaction and the usability of specific systems or products.

**Table 2.** App satisfaction and usability evaluation at 2 focus group sessions (n=20).a.

</tbody>
</table>

aThe values in the table represent the scores of the participants in 2 different focus group sessions, with higher scores indicating higher satisfaction and usability.
bSAM: Suitability Assessment of Materials.
cCVI: Content Validity Index.
dSUS: System Usability Scale.

In focus group 1, participants had an average of 34.89 (SD 5.7) on the SAM questionnaire, indicating moderate satisfaction with the interface of the systems or products under analysis. Regarding the CVI of the SAM questionnaire, the average was 66.11%, suggesting a reasonable assessment of satisfaction. After adjustment, there was a 35.76 increase in the SAM questionnaire results. Therefore, in focus group 3, the results were substantially superior. The participants achieved an average of 70.65 (SD 13) on the SAM questionnaire, reflecting significant satisfaction with the interface. The CVI of the SAM questionnaire, with an average of 89.12%, indicated high satisfaction.

For the SUS questionnaire, participants obtained an average score of 71.23 (SD 4.7), which is a positive evaluation of usability. The CVI of the SUS questionnaire, with an average of 70%, indicated acceptable usability. These results suggest that participants had a more positive user experience in terms of usability than satisfaction with the interface. In the third focus group, there was a 15.91 increase in the SUS questionnaire, with an average score of 87.14 (SD 5.9), indicating excellent usability, whereas the CVI of the SUS questionnaire, with an average of 91.13%, demonstrated that usability was very satisfactory. These results reflect an improvement in the overall user experience, with positive outcomes in both usability and participant satisfaction in focus group 3.

**Results From the Focus Group: Improvements in the Design of the Health App for Older Adults**

During the conduct of the focus groups, with a user-centered approach, older adults were highly engaged in discussing and evaluating the current design of the health app. The aim of these meetings was to gather valuable feedback that allowed us to enhance the user experience and make the app more user-friendly for the older adult population. We present the main findings and adjustment points commented on and documented through audio and video recordings by the focus group participants.

Regarding font size and readability, the following comments were made: “The text is too small. I need my glasses to read it”; “There should be an option to increase the font size”; and “It would be great if the text could be read out loud.”

The need for simplified navigation was addressed with comments such as, “Sometimes, I get lost on the home screen. It should be more straightforward”; “The icons are not self-explanatory. We need hints, maybe without images and just text like WhatsApp”; and “There should be a ‘Back’ button on all screens.”

In terms of visual feedback, the following comments were made: “When we complete a task, it’s difficult to know if it was done correctly; there could be a confirmation message”; “Adding a visual confirmation signal would be helpful”; and “Having a contact with a professional within the app encouraging us to use the system would be a great motivator.”

The personalization of notifications was addressed: “I receive too many notifications. It should be possible to choose which ones to receive” and “It would be nice to set up custom reminders for medications.”

Accessibility was emphasized with comments such as, “Some colors are hard to distinguish for people with weak vision”; “The app should be compatible with screen readers”; and “Bright colors make us more excited to use the app.”

Health measurement integrations touched on points such as “Could it connect automatically to our medical devices?”; “A blood pressure recording feature would be wonderful”; “Is it possible to share health tips on social networks?”; and “Can we present this record to our private doctors?”

Concerning in-app communication support, it was suggested that: “Having a customer support chat for questions would be great”; “Could we share our progress with other users of the same age?”, and “Can we create conversation groups on specific topics, such as cooking and recipes?”
In terms of the simplicity of registration, participants raised the following questions: “The registration process is too long. It should be easier”; “The password is too complicated. It should accept simple passwords”; and “Colors could be more distinct to serve as a guide in the instructions.”

Participants indicated the need for an interactive tutorial with the following remarks: “A step-by-step tutorial would help us navigate better”; “The app should explain its features when we start using it”; and “There could be a video section where I can revisit and see how to use it.” They also discussed points related to social experience, including “Can we share our achievements with our friends?”; “Can we invite our friends to view a map of sports facilities in the city?”; “A rewards system to encourage physical activity would be motivating”; and “Can we create competition groups?”

Figure 5 shows the final design of the screens based on the adjustment points mentioned by the focus groups. These points were crucial in improving the health app and making it more accessible and enjoyable for older adults.

Discussion

Principal Findings

The main findings of this study include the characterization of its participants, revealing similarities in age and cognitive performance between men and women, but significant differences in education, marital status, and occupation. Furthermore, most participants demonstrated an adequate level of health literacy, albeit with some variability in the results. Regarding digital skills, most older individuals showed basic knowledge of technology, internet navigation skills, and mobile app use, but with some difficulties in certain areas. Finally, the satisfaction and usability of the app significantly improved after adjustments, with older adults highlighting areas for improvement such as font size, simplified navigation, and communication support. These results provide valuable insights for future digital empowerment programs and the development of apps tailored to the older adult population.

Participant Characteristics

The discussion of the results obtained in our study concerning literature data is essential for contextualizing our findings and assessing how they align or diverge from existing evidence. Regarding age and scores on the MoCA test, our results indicated that there were no significant differences between men and women. This is in line with several previous studies that did not find consistent differences in cognitive function between the genders [21,22]. However, it is important to note that some studies have reported small differences in certain aspects of cognition, such as verbal memory [23]; however, these discrepancies are not uniform in all studies, as demonstrated by this meta-analysis.

The analysis of education revealed that women in our sample had higher educational levels compared with men, a finding consistent with the literature [24,25]. This may suggest that women in our study had a potential cognitive advantage because of higher education, which should be considered in subsequent analyses.

The discrepancy in marital status is also noteworthy, with only 11% (1/10) married women in our sample, while more than half of the men (6/10, 60%) were married. This may reflect trends broader social contexts, indicating that women are less likely to marry compared to men in some cultures [26,27]. This difference in marital status can influence factors such as social support and support networks, which may have implications for cognitive health.

The occupational differences identified in our sample were also consistent with gender patterns observed in previous studies [28-30]. For example, the exclusivity of certain occupations among women, such as “Homemaker” and some specific professions, reflects gender occupational segregation that persists in many societies. These differences may be related to specific environmental exposures that influence cognitive health.

Regarding the socioeconomic class, the predominance of the upper class among men and the middle class among women is a noteworthy finding that deserves attention. Previous studies have suggested that socioeconomic status can influence cognitive health, with cognitive advantages associated with higher levels of income and education [31]. Therefore, this disparity in socioeconomic class may be an important factor to consider when interpreting our results.

Characterization of Mobile Devices

The analysis of mobile devices used by the participants revealed a significant presence of mobile phone models from Samsung, Motorola, Redmi, and iPhone, reflecting the diversity of choices available in the current mobile device market [31-33]. This finding is consistent with the current technological reality in which consumers have a wide range of device options to meet their individual needs.

The most notable result was that 90% (18/20) of the participants reported that the app worked smoothly on their devices. This
is a positive indicator of the effectiveness of app development for multiple platforms and operating systems, ensuring a satisfactory experience for most users. Such a high level of compatibility is crucial for maximizing the reach and utility of mobile health apps, which often play a significant role in promoting well-being and disease management [34].

The incompatibility detected with Samsung Galaxy A2S models represents a significant issue that deserves attention. Although the overall high rate of app functionality is encouraging, the identification of specific devices that faced problems highlights the complexity of mobile app development. These findings underscore the crucial importance of considering device compatibility during the development process, which is often underestimated but has a substantial impact on user experience [32,33]. Mobile device research and app development have increasingly focused on creating accessible and effective experiences for a wide variety of devices [34]. Variations in hardware, operating systems, and individual settings can create challenges for developers, requiring extensive testing and ongoing optimization to ensure that the app functions reliably in all scenarios. The incompatibility with Samsung Galaxy A2S models highlights the need to consider device and operating system diversity from the outset of the development process [33].

**Health Literacy**

The analysis of the HLS results provided an important insight into health literacy among the older adult population. The scores varied considerably, with most participants demonstrating an adequate level of understanding of health information, as evidenced by the average score of 73.55. Furthermore, approximately 45% (9/20) of the participants achieved scores very close to the maximum score, reaching 98 points. These results are in line with a series of previous studies that have also highlighted the relevance of health literacy in the older adult population [35,36]. For example, a systematic review conducted by Berkman et al [35] consistently highlighted the relationship between low health literacy and adverse health outcomes, including lower treatment adherence, inadequate understanding of medical information, and increased health care costs.

Furthermore, classifying participants into health literacy categories (“adequate,” “inadequate,” and “borderline”) underscores the diversity within the older adult population. This variability in health literacy levels has been consistently observed in previous studies [36,37] and reinforces the need for public health approaches that consider the different needs of specific groups based on their health literacy. However, it is important to emphasize that identifying individuals with “inadequate” and “borderline” health literacy underscores the importance of targeted educational strategies and specific interventions for these groups.

Health literacy promotion programs have been shown to be effective in previous studies [38], highlighting the ability to improve the understanding of health information and, consequently, informed decision-making about health among those with low health literacy.

**Digital Competencies and Skills**

The assessment of digital competencies and skills of the participants in this study revealed a comprehensive picture of how the investigated population deals with digital technology in various categories. In general, most participants demonstrated a reasonable level of digital knowledge and skills, especially when it comes to basic tasks such as turning on and off mobile devices, opening internet browsers, and sending emails. These findings are in line with the increasing penetration of digital technology into contemporary society [39].

However, areas where some participants faced challenges were also identified, such as selecting appropriate keywords for web-based searches, evaluating the quality of information found on the internet, and the effective use of instant messaging apps. These findings highlight the importance of personalized educational approaches to improve digital skills for specific groups, focusing on the areas where they face difficulties [40].

The results of this study will have significant implications for the development of digital empowerment programs and lifelong education. The ability to use digital technology is essential in an increasingly digitized world, especially for accessing health information, education, and communication. Therefore, investing in initiatives that promote digital inclusion and improve digital skills is crucial to ensure that all individuals, regardless of their age or background, can effectively harness the benefits of digital technology [41].

In summary, this study provides a comprehensive insight into the digital competencies and skills of a group of participants and emphasizes the importance of targeted educational strategies to improve these skills, thus promoting digital inclusion and full participation in the digital society.

**Satisfaction and Usability Assessment**

The evaluation of app satisfaction and usability through focus groups provided significant insights into the user experience, and comparing these results with previous studies in the literature enriches our understanding.

Initially, in focus group 1, participants showed moderate satisfaction with the app interface, reflected in an average SAM questionnaire score of 34.89. This initial result is similar to those of studies that have highlighted that satisfaction with app interfaces can vary significantly depending on usability and alignment with user preferences [42].

However, the process of adjusting and refining the app, reflected in focus group 3, had a substantial positive impact on user experience. The participants reported considerable satisfaction, with an average SAM questionnaire score of 70.65, indicating that the implemented improvements aligned the interface with user expectations. This improvement in satisfaction is consistent with the findings of studies that emphasized the importance of adaptability and user-centered design in promoting user satisfaction [43].

Regarding usability, the initial results in focus group 1 already indicated a positive evaluation, with an average SUS questionnaire score of 71.23. This initial result suggests that the usability of the app was in line with previous studies that
emphasized the importance of usability in effectiveness and user satisfaction [44]. However, after the app’s improvements and the subsequent assessment in focus group 3, there was a significant improvement in usability. The average SUS questionnaire score increased to 87.14, reflecting excellent usability. This increase in usability is supported by research emphasizing that improvements in the interface, task simplification, and problem-solving can lead to enhanced usability [45].

In summary, the results of this study and comparisons with the literature emphasize the importance of involving users in the development and refinement of digital systems. This not only improves user satisfaction but also enhances usability, promoting a more positive and effective user experience.

Results From the Focus Groups: Improvements in the Design of the Older Adults Health App

Collecting feedback from the older adults through focus groups played an essential role in identifying areas for improvement in the design of the health app, thereby demonstrating the value of a user-centered approach. The participants highlighted several critical issues that directly affect usability and the user experience.

Regarding readability, concerns about font size and the need for an option to increase it reflect the importance of accessibility for older adults, especially those with vision problems. This is in line with studies that emphasized the need for designs adapted to the specific needs of older adults and bodily changes that occur with aging, such as visual decline [46].

Simplifying navigation was another significant concern, with participants emphasizing the need for a more intuitive interface and self-explanatory icons. This issue is consistent with the literature, which emphasizes the importance of clarity and simplicity in designing apps for older adults—a more straightforward design had better acceptance and adherence in this population [47].

The need for visual feedback to confirm task completion suggests a concern with the effectiveness of actions taken within the app, which can boost user confidence. This aspect is supported by studies highlighting the importance of feedback in user motivation and engagement, showing that it enhances the user’s bond and credibility with the design’s goal [48]. Customization of notifications and integration with medical devices indicate the desire of older adults for a more adaptable and relevant experience. This customization is an important element for improving usability and app acceptance [49].

Accessibility, including compatibility with screen readers and the use of vivid colors, is crucial to meet the needs of older adults with varying levels of visual abilities. This aligns with inclusive design guidelines [50]. The suggestion of communication support and social features reflects the desire of older adults to connect and share experiences with their peers. This social dimension can significantly enhance user engagement and satisfaction [51]. Simplicity in the registration process and the availability of an interactive tutorial are also essential elements to ensure that older adults can make the most of the app. Simplifying the registration process is in line with the literature that emphasizes the importance of minimizing entry barriers and developing fewer back-and-forth paths within screens [52]. Finally, the emphasis on rewards and competitions suggests that gamification elements can be motivating for older adults. This aligns with research demonstrating the benefits of gamification in user motivation and engagement [53].

In summary, the integration of feedback from older adults into the health app design process resulted in a series of improvements that met the needs and preferences of this population. These findings underscore the importance of involving end users, especially the older adults, in the creation of user-centered apps, ensuring a more accessible, user-friendly, and satisfying experience.

Implications for Public Health

The results of this study have significant implications for public health, especially in the context of an aging population and the growing importance of digital technology in delivering health information and services. First, the analysis of participant characteristics highlighted the importance of considering factors such as gender, education, marital status, occupation, and socioeconomic status when developing health promotion strategies. These variables directly influence cognitive health and the ability to use digital technology.

The assessment of digital skills revealed areas where participants can benefit from additional training and empowerment, especially in more advanced tasks such as evaluating web-based information. Therefore, digital literacy programs targeted at older adults can play a crucial role in empowering these individuals to make the most of digital technologies in health and communication.

Furthermore, the assessment of satisfaction and usability emphasized the importance of designing health apps in a user-centered manner based on user feedback. Continuous improvement of the user interface and usability is essential to ensure that apps effectively meet the needs of older adults.

Finally, the broader implications of this study extend to digital health promotion and the development of digital communication strategies targeting older adults. The increasing digitalization of health information and services requires approaches that ensure equitable access to and proper understanding of health information by older adults, considering their diversity in terms of digital skills and health literacy.

Limitations and Suggestions for Future Research

Despite providing valuable insights into the interaction of older adults with health apps, this study has limitations that require consideration. First, the sample used in this study was relatively small, which may compromise the generalizability of the results. Efforts to include a more substantial number of participants could improve the representativeness of this research. Another limitation of this study is related to the inherent selection bias in the sample, which was composed of participants already predisposed to using health apps. This may limit the applicability of the conclusions to a broader population of older individuals who may not have the same degree of familiarity or willingness to adopt such technologies.
In addition, it is worth noting that much of the data collected relied on self-reports from participants, which may have introduced memory bias and inaccuracies in responses. Obtaining objective data, supplemented by external assessments, could strengthen the validity of the findings.

In terms of suggestions for future research, we consider some promising directions. First, the inclusion of more diverse samples, covering different ethnic groups, geographic locations, and socioeconomic characteristics, would allow for a more comprehensive understanding of the interaction dynamics between older adults and health apps.

Comparatively, another promising international research suggestion would be the evaluation of the health literacy questionnaire and digital skills of older adults in different countries and cultural contexts, thus providing insights into the contextual determinants of these variables. Furthermore, future studies can explore the health impacts associated with the use of health apps by older adults, including improvements in the self-management of chronic conditions and quality of life. Specifically, the analysis of specific health apps and their features can reveal detailed information about the design and functionality factors that best meet the needs and preferences of older adults.

Conclusions
In this comprehensive study, we thoroughly examined participant characteristics, mobile device compatibility, health literacy, digital skills, and user satisfaction with a health app designed for older adults. The findings highlight the complexity of the interactions among these factors and underscore the importance of a user-centered approach in the development of digital health apps.

The results suggest that considering the individual differences among older adults, such as gender, education, marital status, and socioeconomic class, is essential to meet their health care needs and ensure an effective digital experience. Furthermore, investing in digital empowerment programs and promoting health literacy can enhance the ability of older adults to use digital technology effectively for accessing health information and services.

The evaluation of user satisfaction and usability of the app emphasized the importance of listening to users and implementing continuous improvements in the user interface. This is crucial to ensure that digital health apps are well received and effective in promoting health and supporting older adults in their health care needs.

Ultimately, this study contributes to the understanding of the intersection between health, technology, and aging, providing valuable insights to inform digital health promotion strategies targeted at this increasingly important population.

Acknowledgments
The authors would like to thank the study participants.

This work was supported by the Fundação de Amparo à Pesquisa do Estado de São Paulo (2017/21361-2), the Conselho Nacional de Desenvolvimento Científico e Tecnológico (485045/2015-3 and 141720/2017-4), and the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior—Brasil (finance code 001).

Authors’ Contributions
ACSS conducted extensive literature research and compiled a comprehensive background section for the research paper and designed and executed experiments, collected data, and performed statistical analysis for the study. GAOG contributed to the theoretical framework of the research, providing critical insights into the conceptual foundation of the study. He played a crucial role in drafting and revising the manuscript, ensuring clarity and coherence in the written content. CRBJ secured the necessary research funding and managed the financial aspects of the project, ensuring the smooth execution of the study. He provided guidance and oversight throughout the research project, contributing to the overall project management and research direction.

Conflicts of Interest
None declared.

Abstract

Background: The syndemic nature of gonococcal infections and HIV provides an opportunity to develop a synergistic intervention tool that could address the need for adequate treatment for gonorrhea, screen for HIV infections, and offer pre-exposure prophylaxis (PrEP) for persons who meet the criteria. By leveraging information available on electronic health records, a clinical decision support (CDS) system tool could fulfill this need and improve adherence to Centers for Disease Control and Prevention (CDC) treatment and screening guidelines for gonorrhea, HIV, and PrEP.

Objective: The goal of this study was to translate portions of CDC treatment guidelines for gonorrhea and relevant portions of HIV screening and prescribing PrEP that stem from a diagnosis of gonorrhea as an electronic health record–based CDS intervention. We also assessed whether this CDS solution worked in real-world clinic.

Methods: We developed 4 tools for this CDS intervention: a form for capturing sexual history information (SmartForm), rule-based alerts (best practice advisory), an enhanced sexually transmitted infection (STI) order set (SmartSet), and a documentation template (SmartText). A mixed methods pre-post design was used to measure the feasibility, use, and usability of the CDS solution. The study period was 12 weeks with a baseline patient sample of 12 weeks immediately prior to the intervention period for comparison. While the entire clinic had access to the CDS solution, we focused on a subset of clinicians who frequently engage in the screening and treatment of STIs within the clinical site under the name “X-Clinic.” We measured the use of the CDS solution within the population of patients who had either a confirmed gonococcal infection or an STI-related chief complaint. We conducted 4 midpoint surveys and 3 key informant interviews to quantify perception and impact of the CDS solution and solicit suggestions for potential future enhancements. The findings from qualitative data were determined using a combination of explorative and comparative analysis. Statistical analysis was conducted to compare the differences between patient populations in the baseline and intervention periods.

Results: Within the X-Clinic, the CDS alerted clinicians (as a best practice advisory) in one-tenth (348/3451, 10.08%) of clinical encounters. These 348 encounters represented 300 patients; SmartForms were opened for half of these patients (157/300, 52.33%)
and was completed for most for them (147/300, 89.81%). STI test orders (SmartSet) were initiated by clinical providers in half of those patients (162/300, 54%). HIV screening was performed during about half of those patient encounters (191/348, 54.89%).

**Conclusions:** We successfully built and implemented multiple CDC treatment and screening guidelines into a single cohesive CDS solution. The CDS solution was integrated into the clinical workflow and had a high rate of use.

**Introduction**

**Background**

**Overview**

Research has shown that a simultaneous, integrated approach to testing and other services targeting multiple diseases on the same population can be feasible and effective in improving accessibility and health outcomes among patients [1]. This integrated approach can be supported by point-of-care resources such as clinical decision support (CDS) system tools that can combine electronic patient health data and up-to-date guidelines and clinical protocols. This paper describes the usability phase of a study on the integration of a CDS tool for managing gonorrhea, screening for HIV, and identifying patients for HIV pre-exposure prophylaxis (PrEP) at Codman Square Clinic.

**Gonorrhea, HIV, and PrEP**

Gonorrhea was the second most commonly reported sexually transmitted infection (STI) in the United States in 2020, with a total of 677,769 cases reported to the Centers for Disease Control and Prevention (CDC) and has shown a 71.49% (395,216/677,769) increase since 2015 [2]. Among both men and women, untreated gonorrhea can cause serious and painful health problems, infertility, and in rare cases, even life-threatening conditions [3-7]. To mitigate these risks, annual screening is recommended for all sexually active women younger than 25 years and those at increased risk for infection. Timely diagnosis through routine screening and prompt, effective treatment—adhering to up-to-date CDC treatment guidelines—is paramount to both reducing gonorrhea and slowing down the threat of antimicrobial resistance [3,8-10].

HIV causes an infection that attacks the body’s immune system, specifically the cluster of differentiation antigen 4 T lymphocytes [11,12]. If left untreated, it can lead to AIDS, opportunistic infections, malignancies, and death [11]. HIV PrEP has been shown to reduce the risk of acquiring HIV infection [13,14]. As a result, the CDC has developed guidance for prescribing PrEP to individuals considered at high risk, and gonorrhea infection is identified as one of those risk factors [15,16].

**Syndemic of STIs: Gonorrhea and HIV Infection**

Patients with STIs have a 2- to 3-fold increased risk of having concomitant HIV infection compared to those without any STI [17,18]. Gonococcal infections, specifically, have also been associated with increased risk of HIV [18-23]. Gonococcal infections cause immune reactions that, among others, recruit cluster of differentiation antigen 4 cells, which can potentially enhance HIV in vivo replication and facilitate acquisition and transmission of HIV infection [20,24-26]. Previous studies have further advanced our understanding of this syndemic and describe the biological, behavioral, social, and structural determinants and their synergisms [20,22,25]. As a result, it has been a long-standing recommendation to screen patients diagnosed with STIs, including gonorrhea, for HIV [8,27].

This synergistic and potentially concomitant nature of gonorrhea and HIV and the overlap between gonorrhea treatment, HIV screening, and PrEP prescription present us with the opportunity to develop a CDC guidelines-based synergistic intervention tool that could target adequate treatment for gonococcal infections, screening for HIV based on risk factors associated with the diagnosis of gonorrhea, and PrEP prescription to relevant populations.

**CDS Systems**

CDS systems are computational tools that leverage information available in electronic health records (EHRs) to provide person-specific evidence-based information, intelligently filtered, and presented at appropriate times to help inform decisions regarding a patient’s care to improve patient outcomes and lead to higher quality care [28-31]. A systematic review of 160 articles representing 148 unique studies describing CDS implemented across diverse settings found that CDS interventions were efficacious on health care process outcomes, but data on clinical and economic outcomes were sparse [32]. The Community Preventive Services Task Force conducted a systematic review of 23 studies and reported that CDS increased HIV screening for both the general population and people at higher risk for HIV infections [33]. Based on the strong evidence of effectiveness, the Community Preventive Services Task Force has now recommended CDS to increase HIV screening [33]. The Sexually Transmitted Infections National Strategic Plan has also recommended increasing the implementation of CDS to support high-quality sexual health assessments, screen for STIs, integrated care models, and reduce adverse outcomes [34]. Gonorrhea treatment recommendations are updated regularly to represent the latest evidence to provide adequate treatment and curb the rise of antimicrobial resistance [3,8]. Keeping up to date with the latest guidelines could potentially pose a challenge to clinical providers, as evidenced with varying degrees of adherence to gonorrhea treatment guidelines [9,10]. Coupled with the synergistic nature of the infection with HIV [18,20-26], this presents an opportunity to develop a
multifaceted CDS intervention to address the needs of the same patient population and improve clinical provider adherence to CDC guidelines on gonorrhea, HIV screening, and providing PrEP for HIV infection, when indicated.

**Objectives**

The primary goal of this study was to translate portions of CDC treatment guidelines for gonorrhea and relevant portions of guidelines for HIV screening and PrEP prescribing, into EHR-based CDS interventions to aid clinicians’ adherence to these guidelines and improve respective patients’ health outcomes. CDC guidelines–based CDS tools for STIs have not been reported in published literature; similarly, 2 or more guidelines have not previously been cohesively built into a single CDS tool. A secondary goal was to assess whether the translated CDS solution worked in a real-world clinical workflow initiated by patients with a gonorrhea diagnosis.

**Methods**

**Ethical Considerations**

This project was designed and executed as a quality improvement project at OCHIN, the implementing partner, and therefore was not considered human subjects research, and institutional review board input was not obtained. The impact of the project was assessed using only aggregated deidentified data. All OCHIN members include language in their patient privacy notices stating that deidentified data may be used for research purposes. There was no compensation for human subjects’ research.

**EHR Platform and Clinical Partner**

**Overview**

We partnered with OCHIN, Inc, a nonprofit community–based health center–controlled network as the EHR provider [35,36]. We selected OCHIN’s Epic EHR [37] as it serves as the primary EHR to almost 1000 health care sites with 21,000 clinicians in 45 states who serve over 6 million patients [38]. OCHIN provides 1 instance of Epic consisting of enterprise-wide master patient index; patients have a single medical record across all clinics in the network, and all data are managed centrally.

Within the OCHIN network, we partnered with Codman Square Health Center, a Federally Qualified Health Center in Dorchester, Massachusetts, to pilot the CDS intervention [39]. We selected Codman Square Health Center as both patients with gonorrhea and HIV are regularly managed in their clinics and they have a well-established STI-reporting practice in place. Typically, they have over 115,000 client contacts per year.

**Intervention Clinic**

While all of Codman Square Health Center had access to the CDS solution, a subset of clinicians within the Internal Medicine clinic, specifically, were selected as the focus of the intervention. This subset of clinicians frequently engaged in the screening and treatment of STIs and provide care under the name “X-Clinic” to allow a level of discretion to the patients they serve. The X-Clinic clinicians were selected for the focus of the intervention due to the high rates of gonorrhea infection and the potential for use of the CDS solution during the pilot period. A clinical champion was identified to provide insight and encourage participation among staff along with 2 project leads, 1 representing the providers and 1 for support staff. While the CDS tool was available to the broader Codman Square Health Center, the X-clinic received targeted training and support to use the tool. This training and support were not extended to the rest of Codman Square Health Center.

**CDS Solution Design**

**Study Design**

An internal review by OCHIN, the implementing partner, determined this work as quality improvement and deemed that an institutional review board review was not necessary. A 12-week study period was planned, beginning August 31, 2021, and ending on November 23, 2021. A mixed methods pre-post design [40] was used to measure the feasibility, use, and usability of the CDS solution. During the time of the planned intervention, COVID-19 altered the typical pattern of patients seeking STI-related care [41,42]. As a result, we determined that the 12-week period immediately prior to the intervention period would be the most representative sample of baseline patient data.

**Practice Coach Engagement**

In addition to the direct training provided, the X-Clinic clinicians received targeted and continual support on the use of the CDS solution using the practice coaching methodology. This included supporting adaptive skills and learning to build capacity and capability for the care team to effectively use the CDS solution, explore change ideas, provide feedback to support the team’s progress as the team becomes more self-sufficient, and engage with iterative learning. Practice coaching (also known as practice facilitation) has been demonstrated to be effective in successfully implementing tools and new evidence into clinical practice [43-46]. A key part of the intervention design included a dedicated practice coach who regularly engaged with the clinical champion and project leads at the X-Clinic. The coach was part of the project team’s kick-off meeting, which included a warm welcome from the CDS solution developer, project orientation from the project manager, training by the trainer to demonstrate the solution, and an overview of the coaching engagement from the coach. The facilitation meetings were held biweekly for the duration of the project, and they typically included discussions about general assessment and feedback, use, perceived effectiveness, and clinical integration of the CDS solution. When available, CDS solution–related data were reviewed for discussion of key insights, opportunities for improvement, and when a need was identified, the practice coach engaged subject matter experts to provide added support and facilitated referrals for technical and application support.

**CDS Solution Development**

OCHIN Epic EHR [37] has native tools to develop CDS solutions in a variety of formats, each performing specific functions. For this CDS solution, we developed four tools: 1) a sexual history data capture form using “SmartForm” (Epic’s name for a method for capturing responses to questions in a structured format) and a patient questionnaire with the same
questions that can be made available to the patient prior to the visit, (2) a “best practice advisory” (BPA; Epic’s name for rule-based alerts), (3) an enhanced STI order set—that included diagnoses as well as links to documentation templates—using “SmartSet” (Epic’s name for order sets), and (4) a documentation template using “SmartText” (Epic’s name for a method of notetaking that prompts clinician with standard information collected and presented during a visit).

We developed a CDS solution by integrating translated information from 3 separate CDC guidelines, specifically to guide clinicians to choose appropriate therapy for gonorrhea [3,8] and—as per the CDC’s guidelines to prevent or diagnose new HIV infections [47-49] and link those individuals considered at risk to relevant prevention and medical services [15,16]—prompt them to screen for HIV and consider PrEP, if patients met those criteria (Figure 1). Health data standards were used wherever possible; ICD-10-CM (International Classification of Diseases, Tenth Revision, Clinical Modification) was used to evaluate the diagnosis of gonococcal infections.

The Sexual History SmartForm and corresponding patient questionnaire were developed to collect sexual history and STI-related symptoms from patients. The form and questionnaire were structured as point and click questions and answers for ease of use; patients had access to the questionnaire via MyChart [50] (Epic’s patient portal) prior to the visit (Figure 1, step 1; Table 1). At the beginning of the clinic visit, nurse navigators reviewed the information collected using the SmartForm and completed the questionnaire, if incomplete (Figure 1, step 2). Based on CDC’s guidelines [15,16,48], patients were considered to be at risk for HIV infection for the following criteria: (1) positive result or diagnosis for gonococcal infection in the last 6 months; (2) reason for visiting the clinic was related to STI; and (3) sexual risk behaviors, known partner with any STI, and if patient or partner using or sharing needles. If the patient’s response suggested a high risk for HIV infection, the SmartForm algorithm presented further questions to gauge awareness and interest for PrEP (Table 1).

Figure 1. Workflow and details of the clinical decision support solution. CDS solution workflow; represented in numerical order in the diagram: 1. "SmartForm" (a native Epic tool for capturing responses to questions) captured detailed sexual history from the patient. It was made available to patients in advance via MyChart (Epic’s patient portal) on their phone app or web browser. 2. At the beginning of the visit, the nurse navigator entered a reason for the visit and chief complaint, reviewed information entered via SmartForm, and completed the SmartForm, if incomplete. 3. When the clinical provider accessed the patient’s chart, a "best practice advisory" (BPA; Epic’s name for rule-based alerts) directed the clinical provider to a "SmartSet" (Epic’s name for order sets) that represented the Centers for Disease Control and Prevention treatment and prevention guidelines for gonococcal and HIV infections. 4. If the clinician opted to open the SmartSet, a detailed list of orders, treatment, and diagnosis options was provided. 5. The clinician documented the visit using a "SmartText" (Epic’s name for a method of taking clinical notes) documentation template specifically designed for sexually transmitted infections (STIs) to standardize the information collected and presented during the visit. Gonorrhea treatment, HIV screening, and PrEP (pre-exposure prophylaxis) prescription guidelines, represented in alphabetical order in the diagram: a. If the patient was considered at risk for HIV infection, additional questions related to PrEP prescriptions appeared in the SmartForm. b. The BPA was displayed to the clinician if the patient met the criteria to treat for gonococcal infection. c. The clinical provider was offered to use the SmartSet which included guidance for screening and treating STIs, and screening and monitoring for PrEP. CDS: clinical decision support.

• Chief complaint  
• Treatment information | | |

aSTI: sexually transmitted infection.  
cEHR: electronic health record.

For patients who (1) had a confirmed positive result for gonococcal infection in the last 14 days, (2) had a chief complaint related to gonorrhea (STI symptoms or concern; penile, urethral, rectal, or vaginal discharge and STI-related screening, testing, follow-up, or visit), or (3) were treated presumptively due to a partner with known gonococcal infection, a BPA would alert the clinical provider (Figure 1, step 3) to use the SmartSet to assist in providing standardized clinical care (Figure 1, step 4; Table 1). The SmartSet was designed to (1) recommend laboratory tests to screen for STI, including HIV, (2) provide PrEP prescription options, (3) present CDC guidelines–based recommendations for medication regimens as preferred options to treat gonococcal infections, and (4) provide a link to gonorrhea treatment guidelines for anything beyond uncomplicated gonorrhea and a link to the SmartText (Figure 1, step 5; Table 1). Opening the BPA did not necessarily mean that clinical providers selected diagnoses or ordered laboratory tests or medication directly from the SmartSet but merely that those options were made available for selection and action. Diagnoses, laboratory tests, and medication orders could also be entered for the patient outside of the SmartSet. The SmartText template was developed to prompt the clinical provider to document in a standardized manner (Table 1). The SmartText included common heading for note taking, prepopulated STI-related laboratory results from the patient’s chart, and risk reduction suggestions.

Use of CDS Solution and Outcomes of Intervention

We evaluated CDS solution use and outcome metrics specifically for any person with confirmed case of gonorrhea or with an STI-related chief complaint. Data were collected on the demographics of the patient population to ensure appropriate
comparison between the baseline and intervention populations, \textit{use} metrics of CDS solutions by X-Clinic, and outcomes following the implementation of the CDS solution. To measure patient and disease characteristics for the baseline period (immediate 12-week period prior to the intervention period), a 1-time data extraction was performed (Table 2). During the intervention period, quantitative data were extracted on a nightly basis.

Table 2. Goal of assessing the clinical decision support solution and their respective data sources.

**Clinical Provider Perspectives and Usability of the CDS Solution**

We conducted 1 midpoint survey to confirm the \textit{use} of CDS solution and identify any challenges faced by the clinical providers using the solution (Table 2; Multimedia Appendix 1). Four end users—or clinical providers who used the CDS solution—completed the survey. We also conducted key informant interviews with 3 end users at the end of the pilot period to assess the \textit{usability} of the CDS solution (Multimedia Appendix 2). The CDS solution design encompassed multiple end user roles such as the SmartForm, which was anticipated to be completed by nurse navigators, and SmartSet, which was anticipated to be completed by clinical providers. We interviewed individuals who represented the various roles such as leadership, clinical provider, and nurse navigator perspectives. The purpose of the key informant interviews was to understand treatment and screening workflows prior to CDS solution implantation, perception, and impact of the CDS solution and solicit suggestions for potential future enhancements (Table 2). We measured the \textit{use} and \textit{usability} of the CDS solution based on the clinical provider role to reveal how perception and familiarity with the CDS solution may have impacted use.

**Data Analysis**

We used quantitative and qualitative means to examine the \textit{feasibility} of this guidelines-based CDS solution in a real-world clinical workflow, where 2 separate guidelines have been cohesively built into a single CDS tool solution, initiated by patients with a gonorrhea diagnosis. Quantitative data were used to describe the \textit{use} metrics and outcomes post implementation of CDS solution and were summarized by descriptive statistics using counts and percentages. To assess \textit{usability} of the CDS tool, qualitative data were systematically coded from interview transcripts, and findings were determined using a combination of explorative and comparative analysis to examine end user (clinical provider) perspectives.

Statistical analysis was conducted to compare the differences between patient populations in the baseline and intervention periods. For continuous variables, to test for a statistically significant difference among populations, a 2-sample \textit{t} test was used. To test for a statistically significant association among outcomes, all categorical variables were tested using Pearson chi-square test, and if an expected count of 5 was not observed for a cell, Fisher exact test was used. If a statistically significant association was observed, odds ratios were calculated. All statistical analyses were conducted using SAS (version 9.4; SAS Institute).

**Results**

**CDS Solution Design**

**Description of Patient Populations: Pre- and Post-CDS Intervention**

During the intervention period, 12,048 patients were provided with clinical care in Codman Square Health Center and 37 were diagnosed with gonorrhea; similarly, 40 patients out of 11,269...
were diagnosed with gonorrhea in the baseline period. The mean age of patients seen in the baseline and intervention periods was 37 (SD 21.46) years and 36 (SD 21.98) years, respectively ($P<.001$). A 2-sample $t$ test analysis of the age groups revealed that the intervention period included younger individuals compared to the baseline period and cannot be considered similar; however, the largest age group of 25-44 years old remained the same with 30.78% (3469/11,269) in the baseline period and 29.58% (3564/12,048) in the intervention period. Using Fisher exact test, it was determined that the patients in the baseline and intervention periods were comparable regarding gender ($P=.25$). While ethnicity distribution was found to be similar ($P=.56$) using Pearson chi-square test, baseline and intervention groups differed significantly by race ($\chi^2=4.36; P=.04$). Nevertheless, the largest patient population served by Codman Square Health Center was Black or African American in both baseline (9040/11,269, 80.22%) and intervention (9565/12,048, 79.39%) periods.

**Use of CDS Solution and Outcomes of Intervention**

**Use**

Throughout Codman Square Health Center, the BPA was triggered 950 (4.07%) times. Within the X-Clinic specifically, the BPA was triggered in one-tenth of all the clinical encounters (348/3451, 10.08%); these 348 encounters represented 300 patients (Figure 2). The SmartForm was opened for about half of the patients (157/300, 52.33%), and in instances when the SmartForm was opened, it was completed 89.81% (141/157) of the time (Figure 2). Of note, while the BPA did not prompt the user to open the SmartForm, the patient cohort where the BPA presented was used for analysis as this represents the target population for this study. For those patients whose responses determined them as high-risk for HIV, further PrEP-related questions were asked (Table 1). Some information about PrEP was known to 63.31% (88/139) of the patients who were asked that question; 6.62% (9/136) of patients reported having taken PrEP and 16.06% (22/137) patients showed interest in PrEP (Figure 2).

Clinical providers could open SmartSet from the BPA (Figure 1, step 4), and this action was taken for about half of the patients (162/300, 54%) for whom BPA was presented. In the target population, the most common diagnosis was “Vulvovaginitis” (ICD-10-CM: N76.0); it was assigned to 34 patients, 21 were assigned to patients for whom BPA was presented, and 13 were assigned where no BPA was presented (Table 3). Diagnoses were assigned, and laboratories were ordered both from BPA-prompted SmartSet and outside of BPA without using the CDS solution (Table 3). No patients were diagnosed with cervicitis but were diagnosed with urethritis, pharyngitis, and proctitis. The most ordered laboratory test was for HIV. More than half (191/348, 54.89%) of the encounters where a BPA was presented received these orders for HIV testing.

In the X-Clinic, SmartText note template was used in most of the clinical encounters (313/348, 89.9%), where the BPA was presented. Clinical providers used SmartText extensively (2343/3103, 75.5%) even during encounters where the BPA did not trigger. The SmartText was accessible either through the SmartSet or a standard “quick button” in the documentation area. The clinical site continued to use the CDS tool beyond the study period.

**Outcomes of Intervention**

In the intervention period, among patients where a BPA was triggered, there were fewer patients with a diagnosis of gonococcal infections (33/750, 4.4%) as compared to the baseline period (41/649, 6.32%; Table 4). While roughly four-fifths (34/41, 82.93%) of these patients diagnosed with gonorrhea were prescribed antimicrobials for treating the infection, the difference in the number of patients treated in the intervention (26/33, 78.79%) and baseline periods were not statistically significant (P=.65). Individuals in the intervention period had a 26% decrease in odds (odds ratio 0.74, CI: 0.60-0.91) of being screened for HIV (310/750, 41.33%) compared to the baseline period (317/649, 48.84%). PrEP was
prescribed 2 times more to patients in the intervention period (12/750, 1.6%) compared to the baseline period (6/649, 0.92%); however, analysis revealed that these numbers not to be statistically significant ($P=.26$).

### Clinical Provider Perspectives and Usability of the CDS Solution

#### Midpoint Survey

Most of the survey responders reported that the CDS solution was not intrusive to their clinical practice workflow (2/4, 50% strongly agreed; 1/4, 25% agreed; and 1/4, 25% was neutral). They also agreed (0/4, 0% strongly agreed; 3/4, 75% agreed; and 1/4, 25% was neutral) that the CDS solution was easy to navigate and provided sufficient time to use it during the patient consultation. They had neutral responses (0/4, 0% strongly agreed; 1/4, 25% agreed; and 3/4, 75% was neutral) about the CDS solution’s ability to present clear recommendations for treatment.

### Key Informant Interviews

The interview revealed 3 major emerging themes. First, the interviewees opined that the CDS solution provided a faster and more standardized approach for capturing the sexual history and treating the patient and planned to keep using it after the pilot was complete. Second, while the CDS solution improved the efficiency and streamlined their existing processes, the interviewees did not change their treatment or screening recommendations based on the solution. Third, they also revealed that the full scope of the CDS solution was not clear to them and reported discovering components of the solution on their own that they were not aware were part of the CDS solution.

There were 3 key themes related to the features of the CDS solution. First, the BPAs alone would not prompt behavior change and use. Interviewees emphasized the importance of education of new guidelines and changes in the EHR tools from someone they know and trust and believed this would promote adherence from clinicians. Second, there were mixed reviews regarding the use of the logic that determined to present PrEP-related questions to some patients considered at high-risk for HIV. While 1 interviewee noted that the unique focus of X-Clinic to specifically address sexual health–related questions and conditions, all patients should be asked PrEP-related questions and noted confusion over the questions being presented to only some patients and not to other patients. Another interviewee indicated that this logic was helpful for colleagues who are less familiar with PrEP to highlight relevance in populations not typically targeted for PrEP, such as heterosexual patients. Third, there was a general sense that SmartSets were hard to navigate. Multiple interviewees commented that they were unable to find SmartSets without BPAs, and once in the SmartSet, it was not easy to leave and come back if an issue outside the scope of the SmartSet needed to be addressed, such as discussions regarding intrauterine devices in relation to gonococcal infections. One interviewee noted handwriting details to remember after completing a task within SmartSet.

### Role-Based Use of CDS Solution

A patient may be seen by multiple providers from more than one provider type category. In the target population (750/12,048, 6.23%) described in Table 4, 32 Doctors of Medicine and Doctors of Osteopathy (MD/DO) provided care for 281 patients and minimally used SmartForms (20/281, 7.12%) but completed most of them once opened (18/20, 90%); 26 advanced practice providers (APPs) provided care to 362 patients, used SmartForms for 20.99% (76/362) of patients, and 81.58% (62/76) completed most of them. In contrast, the “other” category, which included all other clinical staff such as case manager, dentist, laboratory technician, licensed practical nurse, medical assistants, midwives, and social workers, had the highest use, opening SmartForms for half of the patients they served (99/192, 51.56%) and completed most of the forms (83/99, 83.84%). Similarly, “other” category staff administered the highest number of PrEP-related questions, followed by APPs and MD/DOs administered very few. Providers classified as MD/DOs had 309 clinical encounters with 281 patients and opened SmartSets in half of the encounters (157/309, 50.81%) and those classified as APPs had 398 clinical encounters with 362 patients and opened SmartSets slightly lower than half of the encounters (180/398, 45.23%). “Other” staff opened...
SmartSets the least (82/126, 39.42%), with 10 staff who interacted with 192 patients in 208 encounters.

**Discussion**

**Principal Findings**

We integrated translated information from 3 CDC guidelines into a single cohesive CDS solution. This included CDC’s treatment recommendations for gonococcal infections (for appropriate diagnosis, testing, and treatment for gonorrhea) and HIV screening recommendations and PrEP prescription recommendations that stem from the diagnosis of gonorrhea. This CDS solution was implemented at a federally qualified health center where it continued to be used after the intervention period. The CDS solution successfully collected relevant information about the patient, evaluated the patient information against the CDC guidelines to prompt adequate treatment for gonorrhea, and identified at-risk patients for further HIV screening and PrEP prescription. The quantitative data revealed high rates of use of the various tools developed for the CDS solution and demonstrated the feasibility of incorporating such multifaceted guidelines-based CDS solutions in real-world clinical settings.

During our usability testing, clinical providers used all components of the CDS solution, with varying degrees, based on their respective provider type or roles, and familiarity with the CDS solution. Providers classified as MD/DO used the SmartSet more than “other” staff such as medical assistants and social workers and vice versa for the SmartForm that performed the initial screen for patients’ sexual history and PrEP awareness. In the X-Clinic, specifically, the BPA was presented in 10.08% (348/3451) of the encounters; clinicians reported that this was not intrusive and could be used as a benchmark to potentially reduce alert fatigue. The SmartSet was opened in about half of the times alerted by BPA, but fewer orders were directly entered from the SmartSet itself. This does not mean that patients did not receive care. Some insights offered by providers as plausible explanations include (1) clinicians reported benefiting from the reminder and served as a knowledge source even if they performed those actions outside of the SmartSet; (2) clinicians were not accustomed to using SmartSets and reported experiencing difficulties in locating it once they moved away from it during the clinical visit; (3) the BPA alert at the time when the patient record was initially opened may be too early to determine diagnosis, order laboratory tests, and prescribe treatment, delaying the timing of the BPA could be explored; and (4) clinicians had neutral responses when asked about CDS solution’s ability to present clear recommendations since SmartSet presented all treatment options with those aligned to the guidelines marked as “preferred” instead of targeted recommendations for a particular patient.

There was no significant difference between the baseline and intervention patient groups with respect to the treatment for gonococcal infections. It is important to note that X-Clinic is primarily focused on providing sexual health and STI-related care, and the providers were well versed with treatment recommendations, which could be an explanation for the lack of difference. The results also show that one-fifth of the patients in both baseline and intervention periods were not treated with antimicrobials during the visit. A likely explanation is that these patients were empirically treated elsewhere and were referred to X-Clinic for further follow-up, given their specialty in providing STI-related care. Fewer patients were screened for HIV during the intervention period compared to the baseline period. However, key informant interview participants anecdotaly reported an increased interest regarding PrEP in less traditional populations, such as heterosexual women. While PrEP was prescribed to twice as many patients in the intervention period compared to the baseline period, this was not deemed statistically significant.

The widespread adoption of EHRs has provided us with the unique opportunity to leverage CDS approaches to automate and align clinical decisions such as identifying-at-risk patients for further screening and providing adequate treatment with the latest guidelines. This becomes especially important in situations where clinical providers may not be familiar with the latest screening and treatment guidelines. Given the rise in resistance to antimicrobial treatment for gonorrhea, adherence to treatment guidelines is even more important. Further development of standards and tools and examination of workflows to implement useful guidelines-based CDS solutions with the ultimate goal of improving patient care are needed.

**Limitations**

The original design was based upon a 6-month intervention period. A longer pilot period would have allowed the opportunity for a larger data set of patients diagnosed with gonorrhea and potentially more compelling statistical correlations, along with additional time for the clinical staff to acclimate to the new solution.

For this phase of our work, it was important to test the feasibility of the guidelines-based CDS logic, measure the use of the CDS tools, and solicit feedback from end users regarding their experience using the CDS tool. Prioritizing these factors, we decided to leverage EHR-native but vendor-specific tools such as SmartForm, BPA, SmartSet, and SmartText. We factored that OCHIN, our partner organization has many clinics using their instance of Epic EHR across the United States [37,38], and any lessons learned could potentially be replicated and scaled to other interested clinical sites.

Since the focus of this work was to translate multiple CDC guidelines into a cohesive CDS solution, we selected a clinical site that was well versed in STI diagnosis and treatment with a track record of serving a large number of patients seeking sexual health and STI-related care. Due to the same reasons, this clinical setting may not be the best target of clinical providers to measure any potential outcomes of the CDS solution. The CDS solution would better serve clinical providers and settings, where there is less familiarity of treating patients with STIs.

In this study, we report the feasibility, use, and usability of the CDS solution; we did not measure the effectiveness of the intervention. We did not examine any change in clinical practice and its impact on clinical care or the long-term prevention outcomes in the patient population. As a result, we did not randomize the study and did not examine any potential
confounding. Similarly, while we obtained quantitative and qualitative information from end users of various roles, the small sample size poses challenges to draw firm conclusion of usability at scale. Further examination of the CDS solution could be performed by manual chart review with an annotated gold standard measure.

Comparison With Prior Work
In the past, CDC guidelines–based CDS interventions have been designed to recommend appropriate immunizations [51], screening for alcohol use disorder [52], and screening for cervical cancer [53]. A United States Indian Health Services clinic implemented a chlamydia and HIV screening tool and observed increase in screening frequencies of both chlamydia and HIV; however, this was not strictly based on CDC guidelines [54]. Another study described the implementation of CDS tool to encourage appropriate prescription of azithromycin in primary care clinics with the aim to curb rise of antimicrobial resistance, but this study was not targeted toward STIs and was focused on bronchitis and upper respiratory tract infections [55]. To the best of our knowledge, no CDS tools have been implemented with the goal of improving adherence to guidelines for gonorrhea treatment, HIV screening, and HIV PrEP.

Conclusions
It is feasible to integrate multiple CDC guidelines into a single cohesive CDS solution. The CDS solution showed high rates of use, but given the short study period, we could not adequately measure realistic patient outcomes. The clinical site has opted to continue using the full scope of the CDS solution, and perhaps that decision is a measure of success.

Learning from this experience, we will be developing a standards-based EHR-agnostic CDS solution with a longer study period.

Abstract

Background: Adequate sleep is essential for maintaining individual and public health, positively affecting cognition and well-being, and reducing chronic disease risks. It plays a significant role in driving the economy, public safety, and managing health care costs. Digital tools, including websites, sleep trackers, and apps, are key in promoting sleep health education. Conversational artificial intelligence (AI) such as ChatGPT (OpenAI, Microsoft Corp) offers accessible, personalized advice on sleep health but raises concerns about potential misinformation. This underscores the importance of ensuring that AI-driven sleep health information is accurate, given its significant impact on individual and public health, and the spread of sleep-related myths.

Objective: This study aims to examine ChatGPT’s capability to debunk sleep-related disbeliefs.

Methods: A mixed methods design was leveraged. ChatGPT categorized 20 sleep-related myths identified by 10 sleep experts and rated them in terms of falseness and public health significance, on a 5-point Likert scale. Sensitivity, positive predictive value, and interrater agreement were also calculated. A qualitative comparative analysis was also conducted. A qualitative comparative analysis was also conducted. A qualitative comparative analysis was also conducted.

Results: ChatGPT labeled a significant portion (n=17, 85%) of the statements as “false” (n=9, 45%) or “generally false” (n=8, 40%), with varying accuracy across different domains. For instance, it correctly identified most myths about “sleep timing,” “sleep duration,” and “behaviors during sleep,” while it had varying degrees of success with other categories such as “pre-sleep behaviors” and “brain function and sleep.” ChatGPT’s assessment of the degree of falseness and public health significance, on the 5-point Likert scale, revealed an average score of 3.45 (SD 0.87) and 3.15 (SD 0.99), respectively, indicating a good level of accuracy in identifying the falseness of statements and a good understanding of their impact on public health. The AI-based tool showed a sensitivity of 85% and a positive predictive value of 100%. Overall, this indicates that when ChatGPT labels a statement as false, it is highly reliable, but it may miss identifying some false statements. When comparing with expert ratings, high intraclass correlation coefficients (ICCs) between ChatGPT’s appraisals and expert opinions could be found, suggesting that the AI’s ratings were generally aligned with expert views on falseness (ICC=0.83, P<.001) and public health significance (ICC=0.79, P=.001) of sleep-related myths. Qualitatively, both ChatGPT and sleep experts refuted sleep-related misconceptions. However, ChatGPT adopted a more accessible style and provided a more generalized view, focusing on broad concepts, while experts sometimes used technical jargon, providing evidence-based explanations.

Conclusions: ChatGPT-4 can accurately address sleep-related queries and debunk sleep-related myths, with a performance comparable to sleep experts, even if, given its limitations, the AI cannot completely replace expert opinions, especially in nuanced and complex fields such as sleep health, but can be a valuable complement in the dissemination of updated information and promotion of healthy behaviors.

Introduction

An adequate amount of good, restorative sleep is of paramount importance for both individual and public health [1,2]; from an individual standpoint, it helps maintain optimal physical and mental health, facilitating cognitive function, ensuring well-being, and mitigating the risks associated with chronic diseases [3]. In the context of public health, sleep’s impact is profound and multifaceted as well, being a pivotal element in driving the economy, ensuring public safety, and managing health care expenditures. The strategic addressing of sleep-related issues not only alleviates the global burden of disease but also ameliorates the economic strain associated with it [4,5].

The promotion of healthy sleep patterns and the intervention in sleep-related disorders emerge as vital strategies, paving the way for the enhancement of overall societal well-being, boosting productivity, and fostering social cohesion [6]. Such initiatives can yield substantial benefits, at both the individual and community levels, thereby underscoring the role of innovative tools, including digital ones—spanning from dynamic websites to sleep trackers and mobile apps—in promoting and providing education on sleep health [7].

The internet offers a vast, versatile, easily accessible, and cost-effective platform for disseminating up-to-date information about sleep, reaching diverse populations, raising public awareness about the importance of sleep, and providing personalized guidance on sleep health and related topics. People can access the latest findings and recommendations to make informed decisions about their sleep habits, with telemedicine and web-based consultations with sleep experts becoming increasingly popular. The digital realm can enable individuals to monitor their sleep patterns, engaging them in continuous learning about sleep health, and facilitating self-awareness and behavioral changes to improve sleep quality [8].

In the era of generative conversational artificial intelligence (AI) [9,10], characterized by disruptive technological transformation, the importance of sleep health promotion and education becomes even more relevant [11]: conversational AI-based platforms and agents, such as chatbots, can provide instant responses to sleep-related queries, making information readily available at any time. This real-time accessibility can help individuals seeking answers about sleep health, who can receive personalized advice and recommendations based on an individual’s specific sleep patterns and concerns. However, besides being accessible and tailored, this information should also be accurate [12].

There are only a few studies that have assessed sleep-related knowledge of conversational AI-based chatbots, such as ChatGPT-4, which was found very recently to successfully pass the sleep medicine certification board examinations [13] and be conversant in sleep disorders, such as obstructive sleep apnea syndrome [14-16].

On the other hand, conversational AI may contribute to disseminating “factual errors, nonsense, fabricated sources, and dangerous advice” and, thus, spreading biomedical misinformation, including sleep-related misinformation [17]. Therefore, our study was conducted to verify the accuracy of a popular prototype of conversational AI, ChatGPT, in addressing queries concerning sleep health and, in particular, sleep-related myths. These can be defined as widely held “false beliefs about sleep” that “lack an evidence base” and “can persist despite contradicting scientific evidence, potentially impairing” and even degrading population health, by promoting the adoption of unhealthy behaviors and lifestyles, the identification of which “can inform efforts to promote population sleep health” [18].

Methods

Procedure

A list of 20 sleep-related myths, as defined above, was taken from a previously published study [18]. This list was compiled using internet searches of popular press and scientific literature and leveraging a Delphi process that involved 10 sleep experts from the fields of sleep medicine and research. Experts were recruited by convenience sampling, after being identified through literature searches (using PubMed). To be considered an expert, they were required to have published 20 papers that were cited by 20 or more different peer-reviewed sources, and at least one of these publications had to be tagged with the “Medical Subject Headings” “sleep” along with either “circadian rhythms,” “neuroscience,” or “psychiatry.” A total of 20 individuals who fulfilled these requirements were reached out to and out of these 20 experts 10 took part in this study. The Delphi process consisted of selecting and refining myths and was conducted in 3 stages: initially, focus groups were held (phase 1); this was followed by a period of email-based feedback for editing, adding, or removing myths (phase 2); finally, closed-ended surveys were used (phase 3), during which experts assessed the myths. The 20 myths were, then, categorized along six domains: namely, (1) “sleep duration” (n=6), (2) “sleep timing” (n=1), (3) “behaviors during sleep” (n=4), (4) “daytime behaviors that relate to sleep” (n=2), (5) “pre-sleep behaviors” (n=5), and (6) “brain function and sleep” (n=2). Besides providing feedback, experts had to rate myths on 2 dimensions: falseness and public health significance using a 5-point Likert scale from 1 (“not at all false” or “not at all significant”) to 5 (“extremely false” or “extremely significant”) [18].
It should be noted that, while some of these myths are patently false (such as the statement “during sleep, the brain is not active,” which belongs to the “brain function and sleep” domain), other statements such as “lying in bed with your eyes closed is almost as good as sleeping” (belonging to the “behaviors during sleep” domain) contain some elements of truth and other sleep experts may disagree in labeling them as complete misinformation or myths. Indeed, whether “waking rest” and other “resting states” may confer benefits almost as good as deep rest is debated [19,20]: these concepts challenge the conventional dichotomy of sleep and wakefulness conceived as binary and distinct states and suggest that periods of quiet reflection during wakefulness, characterized by a lack of effortful, focused thought and the absence of distracting stimuli, can also contribute significantly to mental rejuvenation, memory consolidation, hormonal regulation, cellular repair, and emotion regulation [21-23]. Altogether, these resting states, defined also as “offline states,” including eyes-closed rest, daydreaming, mind wandering, or inattentive states, represent approximately half of our waking hours [24,25]. However, the existing scholarly literature reports scarce, contrasting, or even negative findings [26], that warrant further research and suggest that these concepts are not yet well established and are continuously evolving [19,20].

Sleep is, indeed, a complex, nonlinear process, and sometimes, our perception of how well we sleep or even whether we are asleep or awake can be incorrect. For instance, “sleep state misperception,” also known as “paradoxical insomnia,” is a condition where individuals believe they are awake for most of the night, despite actually sleeping for a normal duration. This disorder is characterized by a significant discrepancy between perceived and actual sleep time, often associated with personality traits like neuroticism and altered brain activity during sleep, though its causes and prevalence remain under investigation [27-30].

**Ethical Considerations**

Full ethical clearance was waived for this study, as this study is a purely observational study with responses generated by AI (ChatGPT) and secondary analysis of research data, consisting of anonymous or deidentified study data [18].

**Statistical Analysis**

ChatGPT (version 4) was asked both to determine if these 20 sleep-related disbeliefs were true or false and to appraise them using the 5-point Likert scale. To determine if there is a statistical difference between the 6 abovementioned domains in terms of the distribution of true, false, and other categories of responses, a chi-square test of independence was used. This test helped us determine if the differences in proportions across the different domains were statistically significant. Means were also reported for the overall score (along with their SDs) and broken down according to each domain.

In terms of accuracy, the sensitivity and the positive predictive value of ChatGPT in categorizing the sleep-related statements as false were computed.

Finally, ChatGPT’s ratings of falseness and public health significance of sleep-related myths were compared with those provided by sleep experts. The degree of agreement was measured, in terms of consistency, using the interrater reliability analysis, computing the intraclass correlation coefficients (ICCs) [31].

All statistical analyses were carried out using SPSS (version 28 for Windows; IBM Corp). P values less than .05 were considered statistically significant.

**Qualitative Analytical Approach**

A qualitative comparative analysis was also conducted. Initially, responses from ChatGPT and summary responses from the sleep experts [18] were subjected to a line-by-line comparison to identify similarities and differences in content, style, and complexity of information provided. Then, responses were scrutinized to identify themes, concepts, or categories that were entered in a matrix to have a clear snapshot of where ChatGPT and the experts aligned or diverged in their discussions and to make emerging patterns of alignment and divergence between them. This phase was crucial for understanding how ChatGPT’s training data correlated or not with the current consensus among experts and enabled the identification of gaps in ChatGPT’s knowledge base.

**Results**

**ChatGPT’s Falseness Quantitative Analysis of Sleep-Related Myths**

Overall, ChatGPT labeled 45% (n=9) of the statements as “false,” while a further 40% (n=8) of the items were deemed as “generally false.” Of note, concerning the remaining statements, 5% (n=1) and 10% (n=2) of them were considered “true” and “not (entirely or necessarily) true or false,” respectively. In terms of domain, half of the items related to “sleep duration” were considered “false” (n=3), with the remaining half percent being deemed “generally false” (n=3). The statement concerning “sleep timing” was labeled as “generally false” (n=1). Further, 75% (n=3) of the items related to “behaviors during sleep” were correctly identified as “false,” while the remaining 25% (n=1) were classified as “generally false.” All the statements concerning “daytime behaviors related to sleep” were considered “generally false” (n=2). When assessing the accuracy of items concerning “pre-sleep behaviors,” half of them were properly labeled as “false” (n=2), whereas 16.67% (n=1) of the statements were considered “generally false,” with a further 16.67% (n=1) being “not entirely true or false” and the remaining 16.67% (n=1) being even considered “true.” Finally, concerning “brain function and sleep,” half of the statements were correctly appraised as “false” (n=1), with the remaining half being labeled as “not necessarily true or false” (n=1). Further details are reported in Table 1 and Multimedia Appendix 1.
Table 1. ChatGPT’s appraisals of the falseness of sleep-related myths, scored both qualitatively (true or false) and quantitatively (on a 5-point Likert scale, from 1 or “not at all false” to 5 or “extremely false”), encompassing a range of 6 different topics (sleep duration, sleep timing, behaviors during sleep, daytime behaviors that relate to sleep, presleep behaviors, and brain function and sleep).

</table>

The various response categories did not vary depending on the domain of sleep-related myths ($\chi^2_{15}=14.60$, $P=.48$).

On the 5-point Likert scale, the degree of falseness was computed at 3.45 (SD 0.87), according to ChatGPT’s estimates. The highest scores were recorded for “brain function and sleep” (4.00, SD 1.41), “sleep timing” (4.00, single item), and “sleep duration” (3.67, SD 0.98), while the “behavioral domains” scored the lowest. More in detail, “behaviors during sleep” yielded a value of 3.25 (SD 0.50), followed by “pre-sleep behaviors” (3.20, SD 0.84) and “daytime behaviors that relate to sleep” (3.00, SD 1.41). Further details are presented in Table 1 and Multimedia Appendix 2.

Based on these data, ChatGPT demonstrated an overall sensitivity of 85% and a positive predictive value of 100% in categorizing the statements as “false.”

**Quantitative Comparison of ChatGPT’s and Expert Ratings on the Falseness of Sleep-Related Myths**

When comparing with sleep experts, a good interrater agreement could be found between ChatGPT’s categorization of statements...
and expert rating on their falseness. Statements categorized by ChatGPT as “false” and “generally false” were those that received the highest scores by the experts (4.25 and 3.97, respectively), whereas those judged by the AI as “true” and “not true or false” received the lowest scores by the experts (3.75 and 3.44, respectively), as shown in Figure 1. From a more quantitative standpoint, the association yielded an ICC value of 0.83 ($P < .001$), when ChatGPT was asked to rate the degree of falseness of the statement on the 5-point Likert scale (Figure 2).

**Figure 1.** Comparison of ChatGPT’s and expert qualitative ratings on the falseness of sleep-related myths, showing a general good agreement and alignment between experts and artificial intelligence.

![Falseness](image)

**Figure 2.** Scatterplot of the comparison of ChatGPT’s and expert quantitative ratings (on a 5-point Likert scale, from 1 or “not at all false” to 5 or “extremely false”) on the falseness of sleep-related myths, showing a general good agreement and alignment between experts and artificial intelligence.

**ChatGPT’s Public Health Significance Quantitative Analysis of Sleep-Related Myths**

The overall score was 3.15 (SD 0.99). “Sleep timing” was the domain scoring the highest (4.00, single item), followed by “sleep duration” (3.33, SD 1.37) and “behaviors during sleep” (3.25, SD 0.96). “Daytime behaviors that relate to sleep” scored the lowest (2.50, SD 0.71), while both “brain function and sleep” and “pre-sleep behaviors” yielded a mean score of 3.00 (SD 1.41, and SD 0.71, respectively). Further details are presented in Table 2.
Table 2. ChatGPT’s appraisals of the public health significance of sleep-related myths, scored quantitatively (on a 5-point Likert scale, from 1 or “not at all significant” to 5 or “extremely significant”), encompassing a range of 6 different topics (sleep duration, sleep timing, behaviors during sleep, daytime behaviors that relate to sleep, presleep behaviors, and brain function and sleep).

Quantitative Comparison of ChatGPT’s and Expert Ratings on the Public Health Significance of Sleep-Related Myths

Similar trends to those observed for the expert appraisals of the falseness of sleep-related myths could be reported for the expert rating on their public health significance. Items labeled by ChatGPT as “false” and “generally false” corresponded to a score of 3.37 and 3.04, respectively, while statements appraised by the AI as “true” and “not true or false” scored the lowest (2.71 and 2.07, respectively), as pictorially represented in Figure 3.

When comparing the ratings on public health significance provided by ChatGPT with those by the experts, an ICC of 0.79 could be computed (P=.001), as shown in Figure 4.
Qualitative Comparison and Thematic Analysis of ChatGPT’s and Sleep Experts’ Responses

The qualitative comparison between ChatGPT’s and sleep experts’ appraisals of sleep-related myths revealed both similarities and differences across the various misconceptions.

In general, both ChatGPT and sleep experts clarified and, in some instances, strongly refuted these misconceptions, highlighting the importance of adequate sleep for overall well-being, while acknowledging individual differences in sleep needs and patterns, and emphasizing that sleep requirements can vary from person to person. However, differences in responses could be noted: ChatGPT adopted a more conversational and accessible style and provided a more generalized view, focusing on broad concepts, while experts sometimes used technical jargon, providing evidence-based explanations to debunk false beliefs about sleep. Sleep experts tended to provide a more detailed assessment, often including specific medical and physiological contexts, referencing studies, and focusing both on individual (clinical) and public health implications, while a population health perspective was generally missing in ChatGPT’s responses.

Specifically concerning “sleep duration myths,” both ChatGPT and sleep experts clarified the misconceptions, but experts provided a more medically oriented focus, delving into the biological and physiological underpinnings more deeply, while ChatGPT emphasized sleep-related flexibility and individual variability. Further, sleep experts provided a more nuanced...
appraisal of risks and the evidence (or lack thereof) supporting them, focusing not only on temporary or short-term effects but offering detailed perspectives on long-term consequences and recovery too. Similarly, concerning “sleep-related timing myths,” both ChatGPT and sleep experts emphasized the role of circadian rhythms and the importance of sleep timing, but experts gave a more technical assessment focusing on specific physiological processes. Regarding “behaviors during sleep” myths and “daytime sleep-related behaviors” myths, sleep experts delved into physiological, cultural, and habitual aspects and potential adverse outcomes. Concerning “pre-sleep behaviors myths,” sleep experts focused more on the neurophysiological impacts and provided more evidence-based assessments, with more nuanced explanations of the causes and effects underlying sleep phenomena and disturbances. Finally, regarding “brain function and sleep myths,” sleep experts gave a more detailed explanation of brain functions, highlighting the complexity of sleep research and the presence of controversial topics and conflicting results. Further details are reported in Table S1 in Multimedia Appendix 3.

Discussion

Generative Conversational AI and Sleep-Related Myths

AI-driven platforms and agents, including chatbots, can provide sleep-related information and education, ensuring that a diverse global audience can access valuable and customized resources on sleep health. This tailored guidance can be particularly beneficial for improving sleep quality, in that AI-driven chatbots and digital assistants can provide ongoing support and reminders for healthy sleep habits, promoting consistent behavior change over time. However, information disseminated using digital tools must be accurate and reliable.

According to a few studies, the internet can be a useful platform for enhancing sleep-related health literacy, but can also contribute to spreading misinformation, often including commercial biases and incorrect and misleading content. Robbins et al [32] evaluated the understandability, quality of information, and presence of misinformation in popular YouTube videos about sleep compared to those featuring credible experts. The top YouTube videos on sleep or insomnia and 5 expert-led videos were analyzed for clarity and understanding using established tools. Sleep medicine experts agreed on instances of misinformation and commercial bias, with about 67% (n=14/21) of popular videos showing evidence of commercial bias, unlike the expert videos. Misinformation was more prevalent in popular videos that averaged 8.2 million (SD 2.2) views, significantly higher than the expert videos’ 0.3 million (SD 0.2) million views. Most YouTube videos were found to have clickbait and be appealing to shorter attention spans, having engaging content, good visual quality, and being highly relatable to viewers. All this highlights the issue of misinformation and bias in widely viewed sleep or insomnia videos on YouTube and other web-based platforms, suggesting the urgent need for combating digital sleep-related misinformation [33].

ChatGPT is anticipated to play a key role in sleep health promotion and education, enhancing public perceptions of the importance of sleep in daily life and its impact on human health. This analysis demonstrates the potential for AI tools like ChatGPT to provide health information, in particular in the arena of sleep medicine. Considering the overall distribution of responses provided by ChatGPT, a high proportion of sleep-related myths (n=17/20, 85% of the statements) was correctly identified as either false or generally false, suggesting that ChatGPT is aligned with scientific evidence. However, the categorization of some statements as “true” or “not necessarily true or false” indicates ChatGPT’s ability to recognize and label scientific items as accurate can be still improved.

In general, ChatGPT has a good, scholarly understanding of several crucial aspects of sleep health, spanning from sleep duration and timing to behaviors during sleep, while it demonstrates some limitations in the field of sleep hygiene, and in the understanding of sleep-related occupational and public health implications.

Moreover, addressing sleep myths involves a nuanced exploration of sleep-related topics: our qualitative analysis on how common misconceptions are clarified by both AI platforms such as ChatGPT and sleep experts shows a good alignment, though some statements are approached from different angles. From a qualitative comparative perspective, ChatGPT tends to provide more pragmatic advice and tips, emphasizing the importance of regular sleep schedules and practices, even if in the context of a certain degree of flexibility in sleep systems, and the impact of individual behaviors on sleep quality. This approach often includes general recommendations based on a broad understanding of sleep science, aiming to correct misunderstandings such as the notion that less sleep can be habitually sufficient or that lying in bed with eyes closed substitutes for genuine sleep. In contrast, sleep experts delve deeper into the medical and physiological specifics, offering a more detailed assessment that considers individual health conditions, genetic predispositions, and the long-term health risks associated with disrupted sleep patterns. They might focus on the precise effects of sleep deprivation on cognitive function, the specific dangers of certain presleep behaviors, or the complex, nonlinear relationship between sleep stages and overall health. A major difference between ChatGPT and sleep experts is that only the latter have mentioned the public and occupational aspects of sleep, while the former has focused more on the individual level. The dialogue between these perspectives can enrich our understanding of sleep, blending practical guidance with in-depth scientific insights to debunk myths and promote healthier sleep practices across diverse populations.

However, as previously mentioned, some errors by ChatGPT in correctly classifying myths as false statements underscore the current limitations of AI: users should be aware of the shortcomings of AI-based tools in interpreting complex, evolving fields like sleep science and sleep health. ChatGPT’s classifications are not definitive statements of truth but rather reflections of current knowledge and interpretations, which are constantly evolving. In summary, the categorizations by ChatGPT provide an interesting insight into how AI tools process and present information on complex health topics such
as sleep, emphasizing the importance of contextual understanding and the ongoing development of AI capabilities in health education.

**Implications and Future Directions**

ChatGPT’s ability to debunk sleep-related myths has several important implications, both in the field of sleep health and in the context of AI in health care and information dissemination. The ability of ChatGPT to accurately debunk sleep-related myths can significantly contribute to enhancing public health education, including sleep health education. Providing reliable information can help correct widespread misconceptions about sleep, which is vital given the importance of sleep for overall health. ChatGPT can also serve as a tool for supporting health care professionals, helping them to stay abreast of the latest advancements, quickly verify information, and provide evidence-based advice to their patients, potentially improving the quality of sleep health advice given.

Moreover, AI-based platforms such as ChatGPT can make sleep health information more accessible to a broader audience and can offer personalized advice based on individual queries, which is difficult to achieve through traditional health education methods.

This study indicates that AI can be a reliable source of health information. However, it also highlights the need for ongoing evaluation to ensure accuracy, especially in areas with nuanced and complex information, such as sleep health. More in detail, this study suggests that while AI tools such as ChatGPT can be highly effective, they should not replace expert opinion but rather complement it. This is particularly important in complex fields where contextual understanding and professional judgment are crucial. There is a need for continuous learning and updating: AI systems must continuously learn and upgrade their knowledge base to ensure the information they provide stays current with the latest scientific findings and expert consensus.

Moreover, ChatGPT’s ability to identify and correct false information is particularly relevant in an era where misinformation can spread rapidly on the web [34-36]. This capability can play a significant role in public health initiatives. On an individual level, accurate AI-driven advice on sleep health can directly contribute to the prevention of diseases, including sleep-related disorders, which are often linked to chronic diseases such as obesity, diabetes, and cardiovascular issues. By debunking myths and offering personalized guidance on healthy sleep practices, these tools can play a pivotal role in enhancing individual wellness, mental health, and overall quality of life. In the broader context of occupational and public health, provided that the above-mentioned shortcomings of ChatGPT in these fields are properly addressed, the dissemination of reliable sleep-related information via AI platforms can aid in the formulation of more informed public health policies and initiatives. By increasing the general population’s understanding of the importance of sleep, these tools can contribute to a reduction in health care costs associated with sleep disorders and their comorbidities. Furthermore, the implications for public safety are significant. Improved sleep health, guided by AI-based tools, can lead to decreased incidences of accidents and errors attributed to sleep deprivation, such as those in high-risk professions (eg, transportation, health care, etc). This would not only enhance the safety of the individuals in these roles but also safeguard the broader community. Thus, the integration of AI in sleep health education and promotion aligns with broader public health and safety goals, offering a proactive approach to mitigating risks associated with poor sleep and promoting a healthier, safer society.

Finally, this study opens the door for similar applications of AI in other areas of health and wellness, suggesting a potential for AI tools to become more integrated into various aspects of health care delivery, provided that ethical and practical considerations in addressing misinformation and biases are taken into full account. As previously mentioned, there is a need to constantly monitor and improve AI systems to prevent the spread of misinformation and reduce biases in the information provided. Further, in the context of digital health tools, ensuring the privacy and security of user data is paramount, especially when personal health information is involved, underscoring the need for regulatory and ethical oversight in the use of AI in health care to ensure that these tools are used responsibly and for the benefit of individual, occupational, and public health.

**Strengths and Limitations**

This study has some strengths, including its novelty, methodological rigor, and reproducibility. On the other hand, it suffers from several limitations that should be properly acknowledged: future studies should investigate other AI-based tools, such as Google Bard. Not all digital assistants and chatbots have demonstrated efficacy in improving health- and sleep-related behaviors [37,38]. It should be, indeed, considered that each AI-enhanced platform, being trained on different knowledge bases, has specific technical features and capabilities, and, therefore, some AI-based tools may exhibit lower sleep-related knowledge and literacy, demonstrating less capability of correctly identifying the sleep-related statements as false. As such, this implies that monitoring of the AI system should be tool-specific.

**Conclusions**

In the present digital era, the synergy of generative conversational AI and sleep health promotion has the potential to positively impact individual, occupational, and public health by providing easy access to evidence-based information and support. This study’s findings demonstrate the potential of AI tools such as ChatGPT in enhancing public health education, particularly in debunking myths and disseminating accurate information related to sleep health. While promising, it is important to use these tools as supplements to, rather than replacements for, sleep expert opinion and to maintain strict standards of accuracy, privacy, and ethical use.

Abstract

Background: The COVID-19 pandemic brought challenges requiring timely health data sharing to inform accurate decision-making at national levels. In Botswana, we adapted and integrated the Research Electronic Data Capture (REDCap) and the District Health Information System version 2 (DHIS2) platforms to support timely collection and reporting of COVID-19 cases. We focused on establishing an effective COVID-19 data flow at the national public health laboratory, being guided by the needs of healthcare professionals at the National Health Laboratory (NHL). This integration contributed to automated centralized reporting of COVID-19 results at the Ministry of Health (MOH).

Objective: This paper reports the experiences, challenges, and lessons learned while designing, adapting, and implementing the REDCap and DHIS2 platforms to support COVID-19 data management at the NHL in Botswana.

Methods: A participatory design approach was adopted to guide the design, customization, and implementation of the REDCap platform in support of COVID-19 data management at the NHL. Study participants included 29 NHL and 4 MOH personnel, and the study was conducted from March 2, 2020, to June 30, 2020. Participants’ requirements for an ideal COVID-19 data management system were established. NVivo 11 software supported thematic analysis of the challenges and resolutions identified during this study. These were categorized according to the 4 themes of infrastructure, capacity development, platform constraints, and interoperability.

Results: Overall, REDCap supported the majority of perceived technical and nontechnical requirements for an ideal COVID-19 data management system at the NHL. Although some implementation challenges were identified, each had mitigation strategies such as procurement of mobile Internet routers, engagement of senior management to resolve conflicting policies, continuous REDCap training, and the development of a third-party web application to enhance REDCap’s capabilities. Lessons learned informed next steps and further refinement of the REDCap platform.

Conclusions: Implementation of REDCap at the NHL to streamline COVID-19 data collection and integration with the DHIS2 platform was feasible despite the urgency of implementation during the pandemic. By implementing the REDCap platform at the NHL, we demonstrated the possibility of achieving a centralized reporting system of COVID-19 cases, hence enabling timely and informed decision-making at a national level. Challenges faced presented lessons learned to inform sustainable implementation of digital health innovations in Botswana and similar resource-limited countries.
Introduction

The onset of the COVID-19 pandemic resulted in a global public health crisis [1]. The pandemic stretched almost all health care systems to their limits and exposed their weaknesses [2]. Previously documented COVID-19 challenges for the health sector include a lack of the health care services needed for the pandemic, inadequate resources, limited testing ability and capacity for a COVID-19 response, as well as overall poor data management within existing health care systems [1]. It was previously projected that countries in sub-Saharan Africa could see a sharp rise in COVID-19 infection rates and deaths, as such challenges are prominent in resource-limited countries [3]. This projected disproportionate impact of COVID-19 in resource-limited countries comes as no surprise. Currently, the health sector in high-income countries is deemed as underfunded, while in most resource-limited countries, it is reportedly heavily underfunded [4]. It is not a surprise that, in 2001, African leaders through the African Union’s Abuja Declaration agreed to “allocate 15% of the state’s annual budget to the improvement of the health sector” [5]. However, in 2013, only 5 African countries had achieved this target, while in 2018, only 2 countries achieved the target [6].

Access to accurate and current information has been recognized globally as a critical requirement for timely COVID-19 pandemic responses [7]. As such, the pandemic presented the need for robust data management systems in response to the evolving nature of COVID-19 [8]. Ideally, eHealth—“cost-effective and secure use of information and communications technologies (ICT) in support of health and health-related fields, including health-care services, health surveillance, health literature, and health education, knowledge and research” [9]—could ensure reliable information reporting and timely decision-making by governments and relevant stakeholders. However, requirements for such eHealth solutions present a greater challenge for resource-limited countries with documented weak ICT infrastructure, limited maintenance budgets, a lack of health human resource capacity to utilize eHealth systems, and nonuniform unique patient identifiers [10]. According to Archer et al [11], other factors affecting successful implementation of eHealth solutions in resource-limited countries include the absence of eHealth agendas, ethical and legal considerations, common system interoperability standards, and reliable power supplies.

Similar to other nations responding to the pandemic, the government of Botswana, through the Ministry of Health (MOH), identified eHealth as a means to improve COVID-19 data management and address complex data capture and transfer processes at various port of entries and the National Health Laboratory (NHL). Botswana’s eHealth infrastructure was previously reported as generally adequate, with functioning computers and some communication systems such as telephones, email, and Internet services [12]. According to Seifio-Kgokgwe et al [12], almost all public health facilities in Botswana are now connected to the government data network (GDN) with an average Internet connectivity of about 2 Mbps. The authors further highlighted that Botswana’s eHealth initiatives have always operated within a very weak policy and regulatory framework characterized by inadequate health information legislation, national policy, and strategic plan. Fragmentation and inefficient eHealth initiatives were noted as other contributing factors to poor utilization of information in Botswana’s health sector, as well as the lack of appreciation of the important role played by health information in managing health services. Currently, over 52 health laboratories operate in Botswana, 8 of which are accredited with national certifications like the South African National Accreditation System (SANAS), Clinical Laboratory Improvement Amendments (CLIA), International Organization for Standardization (ISO) 15189, or the Southern African Development Community Accreditation Services (SADCAS) [13,14].

The Botswana NHL is one of the accredited laboratories tasked with the management of national COVID-19 testing. The NHL has decentralized its COVID-19 testing services from the capital city Gaborone, by operating satellite testing centers in selected districts with sizable populations and key ports of entry into the country. The NHL data flow is such that specimen data go through each of the 4 laboratory stages of (1) Reception Lab (all incoming lab specimens are captured using a barcode scanner), (2) Extraction Lab (specimen processing for nucleic acid isolation and purification), (3) Detection Lab (sample amplification and detection), and (4) Resulting and Verification Lab (lab results are captured and verified for release to clients). The need to scan laboratory specimen samples at each of the laboratory phases is an important quality assurance step. Accession numbers in laboratory processes are critical to link the specimen with a participant. Despite having an already existing eHealth system at the NHL, electronic data transfers within and across the 4 laboratories were considered tedious, time consuming, and a risk to both data quality and timely COVID-19 results reporting. These limitations required immediate attention.

The authors volunteered their technical support toward implementation of a customizable COVID-19 data management system—Research Electronic Data Capture (REDCap)—at the NHL. REDCap was suggested by the authors following its documented benefits including its utility within a resource-limited country context [15,16], as well as its availability locally through the University of Botswana (UB). REDCap is a secure, web-based platform designed to support electronic data capture. It was developed at Vanderbilt University in the United States in 2004 and can be set up to support a variety of health care environments and scenarios. REDCap is compliant with international standards such as the...
Methods

A participatory design approach was adopted to guide the design, customization, and implementation of REDCap for COVID-19 data management at the NHL.

Study Population, Setting, and Design

Participants

All NHL and MOH personnel responsible for processing COVID-19 specimen samples and data were invited to participate. All potential participants were sent an introductory email describing the background and objectives of the study. A consent form was subsequently shared with all those who showed interest. All invited participants agreed to participate in the study, of which 29 were NHL personnel and 4 were based at the MOH. Of the 29 NHL personnel, 12 were based at the Reception Lab, and 17 were based at the Extraction, Detection, and Resulting and Verification Labs. The study spanned from March 2, 2020, to June 30, 2020.

Data collection was conducted in 3 phases.

Phase 1: Participant Engagement

The authors facilitated a 1-day consultative physical meeting or workshop with the study participants to solicit specific requirements for the COVID-19 data management system. Study participants were requested to define requirements for an ideal COVID-19 data management system. The authors recorded all participants’ responses during the session which lasted for 1 hour. Based on the insights gathered from this exercise, iterative design and testing approaches were adopted for each key deliverable from design, customization, and implementation of the REDCap platform to support COVID-19 data management. A minimum of 2 iterations and a maximum of 4 iterations were incurred per deliverable, and this was influenced by the complexity or noncomplexity of the tasks.

Phase 2: Implementation and Assessment of the Platform to Meet User Requirements

Design and customization of the REDCap platform were followed by implementation of the solution as well as evaluating its feasibility to address the previously noted requirements and specifications. This involved participants testing the REDCap platform and providing feedback on any issues or challenges they encountered.

Phase 3: Human Resource Capacity Development

At each phase of the design, customization, and implementation of the REDCap platform, participants were trained on the various system components and had the opportunity to share their feedback to inform next steps.

Ethical Considerations

This study was approved by the Ethics Committee of the University of Botswana (Reference: UBR/RES/IRB/BIO/GRAD/244). All data experiments were performed in accordance with relevant guidelines and regulations such as the Declaration of Helsinki. All participants were informed of the objective of the exercise as well as their voluntary participation, and all gave informed consent for this study. Those who consented to participate were immediately sensitized and granted access to the REDCap instance at the UB. No compensation was provided for participating in the study.

Data Analysis

NVivo 11 software was used for thematic analysis [21] of data to determine participants’ requirements for an ideal COVID-19 data management system and their postimplementation experiences.

Results

Study participants consisted of all personnel involved with handling COVID-19 specimens and managing all relevant laboratory data at both the NHL and MOH (Table 1).
Table 1. Study participants and their roles in COVID-19 data management.

The authors used participants’ feedback to guide the design of an ideal COVID-19 data flow architecture for this study (Figure 1).
Figure 1. Data flow architecture design for COVID-19 data management at the National Health Laboratory (NHL). CRF: case report form; DHIS2: District Health Information System version 2; DHMT: District Health Management Team; DIT: Department of Information Technology; DMC: Data Management Committee; MOH: Ministry of Health; REDCap: Research Electronic Data Capture; UB: University of Botswana.

The REDCap data security architecture at UB separates the web server from the database server (Figure 2).

Figure 2. Research Electronic Data Capture (REDCap) security architecture supporting COVID-19 data management at the National Health Laboratory (NHL). LDAP: Lightweight Directory Access Protocol; SMTP: Simple Mail Transfer Protocol; SSL: Secure Sockets Layer; VLAN: virtual local area network.

In order to facilitate timely decision-making and address a key technical requirement (“Automated COVID-19 results sync with the DHIS2 system” in Table 2), the REDCap system was linked with the DHIS2 system at the MOH for aggregate data reporting.

Interfacing between DHIS2 and REDCap was controlled by the DHIS2 link application programming interface (API; Figure 3).

The DHIS2 API link supported 3 functionalities: (1) data format conversions between DHIS2 and REDCap, (2) avoiding duplicate synchronizing of data between REDCap and DHIS2, and (3) enabling data access for the DHIS2 front end, which relied on the API to make consistent data available for the 2 systems.
In order to access the DHIS2 API, a RestTemplate object short code was implemented with basic authentication secured by username and password (Figure 4).

Study participants accessed REDCap using their personal account details (unique usernames and passwords) before proceeding to collect, manage, and report on COVID-19 at the MOH (Figure 5).
Of important note, the REDCap platform triggered automated email alerts whenever a COVID-19 positive result was recorded. The email alerts were sent to study coordinators at the MOH.

A third-party web application simplified the process of pulling records from the DHIS2 system into REDCap (Figure 6) and enabled the viewing of specimen barcodes through a web browser (Figure 7).

Challenges and resolutions while implementing the REDCap platform to support COVID-19 data management at the NHL are summarized in Table 3.

Discussion

This paper describes the experiences, challenges, and lessons learned while designing, customizing, and implementing the REDCap platform for COVID-19 data management at the NHL in Botswana. REDCap implementation challenges and lessons identified during the study were categorized under the following 4 themes: (1) infrastructure, (2) capacity development, (3) platform constraints, and (4) interoperability.

Infrastructure

The literature emphasizes the critical need for robust ICT infrastructure to serve as the backbone for successful and sustainable digital health implementation [22-25]. The national eHealth strategy tool kit by the World Health Organization (WHO) and International Telecommunication Union (ITU) identifies essential eHealth infrastructure components as high-speed data connectivity, computing infrastructure, identification and authentication services, directory services, health care provider systems, electronic health record repositories, and health information data sets, all of which underpin a national eHealth environment [26]. The tool kit further urges countries to secure long-term funding for investment in national eHealth infrastructure and services. It is against this backdrop that the WHO recognizes a pressing need for countries to invest in infrastructure to support digital transformation; Internet connectivity; and issues related to legacy infrastructure, technology ownership, privacy, and security while adapting and implementing globally recognized standards and technologies [27].

In this study, infrastructural challenges experienced include weak Internet speed and misalignment of computer network firewalls between the GDN and the UB network. These issues resonate with the identified ICT infrastructural challenges within the Botswana National eHealth strategy [28]. During implementation of the REDCap platform at the NHL, initial Internet download and upload speeds were 12.59 Mbps and 16.84 Mbps, respectively (Table 3). The Federal Communications Commission (FCC) considers minimum Internet speeds of 5 Mbps to 25 Mbps as ideal to support online tasks such as file download and telecommuting [29]. However, despite meeting the FCC requirement, study participants reported the need for the Internet speed to be upgraded to adequately support frequent data transactions and data sharing between REDCap and the DHIS2 platform. This could be due to multiple factors. The following are some example quotes from study participants pertaining to their dissatisfaction with the Internet bandwidth:

Internet connectivity is still slow. [participant, NHL Reception Lab]

Internet bandwidth needs to be upgraded. [participant, NHL Resulting and Verification Lab]

As a mitigation for the slow Internet connectivity, relevant government departments were engaged, and measures were put in place to increase the Internet speed. This includes procurement of mobile Internet routers from private Internet service providers (ISPs) for use during the study. The engagement of private sector stakeholders to support implementation of eHealth initiatives is also highlighted as essential within the “Strategy and Investment” pillar of the Botswana National eHealth Strategy, which emphasizes “eHealth planning, with involvement of major stakeholders and sectors” [28].

Another challenge was the restriction introduced by computer network firewalls resulting in data flow constraints between the GDN and UB networks. A similar issue was encountered in another study, in which implementation of the REDCap platform incurred network firewall challenges hindering participants from using computers outside the Veterans Health Administration network to complete a survey on REDCap [30]. According to Nagpure et al [31], firewall policy conflicts can be complex to eliminate but could be addressed through practical resolution methods such as the “first-match resolution” involving “identifying which firewall policy rule involved in a conflict situation should take precedence when multiple conflicting rules (with different actions) filter a particular network packet simultaneously.” At the NHL, the authors resolved the network firewall challenges by engaging relevant ICT authorities at both governmental and UB IT departments to facilitate reconfiguration of the firewall settings to allow data flow between the 2 networks. This necessitated effective measures for data security, privacy, and confidentiality throughout the study. To achieve this, the authors ensured that the REDcap and DHIS2 servers communicate through an encrypted Internet connection using a 128-bit Secure Sockets Layer (SSL) certificate. The use of SSL has been previously considered a standard technology for securing electronic commerce and
Electronic banking transactions over the Internet [32]. However, recent advances in cybersecurity attacks call for using technologies to detect compromised SSL network traffic [33]. This consideration was brought to the attention of both governmental and UB IT departments. Compliance with the Botswana-specific Data Protection Act [34] could improve the necessary safeguards for the right to privacy of individuals and the collection and transfer of their personal data.

**Capacity Development**

Some study participants lacked the requisite skills to effectively use the REDCap platform, which was another challenge encountered during the study. The lack of competent and experienced REDCap users in some low and middle-income countries (LMICs) has been linked to poor “REDCap penetration” in those countries [35]. For example, in Botswana, only 3 institutions have REDCap instances [36], and unless affiliated with any of these institutions, most health care workers are unfamiliar with the platform. Low ICT literacy is common among health care workers in most LMICs [25] and could affect the ability of some participants to competently use the REDCap platform. Recognizing this challenge, the Botswana National eHealth strategy included “Workforce Development” as one of its pillars dedicated to eHealth capacity building among health care workers [28].

A reported benefit of having a health workforce trained in ICT prior to engaging with a health information system is minimizing avoidable errors, which, in this case, may be influenced by a lack of familiarity with the REDCap platform or poor ICT competency. To ensure the effective use of REDCap at the NHL, the authors continuously trained participants at all stages in the study. The ever-evolving nature of the REDCap platform [16,36] also necessitates that those working with the system must continuously familiarize themselves with its core functionalities and data workflows through support from the REDCap Consortium. Almost all training needs for this study were identified during weekly virtual progress report meetings with all study participants. Training content was also informed by the identified system requirements for the REDCap platform (Table 2). According to Nsaghurwe et al [37], “functional requirements describe what the system should do—such as its ability to exchange client-level data in a single repository, search for records with data quality issues; while non-functional requirements describe how the system should perform,” including system performance, reliability, and user-friendliness.

In essence, a central aspect to the successful implementation of any health information management system is the need to train users on how to appropriately utilize the system to capture and manage data [25]. Recommended approaches from the existing literature include ensuring continuous engagement and availing training materials for trainees’ access and reference at a later stage. In this study, the authors made all training material and manuals available via the REDCap “File Repository” feature for the participants to access at their convenience posttraining.

Informed by the level of participants’ familiarity with the REDCap platform, other measures were put in place such as denying participants “data deletion” privileges on the REDCap system. Instead, participants could add, edit, and view data they required to complete their respective tasks. This minimized accidental data deletion and resonated with the famous “principle of least privilege” by Saltzer and Schroeder [38], which states that “every program and every user of the system should operate using the least set of privileges necessary to complete the job.”

**Platform Constraints**

An important lesson learned was that, although REDCap is often regarded as a complete solution for data management [16], in some instances, support from other software applications could augment its limitations. In this study, the REDCap platform was not able to generate barcodes for the NHL personnel to scan to retrieve previously captured information. This limitation was resolved by developing a web-based application supported by the Angular framework [39] for quick production of scannable barcodes required during the Results and Verification Lab stage at the NHL. Some documented benefits of the Angular framework include support for lightweight web applications; faster software development capabilities; and easily readable, testable, and interoperable software solutions [39]. For this study, the authors leveraged the ability to easily link the Angular web application with the REDCap platform. Moreover, only one username and password combination was used to access the data capture forms between the Angular-based web application and REDCap.

Another constraint encountered was the inability of the REDCap platform to automatically store COVID-19 specimen barcodes on the data collection form. Further, the REDCap system requires that the barcode scanner accept a “tab key” to move to the next field, but the scanner configuration used at the NHL accepted a “carriage return key” instead to move to the next field. This meant that each time a barcode was scanned by the study participants, REDCap would not capture it into the appropriate field unless the user pressed the “tab key” on the keyboard to trigger a move to the next field. This became tedious to participants considering the high number of barcodes required scanning at the NHL during the COVID-19 pandemic. To resolve this, the authors reconfigured the barcode scanners to align with REDCap requirements, that is, use of the “tab key” to capture barcodes versus the initial configuration of the “carriage return key.” Moreover, the MOH procured dedicated barcode scanners for use with the REDCap platform as the previous ones accompanied a different system at the NHL. Overall, REDCap ensured auto-saving of the barcodes as they are being scanned, minimizing data loss in case of network or power failure.

**Interoperability**

The Healthcare Information and Management Systems Society (HIMSS) defines interoperability as “the ability of different information systems, devices, and applications (‘systems’) to access, exchange, integrate and cooperatively use data in a coordinated manner, within and across organizational, regional and national boundaries, to provide timely and seamless portability of information and optimize the health of individuals and populations globally” [40]. Some documented benefits of interoperable health care information systems include improved patient management, quality of care, and decision-making, as
well as reduced health care costs [41]. However, several challenges have been noted that hinder the interoperability of health care systems, affecting their successful and sustainable implementation, especially in resource-limited countries [10].

Despite the documented interoperability challenges, REDCap has been successfully linked to other systems previously. For example, a study in the United Kingdom automated the process by which COVID-19 clinical trial registration records were exported from the WHO International Clinical Trials Registry Platform into external software [42]. A linking script subsequently pulled relevant data, aligned it with the data dictionary in REDCap, and directly imported it, removing any duplicates in the process. Other researchers utilized REDCap as a data harmonizer, managing and combining cancer research data from multiple registries and allowing for the reconciliation of disparate data sets as well as their conversion [43,44]. In another previous study, REDCap served as the platform housing all global data collected with modified survey questions to capture nuances and allowed for individualization to study public health interventions for COVID-19 [45]. Consequently, these applications reinforced REDCap’s utility for cross-continental collaborations, extending beyond any singular institution or setting.

In this study, although linking the REDCap platform with the DHIS2 platform was achieved, the failure of the REDCap system to automatically pull data from the DHIS2 platform was noteworthy. This limitation was a result of constraints within the Dynamic Data Pull (DDP) feature in REDCap. The REDCap DDP is a special feature for importing data into REDCap from an external source system [46]. The DDP feature provides an adjudication process whereby REDCap users can approve all incoming data from the source system before the data are officially saved in their REDCap project. Because the REDCap DDP assumes that all incoming data from the source system may not be trusted as valid or that only a subset of the data coming from the source system needs to be imported, it utilizes an adjudication web page inside REDCap’s interface to allow manual review of the data obtained from the source system before confirming that it be imported into the REDCap repository [46]. It is precisely the adjudication process that hindered the automatic data import from the DHIS2 system into REDCap. To address this challenge, a custom API was developed by the authors to support accessing health records from the DHIS2 platform, staging them for quality assurance checks when interacting with the system.

The datasets used and/or analyzed during the study are available from the corresponding author on reasonable request. Further, this approach helped minimize network traffic whenever data synchronization between REDCap and the DHIS2 systems occurred.

Limitations

The REDCap system was implemented at the NHL in response to the emergency COVID-19 pandemic. Consequently, a systematic approach to its implementation could have been compromised, and essential considerations could have been overlooked. Most notably, multiple training and feedback sessions had to be conducted virtually using the Zoom platform due to restrictions on in-person gatherings. Hence, the authors were unable to frequently visit the NHL in person to provide the necessary technical support and training. Participation in the study was limited and often disrupted, as some NHL personnel were reassigned to efforts such as vaccine distribution or other scenarios not applicable for REDCap use. Last, increased workloads for participants due to COVID-19 surges in Botswana likely contributed to the lack of thorough quality checks when interacting with the system.

Conclusion

Implementation of the REDCap platform to support COVID-19 data management at the NHL in Botswana was successful, albeit with challenges. It is worth noting that, like any software, REDCap as a system possesses limitations that were addressed with other applications to meet requirements for this study. Most challenges encountered were exacerbated by the lack of pandemic response preparedness, as was the case in Botswana and around the world. As such, most of these challenges will not be unique to this specific case of REDCap implementation but will continue to affect the sustainable implementation of eHealth innovations until conscious efforts using key digital health strategies are made that create an enabling environment to support implementation of digital health innovations. Another lesson learned is the essential need for collaborations with key stakeholders to minimize technological barriers while implementing eHealth solutions. Despite the challenges encountered, the REDCap and DHIS2 platforms served as readily available and customizable platforms to address COVID-19 data management at the NHL. To this end, effective planning is essential, including the engagement and training of key personnel to optimize the use of eHealth systems beyond the COVID-19 pandemic.

Acknowledgments

The authors express their great appreciation to the National Health Laboratory (NHL) and Ministry of Health (MOH) management for supporting the implementation of Research Electronic Data Capture (REDCap) at their facilities as well as the supportive study participants for their valued contributions. No generative artificial intelligence (AI) such as ChatGPT was used in any portion of this manuscript.

Data Availability

The datasets used and/or analyzed during the study are available from the corresponding author on reasonable request.
Authors' Contributions

All authors jointly conceived the study, and jointly contributed to its design. KN, OM, AM, and NPM contributed to the customization of the Research Electronic Data Capture (REDCap) platform for use at the National Health Laboratory (NHL) and provided REDCap training sessions to the study participants. KN, KLM, and OM completed the initial data analysis and wrote the first draft of the manuscript. SM, TM, RH, and EL provided substantial editorial and intellectual input and contributed to subsequent revisions. All authors approved the final manuscript.

Conflicts of Interest

TM is an employee of the National Health Laboratory (NHL). KN, AM, OM, and NPM form part of the REDCap technical team in Botswana. The remaining authors have no competing interests.

Abstract

Background: In England, digital technologies are exploited to transform the way health and social care is provided and encompass a wide range of hardware devices and software that are used in all aspects of health care. However, little is known about the extent to which health care providers differ in digital health technology capabilities and how this relates to geographical and regional differences in health care capacities and resources.

Objective: This paper aims to identify the set of digital technologies that have been deployed by the National Health Services clinical commissioning groups (NHS CCGs) in England. In doing this, we respond to calls to shed light on the internal dynamics and variation in the form of digital capability in England in terms of health service regional differences and health diversity, equity, and inclusion.

Methods: We collected 135 annual reports that belong to 106 NHS CCGs in England, comprising more than 18,000 pages in total, released from 2020 to 2021. Using this data set, we identified 2163 pages related to digital technologies and labeled them using content analysis. We follow the construct taxonomy used by digital options theory, a theory from the management information systems field analyzing organizational resource investment choices, in classifying observed technologies according to digital themes—inherent design patterns that we identified and explained. We then used a hierarchical clustering method to extract groups of NHS CCGs that implement similar technology themes.

Results: We found 31 technologies from the reports and grouped them into 9 digital themes. The 9 themes were further assigned to 1 of the 3 constructs of digital options theory, the identification of patients’ requirements (we identified information portals [76/106], digital health engagement [67/106], and digital inclusion support [45/106]), the development of new work patterns (we identified telehealth [87/106], teledermatology [35/106], and care home technologies [40/106]), the realization of improvements in efficiency and public accessibility (we identified online booking [26/106], online triage [104/106], and digital mental health services [74/106]). The 3 clusters of CCGs are identified based on the 8 themes (Hopkins=0.9914, silhouette=0.186), namely (1) digitally disengaged, (2) digitally engaged, and (3) digital torchbearer.

Conclusions: Our findings show prominent digital themes within each construct group, namely information portals, telehealth, and online triage, covering people’s fundamental health information needs. Almost half of CCGs fell into the digitally disengaged group, and all London CCGs (5/106) belonged to this group. We propose that practitioners should offer specialized assistance to regions with limited digital engagement, emphasizing digital health literacy, inclusion support, and ongoing evaluation, rather than concentrating solely on technical advancements.

Introduction

The health care services in England are in a transformational phase due to the increasing pressure to propose and review digital strategies, use continually emerging new digital technologies, and place varied emphasis on digitization according to regional needs [1,2]. Digital technologies are exploited to transform the way health and social care is provided and encompass a wide range of hardware devices and software that are used in all aspects of health care. These technologies are often grouped and examined by their use cases [3,4], such as medical consultations and treatment, patient management, and information campaigns for access to care. Some researchers emphasize the change these technologies may bring (also referred to as “innovation”) and therefore propose a different type of taxonomy. Zweifel [5] categorized technologies serving the purpose of health care innovation into 3 types, including technologies for product innovation, process innovation, and organizational innovation.

Despite these developments, however, health care practitioners and managers often find it difficult to choose and leverage different forms of digital technologies and innovation in their institutions to overcome challenges or inefficiencies [6]. Furthermore, little is known about the extent to which health care providers differ in technology capabilities regarding improving public access to health resources, and how this relates to geographical and regional differences in health care capacities and resources. In the United Kingdom, the availability and usage of medical treatments (measured by, eg, travel distance to attend treatment, waiting time to receive a treatment, and funding for a primary-care practice) vary across regional health services in England [7-10]. We suspect this variation may also apply to the availability of digital technologies as a result of a local strategy priority, prior digitalization level in the area, and the demographics of the local populations.

Drawing from this emerging stream of research, this study identified the digital technologies adopted in 106 National Health Service clinical commissioning groups (NHS CCGs) in England, using 135 annual reports for the years 2020-2021. The CCGs were clinically led statutory NHS bodies responsible for the planning and commissioning of health care services for their local area, which were dissolved in 2022 to be replaced by the new integrated care boards (ICBs). The CCG annual reports were selected for 2 main reasons. First, the CCGs’ structure (106 CCGs in England as of April 2021) provided a finer spatial granularity than the ICBs’ structure (42 ICBs in England as of July 2022). Therefore, they offered crucial insights and statistics for all involved NHS services across different regions, which could offer valuable information regarding differences in digital capabilities and diversity, equity, and inclusion issues across various fine-grained geographical sites. Second, the years 2020-2021 marked an important step in health care digital transformation as the CCGs afterward focused on structural change and were replaced by ICBs nationally. In addition, in response to the COVID-19 pandemic, CCGs were incentivized to make services accessible through digital platforms, aiming to ensure the continual provision of care while mitigating transmission risks. Therefore, the reports in 2020-2021 highlighted important aspects of digital technologies and themes adopted by the CCGs before the structural shift and in response to the COVID-19 pandemic, which were fed into the newly formed ICBs.

We aim to answer the following research questions: What are the digital technologies adopted by CCGs to improve their services as well as widen public access and engagement? How do they vary across regions?

We use the construct taxonomy used by digital options theory [11] to understand the different types of technologies that are used in health care institutions, and how these options support health care providers’ ability to translate their resources into performance. In the management information systems literature, digital options represent an organization’s investment in and adoption of information technologies [12]. Such adoption, as Sambamurthy and colleagues argued [11], together with changes to the organization’s technological environment, impacts an organization’s information technology capabilities. Therefore, digital options are primarily used to examine the evaluation of information technologies [12,13] and to assess how the technologies and digital capabilities in an organization can be transformed into performance improvement [11,14].

Following this set of ideas, in the context of health care, digital options represent opportunities to use new technical tools and features that will increase the service quality, efficiency, and public accessibility. Previous work involving digital options theory and health care focuses on performance improvement, for example, how cost-effective information technology solutions can enhance the financial performance of resource-constrained hospitals [15]. Little effort has been invested to map out the existing set of digital technologies in health care using the taxonomy of digital options.

Drawing on the concepts of digital options theory [16,17], the technologies serving the purpose of health care efficiency can be grouped using three constructs: (1) identifying patients’ requirements that involve recognizing new technical features for the digital health service (such as online community engagement and digital champion events); (2) developing new work patterns that improve internal coordination and working process (such as artificial intelligence [AI] diagnostics and digital prescribing); and (3) realizing improvements in efficiency and public accessibility (such as virtual consultation and direct online booking). We use these constructs as the theoretical lens to categorize the digital tools used in various CCGs in NHS England.

This paper aims to identify the set of digital technologies that have been deployed by the NHS CCGs in England. This study has several contributions. First, it contributes to the health care literature by providing insights into how regional differences in technology, under an NHS system in England, can vary in
their capabilities and efforts in implementing digital technologies. We empirically draw the landscape of digital transformation in health care by unpacking the role of NHS CCGs in adopting technologies and by presenting the regional differences in England. In doing this, we respond to calls to shed light on the internal dynamics and variation in the form of digital capability and patient engagement in England in terms of health service regional differences and health diversity, equity, and inclusion [18,19]. Second, we extend digital options theory to understand its application of constructs within a health care setting. We applied and examined the 3 key approaches, proposed by Rolland et al [12], for technological options to engage patients as technology users and to improve health care service quality. The study demonstrates the complex choices faced by health care providers: while they need to address large numbers of patient queries and appointments through actionable digital options, they are constrained by regional resources and digital capabilities. Similarly, while different types of digital options could offer health care providers with new opportunities to understand patients' needs and coordinate workflows, the actual adoption of options varies significantly across different regions.

**Methods**

**Overview**

In this study, we followed a text-mining approach and content analysis method to analyze the research data. Specifically, we used a text mining approach to extract key paragraphs and texts from the 135 NHS CCG annual reports released for 2020-2021 identifying digital technologies. We further followed content analysis methods to manually code and categorize the extracted paragraphs and texts through the lens of the digital options theory [16,17]. We then clustered the CCGs based on the corresponding technologies to reveal the similarities between CCGs and regional differences in digital technologies’ availability.

**Data Selection**

Secondary data sources, namely annual reports of each NHS CCG, were used in this paper. We decided to use annual reports as they cover each CCG’s performance and accountability in the period, ranging from performance analysis, progress on key initiatives, and public and patient involvement to actual spending, and are the most recent reports before the start of the ICB-forming stage. The reports were downloaded from individual CCG websites directly. In total, there were 106 CCGs across England as of April 1, 2021, which was reduced from 135 CCGs in 2020 with the merger of 38 CCGs into 9. This paper investigates the 135 annual reports, 18,667 pages in total, released from 2020 to 2021. We further group the results according to the 106-CCG structure as it reflected the most recent structure of the CCG systems for 2021-2022.

**Data Preprocessing**

Given that each report contains 44-222 pages and is labor-consuming to go through manually, highlighting the relevant texts visually can support the researchers in locating useful information for content analysis more quickly. The reports were preprocessed using the semantic matching method [20], a text mining technique, to identify and highlight texts that are relevant to author-selected keywords. The processing was implemented in Python (Python Software Foundation).

First, reports from 10 CCGs were manually screened by the first 3 researchers independently, to gather the initial set of keywords. The selected 10 CCGs covered the main geographic regions in England. The whole research team had regular meetings during and after screening to discuss the expansion of or trimming the keyword set. Frequent and relevant keywords were excluded from the set if they might cover a much larger field, such as “digital tool.” To validate the set, the second author applied semantic matching methods using the proposed keyword set on the 10 reports and manually screened the reports again to make sure the relevant contents were highlighted appropriately. The final set contained the following words: “digital,” “technology,” “AI,” “Machine Learning,” “e-,” and “online,” together with their derivations. Using this method, 2163 pages containing selected keywords were highlighted in the 135 reports.

**Data Analysis**

**Content Analysis**

After the preprocessing, we analyzed the extracted 2163 pages through content analysis. Content analysis [21] was conducted by the first author. According to digital options theory, there are three types of options when engaging with technologies, including: (1) identifying patients’ requirements that involve recognizing new technical features for the digital health service (eg, digital survey to gather patient feedback on services), (2) developing new work patterns that improve internal coordination and working process (eg, AI diagnostic tools), and (3) realizing improvements in efficiency and public accessibility (eg, appointment booking system). We first conducted the initial coding by going through the research data and grouping them into categories according to the purpose of the adopted technologies. Second, we went through the categories in detail and mapped them to the 3 options as themes. Regarding reliability, the research team had weekly meetings during and after screening to discuss the expansion of or trimming the keyword set. Frequent and relevant keywords were excluded from the set if they might cover a much larger field, such as “digital tool.” To validate the set, the second author applied semantic matching methods using the proposed keyword set on the 10 reports and manually screened the reports again to make sure the relevant contents were highlighted appropriately. The final set contained the following words: “digital,” “technology,” “AI,” “Machine Learning,” “e-,” and “online,” together with their derivations. Using this method, 2163 pages containing selected keywords were highlighted in the 135 reports.

\textbf{Cluster Analysis}

Hierarchical clustering \cite{26} with Euclidean distance was used to extract common patterns from the code; by doing so the CCGs implementing similar types of technologies were grouped together. We used the identified 9 digital technology themes from the previous step to cluster the CCGs, in which the number of technology types mentioned for each theme was assigned to each CCG. For example, the Sheffield CCG reported they only had 1 technology (remote monitoring) under the telehealth theme, therefore the value of telehealth for Sheffield CCG was 1. In total, for each CCG, there were 9 values describing how engaged the CCG was with each technology theme. These values were further standardized using the \textit{z} score to achieve balanced similarity weights across all 9 themes. The silhouette and elbow method were used to select the optimal numbers for clusters \cite{27}, resulting in a structure with 3 clusters.

\textbf{Ethical Considerations}

This study is based on the secondary analysis of NHS CCG annual reports, which are public information. The ethics approval for the secondary analysis of all data presented in this study was obtained from the University of Sheffield Research Ethics Committee (045790).
Results

Digital Technologies in NHS CCGs

Overview

In total, 18,667 pages from 135 annual reports were preprocessed and 2163 pages containing selected keywords were highlighted in the 135 reports, representing 106 CCGs. Further, 31 types of technologies were then extracted, covering a wide range of tools and purposes. These technologies were then grouped into 9 themes. The full codebook can be found in Multimedia Appendix 1.

The purposes of the digital technologies are typically associated with the patients’ or health care practitioners’ needs across various use cases and regions. Generalizing across all the observed items, these technologies were first grouped under particle themes, specific to either a location (eg, care home), disease (eg, mental health), or a type of service (eg, booking appointment). We then further assigned the identified 9 themes to 1 of the 3 digital options theory constructs. Table 1 describes the digital technologies observed from the NHS CCG annual reports and their associated themes.

Information Portals

The information portal theme consisted of 6 technologies that all involved access to or communication specific health care information via an online format. In total, 72% (76/106) of CCGs contained a mention of this theme via either 1 or more of the 6 technologies. Health care promotion for raising the public’s awareness of available services (35/106, 33%) was the most popular method, followed by online service catalogues (30/106, 28.3%) and webinars designed to briefly or formally announce digital tools (30/106, 28.3%). Providing patients with their own health care records accounted for 6% (7/106). These 4 above all involve having health care information readily available online for patients to locate and use. Other tools were typically more oriented toward the sharing of health care information between health care professionals or to the patients. For example, advice and guidance (16/106, 14.8%) was a tool that allowed general practitioners (GPs) to contact specialists quickly to obtain information for a patient so they did not have to refer the patient to the specialist. In doing so they saved time and could provide appropriate treatment for the patient on the same day. The health practitioners could also share electronic patient records quickly with relevant members through an online system (47/106, 43.5%) to facilitate discussion.

Digital Health Engagement

Digital health engagement was about engaging with the public through digital means (67/106, 63.2%). Differing from the information portal theme aiming to support patients or health practitioners dealing with immediate health needs, this theme focuses on obtaining feedback on service delivery and raising awareness of a disease or healthy lifestyle in the community in a less formal manner. The most popular technologies within this category involved patients in the operations of the health care service within their area through virtual meetings or surveys (63/106, 59.4%). These activities kept patients informed and created and allowed them to give their input on the operations of the health care service. Around 12% (13/106) of the reports discussed the development of a podcast that patients could access anytime that kept them up to date with any health care developments or gave them advice for better self-care management. Around 17.9% (19/106) of reports mentioned the use of digital champions, who are individuals who help staff and patients struggling with the integration of digital technologies and help them develop their digital skills and confidence.

Digital Inclusion Support

The implementation of many digital technologies was vital to keeping the NHS operating during the COVID-19 pandemic, and there was a conscious effort to keep providing adequate health care to those without a means of accessing these services. In total, 42.5% (45/106) of CCGs included recognition of the problem of digital exclusion and how they would tackle it via an alternative digital approach. The Newcastle Gateshead CCG report reflected on the downside of the increase in digital technology, suggesting that it could impact the NHS’ free at point of care policy (eg, using a phone or the internet is not free). Methods such as providing targeted alternative communication methods (eg, text message or physical newsletters; 14/106, 13.2%) or providing essential technology (typically providing hardware to care homes; 38/106, 35.5%) were mentioned.

Telehealth

Telehealth is a theme that aims to incorporate digital technologies to monitor patients’ health information through real time data and provide long-distance health care. At least one form of telehealth was mentioned by 82% (87/106) of the CCGs and was seen by many of them as vital to providing safe health care during the COVID-19 pandemic. Remote monitoring (69/106, 65.1%) typically involved the use of software or hardware technologies such as pulse oximetry and digital blood pressure monitors. The information from these devices would automatically be sent to the patients’ health care record, which allowed the GP to continuously check the patient’s vitals. This allowed the GP to take quick action as needed as they would be notified if any major problems arose. Further, 26.4% (28/106) of the reports mentioned that telehealth tools also helped patients with self-management, particularly for patients with chronic conditions. In addition, this theme involved some innovation and creative use of technology by some CCGs. For example, 6.5% (7/106) of the reports discussed providing Alexa (Amazon Inc) devices to patients who were not able to use traditional computer devices (due to conditions such as vision impairments). The speech recognition software would allow the patient to keep in contact with their GPs, where they could also be monitored remotely. We note that some reports mentioned the use of telehealth tools in general terms rather than naming the specific technology implemented (such as the name or provider of the tool).

Telemedicine

Telemedicine was one of the least mentioned themes among the CCG groups, with it only being mentioned by 33% (35/106) of CCGs. Telemedicine differs from telehealth in that it seeks...
to provide treatment or make a diagnosis for patients using digital technologies. The more innovative approach to digital technologies would lie within this category. This includes health care practices using virtual reality headsets (2/106, 1.9%) to treat patients for their mental health by having them experience scenarios in a digital space. AI diagnostics, mentioned by 9% (10/106) of reports, makes predictions about a patient’s health (eg, heart-related issues or developing cancer), allowing the health care provider to advise a patient so they may mitigate any future health care concerns. We also found that 10.3% (11/106) of the reports mentioned technologies for online prescribing, often for a repeat prescription. Teledermatology, mentioned by 7.5% of the reports (8/106), refers to the use of static digital images to triage, diagnose, monitor, or assess skin conditions without the patient physically meeting the dermatologist. This technology required the users to submit a clear photo of their skin condition before the appointment (either in the form of online meetings or chat). This dependency on trust in technology (so that the users submit personal information through the tool and believe in the results) as well as effort in the form of hardware (such as a virtual reality headset, laptop, or mobile camera for taking pictures and making video calls) from the users, is consistent for all tools in this theme.

**Care Home Technologies**

We refer to care home technologies as digital technologies designed specifically for the care home or training tools for care home residents and staff to use digital technologies. The technologies under this theme contained accessibility considerations particularly designed to support people in the later stage of life and living in care homes; therefore we separated it as a single theme. Care home technologies were only mentioned by about 37.7% (40/106) of the reports. By 2021, it was predicted that more than 400,000 people would live in care homes in the United Kingdom and would likely need close monitoring and more delicate health care due to age or health conditions than older people staying at home. In total, 35.8% (38/106) of the CCGs mentioned the involvement of training staff within these settings so they could adequately use the new digital technologies to care for their residents.

**Booking System**

In total, 24.5% (26/106) of CCGs had started to adopt various forms of online booking systems, especially within GP practices. This is the alternative to the traditional method of a patient telephoning a GP asking for an appointment through these means. The reasons cited for the uptake of this theme by some CCGs can be attributed to three factors: (1) the integration of NHS 111 (a free-to-call single nonemergency number medical helpline) services with GP and emergency departments (EDs), (2) the desire to ease the burden on telephone lines, and (3) the development of the NHS app. Further, 2 types of technologies, namely indirect booking and direct booking, were found within this theme. Indirect online booking was mentioned by 13.2% (14/106) of the CCGs, and this was the process of NHS 111 having the ability to book patients directly into GP or ED appointments. Multiple reports mentioned that the sharing of data between services (such as GPs, NHS 111, and ED) allowed NHS 111 to filter patients through their lines and book patients into appointments that they urgently needed. For example, the Manchester CCG used the Adastra Digital solution to send information between EDs and NHS 111. This improved patient flow and eased the burden on GPs and EDs. Direct online booking is when the patient themselves can book, manage, and also cancel their own appointment online. This was mentioned by 14% (15/106) of the CCGs and many of them cited the integration of the NHS app as a convenient means of allowing patients access to book appointments themselves.

**Online Triage**

Virtually every CCG (104/106, 98.1%) mentioned some form of online triage that was integrated into their effort to adopt digital technologies. This mostly came from the reports covering the use of virtual consultations by their health care professionals. Many reports discussed how the COVID-19 pandemic forced them to accelerate their plans to integrate digital solutions into their health care plans, and virtual consultations became a must for many health care settings so they could continue operating safely (both for the practitioner and for the patients). Typically, this involved practitioners contacting patients via telephone or some form of video consultation services. The video consultation would usually be operated by private health care platforms such as Doctorlink (HealthHero), askmyGP (Evergreen Health Solutions Ltd), or Attend Anywhere (Induction Healthcare Group PLC), in which case the private companies created a process to help practitioners carry out this health care service (either through a telephone call, a smartphone app, or a web app). eConsult is a form of online triage mentioned by 19.6% (21/106) of CCGs and differs from the virtual consultation format as it involves patients filling out an online form and sending it to their health care practice, where it is reviewed and next steps for treatment are provided by a health care professional without directly speaking to the patient. This service was cited as being useful for prescribing repeat prescriptions and removing pressure on phone lines.

**Digital Mental Health Services**

Digital mental health services were popular among CCGs, being mentioned by 70.3% (74/106) of them. We decided to put these technologies into a separate theme due to the increased mental health needs during the pandemic and the innovations used to carry out traditional treatments (such as psychotherapy or counseling). Some mental health treatments involved using digital tools, such as video calls, to offer counseling services before the pandemic. These mental health services often incorporated other digital technologies such as information portals (eg, Instagram accounts) to share advice and tips for self-management. Around 38.7% (41/106) of CCGs developed their own region-specific digital mental health care services that they were able to refer patients to. For example, Mind-BLMK is available for people in Bedfordshire and Luton as well as Milton Keynes, and With Me in Mind is available for people in Doncaster, Rotherham, and North Lincolnshire. However, around 33.9% (36/106) of CCGs discussed how they had integrated private mental health services that they had partnered with to refer their patients to. Kooth was one of the more popular services as it focused on treatment for children and younger people, although other services such as Qwell specialized...
in treatment for adults. Both sites are similar in layout, and they tailor their services to the targeted user group. For example, Kooth offers the opportunity for young people to engage in mini activities to manage their mental health, while Qwell offers more traditional long-form articles that explore different mental health issues and solutions. Both sites also offer online forums to talk to other patients of a similar age using the services, potentially sharing experiences and offering peer support to build a community between each other. Both sites offer access to therapists who specialize in the targeted age groups, as well.

Clusters

Clustering was used to identify groups of CCGs implementing similar types of technologies. We first calculated Hopkins statistics for the data. The Hopkins statistic was 0.9914 (>0.5), indicating the data were highly clustered. A structure with 3 clusters was the optimal cluster structure (average silhouette width of 0.186, SD 0.163), determined using the silhouette and elbow method [27].

Resulting from hierarchical clustering, the first cluster group contained 51 CCGs, the second cluster contained 35, and the third contained 20. The CCGs differed between clusters in their digital themes. Figure 1 helps establish the differences between each group by showing the weighted proportions of technologies in each theme aggregated across CCGs in each group, which we refer to as “scores” in the following text and Figure 1. There were 9 scores assigned to each CCG, each corresponding to a digital theme. Group 1 (orange) will be named “disengaged” (of digital technologies) due to low scores in all of the digital themes within the CCG reports within this cluster (8 out of 9 themes had scores less than 25%). Cluster 2 (blue) will be named “engaged” (with digital technologies) due to the CCG reports within this cluster having a general interest in many of the digital themes (6 out of 9 themes had scores between 25% and 50%). This is especially true for telemedicine, where it excels compared to the other two clusters; however, there is a low score for the digital engagement and telemedicine themes. Group 3 (green) did not have this problem as the CCG reports within this cluster had a high score for technologies in the digital engagement category, as well as a very high score for those in the information portal category. Therefore, this group will be named “torchbearer” (of digital technologies).

Table 2 presents the number of CCGs in each cluster group represented by the region they belong to according to the UK Office for National Statistics. For example, in the southeast region, there were 5 CCGs that belonged to the digitally disengaged cluster and 6 CCGs that belonged to the digitally engaged cluster. Figure 2 displays the geographical distribution of cluster groups in England. The graph does not present a particular spatial pattern, but there are some notable observations. For one, all of the London CCGs fell into the digitally disengaged group. The northwest and Midlands regions have a proportionally very low presence in the digitally engaged cluster group. This may be due to them having a very high presence in the digital torchbearer group.

Figure 1. Three clusters and their scores for each digital technology theme.
Table 2. Regional distribution of cluster groups (n=106) (number of boroughs in each region).

Discussion

Principal Results

The pandemic has disrupted health care support services in the United Kingdom, resulting in the rapid adoption of digital technologies [29]. Nevertheless, the digital technology themes guiding the mass adoption of technology and the potential regional disparities remain to be explored. Based on 135 NHS CCG annual reports, this paper identified digital technology themes and associated technologies adopted by the NHS nationally in 2020 and 2021 and examined their regional differences from a digital divide perspective [30].

Informed by digital options theory [16,17], we identified 9 digital technology themes, which were categorized into 3 main groups, namely, the identification of patients’ requirements, the development of new work patterns that improve internal coordination and working process, and realizing improvements in efficiency and public accessibility. First, the identification of patients’ requirements includes the use of information portals (eg, retrieving and sharing health-related information), digital means (eg, using podcasts for promoting health-related information), and digital support (eg, providing hardware or alternative access for the digitally excluded) to achieve effective communication channels between health care providers and patients. Second, the development of new work patterns that improve internal coordination and working process includes digitizing existing health care services, such as remote monitoring of patient health (ie, Alexa), e-prescriptions (eg, AI diagnostics and online prescriptions), and digital training (eg, staff training on using digital tools in care homes). Finally, the realization of improvements in efficiency and public accessibility results in the use of digital methods to widen public access to health care, including creating online booking systems shared by health care providers (eg, NHS 111 and NHS apps), online triage (eg, online consultation), and online mental health services (eg, Kooth). Our data suggest that there are prominent digital themes within each group. Information portals are mostly adopted by CCGs to achieve effective health care communication among patients and health care providers. Telehealth is primarily adopted by CCGs for digitizing health care services, particularly to monitor patient health remotely. Online triage has been widely implemented by CCGs to provide patients with access to health care during the pandemic. Therefore, these top 3 themes, which cover people’s fundamental health needs, could serve as a starting point for future CCGs and other health care providers when adopting and implementing digital solutions.

In addition, our findings contribute to the new research theme of “digital health citizenship” by highlighting that digital tools
and technologies extend beyond operation efficiency to wider patient engagement, and therefore reshape social relations and interactions among patients as health service users [2]. Regional differences in such social relations and interactions could be linked to the equality and inclusion issues in health service provision. Based on the 9 identified digital themes, 3 main clusters were identified: the digitally engaged, the digitally disengaged, and the digital torchbearer. It is concerning that almost half of the CCGs fell into the digitally disengaged group, showing a low uptake of the aforementioned digital themes. Interestingly, most digitally disengaged CCGs belonged to London areas. This seems to be aligned with the data released by the Office for National Statistics [31] in 2019, suggesting that London has the lowest percentage of internet nonusers in the United Kingdom by population. However, Watson et al [32] also pointed out that a lack of digital devices and private spaces for accessing online health care could also act as barriers to digital health care themes in London. The use of such digital devices and online health care services opens up a new set of digital rights, opportunities, and responsibilities for patients [2], and this needs to be balanced across regions to ensure the equality and inclusion of health care. Our data suggest that CCGs are still not sufficiently efficient when it comes to adopting digital themes.

Furthermore, our findings highlight the impact of COVID-19 on the development of a CCG’s digital technology themes. Many of the reports cited COVID-19 as accelerating the need to digitize health care. For example, the use of telehealth to increase remote monitoring of patients or encourage them to manage their own health increased during the pandemic due to patients not being able to reach their own health care practices as freely. Most of the reports were generally very positive about increasing the inclusion of digital technology. Reasons for the positives statements included making it easier to access health care, providing early treatment, providing more data to improve services, and making the health care practice more agile and efficient. However, some reports cited reasons for concern about increasing digital health care when discussing the possibility of digital exclusion for some patients. Further, one report from the Newcastle Gateshead CCG raised concerns about how the integration of digital technology may impact the NHS policy of being free at point of use. This issue is consistent with concerns expressed by other researchers. For example, Clare [33] and Eruchalu et al [34] have noted the potential limitations of telehealth and telemedicine due to broadband connectivity issues resulting from socioeconomic disparities among regions, particularly among the underprivileged, the medically underserved, and in communities of color. With services becoming increasingly online (eg, many mental health services were all online) and not everyone having access to technology, there is a justifiable concern. To realize equitable benefits from health-related technologies across all populations, it is imperative to thoroughly examine and address complex issues, such as social, cultural, and economic factors that hinder accessibility and adoption among different communities. Otherwise, as pointed out by Ramsetty and Adams [35], despite technological advancements, disparities in health care access and outcomes will inevitably persist, particularly among the most vulnerable during times of crisis. Future research could further investigate this area and how these issues could be addressed.

It is essential to highlight that the absence of digital technology mentioned in a CCG report does not necessarily indicate a failure in its adoption. For example, eConsult is an online triage form that patients can fill out and send to their health care practitioner where it is reviewed and the next steps for treatment are accessed by a health care professional for the patients to take. The Kent and Medway CCG did not make any reference to this digital technology within their annual report [36], however, when investigating individual GP practices that operate under them, the technology is being used. This suggests that the lack of mention of a particular technology by a CCG group does not mean it is not being used at all but indicates the action of using such technology is not applied at the CCG level.

Conclusion
This research mapped out the current digital technology themes adopted by CCGs in the United Kingdom when providing health care services during the pandemic. These identified themes can be used by future health care providers to adopt digital solutions to address different health care issues, such as improving communication, digitizing their existing services, and increasing public access to health care. Furthermore, the research highlights the existence of a digital divide within CCGs in terms of adopting digital technology themes, particularly when it comes to regional disparities. The possible solutions could include providing support to the “digitally disengaged” CCGs in using various identified digital technology themes and becoming more digitally “active” or “engaged.” Caution needs to be taken when offering support as well. For example, we need to fully explore and understand the reasons behind their slow uptake of digital technologies in order to offer tailored solutions. To build upon our findings and promote equal access to digital health benefits for all communities, future research could examine the factors that contribute to regional disparities in digital technology adoption and access within and across CCGs. A comprehensive understanding of the underlying causes of these disparities could help policy makers and health care professionals focus their efforts more effectively toward bridging the digital divide and improving access to health resources and support for the public.

Although our study offers great insights into the digital technology themes adopted by CCGs, there are a few limitations that need to be addressed. Our findings are mainly based on CCG reports. The length, focus, and description details may differ slightly between these reports. In addition, there may be underreporting when it comes to digital technology themes by individual CCGs, resulting in misrepresentation when analyzing reports. Finally, the research focus was on the digital technology themes and the adoption of associated technologies rather than the impact these technologies had on patient satisfaction or patient outcomes. Future research could look at the impact of these identified digital technology themes or individual technologies and their effectiveness through in-depth interviews or questionnaire surveys with patients and health care professionals.

Abstract

Background: The impact that the COVID-19 pandemic has had on health care workers’ mental health, in particular, cannot be ignored. Not only did the pandemic exacerbate mental health challenges through elevated stress, anxiety, risk of infection, and social isolation, but regulations to minimize infection additionally hindered the conduct of traditional in-person mental health care.

Objective: This study explores the feasibility of using Wysa, an artificial intelligence–led mental health app, among health care workers.

Methods: A national tertiary health care cluster in Singapore piloted the use of Wysa among its own health care workers to support the management of their mental well-being during the pandemic (July 2020-June 2022). The adoption of this digital mental health intervention circumvented the limitations of in-person contact and enabled large-scale access to evidence-based care. Rates and patterns of user engagement were evaluated.

Results: Overall, the opportunity to use Wysa was well-received. Out of the 527 staff who were onboarded in the app, 80.1% (422/527) completed a minimum of 2 sessions. On average, users completed 10.9 sessions over 3.80 weeks. The interventions most used were for sleep and anxiety, with a strong repeat-use rate. In this sample, 46.2% (73/158) of health care workers reported symptoms of anxiety (Generalized Anxiety Disorder Assessment-7 [GAD-7]), and 15.2% (24/158) were likely to have symptoms of depression (Patient Health Questionnaire-2 [PHQ-2]).

Conclusions: Based on the present findings, Wysa appears to strongly engage those with none to moderate symptoms of anxiety. This evaluation demonstrates the viability of implementing Wysa as a standard practice among this sample of health care workers, which may support the use of similar digital interventions across other communities.

Introduction

During the COVID-19 pandemic, health care systems and workers were under immense pressure as the rates of infection surged. Health care workers experienced elevated levels of stress and psychological burden [1], due to factors such as excessive work hours and an increased risk of infection [2,3]. In a study of Wuhan’s frontline health care workers’ mental health during this pandemic, respondents reported an increase in symptoms of depression and anxiety, and 59% reported moderate to severe...
perceived stress [4]. Chew et al [5] examined the mental health of health care workers in Singapore and India and found a lower prevalence of psychological symptoms than reported elsewhere but a high prevalence of physical symptoms. These physical symptoms could reflect somatization, as psychological outcomes and the presence of physical symptoms were significantly associated. In a separate study, Tan et al [6] reported that nonmedical health care workers such as allied health professionals, technicians, or administrators had a higher prevalence of anxiety compared to medical staff such as physicians and nurses. This highlights the importance of attending to the mental health of not just frontline medical workers but health care workers as a whole.

Meanwhile, efforts to reduce the spread of COVID-19 have led to nationwide and global lockdowns, resulting in the digitalization of many services. Mental health practitioners likewise adopted web-based strategies to continue supporting clients. Yet, in a time with many in isolation and a worldwide escalation in mental health concerns [7], the urgency for the mainstream adoption of scalable digital mental health services has intensified. In addition to serving as an ad hoc solution during this pandemic, digital mental health interventions through web-based or mobile platforms may provide unique benefits beyond traditional services such as in-person counseling or therapy [8]. For instance, they improve the accessibility and cost of mental health services since traditional mental health interventions are typically subject to standard clinic hours and may not be affordably priced. With digital interventions, individuals can receive on-demand support in moments of crisis, beyond the boundaries of the clinic or therapy room. Digital services can additionally circumvent the stigma-related barriers to mental health treatment since they can be accessed discreetly and at one’s own convenience. In these ways, digital interventions can serve as complements to traditional mental health services, provide interim services for those waiting to receive in-person treatment, and provide new services for those facing barriers to accessing existing clinical interventions [9,10]. Mental health care systems could thus benefit from incorporating digital interventions as part of standard care practices. As an acknowledgment of these advantages, a national tertiary health care division in Singapore piloted the use of Wysa, which is an artificial intelligence (AI)–enabled mental health app among their own health care staff during the COVID-19 pandemic.

Wysa is a mental health mobile app, accessible on the Apple App Store and Google Play Store, designed to address various mental health concerns through self-guided interventions. The app features rule-based AI through a conversational chatbot. This facilitates user interactions, offering personalized support and interventions by comprehending user responses and directing them to relevant resources. Wysa’s AI models operate within a rule-based framework, ensuring clinical safety and adherence to predefined scripts. There is also an option to connect with a human coach, which supplements the app’s fully automated functions.

Due to the primarily self-guided nature of the app, the interventions it provides can be administered to large populations at minimal cost. Moreover, Linardon et al [11] found in their meta-analysis that self-guided interventions significantly surpassed waitlist and active controls in efficacy for reducing symptoms of depression and anxiety. Previous studies examining the utility of mental health mobile apps found Wysa to have high usability and engagement ratings [12,13]. In previous studies, general populations and patients [14] with symptoms of anxiety and depression reported improvements with the use of Wysa. This study serves to evaluate the experience of using Wysa among a population of health care workers during the pandemic.

Wysa is DCB.0129 compliant (the National Health Services [NHS] Clinical Risk Management Standards under the Health and Social Care Act 2012), and its information security management system (ISMS) and privacy information management system (PIMS) have been audited and certified by the British Standards Institution (BSI) for ISO 27001 and ISO 27701. The parent Wysa Android and iOS apps are certified as CE (European Conformity) Medicines and Healthcare Products Regulatory Agency (MHRA) Class 1 Medical Devices. Additionally, Wysa ensures that all user data are encrypted at rest in the storage servers and are hosted by industry leaders who have stringent General Data Protection Regulation (GDPR) and HIPAA (Health Insurance Portability and Accountability Act)–compliant security programs and controls.

### Methods

#### Overview

In this pilot exercise, health care staff from a national tertiary health care cluster were provided access to Wysa through paid licenses. Data regarding this community’s use of Wysa and feedback were obtained over a period of 2 years, from July 2020 to June 2022. Advertisements were internally disseminated to the institutions’ staff to encourage them to activate their licenses and engage with the app to support their mental well-being.

#### Wysa App

While users interacted with the Wysa chatbot, Wysa would prompt them to indicate which challenges they would like support with. The life challenges disclosed by the present sample of health care workers are given in Table 1. These challenges were predetermined categories that users were able to select, and they present an overview of the key concerns that this population sought help with through the chatbot.

Table 2 displays various categories of emotions reported by users during organic interactions with the chatbot. For interpretative purposes, the specific emotions mentioned in users’ chat messages were identified and combined into categories based on similarity. This enables insight into the range of emotions experienced by these users, which yields granularity to better understand the state of mind they were in as they engaged with the app.

Ethical Considerations

The conduct of this service evaluation was granted institutional review board exemption by the National University Health System, and the institutional review board’s requirement for informed consent was waived for this posthoc descriptive analysis. All user data analyzed as part of this service evaluation was anonymous, and user data remained fully confidential. The users who engaged with the app were not provided with additional compensation, as the app use was provided to them for free to engage with as they pleased. Users were not systematically recruited to engage with the app, which enabled an evaluation of genuine receptiveness to the app and engagement rate.

Results

Digital App Engagement

Out of the 500 licenses purchased by the health care institution, 527 users were onboarded to the app. The discrepancy in numbers is due to the Wysa system disregarding users who had logged in only briefly without further engagement. Of the 527 health care staff who were onboarded, 495 users completed at least 1 full session, and 422 completed 2 or more sessions. One session is defined as a full interaction with the Wysa chatbot or an intervention tool. This indicates a high engagement rate of 93.9% engaging at least once and 80.1% engaging at least twice beyond onboarding. On average, the number of in-app sessions completed by each of the 495 active app users over this period of 2 years was 10.9 (SD 23.3), and the number of weeks of use was 3.80 (SD 5.58). The average number of messages sent by a user was 66.3 (SD 147) and the average number of messages exchanged in each session was 6.25 (SD 8.10). The weeks of use were not necessarily consecutive, although 40.5% of users used Wysa consecutively for at least 3 weeks.

From October 28-30, 2020, a “gratitude challenge” was run in which daily emails prompted users to show gratitude to important people in their lives. Wysa also offered shareable gratitude cards for users to share with their loved ones. This “challenge” was designed to facilitate a boost in engagement with mental health support. During this period, 53 users engaged with the app for an average of 2.30 (SD 1.60) sessions. In the 3 days before the challenge period (October 25-27), there were 31 users who used the app for 2.03 (SD 1.69) sessions on average. Out of these users, 16 of them returned during the period of the challenge. In the 3 days after the challenge period (October 31-November 2), 44 users used the app (mean 2.26, SD 2.38). Of these 44 users, 25 of them were returning users who had engaged during the challenge period. This data may suggest that the challenge was successful in bolstering user engagement, since there was a 71% increase in engagement during the challenge compared to 3 days before, and the number of users who engaged with Wysa after the challenge period had increased by 41.9% compared to before. Initiatives similar to
this “challenge” implemented recurrently may have the potential to promote sustained engagement.

While engaging in sessions, users were prompted to provide feedback on their present interaction and experience on a scale of 1-5. Feedback was given by 99 users on 234 sessions at a response rate of 20% (mean 4.07, SD 0.95). Of these, 218 sessions received scores of 3 and above, while 213 sessions received scores of 4 and above, suggesting a strong positive feedback rate of 93.2% and 91% receiving highly positive feedback, respectively. Of the 495 active app users, 158 individuals responded to the Generalized Anxiety Disorder Assessment-7 (GAD-7) and the Patient Health Questionnaire-2 (PHQ-2) screening questionnaires within the app. User-experience feedback was given by 59 out of the 158 users. This response rate of 37.3% is higher than the overall sample’s rate of 20%. The user-experience feedback given by these users as a function of their GAD-7 and PHQ-2 scores is shown in Table S1 in Multimedia Appendix 1. Approximately 30%-40% of individuals falling into each severity category gave feedback, with no obvious differences in the rate of response between categories.

**Clinical Utility**

Wysa contains an assortment of self-guided interventions, which each have a collection of interventions categorized by relevance to a circumstance or emotion. The interventions consist of AI-enabled conversations that target specific interventions. Table 3 gives a breakdown of how the Wysa interventions were used among this community of health care workers. Descriptions of the various interventions can be found in Multimedia Appendix 2. The data are based on users who actively sought help from these interventions by directly clicking on them. The number of unique users provides an indication of use pattern, that is, how many distinct individuals contributed to the total use compared to repeat users. Figure 1 illustrates this ratio (use factor) of unique users to total use. The higher the use factor, the higher the rate of repeat use. For instance, the number of unique users for sleep meditation interventions was 84, suggesting that this handful of users repeatedly engaged with this intervention a total of 564 times, with a high use factor of 6.7. In comparison, although guided visualization interventions were used a total of 502 times (an overall use comparable to that of sleep meditations), these interventions were used repeatedly by a larger number of 172 users with a use factor of 2.9. As such, it appears that a smaller subset of individuals repeatedly used interventions for sleep meditation, whereas guided visualizations were used by a wider range of individuals with a lower use factor.

Unsurprisingly, since sleep difficulties tend to co-occur alongside distressing events, interventions for sleep were overwhelmingly sought after, with high total use levels (Table 3). The next most popular interventions were for anxiety, especially health anxiety, stress, and self-esteem. These use patterns generally coincide with the top life challenges, as reported in Table 1. Furthermore, the popularity of the health anxiety intervention aligns with the backdrop of the COVID-19 pandemic.

GAD-7 and PHQ-2 screening tools were embedded within the app to screen for anxiety and depressive symptoms, respectively, which users were prompted to respond to after their very first chatbot conversation. This initial screening helped to capture baseline indications of the present population. Of the 495 active app users, 158 individuals responded to these questionnaires at this time point (158/495, 31.9% response rate). Table S1 in Multimedia Appendix 1 presents a breakdown of the prevalence of anxiety and depressive symptoms in this sample according to severity (number of users). Overall, 46.2% (73/158) reported symptoms of anxiety, and 15.2% (24/158) were likely to have symptoms of depression.

</table>
The average use rates (number of weeks and sessions) according to users’ GAD-7 and PHQ-2 scores are also displayed in Table S1 in Multimedia Appendix 1. The average number of weeks that users engaged with Wysa provides an indication of how long their symptoms or interest in using Wysa lasted, while the average number of sessions gives an estimate of use frequency. To illustrate, this data demonstrates that health care workers in this sample with moderate anxiety engaged with Wysa for an average of 6.45 weeks. Over these 6.45 weeks, users completed an average of 20.2 sessions.

Individuals with no, mild, or moderate anxiety used Wysa for a high mean number of sessions (mean_total 19.5) and weeks of use (mean_total 6.04), almost 2 times higher than the overall active app user average of 10.9 and 3.80, respectively, while there was a limited sample of individuals with symptoms of severe anxiety. Users who were likely to have symptoms of depression engaged with Wysa more and for a marginally longer duration on average than those who were unlikely, as seen in Table S1 in Multimedia Appendix 1. This finding is promising, as it suggests that Wysa may be more beneficial and motivating to use for individuals with symptoms of depression.

Regardless of GAD-7 or PHQ-2 severity, the most popular interventions used were for sleep, especially for deep sleep, and anxiety, especially for health anxiety (Table S1 in Multimedia Appendix 1). Users falling into the moderate and severe GAD-7 categories were more targeted in using Wysa, specifically to help with sleep and anxiety, and did not explore the other interventions as much as other users. On the other hand, users with no or mild anxiety explored more of Wysa’s other interventions. Likewise, users who were unlikely to have symptoms of depression engaged with a wider variety of interventions than those who were screened as likely. In general, this data emphasizes the popularity of sleep and anxiety interventions among this community and implies that greater severity of mental health symptoms is associated with more targeted engagement with the app.

**Discussion**

**Overview**

Due to heightened restrictions on in-person contact, the COVID-19 pandemic has brought to the forefront the current limitations of mental health care delivery. As such, the advent of the pandemic has proved a catalyst for new digital initiatives to be facilitated [15]. The present community case study is a service evaluation of a pilot exercise within a national tertiary health care division in Singapore using a self-guided, AI-enabled mental health app (Wysa) during the COVID-19 pandemic. The availability of Wysa for this population of health care staff to use was well-received, particularly against this backdrop of pandemic-related anxiety. Even beyond the height of the pandemic (2020-21), the continued use of Wysa by this community suggests that this digital mental health solution has merits surpassing those of temporary pandemic-specific support. The high initial engagement rate of 93.9% of onboarded users completing at least 1 in-app session may have been due to this intervention being introduced through a trusted source—a health care institution or employer [14]. Nevertheless, 80.1% of users returned to engage with the app voluntarily for a full second time, and the mean number of in-app sessions completed was 10.9 for an average of 3.80 weeks. In-app use reflects recurring engagement with Wysa, but users could also engage with the chatbot through the website through a widget. As a whole, the data demonstrates that users may have experienced some real or perceived benefit, which motivated their continued engagement with the app.

Among this community, 46.2% reported symptoms of anxiety, and 15.2% were likely to have symptoms of depression. These prevalence rates are comparable to those of other health care
communities in other parts of the world during the COVID-19 pandemic. For instance, these rates are similar to the 44.6% that had symptoms of anxiety (GAD-7) and 14.8% that had moderate to severe depression (PHQ-9) in a sample of health care workers from China [16]. However, compared to a population of health care workers in the United Kingdom following the pandemic’s first peak, the present sample’s anxiety prevalence was higher than the UK sample’s 34.3%, but depression prevalence was lower than the UK sample’s 31.2% (PHQ-4) [17]. Following a similar trend, the present sample’s rate of anxiety was slightly higher than the pooled prevalence rate of 40%, but depression prevalence was lower than the pooled prevalence of 37% from a meta-analytic study of health care workers across 19 countries during this pandemic [18]. Compared to the general population during the COVID-19 pandemic, this community of health care workers’ anxiety and depression symptom prevalence rates were similarly higher and lower than the global prevalence rates of around 27.3%-31.9% and 33.7%, respectively [19,20].

In general, the intervention use patterns (Table 3) concur with the user-reported life challenges (Table 1). The data regarding the patterns of intervention use indicates that “for deep sleep” was the most popular intervention used by the greatest number of users repeatedly for the most number of times. “Sleep sounds” was used the second-largest number of times, but only by a handful of unique individuals. This suggests that an intervention for sleep sounds may not be attractive to a wide range of users, yet for those who decide to try it, it appears motivating to use, thus resulting in its high repeat-use rate. The “health anxiety” intervention was the next most popular intervention, used by almost as many unique users who engaged with the intervention “for deep sleep.” The popularity of this intervention may be idiosyncratic to the COVID-19 pandemic period. Overall, this data implies that this community of health care workers primarily sought help from Wysa for sleep concerns and anxiety or found these interventions to be the most beneficial. The analysis of most used interventions according to GAD-7 and PHQ-2 severity further indicates that this is true regardless of their mental health status.

Users in this community with moderate to severe symptoms of anxiety were more targeted in using Wysa specifically to help with sleep and anxiety and did not explore the other interventions as much as other users. This was reasonable to expect, as individuals with anxiety often have co-occurring sleep difficulties and would likely allot more attention to addressing these key concerns. Users with no or mild anxiety explored more of Wysa’s other interventions. Their engagement in a greater range of interventions could explain why these individuals continued to use Wysa despite their lack of or few anxiety symptoms. Likewise, those who were unlikely to have symptoms of depression engaged with a wider variety of interventions than those who were likely. Although this may partially be due to a large number of individuals falling under the unlikely category, thus contributing to the heterogeneity of use patterns, engagement in a large range of interventions by users with fewer mental health concerns may reflect their use of this app in a manner relating to principles of positive psychology [21] to further enhance one’s quality of life. This contrasts with the ostensibly treatment-targeted approach taken by users with greater psychopathological challenges. The dichotomous manner of use noted here may attest to the breadth of what the Wysa app could support users with.

Individuals with mild or moderate anxiety symptoms may sufficiently benefit from using Wysa in a self-directed manner, thus leading to high use and positive feedback rates. This hypothesis may be supported by Karyotaki and colleagues’ review [22], which found that individuals with more severe depression may benefit more from guided interventions involving human support, whereas individuals with mild or subthreshold symptoms may be adequately supported by self-guided interventions. Although, in the present sample, this does not hold true with regard to depressive symptoms, since users likely to have depression engaged with Wysa at comparable rates to those who were unlikely (Table S1 in Multimedia Appendix 1). This is an encouraging finding, as it suggests that individuals with symptoms of depression may have derived benefit from, or at least enjoyed, continuing to use this app to support their well-being. Yet, the depression severity in this study was determined using the PHQ-2. More accurate and potentially different results might have been obtained if the PHQ-9 had been used. In addition, individuals with no symptoms of anxiety as reported on the GAD-7 engaged with Wysa at high rates, on par with users with mild to moderate symptoms. This may indicate that Wysa is motivating to use for individuals that may not have any overt mental health struggles, which could imply that Wysa is able to support users in maintaining their positive mental health or to flourish further in eudaimonia, as proposed in a previous paragraph. Nonetheless, grounded conclusions could only be determined through direct qualitative inquiry or more rigorous quantitative pre-post analyses, which this evaluation was not able to perform due to methodological constraints. To summarize, Wysa appears to be beneficial or motivating to use for individuals with no, mild, or moderate anxiety, whereas individuals with severe anxiety symptoms may need to seek other forms of guided clinical care.

As there was a 71.0% increase in use of the app during the “gratitude challenge” period, the challenge appeared to be successful in boosting app engagement. Extant literature provides support for the advantages of practicing gratitude, from experimental research that found gratitude to enhance the psychological benefits of social support [23] to a randomized controlled trial of a gratitude intervention in which gratitude effectively improved well-being [24]. A review by Bono and Sender [25] suggests that gratitude’s ability to amplify social benefits and motivate self-improvement makes it foundational to human development. This powerful potential may have propelled the increase in app engagement. Future endeavors to implement similar digital mental health interventions may benefit from a greater volume of similar initiatives at regular intervals. However, to assess the efficacy of such initiatives more accurately, more robust research is needed to isolate the effect of the challenge from other confounding variables. In addition, the present sample of users who responded to the GAD-7 and PHQ-2 screening questionnaires was too small to draw any conclusions regarding the mental health status of...
individuals that these types of “challenges” may work best on. Future studies should evaluate this further.

Altogether, the present service evaluation shows promising evidence to endorse the implementation of digital mental health interventions as standard practice, as the high repeat-use rates for Wysa’s interventions corroborate with the strong positive feedback and user engagement rates. Health care systems could consider implementing similar digital interventions as part of routine care for patients or to support their own staff internally. Clinicians may leverage these interventions to improve the capacity of mental health care service delivery, since these digital interventions have the potential to greatly increase access to evidence-based psychological support. For such ventures to be implemented, a systematic approach could be taken by first determining the appropriate digital solution for the community in question [9]. Using an integrated tool such as Wysa with its diverse assortment of interventions would be able to cover a wide variety of needs, possibly ranging from treatment-targeting solutions to the eudaimonic enhancement of well-being. Yet, as seen in this study, the majority of this community’s users were chiefly interested in the interventions for sleep and anxiety, regardless of the severity of their symptoms. If the community has more specific needs, perhaps more targeted apps or other digital interventions could be considered.

Limitations
The evaluation of the pilot exercise outlined in this study has several limitations. First, intervention use data from this population was based on users directly clicking on the interventions. As such, this was not able to capture the interventions used that were suggested by Wysa through chatbot conversations. Next, the PHQ-2 was used to collect data on users’ depressive symptoms. However, the PHQ-9 may have been able to yield more precise information. In addition, comparison between baseline and subsequent scores would be required to generate more reliable quantitative results that elucidate Wysa’s ability to moderate symptoms of poor mental health. In the present exercise, insufficient users responded at follow-up screenings in order to conduct meaningful pre-post analyses. Moreover, there was only a moderate response rate of 31.9% to the screening questionnaires at baseline. Conclusions drawn from the present data may thus not be representative of the entire community that participated, and the small sample size of respondents is a limitation in itself. The users who responded to the screening interventions also appeared to contribute to a large proportion of the overall population’s engagement with Wysa, since this sample’s average use rates were approximately twice as high as the overall population’s average rates. This may further indicate a biased sample. Furthermore, although the present data demonstrates the propitiousness of the “gratitude challenge,” its true efficacy in boosting engagement could not be ascertained since a controlled experimental design would be necessary.

Another limitation is that assumptions regarding reasons for engagement with Wysa are speculative; for example, in assuming that users who repeatedly used the app benefitted from its use or that the number of weeks of use reflects how long their symptoms lasted. However, it is possible that these users might not have seen much benefit, yet they were patient in attempting to engage with Wysa. This would thus be more telling of the user’s character or personality than of the app’s effectiveness. Similarly, it is not possible to determine whether the ubiquitous popularity of the sleep and anxiety interventions was due to users being mainly concerned with these challenges or whether this phenomenon was a result of users’ expectations regarding what an app could plausibly help with. To yield more reliable conclusions, qualitative data would be required, collected through feedback through the app or a follow-up focus group discussion. Conducting a focus group may further enable the generation of insight into the lived experiences of these users. This may be especially useful to illuminate the experience of those with severe anxiety symptoms as they attempted using Wysa, to deduce the actual reasons for their low rates of engagement, and for those with no anxiety, to discern whether Wysa simply sustained their mental health or was able to promote even greater degrees of well-being. Nevertheless, due to the anonymous nature of the data, reidentification of the users to follow up with would not be possible. For more rigorous research, a dedicated study would have to be designed with ethical approval and consent obtained from health care workers to participate. Future studies could thus be developed based on the promising findings from this community service evaluation.

Acknowledgments
The authors would like to thank Ms Priscilla Teo (the group chief human resource officer) of the National University Health System, Singapore, for permission to conduct this evaluation and for the purchase of licenses to use Wysa, and Ramakant Vempati and Tanya Malik from Wysa Inc for their support in the conduct of this evaluation. No additional funding was obtained for the running of this formative service evaluation.

Authors’ Contributions
All authors contributed to this study and approved the submitted version. CLC was responsible for the overall preparation of this manuscript. CS and MR assisted with analyzing the data. JCMW implemented the Wysa program with Nicholas Sii, Mae Kng, and Suhana Alwi and directed the data analysis and manuscript preparation as senior author.

Conflicts of Interest
CS and MR are employed by Wysa Inc. All other authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Abstract

Background: In Denmark, outpatient follow-up for patients with chronic kidney disease (CKD) is changing from in-hospital visits toward more remote health care delivery. The nonuse of remote patient-reported outcomes (PROs) is a well-known challenge, and it can be difficult to explain which mechanisms of interventions influence the outcome. Process evaluation may, therefore, be used to answer important questions on how and why interventions work, aiming to enhance the implications for clinical practice.

Objective: This study aimed to provide insight into the intervention process by evaluating (1) the representativity of the study population, (2) patient and physician use patterns, (3) patient adherence to the intervention, and (4) clinical engagement.

Methods: A process evaluation determining the reach, dose, fidelity, and clinical engagement was carried out, alongside a multicenter randomized controlled trial (RCT). We developed and implemented an intervention using PRO measures to monitor outpatients remotely. Data were collected for the PRO intervention arms in the RCT from 4 sources: (1) PRO data from the participants to determine personal factors, (2) the web-based PRO system to identify key usage intervention patterns, (3) medical records to identify clinical factors relating to the use of the intervention, and (4) semistructured interviews conducted with involved physicians.

Results: Of the 320 patients invited, 152 (47.5%) accepted to participate. The study population reflected the target population. The mean adherence rate to the PRO intervention arms was 82% (95% CI 76-87). The questionnaire response rate was 539/544 (99.1%). A minority of 13 (12.9%) of 101 patients needed assistance to complete study procedures. Physicians assessed 477/539 (88.5%) of the questionnaires. Contact was established in 417/539 (77.4%) of the cases, and 122/539 (22.6%) of the patients did not have contact. Physicians initiated 288/417 (69.1%) and patients requested 129/417 (30.9%) of all the contacts. The primary causes of contact were clinical data (242/417, 58%), PRO data (92/417, 22.1%), and medication concerns and precautionary reasons (83/417, 19.9%). Physicians found the use of PRO measures in remote follow-up beneficial for assessing the patient’s health. The inclusion of self-reported clinical data in the questionnaire motivated physicians to assess patient responses. However, some barriers were emphasized, such as loss of a personal relationship with the patient and the risk of missing important symptoms in the absence of a face-to-face assessment.

Conclusions: This study demonstrates the importance and practical use of remote monitoring among patients with CKD. Overall, the intervention was implemented as intended. We observed high patient adherence rates, and the physicians managed most
questionnaires. Some physicians worried that distance from the patients made it unfeasible to use their “clinical glance,” posing a potential risk of overlooking crucial patients’ symptoms. These findings underscore key considerations for the implementation of remote follow-up. Introducing a hybrid approach combining remote and face-to-face consultations may address these concerns.

**Introduction**

Lifestyle and a growing elderly population in Denmark have increased the number of patients with chronic diseases to approximately 1 million in a population of 6 million, with growing health care expenditure as a consequence [1]. To improve efficacy, new ways of delivering health care to people with chronic kidney disease (CKD) have been posited, such as remote monitoring, which is defined as using technology to monitor patients at a distance [2,3]. One way of remotely monitoring patients is to collect information about their symptoms by obtaining repetitive patient-reported outcomes (PROs) while the patients are at home. This allows for frequent capture of important disease-specific outcomes and also allows clinicians direct access to the patients’ health status [4,5]. PROs are measures of a patient’s health conveyed directly by the patient, without interpretation by a clinician or anyone else [6], often gathered from electronic questionnaires. Remote monitoring using PROs is increasingly applied among patients with chronic conditions in Denmark [4,7]. However, several personal and external factors may affect a person’s ability to engage with and use digital health interventions [8,9]. Prior studies have shown sociodemographic and economic inequality in patients who attend [10,11] and adhere to PRO-based remote follow-up [12].

A pragmatic randomized controlled trial (RCT) named PROKID (PRO measures in Kidney care) is currently investigating whether PRO-based remote follow-up is a safe and effective alternative to health care delivery to patients with CKD [7]. The primary outcome in the PROKID trial is renal function measured using the estimated glomerular filtration rate (eGFR) as this is the single-most accurate measurement for CKD progression [13] and thereby indicates the level of safety in remote monitoring. The effectiveness of remote monitoring is measured using clinical data, resource use, and PROs, such as the quality of life and illness perception [14]; also see Grove et al (unpublished data, 2024). PRO-based interventions in other patient populations have shown the ability to (1) reduce the number of outpatient visits [15,16], (2) improve communication between health care professionals and patients [17-20], and (3) offer patients a more comprehensive understanding and greater knowledge of their condition [21-23]. However, several knowledge gaps regarding the use and acceptability of remote PRO interventions are still present. Trials are vulnerable to various biases that may undermine external validity [24]. Evidence suggests that often, this risk of bias is related to patients not using the technology as intended [25]. Thus, examining the quality (fidelity) and quantity (dose) of what was implemented in practice and the extent to which the intervention reached its intended users is essential when evaluating trials [26]. The degree to which patients engage with and use the intervention as intended is a crucial component in evaluations [26]. The nonuse of remote PRO is a well-known challenge [16,27] and may blur the overall interpretation of using PRO as the basis for remote follow-up. However, little is known about the components that might enhance patient and clinical engagement and thus might have the most significant impact in terms of use and adherence to the intervention. The PROKID trial [14] cannot explain which mechanisms of the intervention have an influence on the outcome. Process evaluation may therefore be used to answer important questions on how and why interventions work, aiming to enhance the implications for clinical practice [26].

Thus, we aimed to conduct a process evaluation to obtain insights into the PROKID intervention’s working mechanisms by evaluating (1) the representativity of the study population, (2) patient and physician use patterns, (3) patient adherence to the intervention, and (4) clinical engagement.

**Methods**

**Study Setting**

In 2019, the PROKID trial, a Danish multicenter RCT, was initiated to evaluate the noninferiority of PRO-based remote follow-up compared to usual outpatient clinic visits in managing the decline in renal function and maintaining patients’ quality of life [7]. The intervention was implemented in a real-life setting, and clinicians and patients were involved in the development process. We provided short oral seminars for the staff in the outpatient clinics, where the intervention was discussed and refined. We invited patients to provide input into the design and the patient information sheets of the intervention. Participants were eligible for the trial if they attended follow-up from January 2019 to August 2021 at a renal outpatient clinic in Central Denmark Region and had a renal function of eGFR≤40 mL/minute. In addition, participants had to be ≥18 years old and able to complete a questionnaire. Newly referred outpatients were randomized into the following 3 groups: (1) PRO-based follow-up, (2) PRO-based telephone follow-up, or (3) usual outpatient follow-up (Figure 1).
In the intervention arms, each patient participated in 6 PRO consultations (when PROs were used in a consultation) during 18 months of follow-up. Prior to each PRO consultation, patients needed to undergo blood tests, measure their blood pressure and weight, and complete a disease-specific questionnaire. The questionnaires were sent to patients 7 days ahead of each consultation, and in the case of nonresponse, they were sent reminders on the fourth day and the day just prior to the consultation. The questionnaire included information about blood pressure, weight, self-rated health, renal-specific symptoms, and a free-text box [28]. The physicians accessed the patients’ PRO responses through a graphical overview embedded in the electronic health record system [5]. In the PRO-based follow-up intervention group, physicians had to approve each patient’s responses, manage them according to a color-coded algorithm, and determine whether the patient needed contact. A clinical expert group has assigned a color to each item response according to the severity of the symptom, as previously described: red, yellow, or green [14,28]. Each patient’s need for contact was evaluated based on their PRO responses and other clinical data, such as blood samples and blood pressure. Therefore, it was up to the physicians to decide whether contact with the patient was needed. This applied not only to instances where the color code was red or yellow but also to instances in which the questionnaire displayed a green color code. In the PRO-based telephone follow-up group, the physicians had to approve each patient’s response, call the patient, and document the conversation as conducted. Figure 2 outlines the groups, the content, and the purpose of using PRO.
Figure 2. Overview of the intervention groups in the PROKID trial including patients with CKD at Aarhus University Hospital, Gødstrup Hospital, and Viborg Regional Hospital from January 2019 to August 2021. CKD: chronic kidney disease; PROKID: PRO measures in Kidney care.

Study Design
The process evaluation was an integral component of the PROKID trial and focused on adding information not provided in the trial and clarifying how the intervention was received in practice to increase accuracy in the trial results. The design and methods of the PROKID trial are described elsewhere [7]. The design of this evaluation was influenced by Steckler and Linnan’s [26] process evaluation framework, building on 4 themes: reach, dose, fidelity, and clinical engagement. This study used qualitative and quantitative methods to answer the research questions. The study was reported in accordance with Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth (CONSORT-EHEALTH) guidelines [29].

Participants
We obtained data from patients attending outpatient follow-up at the renal outpatient clinics at Aarhus University Hospital, Gødstrup Hospital, and Viborg Regional Hospital in Central Denmark Region. In the quantitative phase of the process evaluation, aimed to identify the reach of the intervention, the sample consisted of 320 patients, all eligible for randomization. The PROKID trial recruited 152 (47.5%) patients, and the 105 (69.1%) patients allocated to the PRO intervention groups informed the dose and fidelity of the trial. The qualitative phase of the process evaluation consisted of semistructured interviews with physicians (N=10) involved in the PROKID trial (Figure 1). Physicians were purposefully sampled from all involved outpatient clinics. Of the 10 physicians, 5 (50%) were female, 6 (60%) were senior consultants, and 4 (40%) were consultants, and their ages ranged from 37 to 67 years. Most of them had under 2 years of experience in using PRO in clinical practice.

Process Evaluation Components
The research team identified core process questions for the evaluation stages. These related to describing the quantity and quality of what was delivered, covered by the following 4 components: reach, fidelity, dose, and clinical engagement [26]. An overview of the evaluation components and methods is outlined in Table 1.

### Reach

Reach was measured by the degree to which the intended target population participated in the intervention. Participation was defined as patients being eligible and willing to participate in the PROKID trial. Participants and nonparticipants were compared according to demographic information and PROs, measured using questionnaires and clinical data collected before entrance to the trial. All patients who declined to participate were encouraged to provide a reason for refusal. A complete overview of the data sources and the PROs and clinical outcomes is presented in Table S1 in Multimedia Appendix 1.

### Dose

The assessment encompassed measuring the quantity of the intervention components given to the patients, as well as gauging the extent to which patients engaged in and adhered to the intervention. Intervention adherence to PRO-based remote follow-up was exclusively calculated among patients in the intervention groups (N=105). Adherence was defined as the patient being able to complete the questionnaires, measure their blood pressure, and have blood samples taken prior to each of the 6 PRO consultations without assistance from the clinicians or the researcher. The percentage of successfully completed PRO consultations was used as a proxy measure for adherence. An adherence rate of 100% indicated that the patients successfully attended each consultation without assistance from anyone. Engagement in the intervention was measured by calculating as number of questionnaires distributed to patients/number of questionnaire responses received from patients, including the need for sending reminders. The extent of nonresponders was calculated. Furthermore, the item response rate was measured as total number of items distributed to patients/number of item responses. The time spent completing the questionnaire and paper/electronic version distribution was automatically logged in the AmbuFlex database [30].

### Fidelity

Fidelity measured the extent to which the intervention was delivered as planned. Fidelity was measured by counting the number of physicians using the system, including the extent to which the physicians assessed the patients’ responses. Furthermore, the mean number of physicians involved in each patient pathway was reported. The patients’ preferences for mode of contact with their physicians, as well as the extent and nature of the clinical assessment of their responses, was obtained. This information was automatically registered in the AmbuFlex database [30]. A study nurse or the project researcher obtained a quantification of patients who needed course support during the trial and registered in the Research Electronic Data Capture (REDCap) system [31]. Course support was defined as the patient asking for help from the researcher or the project nurse regarding completion of the study procedures. Evaluation components of dose and fidelity were described separately for each PRO intervention group.
Clinical Engagement

There is no universal definition of clinical engagement; it may be an attitude, a behavior, or an outcome [32]. We defined clinical engagement as the physicians’ perception, attitude, and satisfaction of using PRO actively in the decision-making processes in remote renal care. The clinical engagement toward using PRO-based remote follow-up in clinical practice was explored among the renal physicians who delivered the intervention. We used a qualitative approach inspired by Braun and Clarke’s [33] 6-phase thematic analysis. Individual semistructured interviews with purposively sampled physicians (N=10) most experienced with PRO-based follow-up were performed. The interviews were conducted by the project researcher (author BEG) with experience in qualitative research and occurred immediately after the physicians completed the patients’ final PRO consultation in one of the involved outpatient clinics. An interview guide was used to elicit clinical engagement, asking about the physicians’ views toward the PRO intervention and how they had experienced following the patients remotely (Table S2 in Multimedia Appendix 2). During each interview, notes were written down by BEG, and statements were summed up at the end of each interview and confirmed by the interviewee. These notes constituted the data material. For analysis of all the notes, an analytic coding scheme was developed based on the interview questions and an initial reading of the notes from the interviews (Table S3 in Multimedia Appendix 3) [34]. Citations used in this paper have been translated from Danish.

Data Analyses

Quantitative data were analyzed using descriptive statistics, such as frequencies, means (SDs), or median (IQRs), as appropriate. Descriptive quantitative information on reach, dose, and fidelity was provided. The presentation of variations between patients in the 2 intervention arms in terms of dose and fidelity were presented. The participation rate was calculated as number of patients consenting to participate/number of eligible patients. Reasons for nonparticipation were synthesized into categories by 2 researchers. We classified patients with low adherence by using the lower quartile. Thus, adherence<83% was the threshold defining low adherence to PRO-based remote follow-up. The adherence threshold was estimated from patients in both PRO intervention arms. Deceased and patients who withdrew due to ending follow-up at the hospital were excluded from the analyses. Participation and adherence data were linked to demographic data collected prebaseline of the trial. Personal and clinical characteristics of high or low adherence were described. Differences were determined using the χ² test.

Notes from the semistructured interviews constituted the qualitative data. We performed a thematic analysis to extract important aspects that influenced the physicians’ engagement toward PRO-based remote follow-up. First, all notes were read and re-read several times for familiarization with the data. Second, for an overview of the complete data, statements for each patient were entered into a Microsoft Excel spreadsheet by interview question. Third, preliminary themes that were relevant to the aim of evaluation were identified. Fourth, a coding framework was developed based on the initial themes. Finally, themes were identified and reviewed against the original statements and context. The quantitative and qualitative analyses and reporting were conducted prior to knowing the trial outcomes to avoid biased interpretation of the results [26].

Ethical Considerations

Patients provided written consent to participate in the trial, including the use of information from their medical records, the AmbuFlex database, and registers. Additionally, verbal consent was obtained from the physicians participating in the interviews. The study was approved by the Danish Authorities for Health Research (number 1-45-70-8-22).

Results

Reach

In total, 1060 patients with CKD were screened for participation in the PROKID trial (Figure 1). Of these, 320 (30.2%) patients were found eligible, and 152 (47.5%) agreed to participate in the PRO-based remote follow-up intervention. No statistically significant differences in patient and clinical factors were found between participants and nonparticipants (Table 2). A tendency toward lower participation by older age and lower health literacy was seen. The reasons for not participating in the PRO-based intervention are outlined in Table 3.
Table 2. Characteristics of patients with CKD⁹ (N=320) among participants and nonparticipants from Aarhus University Hospital, Gødstrup Hospital, and Viborg Regional Hospital in the PROKID⁹ trial from January 2019 to August 2021.

<sup>d</sup>Died before enrollment, departed, other study participation.

Dose

Of the 152 patients, 105 (69.1%) were allocated to the 2 PRO-based intervention arms. Of those, 8 (7.6%) patients died during follow-up and 4 (3.8%) left the study due to termination of outpatient follow-up, leaving 93 (88.6%) patients adhering to PRO-based remote follow-up (Figure 1). The mean adherence rate to the intervention was 82% (95% CI 76-87). In total, 70 (75.3%) of 93 patients had an adherence rate ≥83%, as indicated by the dotted vertical line in Figure 3. The distribution of patients according to the level of adherence rates is shown in Figure 3.
Overall, no statistical differences were found in patient and clinical factors between patients with high or low intervention adherence, albeit a tendency toward lower adherence by poor self-reported health status and lower patient activation was seen (Table S4 in Multimedia Appendix 4). Patients in the PRO-based follow-up group had a significantly lower adherence rate than patients in the PRO-based telephone follow-up group (Table 4).

The overall response rate was 99.1% (539/544). Accordingly, the item response rates were relatively high, with a mean response rate of 96.7% (14,314/14,788; Table 4). In total, 453 (84%) of the 539 patients responded electronically, and they spent a median of 9.22, IQR (6.87) minutes completing the questionnaire.

Fidelity

The patients completed 539 questionnaires, and in 477 (88.5%) of the 539 cases, a physician assessed their responses (Table 4), leaving 11.5% (62/539) of the questionnaires unnoticed by a physician. The algorithm indicated that 234 (94%) of the 249 patients in the PRO-based follow-up group experienced some disease burden or needed clinical contact flagged by a red or yellow color code. When this was assessed, the physicians found that 137 (55%) of the 249 patients needed to be contacted and 112 (45%) did not need to be contacted. In 288 (69.1%) of all the 417 cases, the physician initiated the contact, and in 129 (30.9%) of the cases, the patient requested contact. The primary causes of contact (242/417, 58%) were attributed to clinical data, including blood samples and blood pressure. Contact based on PRO answers alone accounted for 22.1% (92/417) of the contacts, while concerns related to medication and a precautionary approach prompted the remaining contacts (83/417, 19.9%). In total, 10 (3.4%) of the 290 patients in the PRO-based telephone follow-up group were unavailable when the physician contacted them by phone. On average, 3 (range 1-7) physicians were involved in each patient pathway. A minority of 13 (12.9%) of 101 patients needed assistance to complete study procedures. Common reasons for needing assistance were measuring blood pressure and obtaining information about how to undergo blood tests or how to access the questionnaire. A study nurse or the researcher contacted the patient to address the reasons behind noncompliance and collaboratively devise a plan to ensure future adherence. The majority of those needing assistance were in the PRO-based follow-up group.

Clinical Engagement

The physicians emphasized that their perception and commitment to the use of PRO-based remote follow-up was influenced by the fact that the PROKID intervention enriched their consultations, as a physician explained:

https://formative.jmir.org/2024/1/e48173
I believe patients receive a more thorough and attentive consultation through this approach, where all symptoms are carefully examined. [Physician 9]

However, PRO-based follow-up also seemed to limit their ability to assess the patients’ health status, as explained in the following by a physician:

I find it quite straightforward to assess individuals over the phone. However, what I miss is observing their movement from the waiting room to the consultation room; it reveals a great deal, such as being able to better evaluate characteristics for instance like skin color and psychical impairment. [Physician 4]

On the one hand, all physicians felt that the PROKID intervention is beneficial for their ability to manage and identify patients’ symptoms and estimate their need for contact. The clinicians’ motivation to review the patients’ responses was heightened because the questionnaire included clinical data, such as information about blood pressure and weight.

The clear advantage lies in having everything compiled in this questionnaire, which significantly aids in retaining and managing all the information. [Physician 3]

On the other hand, the physicians were also concerned that they might overlook something in the patients’ health status. This 2-sided notion was described in an interview in the following way:

You might lose some connection with the patients, the familiarity that comes with knowing them, and eventually find yourself relying more on questionnaires and blood tests. This shift can make the interaction feel less personal…Conversely, we receive something self-reported (PRO) that delves into deeply personal matters. The risk lies in potentially overlooking something, especially when the patient prefers minimal contact. [Physician 10]

To remedy this risk of overlooking symptoms, the physicians wished to combine remote and face-to-face consultations in the future implementation of the PROKID intervention’s remote follow-up. Specifically, the assessment of patients in the PRO-based follow-up group troubled the physicians, as these patients were not automatically contacted by phone as opposed to patients in the PRO-based telephone follow-up group. This was described by a physician in the following way:

I sometimes feel concerned about patients in PRO-based follow-up, who does not visit the hospital. For instance, does this woman truly comprehend the extent of her illness? Is she receiving the necessary information? She may be unaware of what she does not know. [Physician 5]

The thematic analysis revealed important aspects that influenced the physicians’ engagement in using PRO. These aspects represented facilitators of and barriers to the implementation of PRO-based remote follow-up in clinical practice. As shown in Textbox 1, the physicians’ engagement in the implementation of PRO-based remote follow-up was supported by several facilitating factors—for instance, PRO enabled an excellent overview of the patients’ health status and increased the possibility for visualization and clarity, as described in this quote:

I wouldn’t have inquired about this if the patient had not communicated it to me. It has completely altered the course of our conversation. [Physician 5]
Facilitators of PRO use in remote care:
• Better overview of the patient’s overall health condition
• Ensured relevant data are available and lined up
• A great basis for visualizing the patient provided by the combination of PRO and blood tests
• Qualified phone consultations
• Enhanced the patients’ ability to reflect on their symptoms
• Enabled patient-centered focus
• More convenient for the physician and the patient compared to usual follow-up
• An excellent supportive tool for patients during a period of stable illness

Barriers to using PRO in remote care:
• Decrease in physicians’ ability to sense the patients’ condition through clinical observation
• Decrease in physicians’ knowledge of patients
• Decrease in crucial knowledge on patient medical history
• Induced risk of forgetting the responsibility of the patient
• Provoked a lower personal relationship with the patient
• Training needed to manage patients’ health status remotely
• Specific patient flow needed to maintain clinical skills of using PRO
• Incentive required by physicians to assess patients’ PRO responses

PRO was also perceived as enabling patient-focused care, to be convenient for both the patient and the clinic, as described by this physician:

_It must be convenient for someone like him, who does not have to make the one-hour trip every third month just to let me pressure his angles a bit. We can just as easily handle that over the phone._ [Physician 2]

However, some barriers to the physicians’ engagement in implementing PRO-based follow-up worked against some of the facilitating factors. Specifically, the physicians faced challenges in accurately evaluating the patients’ health condition and determining their requirement for medical attention and intervention. This was mainly due to the lack of face-to-face interaction and the inability to use their clinical observation skills.

### Discussion

**Principal Findings**

In this process evaluation, the intervention processes of PRO-based remote follow-up (the PROKID trial) were evaluated [7]. In total, 47.5% of the eligible patients participated, and they reflected the target population. Overall, we found high percentages of the utility of the system. The dose ranged from 73% to 99%, with a mean adherence rate of 82%. Fidelity showed high usage by physicians, with 88.5% of the total questionnaires being assessed. In total, 12.9% of patients needed assistance to comply with study procedures; this need was predominantly observed in the PRO-based follow-up group. Ten physicians were interviewed about their engagement in the PROKID intervention; most of them rated PRO as being of additional value. However, some barriers, such as decreased knowledge of patients and a lack of using their clinical observational skills, were highlighted.

Overall, the percentages of utility were high in the PRO-based intervention. We believe that several reasons may explain this success. First, an internal pilot study was conducted in an outpatient clinic before trial onset. The pilot study showed that patients were willing to participate and that it was possible to deliver the intervention. We spent time observing the routines and activities in the outpatient clinic to inform our intervention. We had continuous dialogues and meetings with staff members and patients to target the intervention to existing clinical practice. Several studies have highlighted the importance of patients and health care providers knowing why PROs are used and the relevance of the questions asked [35,36]. The fact that the intervention was implemented in a real-life setting and that the users were involved in its development may have impacted patient and clinical engagement with PRO-based remote follow-up [4,37].

Another possible explanation for the high usage percentages may be the procedures used to approach and recruit patients. We included newly referred patients, and it became clear that most preferred no follow-up or remote follow-up, probably due to a feeling of being more ill when entering a hospital [38] or a general lack of experience attending outpatient follow-up. Patient-reported reasons for nonparticipation confirmed this finding, as 7% of the eligible patients declined participation due to preference for telephone consultation or no attendance. Thus, trial participation had the advantage that patients could attend
remote follow-up, which was not part of the routine practice at the time. Finally, the degree of involvement of the project researcher and the clinical study nurse in the recruitment phase and during the trial may have motivated patients to participate and made them adhere to and use the intervention. In total, 12.9% of the patients needed course support, highlighting the benefit of having someone to call when problems occur. Prior findings from a parallel qualitative study, in which we interviewed 15 patients in the PROKID trial, support this finding [38].

A well-known concern in RCTs is the challenge of inducing selection bias caused by participation of a selected group failing to represent the target population [24]. We did not find any personal or clinical differences between participants and nonparticipants in our study, which adds value to the generalization of the results of the PROKID trial. Wiegel et al [12] found, in a recently published systematic review, an overall adherence to repetitive electronic PROs in populations with chronic diseases ranging between 61% and 96%, which corresponds well with the mean adherence of 82% found in our study. However, the definition of adherence is known to vary between studies [12]. We believe that having a predefined cutoff point for low adherence may help researchers and clinicians identify patients needing further assistance. Presumably, due to low power, we found no differences in personal or clinical factors between patients with low or high adherence. This might challenge clinicians seeking to identify patients most suitable for PRO-based remote follow-up. The definition and threshold for adherence correspond to the goal of using remote PRO in the outpatient clinic, as in the real-life setting, patients should be capable of completing the PRO questionnaire by themselves.

We found a high response rate in our study, contrary to other previous findings [35]. We believe the 2 main reasons for this were the high use of reminders and the fact that a study nurse called the patient if questionnaire responses had not been submitted at the date of the PRO consultations. The use of reminders is known to increase the response rate [39]. Knowledge of the extent of this phenomenon is important to convey to the outpatient clinics when the intervention is widely implemented.

Another interesting finding is the number of physicians involved in each patient pathway. Preferably, patients should have 1 contact physician during follow-up, but we saw that each patient had contact with 3 (range 1-7) physicians during the 18 months’ trial. Evidence from a meta-analysis suggests that for the safety and continuity of care, it is essential to have as few different health care professionals as possible [40]. A qualitative study integral to the PROKID intervention concluded that barriers to patient engagement in PRO-based remote follow-up are unfamiliarity with the physician and remote follow-up challenging the patient-physician relationship [38]. Furthermore, the involvement of multiple physicians in reviewing each patient over the 18 months posed a challenge, leading to diminishing familiarity with the medical history of the patients. Remote monitoring is increasingly substituting traditional hospital visits [41]. A recent study argued that telephone follow-up is as safe as visits to the outpatient clinic, especially if the patient is acquainted with the physician [42]. Thus, it seems crucial to incorporate individual patient-physician consultations to the extent possible.

A prior study of field observations during the PRO consultations showed that the extent to which the physicians incorporated the patient responses into the consultations reached almost 100% [38]. However, data from this process evaluation study found that the physicians merely assessed 88.5% of the questionnaire responses received. This might indicate observer bias in the qualitative study [38], showing a falsely high result, although it might also indicate a false lower result in our study because of recall bias, as it seemed as if the physicians actually opened and assessed the patients’ PRO responses but forgot to approve and document the responses in the AmbuFlex database. However, it is a well-known challenge to get clinicians to assess and approve patients’ PRO responses [19,43]. The qualitative analyses showed that the physicians found PRO-based remote follow-up to enrich the consultations, but it also induced a risk of failing to notice important symptoms. Prior research has shown that engagement decreases when activities or tasks are perceived as wasteful of resources or creating more harm than benefit [44]. Therefore, enhancing the physicians’ satisfaction and perception of the usability of implementing PROs in remote care seems crucial. The physicians emphasized that they needed an incentive to open the patients’ PRO responses. During the interviews, it became clear that the patients’ blood pressure and weight were the physicians’ primary objects of interest. This result was supported in a qualitative study on patient perspectives [38] and has also been found to be an issue in other studies [22,45]. Hence, an important factor driving the assessment of patients’ PRO responses was the incorporation of the self-reported clinical outcomes (blood pressure and weight) in the questionnaire.

The color-coded algorithm showed that most of the patients needed contact with a physician or were burdened by disease-specific symptoms. Thus, the proportion of patients contacted by physicians was relatively high, which may indicate a high claim for clinical attention in this patient group. However, it may also indicate a sensitive algorithm [4]. The clinical experts aimed to develop an algorithm with high sensitivity since a low level of false-negative cases was more important than a high level of false-positive cases. Thus, the physicians’ ability to assess whether to contact patients was pivotal for the follow-up process. Further studies that consider the results of the green-yellow-red color-coded algorithm will need to be undertaken.

Strengths and Limitations

Process evaluation was considered integral to the PROKID trial, and the results of this process evaluation were analyzed prior to knowledge of the trial outcomes. Thereby, the risk of bias was reduced [46]. This study enabled us to perform a more detailed examination of the process of recruitment and intervention adherence to inform the interpretation of trial results and generalizability [47]. A main strength of this study is that it included patients from a well-defined population covering all centers following patients with CKD in Central Denmark Region. Quantitative and qualitative methods complemented one another, and a combination of self-reported, qualitative data
and register-based data was used to link different data sources. Another key strength of this study was the use of Steckler and Linnan’s [26] process evaluation framework, which allowed us to structure the process evaluation appropriately. Observations and interviews had the potential to influence the involved physicians’ and patients’ behavior and commitment. However, we believe that the timing of the evaluation in the finishing part of the trial limited this effect. The evaluator responsible was also the principal investigator in the PROKID trial, which provided insight into and understanding of the context, as an outsider could not have added to the findings.

This study also has some limitations. Initial development and use of a logic model may have better illustrated the underpinning theory [26]. The absence of predefined core questions was also a notable limitation. In the qualitative data analyses, the researcher’s familiarity with the participating departments may have induced a certain risk of bias. This may have led to a more positive attitude toward PRO-based remote follow-up among the physicians. However, it may also have made them confident that critical comments would be received constructively.

Conclusion

The PRO-based PROKID intervention was generally well received by patients and physicians, as we found high percentages of utility across all process evaluation components. Our findings highlight that remote PRO-based follow-up is feasible in a clinical setting and may be a relevant and valuable tool when remotely monitoring patients with CKD. We found high adherence and response rates among the patients, and the physicians assessed the majority of patient responses. However, it seems important to have a key figure who helps patients in need of assistance to comply with PRO-based remote follow-up. The physicians emphasized both enabling factors, such as improved overview and patient-focused care, and barriers, particularly the complexities of evaluating health conditions without direct interaction. Suggestions for future implementations included a combination of remote and face-to-face consultations to address this concern.

Acknowledgments

BEG, AdT, and LMVS conceived the study. BEG collected data. BEG and AKK performed the analyses. All authors contributed to the data interpretation and critical revision of the manuscript. All authors have read and approved the final manuscript and stand by the integrity of the entire work. This paper was written without the use of artificial intelligence technology. The Karen Elise Jensen Foundation and the AmbuFlex – Centre for Patient-reported Outcomes kindly funded this study.

Data Availability

The data sets generated and analyzed during this study are available in anonymous form from the corresponding author on request or by contacting the AmbuFlex – Centre for Patient-reported Outcomes.

Conflicts of Interest

BEG, RG, NHH, AKK, and LMVS are employees of AmbuFlex – Centre for Patient-reported Outcomes. However, this is a public-funded department with no financial benefit.

Exploring the Use of Customized Links to Improve Electronic Engagement With Sexual and Reproductive Health Care Among Young African American Male Individuals: Web-Based Survey Study

Sandy Arena¹, BSN; Mackenzie Adams¹, MPH; Jade Burns¹, PhD
School of Nursing, University of Michigan, Ann Arbor, MI, United States

Abstract

Background: Research has shown that heterosexual African American male individuals aged 18-24 years have a higher prevalence of sexually transmitted infections (STIs) and are more likely to engage in risky sexual behavior. There is a critical need to promote sexual reproductive health (SRH) services among this population, especially in urban settings. Young African American male individuals use social media platforms to access health information, showcasing the potential of social media and web-based links as tools to leverage electronic engagement with this population to promote SRH care.

Objective: This study aims to explore electronic engagement with young African American male individuals in discussions about SRH care. This paper focuses on the recruitment and social media marketing methods used to recruit young, heterosexual African American male individuals aged 18-24 years for the Stay Safe Project, a larger study that aims to promote SRH services among this population in Detroit, Michigan. We investigate the use of TinyURL, a URL shortener and customized tool, and culturally informed social media marketing strategies to promote electronic engagement within this population.

Methods: Participants were recruited between December 2021 and February 2022 through various modes, including email listserves, Mailchimp, the UMHealthResearch website, X (formerly Twitter), Facebook, and Instagram. Images and vector graphics of African American male individuals were used to create social media advertisements that directed participants to click on a TinyURL that led to a recruitment survey for the study.

Results: TinyURL metrics were used to monitor demographic and user data, analyzing the top countries, browsers, operating systems, and devices of individuals who engaged with the customized TinyURL links and the total human and unique clicks from various social media platforms. Mailchimp was the most successful platform for electronic engagement with human and unique clicks on the custom TinyURL link, followed by Instagram and Facebook. In contrast, X, traditional email, and research recruiting websites had the least engagement among our population. Success was determined based on the type of user and follower for each platform, whether gained in the community through sign-ups or promoted at peak user time and embedded and spotlighted on nontraditional media (eg, social media sites, blogs, and podcasts) for the user. Low engagement (eg, traditional email) from the target population, limited visibility, and fewer followers contributed to decreased engagement.

Conclusions: This study provides insight into leveraging customized, shortened URLs, TinyURL metrics, and social media platforms to improve electronic engagement with young African American male individuals seeking information and resources about SRH care. The results of this study have been used to develop a pilot intervention for this population that will contribute to strategies for encouraging sexual well-being, clinic use, and appropriate linkage to SRH care services among young, heterosexual African American male individuals.
Introduction

Nearly half of the 26 million people who are diagnosed with sexually transmitted infections (STIs) in the United States are younger than 25 years old [1]. Within this population, heterosexual African American male individuals aged between 18 and 24 engage in higher rates of risky sexual behavior (eg, early sexual initiation, inconsistent condom use, sex while under the influence, and multiple partners) and face a disproportionate burden of STIs compared to other adolescents and young adults [2-4].

In urban areas, this problem is particularly acute. African American male individuals who engage in low-risk sexual behavior, such as using condoms consistently or having sex with only 1 partner, are still at an increased risk of STIs due to risky social and sexual networks within urban communities that have high rates of violence, incarceration, and poverty [5-7]. A study by Marcell et al [8] found that among an urban sample of 70 African American and Hispanic young male individuals aged between 15 and 24 years, 67% reported having visited a health care provider in the past year, yet only 50% reported receiving HIV testing and only 39% reported receiving STI testing. These daunting statistics regarding sexual health indicate that young African American male individuals have a substantially greater need for sexual reproductive health (SRH) services (eg, preventative services, vaccination, diagnostic testing, and treatment) than other groups [9].

Studies show the significant factors in a young African American male individual’s decision to seek SRH services include concerns about confidentiality, self-confidence, and choice of provider, in addition to stigma, cost of care and contraceptives, and long wait times [8-10]. To explore the central phenomenon of SRH use and clinic access among young African American male individuals, community engagement with this population is crucial. Community engagement is particularly important for reducing HIV and STI disparities among young African American male individuals, and a lack of engagement with SRH care among this population can increase the risk of STIs and other health disparities [11]. Burns et al [12] found that social media can be used to effectively engage with young African American male individuals and provide them with information and resources regarding SRH care. Therefore, engaging with young African American male individuals electronically through social media may be a helpful strategy to ensure that they have access to the information and resources needed to make informed decisions about their SRH.

Social media platforms, particularly among African American adolescents and young adults, are already being used to seek general and sensitive health information due to their accessibility and anonymity [13]. Teadt et al [13] highlight the potential of social media platforms to serve as valuable tools for promoting sexual health awareness, prevention, and intervention development aimed at this population. For instance, in 2018, researchers from the Tulane School of Public Health and Tropical Medicine launched “Check It Nola” [14], a website for their research study geared toward using novel methods in promoting SRH care among heterosexual African American male individuals aged between 15 and 24 years in New Orleans, Louisiana. The “Check It” program used culturally informed marketing strategies (eg, using images of African American male individuals wearing crowns and the tagline “a king knows his status”) to resonate with young African American male individuals on popular social media platforms such as Instagram (Meta Platforms), X (formerly Twitter; X Corp), and Facebook (Meta Platforms), in addition to a website, as a means to engage them in SRH care [15]. This study seeks to create novel strategies similar to the “Check It” program by further exploring electronic engagement with SRH and preventative care services by young African American male individuals.

Following these existing approaches, we developed this study to explore an innovative approach to engaging with young African American male individuals about SRH care through culturally informed advertising on social media platforms (Instagram, Facebook, and X) in addition to traditional methods such as email, Mailchimp, and a participant recruiting website (UMHealthResearch). We used the TinyURL web service to create customized, shortened URLs that allowed us to track which social media and web-based platforms young African American male individuals were engaging with most. This study is part of the Stay Safe Project, a larger study which used a mixed method approach of surveying and focus groups to identify the positive and negative experiences of young African American male individuals when accessing SRH services at community health centers in a large city, the results of which will be reported elsewhere. It is important to recognize that community engagement is essential in order to reduce sexual health disparities among young African American male individuals. The use of social media and web-based links to promote SRH services and increase awareness may be used as an effective way to reach this population and be used to mediate health care–seeking behavior. This study describes the process for electronic engagement with young African American male individuals with regard to SRH services and may be used to promote long-term risk-reduction methods among young male individuals in the community.

Methods

Overview

This study examines electronic recruitment methods for young, heterosexual African American male individuals as part of a larger project, the Stay Safe Project, that seeks to promote SRH services for this population.
Study Population

The priority population for this study was young, heterosexual African American male individuals. Inclusion criteria for the Stay Safe Project were: (1) aged between 18 and 24 years; (2) self-identify as male; (3) live in Detroit, Michigan; (4) self-identify as African American or Black; (5) self-identify as heterosexual and report having sex only with women in the last year; and (6) speak, read, and write in English.

Recruitment

Participants were recruited between December 2021 and February 2022 through traditional email listserves, Mailchimp (an email marketing service or newsletter; Intuit), the UMHealthResearch website for web-based recruitment [16], X, and through Facebook and Instagram using paid advertising.

For each recruitment platform, we created a unique, shortened TinyURL link that led to a web-based recruitment survey for the study so we could track electronic engagement and user data. URL, which stands for Uniform Resource Locator, was first defined in 1994 as “the syntax and semantics for a compact string representation of a resource available through the internet” [17]. In modern terms, a URL is a unique address that identifies a specific web page on the internet. TinyURL is a URL shortening service that allows customers to create branded, customized URLs and track analytics for those URLs [18]. TinyURL allows customers to create shortened, customized links. Today, the terms “URL” and “link” are often used interchangeably. However, a link is defined as a clickable element on a web page that will lead to a specific URL [19]. Each TinyURL link was customized to the platform. All customized links directed participants to the same URL for our recruitment survey.

We offered a US $20 gift card to those who completed the survey, met the study criteria, and participated in the focus groups to incentivize participants to click on the links to our recruitment survey.

Social Media Marketing and Analysis

Photo and banner advertisements were designed to capture the attention of young African American male individuals with the aim of recruiting eligible individuals for this study. Advertisements included images or vector graphics of African American male individuals with headlines calling for the participation of young African American male individuals and visible information on requirements and details about the focus group study, in addition to the US $20 gift card compensation. Advertisements were designed to grab the attention of social media users and were created with bright, appealing colors. The customized TinyURL links, which participants were directed to through our social media advertisements, helped the research team track total clicks, total unique clicks, and total human clicks on our survey link for each recruitment platform (Instagram, Facebook, X, traditional email, Mailchimp, and UMHealthResearch). TinyURL also allowed the research team to track world traffic (where in the world people were clicking on our link), the top browsers and devices people were using, and the popular days and times people were accessing our recruitment survey through Qualtrics (Silver Lake) from each custom link. The survey was developed to evaluate demographic data to determine eligibility for the study in addition to assessing satisfaction with SRH care and behavioral health risk characteristics (eg, sexual activity and substance use).

Additionally, we used Facebook and Instagram Insights (within Meta Business Suite) to further monitor and evaluate the performance of the recruitment campaigns, as well as the audience’s engagement with them. Insights is a tool offered by Meta that provides data and metrics about the performance of profile pages and individual posts on Facebook and Instagram. Using Insights, we were able to track content interactions such as the number of views, likes, comments, and shares, in addition to impressions, reach, link clicks, and profile visits on Facebook and Instagram. We were able to tailor our paid advertisements by sex, age range, and location (male individuals aged between 18 and 24 in Detroit). We tracked the times and days people were the most active on Facebook and Instagram and tailored our posting schedule accordingly with the hopes of increasing engagement with young African American male individuals in our community. Table 1 shows the definitions of terms we used for tracking electronic engagement.
Table 1. Terms and definitions.

**Ethical Considerations**

The University of Michigan Institutional Review Board approved this study (HUM#00156338). All participants were provided with detailed information about the study before participating and were asked to provide their electronic informed consent before beginning the survey. Participants were assured their information would remain confidential and be stored on a secure, password-protected cloud service at the University of Michigan (U-M Dropbox).

**Results**

**Overview**

Overall, using TinyURL metrics allowed us to track important demographic and user information on individuals who clicked on our customized TinyURL links. This information, which is displayed in Table 2, includes the top countries, browsers, operating systems, and devices of the individuals who engaged with our customized TinyURL links. This information was collected in order to gain insight into electronic engagement with our customized TinyURL links and measure the success of our web-based marketing campaigns in reaching our target population. We have chosen to report both total human clicks and total unique clicks on our customized TinyURL links. When measuring successful electronic engagement, we have chosen to focus on total human clicks, as it provides a comprehensive overview of the activity generated by our links and represents whether the same individual clicked on a link more than once. Table 2 reports demographic and electronic user information based on total human clicks, as captured by the TinyURL platform. However, in our analysis we also discuss unique clicks since this information is measured only once, the first time that an individual clicks on the link.

Mailchimp was found to be our most successful platform for electronic engagement, with 245 human clicks and 106 unique clicks on the custom TinyURL link from December 2021 to March 2022. The most popular day users clicked on the TinyURL link for Mailchimp was Thursday, and the most popular times for users were morning and afternoon, occurring between 8 AM and 4 PM. The second-most successful platform was Instagram, which received 190 human clicks and 158 unique clicks from December 2021 to March 2022. The most popular day users clicked on the TinyURL link for Instagram was Sunday, with the clicks being evenly distributed throughout the day. The custom TinyURL link for Facebook found moderate success, receiving 56 human clicks and 46 unique clicks from December 2021 to March 2022. The most popular day users clicked on the custom TinyURL link for Facebook was Monday. Clicks for this link were evenly distributed throughout the day. The custom TinyURL link for X received 39 human clicks and 28 unique clicks from December 2021 to March 2022. Days and times users clicked on the TinyURL link for X were evenly distributed throughout the week and the day. The TinyURL link for traditional email received 31 human clicks and 24 unique clicks from December 2021 to March 2022. These were evenly distributed throughout the week and throughout the day. The custom TinyURL link for UMHealthResearch received 15 human clicks and 10 unique clicks from December 2021 to March 2022. These clicks were evenly distributed throughout the week, falling mostly during weekdays, with the most popular time being in the afternoon and night, occurring between 12 PM and 12 AM.

Instagram and Facebook Insights

In addition to TinyURL metrics, we also used Instagram Insights, Meta Business Suite, and Facebook Insights to measure the performance of our paid advertisements on the 2 platforms. The Instagram Insights feature for businesses allowed us to measure impressions, reach, profile visits, and link clicks for the paid advertisements that we posted on the platform. Using Instagram Insights, we measured impressions, reach, profile visits, and link clicks for 5 paid advertisements from December 2021 to February 2022 (Table 3). Additionally, the use of Meta Business Suite and Facebook Insights allowed us to measure impressions, reach, and link clicks for the posts that we paid to be boosted on the platform. Using Meta Business Suite and Facebook Insights, we measured impressions, reach, and link clicks for 2 paid advertisements in February 2022 (Table 4).
Overview
Our findings suggest that Mailchimp was the most popular platform for electronic engagement, likely due to the fact that we had a well-curated list of email addresses from people who have previously engaged with our research, including colleagues, students, social media site followers, and community members (i.e., individuals residing in Detroit, Michigan, or Southeastern Michigan). The use of Mailchimp allowed us to directly reach this audience and provide them with relevant and targeted content about our SRH care campaign and access to the customized link, resulting in high community engagement. In addition to Mailchimp, we also found that Instagram and Facebook were popular social media platforms for engaging with young people. Our results coincide with the fact that Instagram and Facebook were popular social media platforms for engaging with young people. Instagram is reported to be an especially popular social media platform among young adults and teens, and Facebook remains a widely used platform by a majority of Americans [23].

On the other hand, we found X, traditional email, and UMHealthResearch to be our least successful platforms for electronic engagement. This may have been attributed to several reasons. First, our following on X was smaller than on our other platforms. Second, for emails that were sent, messages may have been filtered as spam and never opened. Traditional emails can be tracked after being sent but only after being opened if connected to an email tracking software system such as Mailchimp [24]. Finally, our advertisements on UMHealthResearch may have faced challenges in attracting engagement due to participants being required to create an account and undergo verification, resulting in a limited sample. UMHealthResearch promoted this study to only individuals who were already using the third-party recruitment platform, so the study advertisement was not as visible compared to other platforms.

Survey Eligibility Results
The survey yielded 525 responses, of which 489 finished the survey and 32 were eligible for the study for focus groups. The survey respondents were removed from the eligible sample if they did not identify as African American or Black (16 removed), were outside of the age range of between 18 and 24 years old (27 removed), did not identify as heterosexual (23 removed), or did not reside in the Southeast Michigan area (391 removed). These exclusions were made to identify an eligible sample.

Discussion
Overview
Our findings suggest that Mailchimp was the most popular platform for electronic engagement, likely due to the fact that we had a well-curated list of email addresses from people who have previously engaged with our research, including colleagues, students, social media site followers, and community members (i.e., individuals residing in Detroit, Michigan, or Southeastern Michigan). The use of Mailchimp allowed us to directly reach this audience and provide them with relevant and targeted content about our SRH care campaign and access to the customized link, resulting in high community engagement. In addition to Mailchimp, we also found that Instagram and Facebook were popular social media platforms for engaging with young people. Our results coincide with the fact that Instagram and Facebook were popular social media platforms for engaging with young people. Instagram is reported to be an especially popular social media platform among young adults and teens, and Facebook remains a widely used platform by a majority of Americans [23].

On the other hand, we found X, traditional email, and UMHealthResearch to be our least successful platforms for electronic engagement. This may have been attributed to several reasons. First, our following on X was smaller than on our other platforms. Second, for emails that were sent, messages may have been filtered as spam and never opened. Traditional emails can be tracked after being sent but only after being opened if connected to an email tracking software system such as Mailchimp [24]. Finally, our advertisements on UMHealthResearch may have faced challenges in attracting engagement due to participants being required to create an account and undergo verification, resulting in a limited sample. UMHealthResearch promoted this study to only individuals who were already using the third-party recruitment platform, so the study advertisement was not as visible compared to other platforms.

The use of customized TinyURL links helped us track which social media platforms were the most effective in reaching young African American male individuals regarding SRH care. TinyURL allowed us to track clicks on each custom URL we created and see information such as country, browser, device, etc from each person. This information can be used to tailor future social media marketing campaigns about SRH to these platforms, which can help to ensure that young African American male individuals have access to the information and resources they need to make informed decisions about their sexual health. Additionally, customized TinyURL links are easy to share and remember, which can lead to stronger engagement, especially with younger populations. Overall, custom TinyURL links allowed us to track clicks on each specific post and advertisement that were the most engaging and which platforms were most effective in reaching people. The information found through tracking TinyURL metrics can then be used to create more effective and engaging content about SRH for young African American male individuals. In addition to informing strategic marketing and content creation, the information from TinyURL metrics can be used to engage young African American male individuals in events and research about SRH care advertised on social media.

By using culturally informed social media advertisements and customized TinyURL links, we were able to effectively engage with young African American male individuals, provide them with information and resources regarding SRH care, and encourage them to seek health care. The results of this study may be useful for improving the effectiveness of future social media marketing campaigns using culturally informed advertising to engage young African American male individuals in SRH care.

Implications
Our findings suggest that customized TinyURL links can be an additional way to promote long-term risk-reduction methods

among young male individuals in the community. Creating a TinyURL link for each platform we used to post content about SRH care allowed us to provide young African American male individuals with an easy way to access information and resources about SRH. By using customized TinyURL links, researchers can engage with young African American male individuals in a memorable, convenient, and trackable way on social media to help this population make informed decisions about their SRH. Custom TinyURL links are convenient and memorable enough to be easily shared between young male individuals, in person or using technology. Researchers using TinyURL can gain insight on how young African American male individuals engage with content and resources provided through those links. Additionally, by tracking which social media platforms are most effective in reaching young male individuals, researchers can target future social media marketing campaigns to these platforms. For example, a clinic seeking to engage with young African American male individuals in their community could use TinyURL to create custom links for their different social media platforms and track which links generate the most engagement. Using customized TinyURL links could inform the clinic’s social media marketing strategy on how to best engage with young African American male individuals about ongoing SRH care, from anonymous surveys to making an annual appointment to chatting with a health care provider virtually.

Limitations
One limitation of this study was the unexpected engagement from users outside the United States, particularly in countries such as Ireland and Kenya, clicking on our links. In the case of Instagram and Facebook, despite us setting target audience parameters for our paid advertisements, such as location, age, and sex, we found that the platforms could not always accurately control who sees the advertisements and limit it to the demographic characteristics of our target population. Factors such as IP address blockers or users intentionally altering their location could also result in engagement from unexpected locations. Additionally, we promoted a US $20 gift card for eligible participants who completed the survey, which could have attracted users from different countries to click on our links, potentially resulting in engagement from a wider audience than initially intended. Further research would be needed to draw definitive conclusions about the reasons for engagement with specific countries. As a result, the generalizability of our findings may be limited.

Another limitation of this study was the high number of survey responses that were ineligible for the study. Out of 525 total responses, only 489 participants completed the survey, and only 32 were ultimately eligible for the study to participate in focus groups. This may be due to web-based social media targeting not being geographically limited enough or the focus on the city of Detroit not being prominent enough in the advertisements, leading to responses from participants who did not meet the study criteria. Additionally, social media platforms such as Instagram and Facebook, where we ran paid advertisements, did not offer the option to specify ethnicity or race when targeting an audience for advertisements, which may have resulted in a large number of responses from participants who did not align with our target population. Meta, the parent company of Facebook and Instagram, removed certain advertisement targeting options that included race, religion, sexual orientation, and political affiliation in January 2022 [25]. Meta’s detailed targeting advertising options are often changing and being refined, and options to target certain specific groups may not always be available [26]. Additionally, there is no guarantee that your advertisement will only be shown within your specific geographic target area; this poses an inherent challenge when using a recruitment strategy for your target population that is centered on social media [27]. This limitation makes it difficult to tailor our recruitment methods, making it difficult to ensure we reach the correct pool of participants. This makes social media advertising somewhat unpredictable, and the effectiveness of this method may be limited by this factor. This inherent limitation calls for a more tailored approach in the design and use of participant recruiting social media advertisements, in addition to rigorous screening to ensure the internal validity of the results.

In reviewing TinyURL metrics for our links, there were missing data as we noticed that TinyURL could not capture all information on country, browser, operating system, and device for all recorded total human clicks for the links we created. For example, with Instagram, while TinyURL had data regarding the top countries for all 190 total human clicks when it came to reviewing the top browsers, TinyURL only had information for 188 of those clicks. For top operating systems, TinyURL only had information for 184 of those clicks. TinyURL identifies these data using user agent strings [20], which may be blocked by specific devices or browsers due to privacy settings. This aspect is important as it limits the collection of these data from users who click on customized links. However, this limitation may have had minimal impact on the insights and conclusions, as information was still viewable to the majority of the users who were able to access and click our links.

In addition, our use of social media as a recruitment strategy may have limited the pool of participants for this study. By using this method, we may have inadvertently excluded those without internet access and those who do not use or do not have social media accounts. It is important to note that social media approaches typically come with this selection bias, and it is important to acknowledge that this may have recruited from a skewed pool of applicants.

Furthermore, we encountered issues with spam responses and participants who may have been solely interested in winning the gift card, which could have affected the validity of our results. A solution to this would be setting up multiple captchas at different phases of the survey (eg, eligibility or payment) or advertisement to assess for human use.

Conclusion
Using customized, shortened URLs and TinyURL metrics to study social media engagement specifically to promote SRH care among young African American male individuals is innovative and provides future researchers with the potential to discover valuable insights into how to reach this population both locally and globally with sexual health information and resources. Social media is a powerful tool that can be leveraged
to reach young people with information about SRH care. TinyURL links offer a modern, quick means to engage with people about SRH care and track their electronic engagement. Customized TinyURL links, in conjunction with culturally informed advertisements and content, can be shared on popular social media platforms to engage with young African American male individuals seeking information and resources about SRH care. The findings from this study have the potential to inform future literature on the topic of improving electronic engagement and content creation with SRH care in unique spaces among young African American male individuals.

Acknowledgments
The authors want to thank the University of Michigan School of Nursing Center for Sexuality and Health Disparities, the Ginsberg Center, and Detroit Community Health Connection for their support. A special thank you to research staff Nidhi Kandi, Julian Lanum, Yi-Chia Hwang, and Freda Frimpong for their contributions to the Stay Safe Project.

Data Availability
The data sets generated and analyzed during this study are not publicly available due to ethical concerns about maintaining the confidentiality of survey participants’ personal information but are available from the corresponding author on reasonable request.

Conflicts of Interest
None declared.

**Abstract**

**Background:** Cancer is the leading cause of death in Canada, and living with cancer generates psychological demands, including depression and anxiety among cancer survivors and caregivers. Text4Hope-Cancer Care SMS text messaging–based service was provided to people with cancer and caregivers during the COVID-19 pandemic to support their mental health.

**Objective:** The aim of this study is to examine the clinical effectiveness of and satisfaction with Text4Hope-Cancer Care in addressing mental health conditions among people living with cancer and caregivers.

**Methods:** The study was conducted in Alberta, Canada. People who were diagnosed or receiving cancer treatment and caregivers self-subscribed to receive 3-months daily supportive cognitive behavioral therapy–based SMS text messages and a web-based survey was sent at designated time points to collect clinical and nonclinical data. The Hospital Anxiety and Depression scale (HADS) was used to examine changes in anxiety and depression symptoms after receiving the service. Satisfaction with the service was assessed using a survey with a Likert scale. Descriptive and inferential statistics were used, and test significance was considered with \(P \leq 0.05\).

**Results:** Overall, 107 individuals subscribed to the service, and 93 completed the program (completion rate 93/107, 86.9%). A significant improvement in the anxiety symptoms (HADS-Anxiety [HADS-A] subscale) was reported after 3 months of Text4Hope-Cancer Care \((t_{11}=2.62; \ P=0.02)\), with medium effect size (Hedges \(g=0.7\)), but not depression symptoms (HADS-Depression [HADS-D] subscale). Subscribers expressed high satisfaction and agreed that the service has helped them to cope with mental health symptoms and improve their quality of life. Most subscribers read the SMS text messages more than once (30/30, 100%); took time to reflect or took a beneficial action after reading the messages (27/30, 90%); and highly agreed (27/30, >80%) with the value of the received supportive SMS text messages as being relevant, succinct, affirmative, and positive. All subscribers recommended SMS text messaging for stress, anxiety, and depression and for cancer care support (30/30, 100%).

**Conclusions:** Text4Hope-Cancer Care was well-perceived and effectively addressed anxiety symptoms among people living with cancer and caregivers during the peak of the COVID-19 pandemic. This study provides evidence-based support and insight for policy and stakeholders to implement similar convenient, economic, and accessible mental health services that support vulnerable populations during crises.

**International Registered Report Identifier (IRRID):** RR2-10.2196/20240
Introduction

Cancer is the leading cause of death and is responsible for 28.2% of all deaths in Canada [1]. The disease mostly affects Canadians aged 50 years and older, but it can occur at any age [1]. In 2018, 1.5 million Canadians were living with or survived cancer [1,2]. However, newly diagnosed cases are projected to increase by 40% between 2015 and 2030 [1].

Living with cancer generates ongoing psychological demands that impose a heavy toll on patients and caregivers (a person who takes care of a patient with cancer) [3]. Depression and anxiety are common mental health conditions among cancer survivors, with nearly 30% reporting clinical symptoms of depression and 40% for anxiety [4,5]. These numbers vary according to different types of cancers [4,5]. Similar results were found for caregivers, where about 1 in 2 experienced symptoms of depression and anxiety. These rates may be as high as 65% and 91% for mothers of children living with cancer [3,6].

Cancer survivors often report depression and anxiety symptoms, including the fear of the recurrence of cancer, low emotional support, social isolation, and feeling lonely or abandoned after the intensive support during the phase of the treatment [4,7-9]. Depression and anxiety symptoms negatively impact the health of cancer survivors and caregivers by eroding quality of life, decreasing treatment compliance, and increasing the risk of morbidity and mortality [4,8,10].

Several interventions have been proposed to address psychological symptoms among cancer survivors and caregivers. These interventions can include educational, cognitive, or mindfulness-based therapies which are effective in addressing mental health symptoms [11,12]. However, these interventions (eg, in-person or facilitated by trained personnel) can be costly and time-consuming when compared to mobile-based interventions (eg, internet-based cognitive behavioral therapy (iCBT) or SMS text messages) that do not require a specialist facilitator [10,13,14].

Furthermore, a major body of literature suggests that remotely delivered interventions are impactful and effective in improving mental health compared to face-to-face services [15,16]. Web-based resources have been embraced as potential solutions that can cross the likely gap between evidence-based therapies and community practice, the gap which has thrived by stigma, underrecognition of psychological symptoms and lack of trained professionals [15,17,18].

SMS text messaging has demonstrated effectiveness in the treatment and prevention of mental disorders among diverse populations [19-22]. SMS text messaging services such as Text4Support effectively reduced the risk of harm to self and other harm symptoms after 6 months of intervention in a randomized controlled trial [23] and improved distress, anxiety, and depression in clinical samples [24]. Similarly, the Text4PTSI program has achieved fidelity and significantly reduced psychological distress among public safety personnel post intervention [25,26]. SMS text message–based population-level messaging programs have reported user satisfaction rates of well over 80%, and most subscribers have reported feeling connected to support systems and improving their ability to manage anxiety, depression, and general life issues, suggesting an improvement in mental health literacy [15,27-29].

In this project, Text4Hope-Cancer Care SMS text message–based service was provided to people living with cancer and caregivers during the COVID-19 pandemic. The service aimed to support their mental health by providing a daily supportive SMS text message based on cognitive behavioral therapy (CBT) principles. The service is designed to reduce stress, anxiety, and depression symptoms associated with the pandemic among this vulnerable population. In this project, we report the results of the Text4Hope-Cancer Care program regarding its clinical effectiveness in addressing mental health conditions and the satisfaction among people living with cancer and caregivers 3 months after receiving the service.

Methods

Study Design and Setting

The study was conducted in Alberta, Canada, where patients diagnosed or receiving cancer treatment and caregivers were eligible to self-subscribe to receive a daily supportive SMS text message for 3 months. The messages were crafted with a CBT framework and were developed by a clinical psychologist, and then reviewed and revised by a multidisciplinary team of psychiatrists, mental health therapists, and counselors who work with patients with cancer and caregivers (Text4Hope-Cancer Care is part of the primary Text4Hope service, which was introduced to support the mental health of the general public during the COVID-19 pandemic among Albertans [30]).

Examples of the Text4Hope-Cancer Care messages are (1) do things you enjoy—these activities can remind you who you are and take your mind off cancer for a while; (2) advocate for your needs using assertiveness—assertiveness is being respectful to you and the other person. Be direct, nonaggressive, and specific; and (3) cancer affects the whole family—to help you and your family cope, try to maximize quality time together, communicate, and create a schedule together.

Ethical Considerations

Participation in the program was voluntary, and completion of the survey did not preclude receipt of subsequent supportive SMS text messages. Subscribers could opt out of the service at any time, and no incentives or inducements for participating in...
the program were offered. Further details of the methodology are described in the study protocol [31]. The study was conducted according to the guidelines of the Declaration of Helsinki. Ethics approval has been granted by the University of Alberta Health Research Ethics Board (Pro00086163).

**Data Collection**

Data collection was run at baseline, 6 weeks, and 3 months, and subscribers were invited to complete these surveys via a link embedded in the received SMS text message at the designated time points. Survey questions were programmed into Select Survey, a web-based survey tool [31].

Overall, 107 subscribers participated in Text4Hope-Cancer Care program during the period between March 19, 2020, and December 19, 2022, and 14 subscribers opted out of the service (14/107, 13.1%), leaving 93 who completed the service (program completion rate of 93/107, 86.9%). From Figure 1, 49 subscribers responded to the surveys across all study time points, yielding a response rate of (49/107, 45.8%). There were a total of 65 eligible surveys received (35 at baseline and 30 at follow-up time points 6 weeks and 3 months), and only 12 subscribers have completed both the baseline and follow-up surveys. Survey questions were designed based on study objectives and available evidence from peer-reviewed literature [28,29]. The survey consisted predominantly of categorical items with Likert-scale responses and few continuously rated items. The items included sociodemographic characteristics such as gender, age, ethnic background, educational level, relationship status, employment status, and housing condition; and COVID-19–related data, such as self-isolation or quarantine due to the pandemic and perspectives regarding the likelihood of contracting COVID-19. The survey additionally included items related to cancer conditions, such as the duration of cancer diagnosis, treatment received for cancer therapy, and treatment postponed due to the COVID-19 pandemic for the participants and the loved ones who were diagnosed with cancer, if any. Clinical and service satisfaction data were also collected.

**Figure 1.** Study flowchart.

**Outcome Measures**

**Hospital Anxiety and Depression Scale**

To assess the effectiveness of the Text4Hope-Cancer Care service, the Hospital Anxiety and Depression Scale (HADS) was used and presented with the 2 subscales HADS-Depression (HADS-D) and HADS-Anxiety (HADS-A) [32]. Each HADS subscale contains 7 items; each item has 4 responses with an ordinal score from 0 to 3 and a total score between 0 and 21 in each subscale, with higher scores denoting higher levels of anxious or depressive state [33]. Some items have reversed responses (ie, from 3 to 0 [3 items for HADS-D and 5 items for HADS-A]). The scale reports how participants felt and behaved during the past week [33]. Since the scale is devoid of items related to somatic symptoms or symptoms of severe psychiatric illness, it was designed to detect the common mental disorders of depression and anxiety in the adult population attending medical (nonpsychiatric) outpatient clinics [33-35]. A total score of 0-7 is considered normal, 8-10 is considered borderline abnormal (borderline case), and 11-21 is considered abnormal (case) [32].
Based on previous studies, the sensitivity and specificity of approximately (0.80) were achieved when a cutoff score of 8 or above was used to define caseness (defined as the possible and probable anxiety disorders and depression among patients in nonpsychiatric hospital clinics [32]), on both HADS-A and HADS-D subscales [34]. Cronbach $\alpha$ for HADS-A was 0.83 (ranging from 0.67 to 0.90), and for HADS-D was 0.82 (ranging from 0.67 to 0.90), and the correlation between the 2 subscales was 0.56 [34]. For this study, the mean scores of HADS subscales were used to detect the differences between the study groups and also to trace changes over time.

**Satisfaction Measures**

A satisfaction questionnaire was provided to collect data related to the dimensions of the study. The dimensions considered included acceptability of the service (subscriber satisfaction or experience), appropriateness (subscriber feedback related to how helpful the daily messages have been in relation to their mental health and cancer diagnosis during the COVID-19 pandemic), and subscribers’ opinion about the use of technology-based services as part of health care during crises times.

**Sample Size Calculation**

Using a web-based script [36], we estimated that the sample size needed to assess the effects of the daily supportive SMS text messages among patients with cancer and caregivers on the outcome variables would be 34 with a projection that the effect size for the reduction in mean HADS-D and HADS-A scores at 3 months from baseline would be 0.2, a population variance of 1.0 for each subscale mean score, a 2-sided significance level $\alpha=0.05$, and a power of 80% ($\beta=0.2$).

**Statistical Analysis**

Descriptive statistics were performed, and chi-square or Fisher exact tests were used to define the distribution of categorical sociodemographic and cancer-related factors against 2 groups of subscribers. The first group (completers) refers to those who completed baseline and follow-up surveys, while the second group (noncompleters) refers to those who responded only to 1 survey. A post hoc analysis was run for the categorical variables with more than 2 response options when it showed a significant association, using adjusted residuals and $z$ score test. A corrected $P$ value was reported on this occasion ($P$ value $\times$ number of comparisons). An independent 2-tailed $t$ test was used to compare the continuous data of baseline mean scores of HADS subscales between the completers and noncompleters.

To examine the changes before and after receiving Text4Hope-Cancer Care Subscription Information text messages for the completers group, a paired $t$ test was used to find the difference in the mean scores of anxiety and depression HADS subscales from baseline to follow-up time points. Imputation of the missing data was applied using the Last Observation Carried Forward method, that is, the last observation (6 weeks) was carried forward (imputed) when the latest response (3 months) was missing [37]. Due to the small sample size of the completers ($n=20$), Hedges $g$ effect size was reported when the result showed significance.

For the satisfaction data, descriptive analysis was run with frequency and percentage for reporting data, using bar graphs. SPSS (version 28; IBM Corp) [38] was used to perform the statistical analysis and statistical test significance was considered with $P\leq0.05$.

**Results**

**Text4Hope-Cancer Care Subscription Information**

At baseline, subscribers were asked (multiple response questions) about their source of knowledge about the Text4Hope-Cancer Care service. The majority heard about the service from a website, such as Alberta Health Services or Mental Health Foundation websites (13/35, 37.1%), followed by social media platforms, such as Facebook and Instagram (Meta Platforms: 7/35, 20.1%). The news (eg, newspaper, web-based articles, and television), advice from a health care professional, and word of mouth (eg, family, friend, and coworker) were equally reported by the subscribers (5/35, 14.3%) each. Other sources such as employers, posters, and public libraries were also reported.

**Baseline and Sociodemographic Characteristics**

Table 1 presents the results of sociodemographic, cancer-related, and clinical characteristics of the study sample. From the table, (16/48, 33.3%) of the participants were between 50 and 59 years inclusive. Participants were predominantly females (42/48, 87.5%), White (47/48, 97.9%), had attained postsecondary education (40/44, 90.9%), were in a relationship (35/44, 79.5%), had employment (25/44, 56.8%), and owned their homes (30/44, 68.2%).

Regarding COVID-19–related questions, nearly a third of the subscribers reported needing to self-isolate or quarantine during the pandemic (15/48, 31.3%). The majority were neutral regarding the likelihood that they will contract COVID-19 (16/35, 45.7%); however, compared to someone who has not been diagnosed with cancer and is not receiving treatment for cancer, half of the subscribers reported that they would more likely contract COVID-19 (9/18, 50%).

Regarding cancer-related data, there were 18 cancer cases and 17 caregivers responded to the survey at baseline. The duration of having a diagnosis of cancer was majorly split between less than 6 months, and 1 year or more duration (7/18, 38.9%), each. In terms of the received treatment for cancer, the highest proportions were reported for surgery (10/18, 55.6%) and chemotherapy (9/18, 50.0%). Having cancer treatment or surgery postponed due to the COVID-19 pandemic was reported by a few participants (3/18, 16.7%).

In terms of the questions related to the loved ones of the participants, most participants reported having had 3 or more loved ones diagnosed with cancer and received treatment for cancer (9/16, 56.3%); having a loved one passed away due to cancer (14/17, 82.4%); mostly were a partner or a parent (6/17, 35.3%, each); the loved one was diagnosed with cancer for 1 year or more (10/17, 58.8%); having received either surgery and chemotherapy (6/17, 35.3%, each); and the majority reported having their loved ones’ cancer treatment or surgery postponed due to the COVID-19 pandemic (15/17, 88.2%).
Table 1. Distribution of the characteristics of the participants who responded to baseline and follow surveys (completers) and the participants who responded to only 1 survey (noncompleters).

</table>
Regarding group differences, only 2 questions from above showed significant differences between completers and noncompleters. A significantly higher proportion of completers reported receiving chemotherapy (6/12, 50.0%) compared to noncompleters (3/23, 30.4%; \( P = .049 \)). Similarly, there was a significant difference regarding the loved ones who were diagnosed with cancer \( (P = .047) \). Post hoc analysis revealed that the proportion of the participants who had a child diagnosed with cancer who completed 2 (50%) surveys was significantly more than expected when compared to those who completed only 1 (0%) survey among the same group \( (z \text{ score} = 2.7; \text{ adjusted } P = .03) \).

Regarding the clinical assessment, the independent t test revealed no significant difference between completers and noncompleters at their baseline scores of HADS-D \( (t_{31} = 0.09; P = .93) \) and HADS-A \( (t_{31} = 0.28; P = .78) \) subscales.

### Clinical Outcome Results

Table 2 shows the changes in the mean scores of the primary outcome subscales, HADS-D and HADS-A, after 3 months from the baseline for participants who completed both the baseline and other follow-up surveys (completers). As illustrated in Table 2, the participants recorded lower mean scores on both HADS-D and HADS-A subscales at follow-up compared to their mean scores at baseline. However, only the HADS-A subscale was statistically significant \( (t_{11} = 2.62; P = .02) \), with a medium effect size \( (g = 0.7) \).

### Satisfaction Data

#### Overview

The feedback regarding the receptivity and satisfaction with Text4Hope cancer care service was reported by the subscribers at the follow-up time points \( (n = 30) \), that is, after receiving the service.

#### Benefits of Text4Hope-Cancer Care SMS Text Messages

Figure 2 demonstrates participants’ satisfaction measure data in relation to their perceived mental and physical health. The figure showed that the majority of the subscribers agreed that the messages have helped them to cope with symptoms related to cancer diagnosis, including stress (23/30, 76.7%), anxiety (21/30, 70%), depression (18/30, 60%), and loneliness (17/30, 56.7%). Similarly, most participants agreed that the supportive SMS text messages helped them feel connected to a support system (25/30, 83.3%), feel hopeful that they can manage issues related to cancer diagnosis (21/30, 72.4%), and that the messages improved their overall mental well-being (23/30, 76.7%). However, only 16 (53.3%) participants agreed that the messages enhanced their quality of life.
Figure 2. Appropriateness of Text4Hope-Cancer Care SMS text messages with patients’ mental well-being and cancer diagnosis.

Receptivity of the Supportive SMS Text Messages

Figure 3A demonstrates that most subscribers agreed that the SMS text messages were always or often relevant (20/29, 69%), succinct (24/28, 85.7%), affirmative (24/29, 82.8%), and positive (27/30, 90%).

In regard to reading the SMS text messages and actions taken after, Figures 3B and 3C show that all subscribers reported reading the messages (30/30, 100%). Similarly, the majority reported their return to read the messages (27/30, 90.0%), and they agreed that after reading the messages, they took time to reflect on the messages (23/30, 76.7%).

Figure 3. Receptivity of the supportive SMS text messages. (A) Agreement that the text messages were relevant, succinct, affirmative, and positive. (B) Reading the text messages. (C) After receiving the Text4Hope cancer care text messages.
**Overall Satisfaction With the Received Supportive SMS Text Messages and Preference of Their Schedule**

Figure 4 shows that most subscribers were satisfied with the service (28/30, 93.3%), preferred receiving the messages once per day (22/30, 73.3%), and the majority preferred the SMS text messages for a 12-month period (13/30, 43.3%).

**Opinions About the Use of Technology-Based Services as Part of Health Care**

Figure 5 demonstrates that most subscribers were in agreement that everyone struggling with cancer in times of crisis, such as the COVID-19 pandemic, would recommend technology-based services as part of their health care. The top-rated recommended items were SMS text messaging for stress, anxiety, and depression (13/13, 100%); SMS text messaging for cancer care support (13/13, 100%); and telephone counseling for stress, anxiety, and depression (13/13, 100%). These were followed by consultation via telephone conferencing for physical (12/13, 92.3%) and mental health care (12/13, 92.3%); consultation via videoconferencing for mental health care (12/13, 92.3%); telephone counseling for cancer care support (12/13, 92.3%); and web-based counseling for stress, anxiety, and depression (12/13, 92.3%). Following that, web-based counseling for cancer care support was recommended by 11 (84.6%) participants. Notably, email services were relatively less preferred by the study subscribers, including email messaging and support for stress, anxiety, and depression (8/12, 66.7%), and email messaging and support for cancer care support (8/12, 66.7%).
Discussion

Principal Findings

This study was designed to address mental health burdens among people living with cancer and caregivers in Alberta, Canada, during the COVID-19 pandemic, using the Text4Hope-Cancer Care service. The study also examined the satisfaction of the end users with the provided service. Overall, 93 subscribers completed the Text4Hope-Cancer Care program, and 49 responded to all surveys across study time points. The principal finding of this study was the significant improvement in anxiety symptoms among the people living with cancer and caregivers who received a daily message for 3 months of Text4Hope-Cancer Care service. Although there was an observed improvement in depressive symptoms after 3 months of receiving daily supportive SMS text messages, the difference was not statistically significant.

Text4Hope cancer care represents a supportive approach provided to a vulnerable population who have been already disadvantaged by their cancer diagnosis during the pandemic time, where operations were canceled, appointments and medical care was disrupted or delayed, and hospitals were closed due to national lockdowns and pandemic obligations [3,39,40]. Other research has tapped into the need for mental health support for people living with cancer and caregivers using diverse modalities, such as cognitive or mindfulness-based, acceptance and commitment, supportive-expressive, educational, and meaning-centered psychotherapy [11,41,42]. Our findings were not different from other SMS text messaging services provided in different contexts. Text4Support, for example, has demonstrated clinical effectiveness in reducing the risk of harm to self and other harm symptoms after 6 months of intervention in a randomized controlled trial [23,24]. The findings from this study, however, contradict findings from other studies in relation to addressing depressive symptoms. In 2 randomized controlled trials that used supportive SMS text messages, patients with depression showed symptom reduction on standardized self-report scales compared to a patient group not receiving messages (with large effect sizes: Cohen $d=0.85$ and 0.67) [21,22]. This could be explained by the heavy toll that those who live with cancer or caregivers are experiencing, particularly, during the COVID-19 pandemic. It is, however, possible, that the participants’ baseline depression would have deteriorated across the study time points without the daily supportive SMS text messages. Due to ethical considerations, this study did not include a control group who would not have received the supportive messages during the pandemic, to compare them to those who have received the service.

During the COVID-19 pandemic, people need to feel connected to a health support system. Therefore, several initiatives that included SMS text messaging services were provided and have reported comparative effectiveness to our study. Text4Hope service was provided to support the mental health of the general public in Alberta; the service reported quite similar findings to our study, where a significant reduction in stress, anxiety, depression symptoms, and suicidal ideation was achieved [14,30,43,44]. Another related service, the Text4Hope-Addiction program, was introduced to people living with substance use disorders; the service reported significant improvement in
standardized measures for craving, anxiety, and depression in subscribers [45]. Similarly, the Text4PTSI program significantly reduced psychological distress among public safety personnel postintervention [25,26].

The gap in the health care service experienced by patients living with cancer seems evident and could be attributed to the lack of social and mental health support. A recent systematic review of 33 studies has highlighted the lack of social support, among others, as an exacerbating factor within the social construct for developing depression and anxiety among older patients living with cancer [9]. Such mental health symptoms, particularly depression, are linked to increased risk of mortality among people living with cancer due to psychosocial reasons such as reduced adherence to therapy and appointments; thus, the accessibility to cancer control activities and mental health support can control cancer incidence, morbidity, and mortality rates [1,9].

Our study noticed that most of the subscribers were recently diagnosed and living with cancer for less than 1 year, compared to the caregiver group, whose loved ones were living with cancer for more than 1 year. This may reflect the critical and intense periods in which these vulnerable groups may need mental health support that can span over the duration of the disease, during its early stages, as seen with people living with cancer, or later as seen with caregivers. From the literature, it was reported that the third to fifth year after diagnosis is a period that typically requires close clinical follow-up, as well as supportive care, compared to 5 years after the diagnosis, where most survivors would likely have completed their treatment [1].

Another observation in this study is that caregivers whose children were diagnosed with cancer were more committed to completing the follow-up surveys. This was supported by the fact that childhood cancer diagnosis impacts the entire family, who in turn need mental health support [46]. Aligned with this observation, a population-based cohort study in Ontario reported that the mothers of children with cancer had an increased rate of mental health outpatient visits compared to mothers in the general population [46]. This observation has persisted over decades of follow-up, reflecting the critical needs along with the commitment of the mothers of children with cancer to the provided mental health support services.

Regarding the satisfaction with the service, study subscribers expressed a high degree of satisfaction with the service in terms of coping with mental health symptoms, such as anxiety and depression and improved overall mental well-being. The subscribers highly agreed with the value of the received supportive SMS text messages, as being relevant, succinct, affirmative, and positive. These results were not different from the satisfaction levels achieved with similar services. Among the users of Text4Mood and Text4Hope, more than 3 in 4 have also endorsed an improvement in their ability to manage anxiety, depression, and general life issues, suggesting an improvement in their resilience and mental health literacy [28,29]. Several SMS text message–based population-level SMS text messaging programs have reported user satisfaction rates of well over 80% [15,27,28]. Similarly, most of Text4Mood and Text4Hope respondents reported feeling connected to support systems, as compared to our study [28,29]. In the same context, well above 50% (16/30) of the subscribers reported that the service has improved their quality of life. This parameter is of particular importance in people living with cancer who often report marked unmet survivorship care needs that consequently compromise their quality of life [8].

Participants’ responses showed satisfaction with the SMS text messages’ content and frequency. Most subscribers read the SMS text messages more than once and took time to reflect or take beneficial action after reading the messages. A similar result was obtained with Text4Hope and Text4Mood services, where more than 1 in 5 reported returning to read the SMS text messages [28,29]. Most subscribers (13/30, 43%) preferred receiving the SMS text messages for a 12-month period, as compared to lower populations who opted for 3 (23%) or 6 (27%) months. This may reflect the significant psychological burden imposed by cancer diagnosis and the ongoing need for psychological support services that give them a sense of belonging and attachment to a health care system, particularly during the tough time of the COVID-19 pandemic. Therefore, the study participants probably opted for an extended length of the service to maintain the same sense of security and belonging.

Seeing the technology services, that could be part of the health care system, support people struggling with cancer during crisis times, SMS text messaging and phone counseling were among the top-rated care services either for mental health issues or cancer-related care. This was not surprising since, nowadays, phones represent an integral part of almost everyone’s life that could facilitate communication and provide channels of support when other conventional lines are obstructed or disrupted due to crises, such as the COVID-19 pandemic. Notably, compared to phone services, email services were relatively less preferred by the study subscribers. This could be attributed to the lack of accessibility to the internet required to access emails, particularly compared to the widely spread phones and available cellular plans.

Digital technology, therefore, introduces future opportunities to support the development of a scalable mental health workforce with the potential to leverage these technologies for integrating into mental health care, particularly for people with severe mental illness and economically disadvantaged communities [19,47,48].

Strengths and Limitations

The study is not without limitations. The low number of subscribers to the program was one of the limitations that curbed the evidence of Text4Hope cancer care to be evaluated among the rest of the community of people living with cancer and caregivers. Notwithstanding, the study reached the desired sample size as previously determined. The dropout rate of this study was aligned with other SMS text messaging services, such as Text4Hope Canada, where the dropout rate was similar (13%) and relatively higher than other web-based services (eg, iCBT) with a reported adherence rate of (52.8%) [10,43]. It is also of note that this study did not report on the time points at which the subscribers dropped out of the study (n=14); this information could have been helpful in better understanding the receptivity of the service among the targeted population and supporting...
the planning of future support services. Additionally, although the response rate was relatively low (49/107, 45.8%), as compared to the program completion rate (93/107, 87%), lower response rates are usually encountered with such web-based surveys, particularly when no monetary incentives were used, as the case in this study [43,49,50]. On the other hand, the relatively high response rate is one of the strengths of the study which reflects subscribers’ commitment to provide their feedback; thus, the results of the study could be generalized to all cohorts of the study.

Conclusions

Text4Hope-Cancer Care represents the health system and community response to close the gap during the pandemic time via providing mental health support to a vulnerable sector of the community during the pandemic time. The service was well-perceived and has successfully achieved significant effectiveness in addressing anxiety symptoms among people living with cancer and caregivers during the peak time of the COVID-19 pandemic. Compared to the costly and time-consuming conventional interventions, the SMS text messaging service represents a scalable, cost-effective intervention that can be used on any mobile technology, does not require technical skills, and does not require expensive data plans. This study provides the necessary evidence-based support and insight for policy and stakeholders to implement and guide future resource allocation to convenient, economic, and accessible mental health services that support vulnerable populations during crises.

Acknowledgments

This study was supported by grants from the Mental Health Foundation, the Calgary Health Trust, the University Hospital Foundation, the Alberta Children’s Hospital Foundation, the Royal Alexandra Hospital Foundation, and the Alberta Cancer Foundation. The funder had no role in the design and conduct of the study, collection, management, analysis, interpretation of the data; preparation, review, and approval of the study; or the decision to submit the results for publication. Support for the project was received from Alberta Health Services and the University of Alberta.

Abstract

Background: The self-monitoring of physical activity is an effective strategy for promoting active lifestyles. However, accurately assessing physical activity remains challenging in certain situations. This study evaluates a novel floor-vibration monitoring system to quantify housework-related physical activity.

Objective: This study aims to assess the validity of step-count and physical behavior intensity predictions of a novel floor-vibration monitoring system in comparison with the actual number of steps and indirect calorimetry measurements. The accuracy of the predictions is also compared with that of research-grade devices (ActiGraph GT9X).

Methods: The Ocha-House, located in Tokyo, serves as an independent experimental facility equipped with high-sensitivity accelerometers installed on the floor to monitor vibrations. Dedicated data processing software was developed to analyze floor-vibration signals and calculate 3 quantitative indices: floor-vibration quantity, step count, and moving distance. In total, 10 participants performed 4 different housework-related activities, wearing ActiGraph GT9X monitors on both the waist and wrist for 6 minutes each. Concurrently, floor-vibration data were collected, and the energy expenditure was measured using the Douglas bag method to determine the actual intensity of activities.

Results: Significant correlations \((P<.001)\) were found between the quantity of floor vibrations, the estimated step count, the estimated moving distance, and the actual activity intensities. The step-count parameter extracted from the floor-vibration signal emerged as the most robust predictor \((r^2=0.82; P<.001)\). Multiple regression models incorporating several floor-vibration–extracted parameters showed a strong association with actual activity intensities \((r^2=0.88; P<.001)\). Both the step-count and intensity predictions made by the floor-vibration monitoring system exhibited greater accuracy than those of the ActiGraph monitor.
Conclusions: Floor-vibration monitoring systems seem able to produce valid quantitative assessments of physical activity for selected housework-related activities. In the future, connected smart home systems that integrate this type of technology could be used to perform continuous and accurate evaluations of physical behaviors throughout the day.

Introduction

There is evidence associating regular physical activity with lower risks for mortality and noncommunicable diseases [1], encouraging researchers, policy makers, and health care companies to develop strategies for the promotion of active lifestyles. The self-monitoring of physical behavior is one approach that has been described as effective for helping people increase their level of physical activity [2-5]. The recent expansion of the activity tracker device market has opened new perspectives for the promotion of active behavior [3,6].

Technology that enables the objective assessment of physical behaviors has evolved considerably over the past decades [7]. Modern activity trackers are generally worn at the waist or the wrist, and while the most recent devices usually feature multiple sensing abilities, the evaluation of physical behaviors mostly results from the treatment of acceleration data acquired by an integrated 3-axis microelectromechanical accelerometer sensor chip [8]. Software tools are able to compute a wide range of parameters related to physical behaviors, such as sedentary time, step count, and estimated energy expenditure [9]. Activity tracker devices can be paired with smartphone apps, transforming smartphone handsets into genuine hubs for the monitoring of physical activity and sedentary behaviors. Although waist- and wrist-worn activity tracker devices have been linked to inaccurate energy expenditure predictions [10-12], the emergence of the 5G and Internet of Things devices opens up room for more accurate and continuous monitoring, where multiple connected devices can collect a wealth of information about people’s physical behaviors throughout the day. In such a connected environment, and while housework-related activities account for a substantial proportion of daily physical activity in some populations [13], smart home systems could provide crucial information to (1) support the continuity of the monitoring of physical activity and sedentary behaviors when people stay at home by allowing them to remove their wearable activity tracker device and (2) improve the accuracy of energy expenditure predictions related to home-based activities. However, although various smart home projects have already included technological features allowing monitoring of the physical behaviors of the occupants, to date, the information has mainly been used as input to smart appliances to adapt to the living environment, assist occupants with disabilities, or optimize domestic energy consumption [14-17]. In these projects, various monitoring technology devices have been considered, including motion sensors, low-resolution video cameras, Kinect systems (Microsoft), and accelerometer-based wearable monitors [16,18-20]. Floors with sensing capabilities have also been developed. For instance, binary pressure detection floor systems have been used to detect the position of occupants [21,22]. Floor geophones and accelerometer sensors have been used to locate footsteps or evaluate room occupancy [23,24]. Unfortunately, none of these projects have prioritized the objective and quantitative assessment of physical behaviors with the ultimate goal of providing lifestyle-oriented feedback to the occupants. Nevertheless, smart home systems capable of monitoring physical activity and sedentary behaviors while providing feedback to the occupants have the potential to encourage individuals to adopt more active and healthier behaviors throughout the day [2-5].

In this study, the floor-vibration measurement system of the experimental Ocha-House was used to collect information about the floor vibrations generated by the occupant and estimate the energy expenditure and step count. A structured experiment consisting of the completion of 4 typical home-based activities was conducted to assess the validity of these estimations with respect to the actual measurements performed by indirect calorimetry (energy expenditure) and direct observation (step count). The estimations of the floor-vibration monitoring system were also compared with those of wrist- and wrist-worn research-grade activity tracker devices. It is hypothesized that the floor-vibration monitoring system is capable of correctly predicting energy expenditure.

Methods

The Ocha-House Project

The experimental Ocha-House is in the Bunkyo district in the central area of the Tokyo metropolitan region. The project was originally designed as a ubiquitous computing house that allows the mounting of various sensing devices [25]. According to Japanese standards, the Ocha-House corresponds to an extended 1LDK dwelling, that is, a 1-bedroom apartment with a kitchen separated from the living and dining areas. An overview of the building and experimental area is shown in Figure 1.
Figure 1. Overview of the Ocha-House and the experimental area. (A) External view of the building (image captured from southwest corner of the yard). (B) Plan of the house and the experimental area, with furniture indicated in light gray, and green squares (labeled 1-8) indicating sensor positions. The house comprises 2 distinct areas separated by a wall. The west side features a fully open space housing a bedroom corner and a living room without any additional partition wall. On the east side, the kitchen and dining room are interconnected through an open space. The toilet and bathroom corners are situated in enclosed spaces on the east side of the building.

The experimental Ocha-House is in the Bunkyo district in the central area of the Tokyo metropolitan region (Figure 1A). The total experimental surface area was 42 m$^2$ (Figure 1B). A total of 8 high-sensitivity uniaxial accelerometers (shear-type pickup PV-87; Rion Co. Ltd) were installed on the floor to measure the floor vibrations occurring on the experimental surface. The PV-87 sensor characteristics were specified as follows by the manufacturer: charge sensitivity $+40 \text{ pC to } -40 \text{ pC/m/s}^2$; range of detection 1 to 3000 Hz; dimensions 24 mm (hex) x 30.5 (H) mm; mass 115 g. The optimal number of sensor units and their locations were determined through a series of preliminary experiments. These experiments involved progressively increasing the sensitivity setting of the sensors and the number of units placed on both the west and east sides of the Ocha-House. The operation continued until the coverage was deemed sufficient to detect human motion across all parts of the experimental surface. The data related to these preliminary experiments are not presented here. The sensors were mounted on the floor using double-sided tape, as recommended by the manufacturer, and connected to 4 UV-16 2-channel charge amplifiers (Rion Co Ltd) configured in accordance with the manufacturer’s recommendations. The floor-vibration data acquisition was performed using USB-6008 data acquisition devices (National Instrument Corp), a laptop equipped with MATLAB 2015b, and the necessary data acquisition toolbox (MathWorks Inc). The signal was digitized at a 100-Hz sampling rate with a resolution of 12 bits. The abovementioned system is described hereafter as the floor-vibration monitoring system.
Study Protocol
In total, 10 female participants engaged in 4 activities in the Ocha-House. Participants were recruited from the Ochanomizu University campus, which is a women’s university. They were selected based on the inclusion criterion of being aged $\geq 18$ years, with the exclusion criterion being physical imbalance. Participant characteristics are summarized in Table 1, and the details of the 4 activities performed at the Ocha-House are presented in Figure 2. Before the commencement of the experiment, each participant completed a brief walking trial in the Ocha-House, lasting approximately 1 minute. In total, 2 researchers with expertise in gait analysis visually determined the gait type of each participant, specifically identifying whether they exhibited a heel strike or a lighter mid-strike or forefoot-strike landing. The walking trial revealed that all participants could be categorized into either heel-strike landing or mid-strike or forefoot-strike landing categories, with no other gait types observed. All experiments were conducted without any footwear, including slippers. In total, 9 participants wore socks. Moreover, 1 participant did not wear socks on the day of the experiment and completed the protocol barefoot.

**Gait type**
- Heel strike: 3
- Mid- or forefoot strike\(^a\): 7

\(^a\)The column “gait type” refers to the number of participants presenting a strong heel strike during the walking gait cycle, as opposed to participants who presented a lighter mid-strike or forefoot-strike landing. The gait type of the participants was visually determined during the walking calibration trial.

Figure 2. Images of experiments. (A) Sitting and watching videos; (B) ironing, folding, and hanging clothes; (C) cooking, setting the table, and serving food; and (D) cleaning the room.
In total, 4 activities were selected from the “inactivity quiet/light” or “home activities” categories of the compendium of physical activities [26]. The metabolic equivalent of task (MET) values, indicating the intensity of each activity, were reported in the compendium as follows:

- Sitting and watching videos, hereafter referred to as *sitting* (approximately 1.3 MET, activity code 07020).
- Ironing, folding, and hanging clothes, hereafter referred to as *ironing* (1.8-2 METs, activity codes 05070 and 05090).
- Cooking, setting the table, and serving food, hereafter referred to as *cooking* (approximately 2.5 METs, activity codes 05051 and 05052).
- Cleaning the room, hereafter referred to as *cleaning* (approximately 3.3 METs, activity code 05030).

Each activity lasted 6 minutes. To balance the contribution of the 3 tasks within “cooking, setting the table, and serving food” and considering the volume of the Douglas bag used for energy expenditure measurement (see the section Indirect Calorimetry), participants were orally given time information. This ensured that they spent approximately 40 seconds on each task every 2 minutes. The floor-vibration monitoring system recorded floor vibrations, estimate the number of steps, and compute quantitative parameters as described in the Floor Vibration Signal Treatment and Data Feature Extraction section. The participants wore 2 ActiGraph GT9X monitors (ActiGraph LLC) at the waist and wrist. The 10-second epoch activity count and the step-count prediction were recorded for each activity. Finally, Douglas bags were used during the last 2 minutes of each activity to collect the air expired by the participants, perform indirect calorimetry measurements, and obtain the actual energy expenditure. Throughout the experiments, the researchers stood quietly on an insulated part of the floor outside the experimental area to avoid producing confounding vibrations. The experiments were video recorded (data not shown).

**Ethical Considerations**

The experimental protocol was approved by the Ochanomizu University Research Ethics Committee (2018-18). All the participants provided written informed consent and they did not receive any compensation. The individual shown in Figure 2 provided informed consent for the publication of their image.

**Floor-Vibration Signal Treatment and Data Feature Extraction**

The 8-sensor floor-vibration data of each 6-minute activity corresponded to 8 time series of 36,000 samples. Raw data were expressed in volt. For each series, the floor-vibration signal was rectified and smoothed using a Butterworth filter. The vector norms of the 8 sensors were then computed. A location-based calibration coefficient was applied to the vector norm for each data sample to uniformize the vibration magnitudes throughout the experimental surface (Multimedia Appendix 1). The 3 following data features were extracted:

- Floor count—for each participant and each activity, 36,000 sample values (6-min ×100 Hz sampling rate) of the uniformized vector norm time series were summed to obtain the *floor count* parameter.
- Step count—data from the uniformized vector norm time series were cut in windows of 1 second with an overlap of 50%. For each window, the number of steps was computed using a standard peak detection algorithm configured to detect vibration peaks with a minimum prominence of 1.05 SD and a minimum interval of 250 ms [27]. The *step count* parameter was computed for each activity of each participant by summing the number of unique peaks throughout the activity (6 min). The step count parameter was used as both a data feature, allowing the prediction of energy expenditure and a physical activity parameter to be compared with the direct observations and the outcomes of the waist- and wrist-worn ActiGraph devices.
- Moving distance—the uniformized vector norm time series was cut into windows of 1 second and averaged for each window. The window average was compared with a criterion value calculated for each individual from the data collected during the walking trial to determine whether the participant was moving. Subsequently, the filtered data of the 8-sensor time series corresponding to the windows where the participant was moving were used to compute their location in the house. The distances between all locations taken sequentially were summed for each activity to obtain the *moving distance* parameter (6 min). This parameter was tested and validated against the moving distance estimated from the observation of the video records (Figure S1 in Multimedia Appendix 2).

The signal treatment and computation of the 3 previously described parameters were performed using the toolboxes included in the SciPy library [28]. An overview of the entire data processing process is shown in Figure 3.
Figure 3. Floor-vibration signal flow processing chart. From 8 time series of raw signals to the extraction of 3 floor-vibration–based data features.

Actigraphy
The participants were equipped with 2 ActiGraph GT9X monitors worn on the waist and the wrist. The waist-worn device was positioned near the right hip of the participant, on the belt, or on the upper edge of the skirt or the bottom of the trousers. An elastic belt provided by the manufacturer was used when the clothes worn by the participant did not allow the tight mounting of the monitor. The wrist-worn GT9X device was mounted tightly on the nondominant hand always in the same direction. The 2 monitors were mounted by the same experimenter for all participants. The ActiGraph monitor data were collected in 1-second epochs. The 10-second epoch activity count data were extracted from the wrist-worn as well as waist-worn devices, and the “Crouter adult (2010)” equation was used to compute energy expenditure predictions (ActiLife 6; ActiGraph LLC) [29]. This algorithm uses a refined 2-regression model to distinguish between walking and lifestyle activities. In this study, the activity intensities were expressed in MET (ie, energy expenditure/participant weight/6 min). The number of steps estimated by the waist- and wrist-worn monitors was also recorded.

Indirect Calorimetry
The actual energy expenditure was measured using the Douglas bag method during the last 2 minutes of each activity. The air composition of the bags was analyzed using a mass spectrometry gas analyzer (ARCO-1000; Arco System) calibrated on each experimental day in accordance with the manufacturer’s instructions. The gas volume was determined using a gas meter (DC-5; Shinagawa). The energy expenditure was estimated from oxygen consumption (VO₂) and carbon dioxide production (VCO₂) using the Weir formula (ie, 3.9VO₂+1.1VCO₂). In addition, the resting metabolic rate of each participant was evaluated before the experiment. The participant lay for 15 minutes on the bed of the Ocha-House, and the expired air was collected during the last 2 minutes. The actual MET value for each activity was calculated as the activity energy expenditure divided by the resting metabolic rate.

Video Recording
The experimental sessions were video recorded using an Arrows M03 smartphone (Fujitsu Ltd) or an iPad Mini 3 (Apple Inc). In total, 2 independent investigators inspected the videos and counted the number of actual steps for the 4 activities of each participant. In this study, a “step” is defined as the shift of the body weight support from one leg to the other, which includes a single-leg support phase and occurs at least partially on the anterior-posterior axis.

Statistical Analysis
The 4 activities were compared for the floor count, step count, moving distance parameters using an ANOVA or the
Kruskal-Wallis test, and multiple comparison procedures (Tukey or Nemenyi tests) were performed to locate differences. The same analysis was conducted for parameters extracted from the waist- and wrist-worn GT9X monitors and for the indirect calorimetry measurements. The relationships between the actual intensities measured by indirect calorimetry and floor count, step count, and moving distance were investigated using single linear regression tests. Multiple regression models were used to explore the relationship between different combinations of descriptors, including floor count, step count, and moving distance, and the actual intensities measured using indirect calorimetry. This analysis was conducted hierarchically. First, the regressions were only performed on the floor-vibration–extracted parameters. Second, the participant characteristics (ie, body weight and gait type) were included in the model descriptors. Additional hierarchical models are presented in Multimedia Appendix 2. The model with the highest $R^2$ value best explained the variation in the data and was selected for subsequent testing. Finally, mixed model ANOVA and post hoc pairwise operations were used to compare the performance of the best models built on data obtained with the floor-vibration–based monitoring system, the waist- and wrist-worn GT9X monitors, against the actual intensity and the actual number of steps.

The underlying assumptions for each test were evaluated before conducting the analyses. Data are presented as mean (SD). The statistical analysis was performed using the following Python libraries: StatsModels (0.13.2), Pingouin (0.5.3), and Scikit-Posthocs (0.7.0) [30,31]. Data used for the statistical analysis are shared in the Multimedia Appendix 3.

**Results**

### Actual Intensities and Number of Steps

Activity intensities calculated from indirect calorimetry measurements were as follows: 1.2 (SD 0.2) MET for the sitting behavior, 1.9 (SD 0.4) MET for the ironing activity, 2.5 (SD 0.4) MET for the cooking activity, and 3.7 (SD 0.6) MET for the cleaning activity (Figure 4A). Pairwise comparisons indicated significant differences in intensity between sitting and cooking, between sitting and cleaning, and between ironing and cleaning ($P=.004$, $P<.001$, and $P=.01$, respectively). The actual number of steps was 0 (SD 0) for sitting, 48 (SD 36) for ironing, 133 (SD 35) for cooking, and 281 (SD 48) for cleaning (Figure 4B). Pairwise comparisons indicated significant differences in steps between sitting and cooking, between sitting and cleaning, and between ironing and cleaning ($P=.003$, $P<.001$, and $P=.003$, respectively).
Figure 4. Comparison between the 4 experimental home activities. (A) actual intensities (indirect calorimetry evaluation); (B) actual number of steps (video observation); (C) activity intensity predicted by the waist-worn ActiGraph GT9X device; (D) activity intensity predicted by the wrist-worn ActiGraph GT9X device; (E) floor-vibration–based computed floor-count; (F) floor-vibration–based computed step-count; (G) floor-vibration–based computed moving-distance. The intensity predictions of the GT9X monitors were computed using the “Crouter adult (2010)” equation [29]. Yellow line: median. Green point: average. Outliers are not depicted. MET: metabolic equivalent of task. *P<.05, **P<.001.

Floor Count, Step Count, and Moving Distance Parameters Computed From Floor Vibrations

The floor count parameter (arbitrary units) was as follows for each activity: 113 (SD 58) for sitting, 610 (SD 277) for ironing, 1046 (SD 748) for cooking, and 2323 (SD 1255) for cleaning the room (Figure 4E). Pairwise comparisons indicated significant differences in intensity between sitting and cooking, between sitting and cleaning, and between ironing and cleaning (P=.006, P<.001, and P=.04, respectively). The estimated number of steps was as follows: 12 (SD 7.3) for sitting, 78 (SD 27) for ironing, 133 (SD 53) for cooking, and 251 (SD 59) for cleaning.
The mixed model ANOVA showed a significant effect of the measurement method and a significant interaction with the activity for both the predictions of the number of steps and activity intensities ($P<.001$).

**Activity Intensity Predictions**

The wrist-worn activity tracker estimated the activity intensities as follows: 1.8 (SD 0.4) MET for *sitting*, 6.4 (SD 0.5) MET for *ironing*, 5.6 (SD 0.7) MET for *cooking*, and 6.8 (SD 0.4) MET for *cleaning* (Figure 4D). Pairwise comparisons indicated significant differences between *sitting* and *ironing* and between *sitting* and *cleaning* ($P=.002$ and $P<.001$, respectively). The estimated number of steps was as follows: 11 (SD 5.7) for *sitting*, 177 (SD 39) for *ironing*, 131 (SD 37) for *cooking*, and 197 (SD 35) for *cleaning* (Multimedia Appendix 2). Pairwise comparison analyses indicated significant differences between *sitting* and *ironing* and between *sitting* and *cleaning* ($P<.001$ for both).

The results for the activity count parameters of the wrist- and wrist-worn devices are shown in Multimedia Appendix 2.

### Relationship Between the Floor-Vibration–Based Outcomes and the Actual Activity Intensities

As presented in Table 2, *floor count*, *step count*, and *moving distance* were significantly associated with the intensity of physical behavior ($r^2=.56$, $r^2=.82$, $r^2=.66$, respectively; $P<.001$). Combining the 3 parameters resulted in an $r^2$ value of 0.84. Combining *floor count*, *step count*, and *moving distance* with participant personal characteristics, such as body weight and gait type, allowed predicting the intensity of physical behaviors with an accuracy of 88% (Table 1). The results of the additional hierarchical models are presented in Multimedia Appendix 2.

**Step Count and Activity Intensity Predictions**

The mixed model ANOVA showed a significant effect of the measurement method and a significant interaction with the

\[ \text{Step Count} = -0.155 \times \text{Gait type} - 0.08 \times \text{Body weight} - 0.224 \times \text{Floor count} + 0.259 \times \text{Moving distance} - 0.43 \times \text{Floor count} + 0.971 \times \text{Step count} - 0.361 \times \text{Moving distance} - 0.745 \times \text{Floor count} + 0.904 \times \text{Step count} + 0.815 \times \text{Moving distance} \]

### Actigraphy

The waist-worn activity tracker estimated the activity intensities as follows: 1.1 (SD 0.2) MET for *sitting*, 1.2 (SD 0.3) MET for *ironing*, 2.1 (SD 0.4) MET for *cooking*, and 4.2 (SD 0.7) MET for *cleaning* (Figure 4C). Pairwise comparison analyses indicated significant differences between *sitting* and *cooking*, between *sitting* and *cleaning*, and between *ironing* and *cleaning* ($P=.03$, $P<.001$, and $P=.03$, respectively). Furthermore, a significant correlation was found between the *moving distance* outcomes computed from the floor-vibration signal and the *moving distances* estimated from the video records (Figure S1 in Multimedia Appendix 2).

### Relationship Between the Floor-Vibration–Based Parameters and Actual Activity Intensities Evaluated by Indirect Calorimetry

As presented in Table 2, *floor count*, *step count*, and *moving distance* were significantly associated with the intensity of physical behavior ($r^2=.56$, $r^2=.82$, $r^2=.66$, respectively; $P<.001$). Combining the 3 parameters resulted in an $r^2$ value of 0.84. Combining *floor count*, *step count*, and *moving distance* with participant personal characteristics, such as body weight and gait type, allowed predicting the intensity of physical behaviors with an accuracy of 88% (Table 1). The results of the additional hierarchical models are presented in Multimedia Appendix 2.

**Step Count and Activity Intensity Predictions**

The mixed model ANOVA showed a significant effect of the measurement method and a significant interaction with the activity for both the predictions of the number of steps and activity intensities ($P<.001$).
Significant underestimations in the number of steps were noted for the wrist-worn ActiGraph device predictions when all activities were considered together (Figure 5A, "total").

Regarding the prediction of activity intensities (Figure 5B), the pairwise comparison analyses revealed statistically significant overestimations for the wrist-worn ActiGraph device across all activities. The wrist-worn device and the floor-vibration system did not exhibit any difference with the actual number of steps. When activities are considered separately, pairwise comparisons indicate that the wrist-worn ActiGraph device underestimated the number of steps completed during cleaning but overestimated it for sitting and ironing activities. The floor-vibration–based predictions overestimated the number of steps required for sitting.

Regarding the prediction of activity intensities, the pairwise comparison analyses revealed statistically significant overestimations for the wrist-worn ActiGraph device across all activities. The floor-vibration system did not show any differences with the actual intensities evaluated by indirect calorimetry. Finally, the wrist-worn ActiGraph device showed a slight but significant underestimation for the estimations of the ironing activity intensities. The results are shown in Figure 5.

Figure 5. Comparison of prediction methods for each activity. (A) number of steps; (B) activity intensity. Energy expenditure measurements were collected for 2 minutes over the 6 minutes of each activity. Therefore, comparisons of measurement methods for the total energy expenditure are not presented in this figure. In panel B, the green bar shows the prediction of the model with the highest coefficient of determination (model 5; Table 2). The marks indicate a significant difference against the actual number of steps. MET: metabolic equivalent of task. *P<.05, **P<.001.

Discussion

Principal Findings

This study presented a novel quantitative method that uses the monitoring of floor vibrations for the evaluation of physical behaviors at home. The floor count, step count, and moving distance parameters were computed from the floor-vibration signal. Statistical models combining these 3 parameters showed significant correlations with the actual energy expenditure measured in 10 participants in a structured experiment that included 4 common home-based activities. In addition, the step count parameter did not show any significant difference with the number of steps completed by the participants during the experiment. The predictions of the floor-vibration monitoring system for both the activity intensity and number of steps were equal to or more accurate than those obtained by the Actigraphy method using the refined 2-regression model.

Floor Vibration for the Quantification of Physical Behaviors

The actual activity intensities measured by the indirect calorimetry for the 4 activities increased in accordance with the intensities presented in the compendium of physical activities [26], that is, 1.2 versus 1.3 MET; 1.9 versus 1.8 to 2.0 MET; 2.5 versus 2.5 MET; and 3.7 versus 3.3 MET for sitting (and watching video), ironing (and folding clothes), cooking (and setting the table), and cleaning the room, respectively (Figure 4A). The floor count, step count, and moving distance parameters also increased gradually for the 4 activities, indicating the feasibility of evaluating the intensity of physical behaviors in the home environment using the information provided by floor vibrations (Figures 4E-4G). Among them, step count was the only parameter that showed significant differences between all 4 activities. The single regression analyses also indicated a strong association between the step count and the actual activity intensities ($r^2=0.82; P<.001$), whereas floor count and moving distance showed a weaker but still significant association with the actual activity intensities ($r^2=0.56$ and 0.66, respectively; $P<.001$ for both). These pieces of information taken together may suggest that the estimated number of steps extracted from the floor-vibration signal could be used to make a reliable quantitative estimation of physical behavior in home settings. All the 3 parameters were designed to describe the inhabitant’s motion. Although the step count and floor count parameters can capture the physical dimension of the movement, the moving distance parameter adds a spatial dimension to the evaluation. The better performance of step count alone compared with moving distance alone may be due to the location approximation inherent to the limited number of sensors used to cover the entire house surface (Multimedia Appendix 2). A step is detected and not affected by any approximation. On the other hand, floor count may also be susceptible to inaccuracies, potentially due to variations in floor-vibration wave attenuation. Factors influencing this attenuation include the proximity of furniture, its weight and
contact surface with the floor, proximity of support beams and walls, and the irregular geometry of the Ocha-House floor area.

Despite the possible weaknesses of the floor count and moving distance parameters, multiple linear regression models combining step count, floor count, and moving distance still exhibited stronger associations ($r^2 \geq 0.85$; Table 1; Table S1 in Multimedia Appendix 2). As presented in Table 2, the inclusion of body weight and gait type parameters as descriptors greatly lowered the contribution of floor count to the model. Indeed, although floor count does not correlate with either body weight or gait type (Table S2 in Multimedia Appendix 2), it is still the only parameter extracted from floor vibrations that can quantitatively capture the forces applied on the floor. Given that the actual body weight can be easily inputted into any smart home system, the question of the relevance of extracting and using the floor count parameter to make accurate predictions of energy expenditure remains open. Additional studies, including a population with more heterogeneous anthropometric characteristics, may be needed to address this question further.

Finally, the ANOVA revealed that the predictions made by the floor-vibration monitoring system also showed less deviation than those of the 2 research-grade ActiGraph GT9X monitors for both the number of steps and activity intensity end points (Figure 5). The underestimation of the number of steps noted for the wrist-worn ActiGraph device may be related to walking gait characteristics when movements are performed in closed and narrow spaces. Such environments may not allow sufficient acceleration to meet the necessary signal processing threshold criteria required to count a step, as suggested elsewhere [32]. In contrast, the overestimated number of steps observed for the wrist-worn device may be the result of confounding upper limb movements performed in a frequency range similar to that of walking gait, which may occur in the course of completing housework-related activities.

Regardless of the performance of the ActiGraph GT9X monitors and although no external validation experiment has been conducted, taken together, these observations emphasize the good performance of the floor monitoring system for the quantitative evaluation of physical behaviors performed in home settings.

**Perspectives**

Although the market for wearable activity trackers is still in its growing phase [6], waist- and wrist-worn physical activity monitors, including research- or consumer-grade devices, have been associated with inaccurate predictions of daily physical activity [10-12]. During the past decade, the computation of accurate predictions for housework-related activities using traditional accelerometer-based activity tracker devices has been the object of specific software development [33,34]. However, this study still showed statistical differences between the predictions made by the ActiGraph GT9X monitors and the actual values for both number of steps and activity intensities. These observations emphasize the necessity of developing new methods that can accurately evaluate physical behaviors at home to improve the computation of daily physical activity metrics. When considering long-term use, it is crucial to distinguish between consumer- and research-grade devices. This study used 2 ActiGraph GT9X monitors, recognized as research-grade devices, in the context of a short semistructured experiment. However, consumer-grade physical activity tracking devices used in everyday life are subject to additional extrinsic limitations that can impede their ability to provide continuous monitoring. For instance, the common practice of removing watches and other wearables at home can have significant impacts on the evaluation of physical behaviors in home settings.

Considering the current limitations of wearable activity tracker devices, smart home systems, such as floor-vibration monitoring technologies similar to those used in this study, present a suitable opportunity to enhance the self-monitoring of daily physical activity. Such systems offer a novel approach to improve the accuracy of estimating energy expenditure and the number of steps performed at home, especially when considering their integration with a 5G network composed of interconnected devices dedicated to the evaluation of daily physical activity. By ensuring accurate and continuous measurements when individuals are at home, smart home systems could help maintain people’s interest in self-monitoring, making them a pivotal factor in promoting and sustaining active and healthy lifestyles. However, the potential widespread adoption of such systems should not only be considered from a technological perspective but should also acknowledge the role of sociocultural factors in shaping user acceptance and usability.

**Limitations and Strengths**

The main limitation of this study is that the proposed method only assesses the physical behaviors of 1 inhabitant at a time. Quantifying the physical behaviors of multiple individuals would require additional signal processing tools to link vibration events with the individuals generating them. Although each individual may exhibit a unique gait signature reflected in the floor-vibration signal, extracting such information is beyond the scope of this study. This limitation could also be addressed by analyzing the sequence of interactions with smart and connected home furniture devices, similar to what has already been described elsewhere [35]. Furthermore, it is important to note that the experimental Ocha-House used in this study was originally designed for a single inhabitant, aligning with the living environment of millions of Japanese people. The structured nature of the experimental protocol may be cited as a second limitation of the study, which restricts the generalization of the observations to what may happen under free-living conditions. To further evaluate the feasibility of using the floor-vibration–based monitoring method, semistructured experiments using a portable breath-by-breath gas exchange analyzer could be conducted to assess energy expenditure during longer periods of activity. A third limitation is that the external validity of the floor-vibration parameter–based activity intensity prediction models (Table 2) was not tested, thus mitigating the interpretations of the comparison test performed against the actigraphy method. The cost of the system is also considered to be a limitation. In this study, expensive, high-sensitivity shear-type accelerometer sensors were used. Further studies are necessary to explore the feasibility of using cheaper accelerometer sensors similar to those commonly used in wearable devices. The results of the
multiple regression analyses (Table 2: Multimedia Appendix 2) indicated that the floor-vibration–based step count and moving distance parameters contributed more to the activity intensity prediction models. These 2 parameters may not require the computation of a high-resolution signal. Fourth, the quasi-absence of responses in the floor count, step count, and moving distance parameters during sitting and watching videos may suggest that the floor-vibration monitoring system may also be capable of evaluating sitting behaviors (Figures 4E–Figures 4G). However, owing to the structured nature of the protocol, which involves short observation windows, further interpretations regarding the accuracy of the system in predicting energy expenditure for home-based sitting activities cannot be made. Given the importance, complexity, and intricacies of sedentary behaviors that can occur at home, specific studies should be designed to understand how floor-vibration monitoring systems may contribute to the objective assessment of home-based sedentary behaviors. Finally, the participants in this study were all women and exhibited relatively homogeneous characteristics in terms of age and weight. The BMI scores indicated a limited variability in physical fitness. These observations constrain the generalizability of our results to a more diverse population. Given that age and physical fitness are recognized determinants of energy expenditure, future investigations should aim to recruit a more diverse sample of participants and consider a broader spectrum of personal characteristics in the development of energy expenditure prediction models.

This study has several strengths and originalities. First, the results of the present experiment are in line with those of previous studies, which described a good relationship between the force exerted by an individual on the floor of a small squared 6.25 m² metabolic chamber equipped with a force transducer and the actual energy expenditure [36-38]. They allow extending the previous observation to a different sensing technology, larger non–squared living surfaces, and a wider range of activities that are usually performed at home. Another strength of this study is that it is the first to compare the outcomes of a smart home system with those of research-grade activity trackers.

Conclusions

This study presents a novel floor-vibration monitoring system that can be used in smart home settings to quantify physical activity at home. The hardware included high-sensitivity accelerometers. In this case, 8 sensors were required to cover a surface area of 42 m². The software includes a simple data processing workflow for the computation of the floor count parameter, which is a quantitative index of the floor vibrations, and the step count and moving distance parameters. Regression models combining the information of these 3 parameters showed a strong association with the actual intensities measured using indirect calorimetry for the 4 tested home-based activities. A significant association was also observed between the step count parameter computed using the floor-vibration signal and the actual number of steps. Further studies, conducted under real-life conditions or using semistructured experimental protocols, are necessary to extend the results of this study and validate the monitoring of floor vibrations as a surrogate method for evaluating physical behaviors at home. Considering the current evolution of 5G technologies and IoT devices, smart home systems are expected to contribute to a more continuous evaluation of daily physical activity.

Acknowledgments

The authors would like to thank the individuals who participated in this study. NM, YO, and JT would like to acknowledge all the research students who contributed to the Ocha-House project in the past: Chihiro Nakajima, Saki Kaneko, Mana Akao, and Mio Sasaki. This study has received research grants from the Japan Society for the Promotion of Science (Grant-in-Aid for Young Scientists-B 15K20997 directed to JT and Grant-in-Aid for Scientific Research-C 21K11335 directed to JT and YO) and from the Japanese Foundation for the Promotion of Precision Measurement Technology (精密測定技術振興財団研究費).

Abstract

Background: Alzheimer disease is a degenerative neurological condition that requires long-term care. The cost of these responsibilities is often borne by informal caregivers, who experience an elevated risk of negative physical and psychological outcomes. Previously, we designed a positive emotion regulation intervention that was shown to improve well-being among dementia caregivers when delivered through one-on-one videoconferencing lessons with a trained facilitator. However, the format required significant resources in terms of logistics and facilitator time. To broaden the reach of the intervention, we aimed to develop the Social Augmentation of Self-Guided Electronic Delivery of the Life Enhancing Activities for Family Caregivers (SAGE LEAF) program, an iteration of the intervention in a self-guided, web-based format with enhanced opportunities for social connection.

Objective: The aim of this study was to gather feedback to inform the design of social features for the SAGE LEAF intervention. In the absence of a facilitator, our goal with the self-guided SAGE LEAF intervention was to integrate various social features (eg, discussion board, automated support, and profiles) to maximize engagement among participants.

Methods: Qualitative data were collected from 26 individuals through (1) interviews with participants who completed a previous version of the intervention via videoconferencing with a facilitator, (2) focus groups with dementia caregivers who had not previously experienced the intervention, and (3) focus groups with Alzheimer disease clinical care providers. We conducted a qualitative thematic analysis to identify which social features would be the most helpful and how they could be implemented in a way that would be best received by caregivers.

Results: Interview and focus group feedback indicated that participants generally liked the potential features suggested, including the discussion boards, multimedia content, and informational support. They had valuable suggestions for optimal implementation. For example, participants liked the idea of a buddy system where they would be matched up with another caregiver for the duration of the study. However, they expressed concern about differing expectations among caregivers and the possibility of matched caregivers not getting along. Participants also expressed interest in giving caregivers access to a podcast on the skills, which would allow them to review additional content when they wished.

Conclusions: Taken together, the discussions with caregivers and providers offered unique insights into the types of social features that may be integrated into the SAGE LEAF intervention, as well as implementation suggestions to improve the acceptability of the features among caregivers. These insights will allow us to design social features for the intervention that are optimally engaging and helpful for caregivers.

Introduction

Background
The impact of Alzheimer disease (AD) continues to broaden as the global average life expectancy grows [1,2]. Consequently, the number of individuals who will assume the role of a primary caregiver of a friend or family member with AD is expected to rise, with estimates indicating that informal care accounts for 40% of the total cost of care [3]. In the United States alone, this amounts to an estimated annual total of 18.6 billion hours of unpaid care [4].

At the individual level, the protracted nature of AD results in an extended caregiving role that intensifies as the care recipient’s health gradually declines [5]. For example, initial caregiving responsibilities may include assisting with activities of daily living such as providing transportation, preparing meals, and helping with chores [6]. However, in more advanced stages of the disease, caregivers often have to cope with agitation, aggression, and wandering [7] while shouldering an increasing logistical and financial burden of coordinating care [8,9].

The weight of these responsibilities comes at a cost to caregivers, who experience adverse mental health outcomes such as increased depression, anxiety, and suicidality [10-13] as well as negative consequences for physical health, demonstrated by increased sleep disturbance, fatigue, and undernutrition [14,15]. This, in turn, may lead to a decline in the quality of care and, subsequently, poorer outcomes for the care recipient [5].

In light of the growing recognition of the stress of AD caregiving, researchers are developing targeted interventions that offer a combination of psychoeducation, social support, and psychological support for caregivers [16,17]. Of note, researchers are increasingly using eHealth technologies that leverage electronic information and communication (eg, telehealth, mobile apps, and web-based applications) to broaden the dissemination of these resources [18,19]. After the onset of the COVID-19 pandemic, eHealth technologies found renewed significance when in-person AD support services were suspended, necessitating a rapid shift to telehealth offerings [20].

This study was the first step in the adaptation of an existing caregiver intervention into a socially enhanced web-based intervention—Social Augmentation of Self-Guided Electronic Delivery of the Life Enhancing Activities for Family Caregivers (SAGE LEAF). SAGE LEAF will comprise a positive emotion regulation curriculum that has been shown to be helpful for individuals experiencing significant life stress, including those with type 2 diabetes, metastatic breast cancer, HIV, and depression [21-24]. In a previous study, the intervention was also tailored specifically for dementia caregivers and delivered through videoconferencing by trained facilitators [25]. The intervention was effective at reducing symptoms of depression while improving self-reported physical health and positive emotion outcomes. However, the one-on-one facilitation that was provided for participants required a significant commitment of resources in terms of recruiting and training facilitators as well as an estimated 6 to 8 individual contact hours per participant over the course of 6 weeks. Hence, our goal was to tailor the self-guided, web-based version of the intervention for caregivers while incorporating unique social features that may help foster engagement among participants.

Objectives
Specifically, our aim was to enhance social presence, defined by computer-human interaction researchers as the perception of others in a virtual environment [26-28]. The construct has been shown to be associated with enhanced perceived learning and satisfaction in e-learning environments [29]. However, to identify potential social features that may be helpful for AD caregivers, it is also necessary to first understand how they currently use social technologies to support their caregiving activities and emotional well-being. For example, caregivers may use discussion boards hosted by the Alzheimer’s Association [30] or on social platforms such as Facebook or Reddit [31]. Furthermore, in the context of the COVID-19 pandemic, caregivers are now increasingly reliant on these social technologies with the rapid shift from in-person to virtual support resources, which include videoconferencing support groups for caregivers [32].

Hence, to examine the preferences and requirements of AD caregivers, this study aimed to solicit feedback on a set of potential social features for the SAGE LEAF intervention. These were identified from a review that we conducted on social features that were being implemented on research-focused and commercial eHealth applications (I Kwok, unpublished data, May 2021) in consultation with study team members and developers who were involved in the design of previous versions of the intervention (Textbox 1).

We collected feedback through (1) individual interviews with caregivers who completed the previous version of the intervention [25], (2) focus groups with dementia caregivers who had not yet been exposed to the intervention, and (3) focus groups with clinical providers of people with AD. The findings will inform the types of social features to be included in the SAGE LEAF intervention and how they can be implemented in a way that is most beneficial for caregivers.
Individual interviews: dementia caregivers who participated in a previous version of the intervention [36].

Profiles: a profile page that may be shared with others. Examples of profile content include being able to choose an avatar and answering some questions about themselves. Such features involve varying levels of self-disclosure, data management, and personalization that may enhance the sense of the presence of others in the intervention [36-38].

Private messaging: participants are able to send each other private messages. Some examples include messaging through SMS text messages [39,40] or commercially available applications such as Facebook and WhatsApp [41] or built into the eHealth intervention [42,43].

Buddy system or matching: pairing participants who are going through the intervention at the same time. Some examples include matching participants who are going through the intervention at the same time or with someone who has previously completed the program as a “peer mentor” for each other or enrolling a partner whom the participant has an existing relationship with [44-46].

Videoconferencing group: a facilitated group with participants through videoconference. Similar formats include support group and education or training videoconferencing sessions [47,48].

Discussion board: a web-based discussion board on the content of the lessons. Possible discussion board enhancements include notifications for when other users like or comment on their posts [49-51].

Automated support: this may include reminders or notifications for participants who are not logging in or feedback collected at the end of lessons. Such features have been shown to enhance adherence in eHealth interventions [52,53].

Multimedia, videos, or podcasts: these forms of multimedia are commonly used to disseminate educational material in a way that engages participants, thereby promoting literacy and enhancing health-related outcomes [54]. This might include testimonials and quotes from previous participants or messages from the study team.

Informational support: frequently asked questions or other information about how to connect with caregiver organizations, online support groups, and mental health care providers. Such resources may enhance a participant’s sense of perceived support and information competence [55].

Methods

Design

A combination of focus groups and interviews was conducted to solicit feedback on the short list of potential social features for the SAGE LEAF intervention. Subsequently, a qualitative analysis was conducted on the transcripts to identify and gather feedback on each feature.

Sample and Sampling

Three groups of participants were recruited (Tables 1 and 2):

1. Individual interviews: dementia caregivers who participated in a previous version of the intervention [36]. We emailed individuals who had previously provided consent for recontact and provided them with information about the interviews. If they wished to participate, they completed a screener survey to determine whether they met the following eligibility criteria: (1) currently identifying as the primary family caregiver of a person with dementia, (2) ability to speak and read English, (3) access to high-speed internet, and (4) access to a webcam for videoconferencing. The interviews were conducted by the lead author (IK), who adhered to a semistructured interview protocol to guide the discussions. They lasted approximately 45 to 60 minutes, and topics included (1) the types of social connection technologies that participants use in their everyday life, (2) reactions to potential social features that may be implemented for SAGE LEAF (eg, private messaging, discussion board, and virtual profiles), and (3) solicitation of suggestions for other social features not previously mentioned.

2. Caregiver focus groups: dementia caregivers from Northwestern Memorial Hospital’s Cognitive Neurology and Alzheimer’s Disease Center (CNADC) were recruited for 2 focus groups comprising 5 caregivers each (n=10). We emailed caregivers who had previously provided consent to be contacted for research purposes through the CNADC and provided them with information about the focus groups. If they wished to participate, they were asked to complete a web-based screener survey to determine whether they met the following eligibility criteria: (1) currently identifying as the primary family caregiver of a person with dementia, (2) ability to speak and read English, (3) access to high-speed internet, and (4) access to a webcam for videoconferencing. The focus groups lasted approximately 90 to 120 minutes and were similar in content to the interviews.

3. Clinician focus groups: we contacted clinicians who provided care for people with AD or their family or informal caregivers (eg, physicians, nurses, and social workers) from the CNADC and the University of California, San Francisco’s Memory and Aging Center via email. Both are comprehensive research and care centers that treat AD; hence, clinicians are involved in a broad range of AD programs that integrate patient care, training, and research. Interested clinicians completed a screener survey where they could indicate their professional experience to determine whether they met the following eligibility criteria: (1) current employment as a clinician for patients with AD and their caregivers (eg, physicians, nurses, and social workers), (2) access to high-speed internet, and (3) access to a webcam for videoconferencing. One focus group was conducted for AD care providers (n=6).

Data Extraction Procedure

We conducted a qualitative thematic analysis to identify (1) positive and negative feedback and implementation suggestions for each of the potential social features and (2) additional social features suggested by participants.

The interview and focus group recordings were transcribed and uploaded to the Dedoose qualitative and mixed methods research application (SocioCultural Research Consultants) in preparation for thematic analysis. Because the interviews and focus groups followed a similar structure, with questions asked about the same set of features, all transcripts were collated and analyzed together. In total, 2 independent coders performed the coding (IK and CL). First, they conducted open-ended coding of a test transcript to extract a preliminary list of codes. The coders met to discuss their observations, resolve differences in these observations, and refine the list of codes. An additional study team member (JM) was involved in reviewing the list to ensure that it captured the potential range of feedback. Next, to ensure a high level of agreement, the coders performed an interrater reliability test on 3 transcripts. While there is debate about the applicability of interrater reliability in interpretive qualitative research, its measurement allows for greater transparency and motivates adherence to the established coding guidelines [57]. During the test, a Cohen κ of 0.68 was achieved, which is regarded as a substantial level of agreement [58]. Subsequently, the coders met to resolve the discrepancies highlighted by the test and refined the codebook once again.

Next, the coders proceeded with a first round of independent coding that comprised 5 transcripts. They randomly selected one of the transcripts to be double coded and met to discuss any discrepancies in their coding. Finally, they proceeded with a second round of independent coding of the 5 remaining transcripts.

The codes were organized based on the type of social feature that they referenced. For each social feature, subcodes were created for positive feedback, negative feedback or barriers, and implementation suggestions. Additional codes were created for other social technologies mentioned (eg, WhatsApp and Facebook), web-based resources, and additional ideas suggested by participants. In the Results section, the results are categorized by social feature type. Quotes from participants are presented with the following identifiers: (1) “PX” to denote participants who completed a previous version of the intervention, (2) “CR” to denote caregivers who participated in the focus groups, and (3) “PR” to denote providers who participated in the focus groups. Due to the personal nature of the interviews and focus groups, the full transcripts are not publicly available.

Ethical Considerations

The protocol for this study was approved by Northwestern University’s institutional review board (STU00215548) before conducting the study. Eligible participants were sent an electronic consent form via email delineating the risks and benefits of participation, at which point they could confirm their preference to participate or decline participation in the study. Data collected from REDCap (Research Electronic Data...
Peer Groups or Cohort

Participants generally liked the idea of being in a peer group, and caregivers drew comparisons to their previous participation in caregiving support groups. However, they expressed concern as to how they would be matched into groups:

I think if you want to have peers, you do need to match them up closely. By the progression of disease maybe. [CR2]

I think that you have to be careful as to who’s in the peer group...I’ve been in other support groups where [caregivers were caring for] somebody had dementia, somebody with Alzheimer’s, and [another caregiver was caring for someone with] PPA (primary progressive aphasia). And they’ve got similarities, but they’re so drastically different. [CR3]

Furthermore, participants had varying opinions on how caregivers should be grouped together. Some suggestions included grouping by age, relationship to the care recipient, or type of dementia. One participant also suggested that it may be helpful to group individuals based on their recreational interests instead of their caregiving status:

I think it’s also good to have in a peer group...And I don’t think gender or anything like that matters whatsoever, it’s more about where they are and what they’re doing at the time, with the same type of diagnosis. [CR1]

Well, I think that general background is so important...You know, educational—the number of degrees you get isn’t as important as interests. Are you interested in art? Are you interested in gardening?...It’s one way that certainly people get together. [PX1]

Hence, type of dementia or progression of the disease were the most preferred methods of grouping individuals. Participants in the focus groups and interviews were able to readily articulate their grouping preferences by tapping into their own experience of caregiving and their specific needs based on their care recipient’s diagnosis. This underscores the utility of segmenting future participants by type of dementia diagnosis.

Profiles

There is a high degree of variability in how user profiles are used in eHealth platforms, ranging from toggling basic settings to more extensive social features such as managing invites, notifications, and social groups. Our proposed enhanced user profiles would allow participants to customize the way in which they present themselves in the virtual space and would help lay the groundwork for future social interaction on the SAGE LEAF platform. Such user profiles might include the ability to select an avatar or allow participants to display their name and other personal information if they choose to do so.

Similar to the feedback on the peer groups, focus group and interview participants were primarily interested in the caregiving-related characteristics of other users, such as the relationship between the caregiver and care recipient and type of dementia diagnosis:

Family relationship. If they’re the adult child or spouse/partner. I’ve also—if it’s the younger onset versus later onset. [PR1]

I think people would be interested in knowing the diagnosis of the person the other caregivers are caring for. So, if someone is an adult child caring for their parent with Alzheimer’s, I feel like they would be interested in meeting other people in similar situations. [PR3]

I think age is a big factor. I’ve had a lot of people who are younger, like maybe family caregivers, who are more interested in talking with somebody their own age. Or around—near their own age. [PR4]

Taken together, this feedback suggests that the information that is shared in the profiles may be similar to the variables by which participants might be grouped together. This emphasizes the synergy between these features and how they may foster a sense of shared identity among participants.

Private Messaging

A private messaging function would allow participants to contact each other individually on their own and would function similarly to social networking platforms such as Facebook and Instagram that allow for direct messaging. Overall, feedback was positive, but one clinician articulated their concerns about privacy and security:

...in my support group there are people who request, you know, to be connected to each other. And I think I always try to make sure that I ask both parties before I connect them...So maybe the option to stay private or to be public. [PR5]

Contrary to our expectations that caregivers may share similar concerns about security and privacy regarding being contacted, the feedback suggests that caregivers were open to the idea of being able to send and receive messages and expressed minimal hesitation toward the private messaging feature:

Oh, I think that would be fine. You know, I see nothing wrong with that. I think, you know, friendships could be formed out of that. And private support and like-minded thinking people...I see absolutely nothing wrong with that. [PX10]

I think that’s fine. I think that would be good because you’re going to have to find a way to build trust, and then it’s also somebody who is in a similar circumstance than yourself. So, yeah, so that’s how I would look at it. [PX12]
Hence, feedback was generally positive on the ability to connect with other caregivers through a private messaging feature. Participants emphasized that their potential willingness to use this feature was based on the assumption that other participants would be in a similar caregiving situation to theirs. For instance, participants indicated that the similarity of the diagnosis of their care recipient or whether they were also spousal or other family caregivers were important attributes that might influence their use of this feature.

**Buddy System or Matching**

To maximize the sense of social presence that future participants might experience, we initially proposed a buddy system where participants would be paired up with a peer or “buddy”—either with someone who was going through the program at the same time as them or with participants who had previously completed the intervention. This social feature would complement the peer groups in that participants would be able to feel like they were part of a group while being able to connect individually with other participants. Alternatively, this could be deployed as a stand-alone feature in the event that there were not enough participants to form a cohort. Overall, we received mixed feedback from caregivers and clinicians on the concept of a buddy system.

In their feedback, caregivers expressed interest in this idea because it would provide accountability for progressing through the program to their potential buddies and enhance their motivation to engage with the content:

> Oh, it totally would [be helpful]. Because I would be more concerned about disappointing the other person. “Oh, they need me! I have to check my email,” or “I have to check that text. I don’t want to disappoint them.” [CR3]

> I think it’s a great idea. You know, it would have been nice, if I had had one, but I was just flying by the skin of my teeth and sometimes I crash landed. [PX7]

In contrast, clinicians expressed significant concerns about the implementation of a buddy system. They described past experiences with similar efforts where the matching was unsuccessful or burdensome and led to a disappointing experience for the caregivers involved:

> I’ve tried connecting caregivers that I work with, and unless they really hit it off naturally in most cases it doesn’t work out. [PR5]

> I think there can be a problem in the two caregivers having really different expectations about what the relationship is going to be...I think it would add a level of burden to caregivers too... [PR2]

Hence, while caregivers expressed enthusiasm for this idea, clinicians spoke from their own past experiences and were strongly against the idea of matching because they found it challenging to establish shared expectations and to anticipate whether caregivers who were matched would get along well. Therefore, it is unclear whether the benefits of the buddy system may be outweighed by potential complications that arise from these unanticipated social dynamics.

**Videoconferencing Group**

At present, support groups form a crucial resource for AD caregivers, as demonstrated by the wide range of group programming in both virtual and in-person formats [17,59]. Hence, another possible feature was a videoconferencing group where participants would be able to log in at a given time during the week to connect with other caregivers with the specific focus on discussing the skills being taught in the program.

The onset of the COVID-19 pandemic hastened the transition of in-person support groups to web-based videoconferencing groups. This transition was demonstrated in the readiness that caregivers expressed in adopting these videoconferencing technologies. It should be noted that all the interviews and focus groups took place at the start of the pandemic:

> I have been surprised that the Zoom meetings—I’ve gone to many of them...I should point out I’m 83 years old, okay?...via online, that sort of thing, would be very good for a person like me. [PX1]

In terms of implementation suggestions, one participant highlighted that these videoconferencing groups would be a good addition to the program as long as participation was optional. This underscores the importance of building flexibility into the social features being offered as caregivers have competing demands or may simply prefer different features:

> I think if you could make it as an offering but not a requirement...But I think you have to be understanding of the fact that not everybody’s going to be able to do that at the same time...it’s hard for me to commit weekly to a certain time. [PX10]

One concern that was expressed by both caregivers and clinicians was the importance of making sure that the videoconferencing group discussions stayed on topic. Caregivers articulated various past experiences where their time was not spent efficiently because other participants deviated from the focus of the discussions:

> ...I would go and check out other groups, and that was always a real disappointment. And I would not go back to those when, you know, somebody would just insist on eating up the entire hour with their issues. And so that’s a problem... [PX11]

> I would gravitate toward anything where there was some real-time moderation or facilitation, just to help keep the learning on track. [CR5a]

The feedback suggests that videoconferencing groups can be helpful for caregivers. However, there was concern about the efficiency of these meetings, which could be addressed by having a facilitator who is able to moderate and guide the discussions. A facilitated group would allow participants to discuss the topics freely while ensuring that the time is directed toward the topics and skills taught in the program. Participants also liked the idea of having a portion of the videoconferencing group sessions be not necessarily related to caregiving or the positive emotion skills taught in the program, with several participants expressing interest in an informal happy hour where they could connect with each other casually.
Discussion Group

Caregivers often seek information about their care recipient’s diagnosis, behaviors, and symptoms through the internet. Hence, many already participate in AD-specific discussion groups that are associated with the Alzheimer’s Association or informal groups that proliferate on social media platforms such as Facebook and Reddit. In line with our expectations, participants were generally open to the idea of using a discussion board. One clinician suggested that there may be some overlap with these existing platforms, which could present a barrier to participants using the discussion board:

...some of the feedback we get from caregivers is that, “You’re asking me to do something I already have a mechanism for doing that. So, I already have a way to share photos with people that I’m close to, it’s called Facebook or whatever. But you’re asking me to sort of do it in this different venue.” So that’s been a negative when you’re asking somebody to do something, that they already have a way to do that. [PR2]

Furthermore, both participants and providers emphasized that the use of the discussion board would be contingent on how the benefits of engaging with it were conveyed to participants. Some of their suggestions included highlighting how the discussion board could amplify their practice of the skills or allow them to feel more connected with other participants in the study:

I think there are some advantages, and that if you really say the discussion board is to really talk about the skills or share examples of where you use the skills...And if you framed it so that—I could even see it as being a way to amplify the skills. [PR3]

...to encourage people and say, “Hey, look at, you know, it’s normal for you to feel isolated and trying to get questions answered. It’s worth it to try and work with these tools.” [PX12]

This feedback suggests that caregivers may be open to using the discussion boards, yet there were concerns about how these discussion boards might duplicate existing resources. Thus, it is essential to highlight the benefits of engaging with the discussion board associated with the positive emotion skills program to encourage its use. This may be in the form of prompts or reminders to participants about these benefits.

Automated Support

As described in Textbox 1, automated support would comprise notifications or reminders that are sent out based on certain triggers, for example, if a participant does not log on to the platform for a certain number of days or if they endorse poor mood for an extended period. With automated support, the intention is to provide caregivers with a sense that their participation is valued and that we would be responsive to their level of engagement. Similar to the feedback collected in previous versions of the intervention, participants found the concept of reminders helpful but expressed the need for these messages to be framed in a way that was supportive and encouraging:

I guess that’s where I would give them points, and like, more like entice them rather than nag them. [PR5]

Because when you first said it [automated support], it was totally irritating to me. I thought, “I’m doing this to take care of myself, and now you’re making me accountable?!” I don’t have time today!” And then after you talked a little more, then I felt better about it...I think it’s how you frame it. Or how I frame it for myself. [CR3]

You could try to be really empathetic and kind of understand why they didn’t get to it, versus the risk that if someone got an automated message that might just add to their sense of everything negative about why they haven’t done the skills. [PR2]

Across the board, providers and caregivers reiterated the importance of supportive and encouraging messaging when implementing the automated support features. This underscores the importance of emphasizing the rewarding aspects of participation—instead of reprimanding or penalizing caregivers for not using the various features. Furthermore, it may be helpful for this supportive language to be integrated not only into the automated support features but throughout the intervention as well—for example, using the registration emails, videos, and podcasts as opportunities for cheerleading and supporting participants.

Multimedia, Videos, or Podcasts

Multimedia content such as videos and podcasts may help enhance the perception that there are study staff members behind the program and other caregivers who are involved in the study. In previous versions of the intervention, caregivers worked one-on-one with a facilitator to learn the skills. To compensate for a lack of face time in this self-guided format, we proposed the addition of multimedia content to make the skill-building lessons more engaging by hearing directly from the team members involved in the development of the intervention. In their feedback, participants unanimously liked the idea of including this multimedia content:

I think that would be good. I mean, again, it takes the program out of being a program and puts it into a dialogue with someone. And I think it’s always good to see the face of the people who are running the program. [PX1]

It might be encouraging for them to hear and see that they’re not alone, that others have gone through it and have come out on the other side. [PX14]

Some participants suggested the idea of including a podcast as part of the program. This would allow caregivers to review the material at a time that is most convenient for them. This is consistent with feedback on other social features, in which participants suggested that flexibility may be helpful for caregivers who are busy:

And I like the idea of the podcast, so that you can do it on your time and when it’s convenient for you...ten, less than ten minutes here and there throughout the week... [CR1]
I participate in a 30-day class right now...It is a five-minute podcast that she sends, along with a list of daily activities and a curriculum has been provided in advance. So, you know that the five-minute podcast is five minutes out of your day, and you can do that, it's pretty easy to find five minutes. [CR4]

The overwhelmingly positive feedback on the proposed multimedia social features demonstrates that participants are interested in the sharing of insights from the study team as well as from previous participants. In the absence of live communication, their feedback suggests that such multimedia features may be central to developing a sense of social presence.

Informational Support

Caregivers often use web-based resources to seek information about providing care for their loved ones with dementia. While participants felt that informational support could be helpful, their feedback suggests that it was important for it to be targeted and provide specific information that was useful for caregivers:

But be real specific...the specific information is way more helpful. [PX6]

...my husband’s diagnosis is not specifically Alzheimer’s...a lot of the things that have to do with the Alzheimer's Association don’t apply to him... [PX10]

...the referral...You know, a piece of paper with 20 different organizations on it were not helpful. [CR5a]

Their feedback also suggests that many caregivers are discerning about such resources and sophisticated in their information search methods. Hence, the informational support provided by the intervention should be thorough and specific for it to be meaningful for participants. For example, participants indicated that it would be helpful if such resources were organized by geographic location or if they could be sorted in a way that would make it easy for participants to find the resources that are most helpful to them. Another approach would be to provide additional resources that relate specifically to the skills that are being taught.

Other Social Features

We also collected feedback on other social features that might be helpful for caregivers. One participant suggested that the study team solicit participants’ input throughout the program to foster a sense of involvement. This has some similarities to the brief survey that we will provide at the end of each lesson asking participants to rate how they felt about the lesson on a scale from 1 to 5 stars. While this feature was not previously considered a social feature, the act of soliciting feedback provides participants with an opportunity to express their thoughts about the program and reinforces the sense that there is a study team who is collecting the feedback and trying to improve the intervention for the benefit of caregivers:

I think asking for opinions...getting involved in just what you’re doing and asking what I think. “Okay, what do you think of the program?” It’s certainly one way to get involved, as long as it’s done in such a way that it’s meaningful. [PX1]

Participants also mentioned how the use of other platforms such as Instagram or Facebook may complement the intervention. The feedback suggests that creating a parallel dialogue on these already used platforms could foster an enhanced sense of social connection. One benefit to using these platforms is that participants would be able to connect with each other regarding the positive emotion skills across multiple platforms, which may enhance their learning. Participants also mentioned how the COVID-19 pandemic heightened their sense of social isolation; hence, the integration of these popular social networking platforms may help caregivers feel more connected as they complete the study:

I think if you had something that allowed people to respond to one another, whether it was a chat room...they create a Facebook group that is specific to that course...And that those people during that course can talk to each other, and every now and then the instructor chimes in if she feels that there’s something that she can add to it or some guidance. But I think something where people could connect would be nice. [PX10]

I was thinking along the same lines of connecting on a specific theme, you mentioned gardening or cooking, I think those are the kinds of things that people do on Instagram or Facebook. But the WhatsApp group can be more private, so it can be formed just with the people who meet each other, and then they can share... [PR5]

Discussion

Principal Findings

In this study, we collected feedback on social features that may be implemented for a web-based positive emotion skills intervention for AD and other dementia caregivers. Through (1) individual interviews with participants who completed a previous version of the intervention, (2) focus groups with dementia caregivers, and (3) focus groups with AD clinicians, we collected information about the specific needs and preferences of caregivers in the implementation of these social features. Participants provided a number of insights into how to implement these features in a way that may be best received by caregivers.

Overall, participants provided extensive feedback on the proposed features and how they could be best implemented. However, they had fewer suggestions for additional features that might enhance a sense of social connection. This may be because we asked participants open-ended questions about additional features toward the end of the interviews and focus groups, at which point they may have exhausted their ideas or there may have been overlap with our proposed features. Nonetheless, participants were engaged throughout the discussions and provided unique insights into how we could refine our feature set.

Participants generally liked the proposed social features and provided valuable suggestions for how they could be improved. One such example is the multimedia content proposed for the
intervention, for which participants suggested a podcast format to allow caregivers to review this additional material at their convenience. This is similar to other exploratory eHealth interventions that have used this delivery format to enhance health literacy [60], weight loss [61], and self-compassion [62].

Other feedback related to the automated support features, in which participants emphasized the importance of providing encouragement to caregivers instead of shaming them for nonadherence. In a study of a physical activity intervention for older adults, it was found that, when the messaging was positively framed (ie, described in terms of the rewards and benefits of exercise as opposed to the costs of inactivity), participants’ pedometer readings indicated that they had walked more compared to those who received negative or neutral messaging [63]. Therefore, we could incorporate this positive framing, for example, if participants have not logged into the website for several days, and send personalized email messages letting them know that their participation is missed, while recognizing that caregivers have busy schedules, and reminding them that they might receive a boost in positive emotion by spending just a couple of minutes completing the home practice activities.

There were certain instances in which caregivers and clinicians differed in their feedback. For example, caregiver participants were generally open to the idea of being paired up with a buddy in the program. However, clinicians who had implemented similar programs were able to speak from their own experiences with attempts to match participants that were not successful based on differences in life experiences and expectations for engaging with a buddy program. Thus, although caregivers thought that they would enjoy a buddy feature, clinicians noted significant barriers to the implementation of this feature. Another example of disagreement between caregivers and clinicians was the private messaging feature, where one clinician highlighted concerns about privacy and security that caregivers did not report. Across eHealth interventions, researchers have far more information about how these platforms work and the accompanying benefits and risks compared to their participants [64]. Hence, researchers have an ethical responsibility to convey this information to participants. Recognizing these differing perspectives underscores the importance of integrating feedback from both caregivers and clinicians in refining these social features.

Participants were asked for additional suggestions for features that would enhance social connection or a sense of social presence. Their suggestions included soliciting feedback from caregivers as they progress through the program and using existing social media platforms to foster a sense of social connection beyond the SAGE LEAF intervention.

Further Research and Implications

The feedback collected from the focus groups and interviews will be used to inform the development of the social features for the SAGE LEAF intervention. This will include developing a list of “trigger events” for the automated support features and wording the notifications or reminders in a way that would be supportive to participants. We will also include enhanced user profiles where participants can toggle how they would like to receive notifications and share more detailed information about their caregiving status to other users if they wish to. We will also include videos and podcasts where study team members will introduce each positive emotion skill and suggest methods for mastering it.

The feedback from the focus groups and interviews also helped clarify which social features may be potentially challenging to implement, such as the buddy system. In future versions of the intervention, a study team member could facilitate a matching process among participants. However, this may require additional resources to implement.

The feedback made clear that informational resources were extremely helpful for caregivers. However, it was apparent that caregivers already seek these resources through web-based groups or informational websites hosted by caregiver organizations. Furthermore, it appeared that this information is most helpful when it is specific and tailored for the caregiver and care recipient. Recognizing that the primary aim of the intervention was to deliver the positive emotion skills and not more general caregiving skills per se and acknowledging that it would take significant resources to successfully implement these informational support features, this feature is less likely to be prioritized for inclusion in future iterations of SAGE LEAF.

While this study focused on all the potential social feature enhancements (ie, discussion boards, podcasts, and automated notifications) intended for SAGE LEAF, future versions of the intervention could explore which enhancements are most effective by using a factorial design where participants are randomly assigned to different combinations of the features to determine which can be most helpful or may best enhance a sense of social connection. In a randomized controlled trial of a previous version of the intervention designed for individuals with depressive symptoms [50], we randomly assigned participants to different combinations of enhancements and found that facilitator contact in combination with virtual badges yielded the highest participant engagement. Given that SAGE LEAF will be entirely self-guided, future research should explore which features, individually and in combination, lead to the biggest impact on caregiver engagement and well-being. For example, user profiles may help caregivers disclose more information about themselves and their caregiving circumstances, which may then enhance the quality of the interactions that take place on the discussion boards. Additional research may also involve measuring the extent to which these combinations of features lead to measurable increases in social presence—which is hypothesized to mediate the relationship between the application of these social features and desired intervention outcomes.

Strengths and Limitations

The feedback collected from caregivers and providers offered valuable perspectives not only on features that may be helpful and engaging but also on ways in which they may be implemented to best benefit caregivers. In addition, the combination of interview and focus group formats allowed for both individual feedback and group discussions to aid in the generation of ideas.
However, the semistructured format of the interviews and focus groups potentially limited the range of feedback collected. With our questions focusing primarily on the proposed features, this may have constrained the participants’ ability to provide novel ideas for new social features.

Another limitation to our study is the lack of ethnic diversity in our caregiver sample, which consisted of primarily White participants. To achieve a more diverse sample and perspectives in future studies, future research should oversample for underrepresented ethnic groups if needed.

Conclusions
This study involved a qualitative analysis of focus groups and interviews with caregivers and clinicians to determine which social features might be most helpful in tailoring a self-guided positive emotion intervention for AD caregivers. The feedback collected suggests that the participants were mostly open and receptive to the innovative social features we proposed. However, their lived and professional experiences provided unique insights into how best to implement these features in a way that would be helpful and engaging for caregivers participating in future versions of SAGE LEAF.

Acknowledgments
The authors would like to express their gratitude to the Mesulam Center for Cognitive Neurology and Alzheimer’s Disease for their collaboration in this research. This study was supported in part by a Small Business Innovation Research grant (R43AG065080) from the National Institute on Aging to BrightOutcome. In addition, this study was supported in part by an Alzheimer’s Disease Core Center grant (P30 AG013854) from the National Institute on Aging to Northwestern University, Chicago, Illinois. The authors gratefully acknowledge the assistance of the Clinical Core and its participants. Generative artificial intelligence was not used in the writing of this manuscript.

Abstract

Background: Type 2 diabetes disproportionately affects South Asian subgroups. Lifestyle prevention programs help prevent and manage diabetes; however, there is a need to tailor these programs for mobile health (mHealth).

Objective: This study examined technology access, current use, and preferences for health communication among South Asian immigrants diagnosed with or at risk for diabetes, overall and by sex. We examined factors associated with interest in receiving diabetes information by (1) text message, (2) online (videos, voice notes, online forums), and (3) none or skipped, adjusting for sociodemographic characteristics and technology access.

Methods: We used baseline data collected in 2019-2021 from two clinical trials among South Asian immigrants in New York City (NYC), with one trial focused on diabetes prevention and the other focused on diabetes management. Descriptive statistics were used to examine overall and sex-stratified impacts of sociodemographics on technology use. Overall logistic regression was used to examine the preference for diabetes information by text message, online (videos, voice notes, or forums), and no interest/skipped response.

Results: The overall sample (N=816) had a mean age of 51.8 years (SD 11.0), and was mostly female (462/816, 56.6%), married (756/816, 92.6%), with below high school education (476/816, 58.3%) and limited English proficiency (731/816, 89.6%). Most participants had a smartphone (611/816, 74.9%) and reported interest in receiving diabetes information via text message (609/816, 74.6%). Compared to male participants, female participants were significantly less likely to own smartphones (317/462, 68.6% vs 294/354, 83.1%) or use social media apps (Viber: 102/462, 22.1% vs 111/354, 31.4%; WhatsApp: 279/462, 60.4% vs 255/354, 72.0%; Facebook: Messenger 72/462, 15.6% vs 150/354, 42.4%). A preference for receiving diabetes information via text messaging was associated with male sex (adjusted odds ratio [AOR] 1.63, 95% CI 1.01-2.55; P=.04), current unemployment (AOR 1.62, 95% CI 1.03-2.53; P=.04), above high school education (AOR 2.17, 95% CI 1.41-3.32; P<.001), and owning a smart device (AOR 3.35, 95% CI 2.17-5.18; P<.001). A preference for videos, voice notes, or online forums was associated with male sex (AOR 2.38, 95% CI 1.59-3.57; P<.001) and ownership of a smart device (AOR 5.19, 95% CI 2.83-9.51; P<.001). No interest/skipping the question was associated with female sex (AOR 2.66, 95% CI 1.55-4.56; P<.001), high school education or below (AOR 2.02, 95% CI 1.22-3.36; P=.01), not being married (AOR 2.26, 95% CI 1.13-4.52; P=.02), current employment (AOR 1.96, 95% CI 1.18-3.29; P=.01), and not owning a smart device (AOR 2.06, 95% CI 2.06-5.44; P<.001).
Conclusions: Technology access and social media usage were moderately high in primarily low-income South Asian immigrants in NYC with prediabetes or diabetes. Sex, education, marital status, and employment were associated with interest in mHealth interventions. Additional support to South Asian women may be required when designing and developing mHealth interventions.

Introduction

The South Asian population represents one of the fastest-growing minoritized groups in the United States [1]. Between 2010 and 2017, the population size grew from 3.5 million to 5.4 million, representing an increase of 40% [2]. South Asians include a diverse group of individuals with ancestry from India, Bangladesh, Pakistan, Nepal, Bhutan, Sri Lanka, and the Maldives, and the majority of South Asian individuals in the United States are foreign-born immigrants [1,2]. Approximately 10% of South Asian immigrants in the United States live in poverty, with immigrants from Bhutan (33.3%), Bangladesh (24.2%), Nepal (23.9%), and Pakistan (15.8%) having the highest poverty rates [3]. In New York City (NYC), compared to the 13% poverty rate among the non-Hispanic White population, poverty rates were reported to be much higher for the Bangladeshi (32%) and Pakistani (29%) populations [4]. A significant proportion of South Asian individuals have limited English proficiency (LEP) and are engaged in low-wage jobs (eg, taxi drivers, cashiers, and restaurant workers) [3].

Type 2 diabetes (T2D) disproportionately affects many racial/ethnic minorities in the United States, including the South Asian population [5]. The MASALA study, conducted between 2010 and 2013, found that the age-adjusted prevalence of T2D was 23% among individuals of South Asian ethnicity, compared to a prevalence of 9.4%, 13.3%, and 10.3% in the White, African American, and Hispanic American populations, respectively [5,6]. Similar patterns were observed in another population-based study, which reported that T2D prevalence was 17% in US Asian Indian, 15% in Native American/Alaskan native, 13% in non-Hispanic Black, 10% in Hispanic, and 8% in non-Hispanic White populations [7]. Given the high economic and societal costs of T2D, there is an urgent need to develop interventions to prevent and manage the T2D burden in the South Asian population.

Lifestyle counseling programs such as the National Diabetes Prevention Program or Diabetes Self-Management Education and Support program are evidence-based interventions that provide important counseling and support to individuals to manage or prevent T2D [8,9]. However, access to these evidence-based programs has been significantly limited among underserved immigrant communities [10]. First, these programs are often offered during in-person visits, which can be a significant barrier for many low-income South Asian immigrants who do not have a driver’s license or do not know how to navigate the public transportation system [11,12]. Second, most of these existing programs lack cultural and linguistic tailoring of the content [13]. A significant percentage of South Asian immigrants reported LEP and had difficulty understanding their health care providers during office visits [11,13]. In addition, the lack of cultural tailoring can make it challenging for this group of immigrants to initiate dietary and behavioral changes. Lastly, a lack of insurance or other financial barriers can further prevent South Asian immigrants from benefitting from these programs [14].

Given such barriers, mobile health (mHealth) has been rapidly growing over the past few decades and could be a promising approach to increase access to these evidence-based programs among South Asian immigrants [15,16]. Several studies suggest that text message–based interventions among minoritized populations can improve glycemic control for patients with T2D [17-19]. Using text messaging and social media platforms may be promising for immigrant populations, owing to their social needs to stay connected with friends and families in their home countries [20-22]. One mHealth study conducted in India found that participants receiving motivational messages to reduce diabetes risk behaviors had a greater improvement in health behaviors when compared to that of control participants [23].

The inclusion of culturally tailored mHealth interventions among South Asian individuals living in the United States has been largely limited [24,25]. While several research teams have reported using telephones to follow up or conduct motivational interviews with participants [26-28], the use of smartphone or remote technologies remains understudied among South Asian immigrants and there is little data characterizing the use and access of mHealth tools in this population. In a post–COVID-19 world, such information is urgently needed, given the increasing interest in telehealth. To address this knowledge gap, this study leveraged baseline data from the intervention groups of two parent clinical trials whose primary aims were to examine the effectiveness of a community-clinical linkage intervention on diabetes prevention and control in a primarily low-income South Asian immigrant population.

For this study, we examined technology access, current use, and factors associated with preferences for health
communication among South Asian immigrants in NYC. Given that South Asian women bear a higher T2D burden [29] than their male counterparts and face significant cultural barriers to health care–seeking behaviors [30], we also examined whether there were sex differences in technology access, current use, and preferences for health communication. Finally, we examined factors associated with interest in receiving diabetes information by (1) text message, (2) online (videos, voice notes, online forums), and (3) none or skipped, adjusting for sociodemographics and technology access. This information will serve as a critical first step to the development of tailored mHealth interventions for the South Asian immigrant population in the United States.

**Methods**

**Study Design**

We used data collected in two ongoing clinical trials focused on diabetes prevention and management among South Asian immigrants living in NYC (ClinicalTrials.gov NCT03333044 and NCT03188094) [31,32]. Both trials aimed to examine the effectiveness of an integrated community-clinical linkage intervention on health outcomes among low-income South Asian immigrants. For the diabetes prevention trial, the primary outcome was the proportion of participants achieving 5% weight loss at the 6-month follow-up. For the diabetes management trial, the primary outcome was the proportion of participants achieving a hemoglobin A1c (HbA1c) value of 7% or less at the 6-month follow-up. For both trials, primary data outcomes included measurements taken from electronic health records and survey data were only collected from intervention group participants; control group participants were not contacted. We conducted a cross-sectional analysis of deidentified data collected during the baseline period of the intervention for the participants from these two parent studies.

**Sample Recruitment**

Seven bilingual community health workers (CHWs) led the recruitment effort of the parent clinical trials. Participants were recruited from 18 primary care practice sites in NYC serving primarily South Asian patients (>70%). Registry reports were generated at each site to identify potentially eligible patients. Following the randomization of potential participants on the registry list, an introduction letter was mailed to all patients randomized to the treatment group. After 1-2 weeks, a CHW followed up with a phone call to provide further information.

To be eligible for the parent study, participants had to: (1) self-identify as South Asian; (2) be between 21-75 years old; (3) have an appointment with a physician for routine nonemergency primary care in the last 12 months; (4) have a diagnosis of diabetes for at least 12 months (for diabetes study participants); (5) have an HbA1c of at least 7% in the last 12 months (for diabetes study participants); and (6) have a BMI of ≥23 kg/m², as the threshold for overweight for Asian individuals [33] (for prediabetes study participants).

The study team first finalized all materials (flyers, consent forms, surveys) in English. One of the bilingual CHWs performed the translation and then conducted back-translation to account for discrepancies. Translated documents were then reviewed by separate bilingual CHWs to ensure accuracy and use of lay language. If there was any discrepancy, the group of CHWs met with the administrative team to reach an agreement. All study materials were available in English, Bengali, Urdu, and Punjabi. Surveys were administered by bilingual CHWs in the participant’s preferred language via face-to-face interviews or over the phone between 2019 and 2021.

**Ethical Considerations**

The parent studies (S17-00693 and S17-01479) were approved by the New York University Grossman School of Medicine Institutional Review Board (IRB). All participants provided informed consent. The parent IRB approvals cover the secondary analysis of deidentified data without additional consent from participants. In the parent studies, participants received a US $20 gift card for completion of the 6-month follow-up survey. The data used in the analyses were deidentified.

**Outcome Variables**

The outcome of interest was the participants’ preference in receiving diabetes information through the following modalities: (1) text message, (2) online (videos, voice notes, online forum), or (3) none/skipped question (suggesting no interest).

**Predictor Variables**

Sociodemographic information included age (continuous), sex, education level (high school or below vs above high school), marital status (married vs not married), employment status (employed, not employed, retired), LEP (speaking English less than very well vs well, not well, or not at all), and number of years lived in the United States (continuous).

Questions were adapted from the National Cancer Institute Health Information National Trends Survey [34] to assess technology access, current use of technology for health management, current social media use, and interest in mHealth interventions. The questions were reviewed by bilingual CHWs and our community advisory board for cultural relevance. Participants were asked if they owned a basic mobile phone, a smartphone, a tablet, or none of these (all options that apply could be selected). Participants owning a smartphone or tablet were asked whether any health-related apps were installed on the device (“yes” vs “no” or “don’t know”). All participants were asked if Wi-Fi was installed at home (“yes” vs “no”) and if they had used an electronic device (eg, Fitbit, blood glucose meter, or blood pressure monitor) to track their health in the past 12 months. Participants were asked if, over the past 30 days, they had used: (1) Viber, (2) WhatsApp, (3) basic text messaging through a phone carrier, (4) iMessage, (5) Facebook Messenger, and (6) IMO (a messaging app that is popular in South Asian countries).

**Statistical Analyses**

Descriptive statistics were used to examine the distribution of sociodemographic variables, technology access, current use, and interest in receiving diabetes information in the future in the overall sample and stratified by sex. Means and SDs are reported for continuous variables, whereas frequencies and

https://formative.jmir.org/2024/1/e52687
percentages are reported for categorical variables. Differences by sex were assessed using *t* tests and $\chi^2$ tests.

Bivariate analyses were run to examine each outcome and all potential predictor variables. The $\chi^2$ test was used for comparisons of categorical variables and ANOVA was used for comparisons of continuous variables. All variables found to be significant at $P<.01$ (with any of the three outcomes) were included in the initial regression models, along with variables that were not statistically significant in bivariate analyses but with theoretical significance. A total of three multivariable logistic regression models were used to examine factors associated with interest in receiving diabetes information via different mHealth modalities (dependent variable), including (1) by text message, (2) via combined online format (videos, voice notes, or online forum), and (3) not interested in receiving any diabetes information or skipped the question. In these multivariable logistic regression models, independent variables included age, sex, education, marital status, employment status, years in the United States, English proficiency, access to Wi-Fi at home, and access to a smart device. Adjusted odds ratios and 95% CIs were calculated. All analyses were performed with SPSS version 28.

## Results

### Participant Characteristics

The sample included 816 participants, with 413 (50.6%) in the prediabetes study and 403 (49.4%) in the diabetes study. The mean age of the participants was 51.8 (SD 11.0, range 22-75) years; 92.6% (756/816) of the participants were married and 89.6% (731/816) reported LEP. More than half the sample identified as female (462/816, 56.6%), reported a high school education or less (476/816, 58.3%), and were unemployed or retired (431/816, 52.8%). The majority of individuals were Bangladeshi, followed by Indian, Pakistani, Indo-Caribbean, and Nepali. All were born outside of the United States and the mean time lived in the United States was 12.9 (SD 8.7) years (Table 1).

There were sex differences in most sociodemographic characteristics (Table 1). Compared to male participants, female participants were significantly more likely to be younger, living in the United States for less time, have a high school education or less, be unemployed or retired (334/462, 72.3%; 97/354, 27.4%), and report LEP (Table 1).

Technology Ownership and Current Use

As shown in Table 2, nearly three-quarters of the participants reported having a smartphone, whereas less than 2% reported having a tablet. Of those with a smart device (smartphone or tablet), 22.1% (136/615) reported having apps related to health or wellness. Approximately one-quarter of the sample used an electronic device or monitor (eg, blood glucose meter, Fitbit band) to track their health in the past 12 months. The majority reported having Wi-Fi at home. The most common social media forms used in the past 30 days included basic text message via a cellular carrier and WhatsApp, followed by Viber and Facebook Messenger. When asked about interest in receiving diabetes information, three-quarters of the participants indicated interest in receiving diabetes-related information via text message, followed by videos, while 17.6% (144/816) of the participants were not interested in receiving diabetes information or skipped the question.

</tbody>
</table>
Similar to the sample characteristics, we also noted differences by sex (Table 2). Compared to male participants, female participants were significantly less likely to own a smartphone; have health-related apps on their smart devices; use Viber, basic text messages, WhatsApp, IMO, and Facebook Messenger among those with a smartphone or tablet; or report interest in receiving diabetes intervention via text message or videos. Conversely, female participants were significantly more likely to have a basic mobile phone and to report no interest or skipped the question about receiving diabetes intervention information compared to male participants.

**Factors Associated With Interest in Receiving Diabetes Intervention**

Table 3 provides a summary of the regression analysis to identify factors associated with an interest in receiving diabetes information. The significant factors associated with receiving information via text messaging included male sex, current unemployment, above high school education, and owning a smartphone or tablet.

When combining responses on videos, voice notes, and online forums/online support groups, participants who identified as male and who had a smartphone or tablet were more likely to report an interest in receiving diabetes information through these online formats.

Factors associated with no interest in receiving diabetes information or skipping the question included female sex, not married, currently employed, high school education or below, and not owning a smart device.

Discussion

Principal Findings

This study examined technology access, current use, and factors associated with preferences for health communication in a large sample of predominantly low-income South Asian immigrants with prediabetes or T2D. We found a moderately high level of technology ownership and social media usage, and that participants who were of the female sex, currently employed, not married, had high school education or below, and no smart device were less likely to report interest in mHealth programs.

Our data revealed that approximately three-quarters of South Asian immigrants in NYC had a smartphone and over 60% used social media or text messaging apps. These results revealed some gaps in access to smart devices between South Asian immigrants and the general US population. According to national mobile device ownership data compiled by the Pew Research Center, 85% of the overall US general population had a smartphone, including 85% of non-Hispanic White adults, 85% of non-Hispanic Black adults, and 83% of Hispanic adults [35]. While over 50% of the US general population owns a tablet, less than 2% of the South Asian immigrants in our sample reported owning a tablet. These data suggest that underserved low-income South Asian immigrants may need additional resources and infrastructure support to benefit from telemedicine or telehealth programs in the post–COVID-19 era.

Compared to male participants, female participants were less likely to own a smartphone, have health-related apps on the smartphone, use social media apps, or report interest in text messages– or video-based diabetes information. These differences may be explained by the different sociodemographic characteristics of female and male participants in our study. Compared to male participants, female participants were more likely to have a lower level of education and to be unemployed, which have been reported to be significant predictors of technology engagement and interest in mHealth-related interventions [36-39]. In addition, the gender norms in South
Asian culture may also contribute to these disparities. Past studies have noted patriarchal cultural norms in South Asian families, contributing to differences in health care–seeking and behaviors between men and women [30]. Future research studies may need to explore culturally tailored strategies that may better engage South Asian women in health and mHealth interventions [40].

Our findings also suggested that participants with less than a high school education, currently employed, and not having a smart device were more likely to report no interest in mHealth interventions or skip the question. These factors were consistent with several prior reports, which found that education, employment status, sex, and access to technologies significantly affect people’s current and future interest in mHealth interventions [36,38,40], as well as a study among South Asians in Canada [41]. Those with limited education and access to technology may have less exposure and experience with technologies and have limited digital literacy, and thus show no or little interest in technology-based interventions [38,39,42]. Future studies need to consider how to reach this group and design an appropriate intervention that meets their needs, which can help to ensure equity in the implementation of diabetes interventions and ultimately equity in health disparities driven by social factors.

Strengths and Limitations

There are several limitations of this study to note. We used available data from two clinical trials that aimed to test the effectiveness of an integrated intervention on diabetes prevention and management in South Asian immigrants in the United States [31,32]. To minimize participant burden, we did not include an extensive list of questions about digital literacy, prior experience with various technologies, and current use of various apps or health websites. In addition, some of the data were collected during the COVID-19 pandemic. Due to remote work and learning, some participants may have purchased a smartphone or Wi-Fi or used telemedicine services due to COVID-19 [43,44]. This may lead to higher rates of smart device ownership or interest in mHealth interventions. Finally, the study sample consisted of predominately low-income South Asian immigrants, largely those from Bangladesh, who participated as volunteers in our clinical trials; therefore, our findings related to technology use may not be generalizable to the broader South Asian community in NYC.

We also want to highlight several strengths of the study. This is a relatively large sample size with a sizeable number of male participants for a health intervention. All participants were recruited from clinical settings, which greatly enhances the representation of our sample. In addition, bilingual and bicultural CHWs took the lead in recruitment, which makes the inclusion of non-English–speaking participants possible. These populations were often overlooked or not included in clinical trials that focus on English-speaking populations [45,46].

Practice Implications

Compared to those of the general US population, the rates of technology access and adoption are relatively lower among underserved low-income South Asian immigrants, particularly among low-income South Asian women. When working with this community, it may be helpful to consider basic and simple technologies such as telephone calls and basic text messages. Although it is possible to engage this community in telemedicine or telehealth programs, this requires hands-on technology training and community engagement strategies. Due to COVID-19, our group transformed several in-person diabetes intervention programs into remote formats (eg, Zoom-based group sessions). Our preliminary data demonstrated great engagement and retention [15]. Our data also revealed that South Asian women were less likely to have access to technology or interest in mHealth interventions. Future work needs to explore barriers and develop tailored strategies to engage this unique group.

Conclusions

We found that technology ownership, access, and social media usage were moderately high in primarily low-income South Asian immigrants living in NYC with a diagnosis of prediabetes or diabetes. Significantly higher usage and technology access was seen among male participants than among female participants. Most participants reported interest in receiving diabetes-related information via text messaging or videos. However, disparities existed within our study sample. Female participants who had limited education and no smart device were more likely to report no interest in mHealth interventions. Future studies may consider strategies to engage South Asian women and leverage text messaging and social media apps as a potential strategy to disseminate culturally and linguistically adapted diabetes information in this underserved immigrant population.

Acknowledgments

We are grateful to all study participants for their time and participation in the parent studies. Abstract

Background: The COVID-19 pandemic has forced many health care providers to make changes in their treatment, with telemedicine being expanded on a large scale. An earlier study investigated the acceptance of telephone calls but did not record satisfaction with treatment or patients’ preferences. This warranted a follow-up study to investigate acceptance, satisfaction, and preferences regarding telemedicine, comprising of phone consultations, among health care recipients.

Objective: The primary aim was to assess the acceptance and satisfaction of telemedicine during the subsequent months of 2021-2022, after the initial wave of the COVID-19 pandemic in Switzerland. Furthermore, we aimed to assess patients’ preferences and whether these differed in patients who had already experienced telemedicine in the past, as well as correlations between acceptance and satisfaction, pain intensity, general condition, perception of telemedicine, and catastrophizing. Finally, we aimed to investigate whether more governmental restrictions were correlated with higher acceptance.

Methods: An anonymous cross-sectional web-based survey was conducted between January 27, 2021, and February 4, 2022, enrolling patients undergoing outpatient pain therapy in a tertiary university clinic. We conducted a descriptive analysis of acceptance and satisfaction with telemedicine and investigated patients’ preferences. Further, we conducted a descriptive and correlational analysis of the COVID-19 stringency index. Spearman correlation analysis and a chi-square test for categorical data were used with Cramer V statistic to assess effect sizes.

Results: Our survey was completed by 60 patients. Telemedicine acceptance and satisfaction were high, with an average score of 7.6 (SD 3.3; on an 11-point Numeric Rating Scale from 0=not at all to 10=completely), and 8.8 (SD 1.8), respectively. Respondents generally preferred on-site consultations to telemedicine (n=35, 58% vs n=24, 40%). A subgroup analysis revealed that respondents who already had received phone consultation, showed a higher preference for telemedicine (n/N=21/42, 50% vs n/N=3/18, 17%; χ² [N=60]=7.5, P=.02, Cramer V=0.354), as well as those who had been treated for more than 3 months (n/N=17/31, 55% vs n/N=7/29, 24%; χ² [N=60]=6.5, P=.04, Cramer V=0.329). Acceptance of telemedicine showed a moderate...
positive correlation with satisfaction ($r_s=0.41, P<.05$), but there were no correlations between the COVID-19 stringency index and the other variables.

**Conclusions:** Despite high acceptance of and satisfaction with telemedicine, patients preferred on-site consultations. Preference for telemedicine was markedly higher in patients who had already received phone consultations or had been treated for longer than 3 months. This highlights the need to convey knowledge of eHealth services to patients and the value of building meaningful relationships with patients at the beginning of treatment. During the COVID-19 pandemic, the modality of patient care should be discussed individually.

**Introduction**

Throughout the COVID-19 pandemic, there have been various measures to curb the spread of the virus, including restrictions on nonurgent care. In Switzerland, this resulted in the temporary suspension of most outpatient visits and the switch to telemedicine, that is, mostly phone consultations. This trend has been encouraged by various interest groups and associations advocating the rapid transition to remote services [1], especially because it can be argued that the COVID-19 pandemic not only exacerbates already persistent pain conditions but also increases the incidence of new-onset pain [2]. While some studies have examined the efficacy of eHealth for the treatment of several conditions (eg, osteoarthritis [3], musculoskeletal conditions [4,5], and chronic pain [6]), evidence from the patients’ perspective remains scarce, so that patients’ preferences are largely unknown, especially during this new era of the COVID-19 pandemic.

A previous survey conducted with 60 patients at our clinic showed that patients’ acceptance of telemedicine during the first wave of the pandemic was high [7]. However, at the time, satisfaction was not recorded. As this is an important aspect of patient-centered care [8], satisfaction has become part of the core outcome domains for chronic pain clinical trials [9] and serves as an anchor for clinically important differences in pain intensity and other outcomes [10]. Further, high satisfaction is associated with the appropriateness of care [11] and contributes to therapy adherence [12]. Likewise, preferences were not assessed in our first investigation. However, as fulfillment of patients’ preferences is linked to better adherence to therapy and better allocation of resources [13], it is important to know what patients actually favor.

Furthermore, psychological factors have a big impact on pain-related outcomes: generalized anxiety disorders can be linked to poor global well-being and life satisfaction [14] and hypochondriacal attitudes and beliefs have been shown to predict patients’ satisfaction [15]; therefore, these factors are important to take into account.

Finally, various studies provide evidence of the detrimental effect of physical distancing during the pandemic on mental health [16-19]. It is conceivable that governments’ restrictions influence patients’ acceptance and satisfaction with telemedicine.

This warranted a follow-up study to investigate (1) the levels of acceptance and satisfaction in the subsequent months, whether levels of acceptance changed after the first wave of the COVID-19 pandemic and what levels of satisfaction were achieved with telemedicine; (2) patients’ preferences for care during the pandemic and whether preferences differ in patients who had already experienced telemedicine; (3) correlations between acceptance and satisfaction, current pain intensity, general condition, as well as several measures of pain-related self-reports (anxiety, hypochondriacal worries, and catastrophizing) to assess whether these are associated with acceptance itself and patients’ preferences; and finally (4) correlation of acceptance with the severity of restrictive measures ordered by the government, to investigate whether more restrictions relate to higher acceptance.

**Methods**

**Sample**

We conducted an anonymous, voluntary survey between January 27, 2021, and February 4, 2022, at the Pain Center of the Bern University Hospital, Switzerland. Patients who were seen in person in our clinic received an invitation to complete the digital survey. Inclusion criteria were aged at least 18 years, with chronic pain, all conditions included. Patients with an acute illness requiring emergency procedures [20] were excluded.

**Procedure and Study Design**

A cross-sectional web-based survey was created to assess patients’ satisfaction with telemedicine consisting of phone calls (for the full questionnaire see Table S1 in Multimedia Appendix 1). In contrast to our previous study [7], the current investigation was conducted after the shutdown and with patients who were seen in person during routine outpatient treatment at our Pain Center. Whereas our previous study only accounted for first contacts with patients over the phone, the follow-up survey also involved patients who had already received a phone consultation. These respondents additionally rated their satisfaction as well as their perceptions of various aspects of telemedicine. A questionnaire was placed at the reception of our outpatient pain service, and newly referred patients were encouraged to complete it by scanning a QR code. We conducted this study solely by relying on departmental resources, without external funding.
Ethical Considerations

All the included patients provided informed consent for the reuse of their data. A jurisdictional inquiry was submitted to the Ethics Committee of the Canton of Bern, Switzerland (BASEC Req-2020-01406). The Ethics Committee decided that this study had no jurisdiction and was therefore exempted from ethics approval. Due to the anonymous assessment via QR code, it was impossible to identify individual patients. The participants received no financial compensation.

Materials

First, participants provided demographic data (sex and age) and reported the intensity and duration of their pain, their general condition, and previous interventional pain treatments.

Subsequently, the perceived acceptance of telemedicine and other aspects of patients’ expectations concerning the COVID-19 pandemic were assessed on a Numeric Rating Scale (0=not at all and 10=completely), that is, regarding their confidence in dealing with pain and with the pandemic, whether they feared a severe COVID-19 infection, and whether they thought the health care system and politics had taken the correct steps to cope with the consequences of the pandemic.

The validated German version of the generalized anxiety disorder 2-item [21,22] was used to assess the level of general anxiety with 2 items (eg, “nervousness, anxiety, or tension”) on a Likert scale from 0 to 3, ranging from “not at all” (0) to “nearly every day” (3), leading to a total score of 0 to 6, with a cutoff value of 3 for a generalized anxiety disorder.

To measure pain catastrophizing, the German short form of the Pain Catastrophizing Scale (PCS-6) was used [23]. The PCS-6 consists of 6 items (eg, “I keep thinking about how much it hurts”) that are rated on 5-point Likert scales, ranging from “not at all” (0) to “all the time” (4), leading to a total score of 0-24.

The Whiteley Index [24] was used to assess hypochondriacal worries and beliefs using 6 items (eg, “Do you often worry about the possibility that you have got a serious illness?”), rated on a 5-point Likert scale, ranging from “not at all” (1) to “very much” (5), leading to a total score of 6-30 [24,25].

Respondents were then asked to choose their preferred type of consultation during the COVID-19 pandemic: in person, by telephone, and/or by telemedicine. To check that our sample was representative, we compared the demographic data of our participants (sex, age, and pain intensity) with those of all patients who had been referred to the clinic during the study period. To analyze correlations with satisfaction, pain levels, general conditions, and other self-reported measures, as well as the severity of restrictive measures, a Spearman correlation was computed, with correlations of 0.2-0.4 considered weak, 0.4-0.6 moderate, and 0.6-0.8 strong [27].

Regarding preferences, we first analyzed them descriptively and then assessed whether they differed in participants who had previously received phone consultations, as well as whether there were differences between patients who had been treated for longer than three months at our clinic and newly treated participants. Using a chi-square test for categorical data, these groups were further evaluated with Cramer V statistic to assess effect sizes. A magnitude of 0.1 was considered small, 0.3 medium, and 0.5 large [28]. For continuous data, a 2-sided Student t test with equal variance or Welch t test in the case of unequal variance as indicated by the Levene test at P<.05 was calculated.

Descriptive analyses were performed with jamovi (version 2.2; jamovi project) [29]. Visualizations were performed using GraphPad Prism (version 8.0.0 for Windows, GraphPad Software), and R Studio Team (Posit). Correlations and corresponding graphs were computed in R Studio: Integrated Development for R (RStudio, PBC). Statistical significance was set at a P value of <.05.

Results

Demographic Data

The survey was accessible between January 27, 2021, and February 4, 2022. During this time, a total of 816 new patients were seen at our center. In total, 77 (9.4%) patients logged in, 60 (77.9%) patients of whom completed the questionnaire. Most participants were female (n=39, 65%) with an average age of 50.8 (SD 18.3) years (Table 1). About half of them (n=29, 48%) had been newly treated at the Pain Center, and the majority had already received phone consultations as part of their routine treatment (n=42, 70%). More than half of the respondents had previously received interventional pain therapy (n=31, 52%); however most procedures were either unsuccessful or had only provided short-term pain relief (n=24, 77%).

The mean pain intensity score was 6.3 (SD 2.3) and the general condition was reported to be 6.5 (SD 2.2; Table 2). A comparison with all patients who had been referred to the clinic (with acute and chronic conditions) during this study period revealed no statistically significant differences in terms of sex...
or age, indicating that our sample may be considered representative of all patients seen during this time (Table S2 in Multimedia Appendix 1).

<sup>i</sup>GAD-2: generalized anxiety disorder 2-item.
<sup>j</sup>PCS-6: Pain Catastrophizing Scale 6-item.
<sup>k</sup>WI-6: Whiteley Index 6-item.

**Acceptance and Satisfaction With Telemedicine**

The acceptance of telemedicine varied among patients, with a mean score of 7.6 (SD 3.3). Most reported that they would also have made use of telemedicine without the necessity imposed by the COVID-19 pandemic restrictions (item “phone consultation without COVID-19,” mean 7.7, SD 3.2) and those patients who had received phone consultation reported high levels of satisfaction (mean 8.8, SD 1.8). These respondents felt that their concerns had been taken seriously (mean 9.1, SD 1.6), that their questions had been addressed (mean 9.2, SD 1.3), and that they could be helped (mean 7.9, SD 2.7). The distributions of acceptance, satisfaction, pain, and anxiety are displayed in Figure 1.
Figure 1. Baseline characteristics of satisfaction, acceptance, pain, and anxiety. Violin plots showing the distribution of respondents’ answers (N=60) on an 11-point scale for acceptance, satisfaction, and pain (left y-axis). On the right and separated, anxiety scores are indicated on the 6-point GAD-scale (right y-axis). Continuous line indicates the median and dotted lines the 1st and 3rd quartile. GAD: generalized anxiety disorder.

Affective State and Processing of Pain During the COVID-19 Pandemic

Participants tended to think their pain would improve over the long term (mean 6.8, SD 2.5). They were even more optimistic concerning their ability to cope with pain (mean 7.5, SD 2.2) and with the COVID-19 pandemic (mean 9.0, SD 1.8). There was high variability in responses to the “fear of pain not being addressed adequately in the future” and “fear of a severe COVID-19 infection.”

Screening for anxiety using the generalized anxiety disorder 2-item showed low scores (mean 2.0, SD 1.7; see Table 2 and Figure 1). However, using a cutoff of ≥3 points [22], we found about 1 quarter (n=17, 28%) of our patients had a high likelihood of having generalized anxiety or panic disorder. Catastrophizing scores using the PCS-6 were generally high (mean 10.3, SD 6.1), while the assessment of hypochondriacal worries and beliefs (operationalized with Whiteley Index 6-item) showed rather low values (mean 7.0, SD 5.6).

Patients’ Preferences for Care

In total, 24 participants (n=24, 40%) preferred telemedicine to on-site consultations (see Table 2). Nonetheless, a more detailed analysis revealed substantial differences between subgroups. The predilection for on-site consultation was distinctly higher in patients who had never had a phone consultation (14 of 18 patients, 78%), whereas half of the respondents who had already experienced telemedicine preferred on-site consultation over phone consultations (21 of 42 patients, 50%). A chi-square test showed a significant association with a medium effect size (χ² [N=60]=7.5, P=.02, Cramer V=0.354).

Likewise, participants who had been treated for less than three months tended to prefer on-site consultations (21 of 29 patients, 72%), whereas those treated for longer durations slightly preferred telemedicine over on-site consultations (17 of 31 patients, 55%). Here, the chi-square test was also significant with a medium effect size (χ² [N=60]=6.5, P=.04, Cramer V=0.329).

Correlation Analysis

Acceptance of telemedicine showed a moderate positive correlation with satisfaction (rₛ [58]=0.41, P<.05) and a strong correlation with patients’ intention to use phone consultation outside of the COVID-19 pandemic as well (rₛ [58]=0.65, P<.05). In addition, in patients who had already experienced telemedicine, strong correlations were observed between satisfaction and quality-related items, such as the perception of sincerity and patients’ opportunities to clarify their questions (rₛ [58]=0.85-0.91, P<.05). Pain and psychometric scores showed moderate to high correlations. Figure 2 provides an overview of statistically significant results (P<.05) of the correlation analyses with at least a moderate strength (rₛ ≥0.4). There were no statistically significant correlations below moderate strength.
Correlation of Acceptance With the Severity of Restrictive Measures

The COVID-19 stringency index reached a median of 50.93 (IQR 48.15-56), and measures remained largely the same over the course of this study period. The severity of restrictive measures did not correlate significantly with acceptance of telemedicine or any other investigated items (satisfaction, pain, general condition, catastrophizing, anxiety, hypochondriacal worries and beliefs, confidence regarding the COVID-19 pandemic, fear of severe coronavirus infection, or impressions regarding correct medical or political steps).

Discussion

Principal Findings

This study sheds light on the clinical reality of the COVID-19 pandemic, including how remote services are perceived and what patients actually prefer. We found high acceptance and satisfaction levels of telemedicine. Nevertheless, respondents generally favored on-site consultations, while our subgroup analysis revealed that this was associated with whether they had already received a phone consultation or had been treated for more than three months at our Pain Center. Acceptance was moderately associated with satisfaction and strongly associated with willingness to use telemedicine outside of the COVID-19 pandemic. None of the assessed items were associated with the strictness of measures against the COVID-19 pandemic.

Compared to our previous investigation [7], the general condition was rated slightly higher in our sample, while the average pain intensity was comparable.

Acceptance, Satisfaction, and Preferences

Our findings underscore a central point: acceptance and satisfaction are not the same as preference. This seems to be overlooked often, as most studies have not assessed what patients favor when offered several options for consultation.
Some might accept and be satisfied with 1 service but still prefer the other [30]. For example, a recent investigation found high acceptability of a telemedicine pilot initiative for patients with chronic noncancer pain, but patients’ preferences were not examined specifically [31]. It is important to note that in our study, patients who had never experienced telemedicine or had only been treated for several weeks, preferred on-site consultations. One potential explanation could be that telemedicine is still largely unknown or underused by many patients. This is in line with a previous study that showed that one of the main reasons for not using telehealth was a lack of knowledge about it [32]. The good health coverage in Switzerland may contribute to this factor, as it is easier to find a timely appointment in person than in countries with more remote areas. Another reason could be barriers to accessing telemedicine in the senior population [33], who may not be as familiar with modern or unconventional modes of care. An additional factor could be trust in the practitioner, which has been shown to improve satisfaction as well as other patient-reported outcomes, such as quality of life [34]. In our case, it is conceivable that patients who had already had a telephone consultation and had a good experience gained more trust. The same applies to people who have been in treatment for longer than 3 months; they had more time to gain trust in the treating doctor.

In summary, telemedicine acceptance in our study was high and comparable to other investigations that have examined acceptance in other collectives: for example, 1 study in patients who were urogynecologic found 87% acceptance [35], while 2 scoping reviews found high acceptance of telemedicine in palliative care [36] and older adult patients with tumors [37]. In another cross-sectional study of patients with tumors, high satisfaction was found, with a mean of 5.5 out of 7 [38]. Nevertheless, while acceptance of and satisfaction with telemedicine were high in these investigations, these findings cannot be applied to every patient as a “one-size-fits-all” rule, as patients’ individual preferences (and needs) might differ. This was exemplified in a recently published systematic review with meta-analysis on outcomes of web-based pain management for chronic widespread musculoskeletal conditions where the investigators found clinically significant improvements but failed to show a clinically relevant change [39]. Based on our findings, we would recommend asking patients specifically what service and mode of treatment they prefer and to build upon personal therapeutic relationships, thus improving patient-centered care.

Furthermore, the COVID-19 pandemic has led to barriers to seeking emergency care [40], and this should be considered as promoting the implementation of digital services, such as telemedicine and digital triage [41]. Nevertheless, it is currently an open question how telemedicine will continue to develop in the Swiss population after the first waves of the COVID-19 pandemic, and to what extent the initiated changes will last. Research on the future use of telehealth, which considers the experience of COVID-19 and the impact of the COVID-19 pandemic on health care providers and patients, is essential.

**Correlation Analyses**

The values regarding perception of care were highly correlated with each other and satisfaction. While this is an unsurprising result, it highlights the importance of maintaining high-quality services, directly translating into how satisfied patients feel. Concerning the COVID-19 stringency index, we were unable to show any meaningful influence on satisfaction, acceptance, preferences, or the perception of treatment, which does not support the idea that patients are substantially driven by their perception of the “strictness” of governmental measures. Previously, we hypothesized that due to government restrictions, acceptance of and preference for telemedicine would be higher (as it is a measure of reducing personal contacts). Another explanation for the lack of correlation could be that during this study period, government measures were largely stable and varied only mildly, whereas, in theory, they could range between scores of 0 and 100. Therefore, the stringency index may show associations as soon as it exhibits greater change.

**Limitations**

Our study is limited by the small sample size and the low response rate, which is a problem for reliability and generalizability and can lead to a nonresponse bias. We attempted to address this by comparing the general patient population seen at our clinic with our study respondents to ensure representativeness. One reason why so few patients participated could be the number of standard questionnaires that they received before an appointment at our clinic. It is conceivable that this could lead to reluctance to fill out additional forms if they are not necessary for treatment. Additionally, as this was a web-based survey only, this could exclude patients who are not familiar with QR code scanning and handling of technical devices [42]. It is also important to note that measuring acceptance and satisfaction on an 11-point scale only allows a very general impression with no further information on why telemedicine was accepted or rejected. By contrast, validated questionnaires [43,44] could paint a more accurate picture. This limitation was somewhat mitigated by the fact that we also asked whether the patients felt taken seriously, whether their questions were answered, whether they could be helped, and whether they would use telemedicine even without the COVID-19 pandemic. These items were all strongly correlated with satisfaction, which can be interpreted as an indication of their importance to satisfaction itself. Additionally, this study lacked information on socioeconomic status, income, level of education, digital competence, and literacy. This is important to consider in the overall context, as lower literacy, for example, can be seen as a significant factor in the failure of a medical intervention. Future studies should consider these points to evaluate a more comprehensive assessment of access to health care, including telemedicine. A possible template for such a study is the Levesque access framework, which, in addition to the determinants of health care (approachability, acceptability, availability or accommodation, affordability, and appropriateness), also takes into account the individual possibilities of patients and can thus capture possible barriers to health care in a differentiated way [45,46]. The qualitative or quantitative assessment of these aspects is likely to play an increasingly important role in the future, especially in the...
implementation of more modern technologies, such as chatbots [47] or other automated systems controlled by artificial intelligence [48]. In our view, the evaluation of patient acceptance and satisfaction in these areas is crucial for ensuring patient-centered care. In patients with chronic pain, it would be interesting to investigate whether there are patient groups that particularly benefit from telemedicine (for example, those with limited mobility, more comorbidities, those with frequent medication adjustments, or the need for a higher frequency of care, such as cancer pain). Furthermore, the term “telemedicine” is widely used nowadays, and in our case, it was applied only to phone consultations. It is possible that participants in other outpatient settings using other services such as video chats might experience telemedicine differently and prefer these methods. Owing to administrative and legal hurdles in Switzerland, the general introduction of video consultations remains a challenge in the near future. Finally, options for billing patients are restricted to a maximum time limit of 20 minutes for an appointment by phone or video call according to the Swiss tariff structure [49].

**Conclusions**

Although telemedicine was widely accepted in our patient population and patients were generally very satisfied with it, they nevertheless preferred on-site consultations. In contrast, patients who had already experienced telephone consultation or those who had already undergone treatment for more than three months showed significantly higher preferences for telemedicine. This highlights 2 points: first, knowledge of eHealth services needs to be conveyed to patients to make use of its many advantages. Second, our investigation stresses the importance of building meaningful relationships with patients at the beginning of treatment and how this can improve patients’ perception of care. During the COVID-19 pandemic, the modality of care should be discussed individually for each patient.

**Acknowledgments**

The authors thank Jeannie Wurz (Department of Anaesthesiology and Pain Medicine, Inselspital, Bern University Hospital) for reviewing and providing helpful feedback during the development of this paper. Only departmental funding was provided for this study. No generative artificial intelligence (AI) was used in the preparation of this paper.

**Data Availability**

The data used to support the findings of this study are restricted by the Cantonal Ethics Committee of Bern, Switzerland, to protect patient privacy. Data are available upon reasonable request from MAH, Doctor of Medicine, for researchers who meet the criteria for access to confidential data.

**Authors' Contributions**

MAH takes responsibility for the integrity of the work. He designed this study together with KS, acquired data, conducted the main analyses, wrote the interpretation, drafted this paper, implemented revisions by the other authors, and approved this version. AS acquired data, conducted the main analyses, revised this paper critically, and approved this version. LB helped with the design of this study, revised this paper critically, and approved this version. ZN acquired data, helped with data interpretation, revised this paper critically, and approved this version. TCS helped with data interpretation, revised this paper critically, and approved this version. AL helped with the design of this study, helped with data analysis and interpretation, revised this paper critically, and approved this version. MgH helped with the design of this study, revised this paper critically, and approved this version. KS takes responsibility for the integrity of the work. He designed this study together with MAH, acquired data, helped with data interpretation, revised this paper critically, and approved this version.

**Conflicts of Interest**

The authors have no conflicts of interest to declare. TCS holds the endowed professorship for emergency telemedicine at the University of Bern, Switzerland, founded by the Touring Club Switzerland. The founders do not influence the general direction of telemedicine research. In particular, there is no influence on the content of this publication or the decision to conduct or publish this study. All coauthors have seen and agreed with the contents of this paper and there are no financial interests to report.

Abstract

Background: The adoption of mobile health (mHealth) apps among older adults (>65 years) is rapidly increasing. However, use of such apps has not been fully effective in supporting people with dementia and their caregivers in their daily lives. This is mainly attributed to the heterogeneous quality of mHealth apps, highlighting the need for improved app quality in the development of dementia-related mHealth apps.

Objective: The aims of this study were (1) to assess the quality and content of mobile apps for dementia management and (2) to investigate the relationship between app quality and download numbers.

Methods: We reviewed dementia-related mHealth apps available in the Google Play Store and Apple App Store in Taiwan. The identified mobile apps were stratified according to a random sampling approach and evaluated by five independent reviewers with sufficient training and proficiency in the field of mHealth and the related health care sector. App quality was scored according to the user version of the Mobile Application Rating Scale. A correlation analysis was then performed between the app quality score and number of app downloads.

Results: Among the 17 apps that were evaluated, only one was specifically designed to provide dementia-related education. The mean score for the overall app quality was 3.35 (SD 0.56), with the engagement (mean 3.04, SD 0.82) and information (mean 3.14, SD 0.88) sections of the scale receiving the lowest ratings. Our analyses showed clear differences between the top three- and bottom three-rated apps, particularly in the entertainment and interest subsections of the engagement category where the ratings ranged from 1.4 to 5. The top three apps had a common feature in their interface, which included memory, attention, focus, calculation, and speed-training games, whereas the apps that received lower ratings were found to be deficient in providing adequate information. Although there was a correlation between the number of downloads (5000 or more) and app quality ($t_{15}=4.087, P<.001$), this may not be a significant determinant of the app’s perceived impact.

Conclusions: The quality of dementia-related mHealth apps is highly variable. In particular, our results show that the top three quality apps performed well in terms of engagement and information, and they all received more than 5000 downloads. The findings of this study are limited due to the small sample size and possibility of disregarding exceptional occurrences. Publicly available expert ratings of mobile apps could help people with dementia and their caregivers choose a quality mHealth app.

Introduction

Background

The global aging population is experiencing an astonishing surge, which will inevitably result in a significant rise in the prevalence of dementia [1]. Consequently, it has become crucial to identify efficacious strategies to support people affected by dementia and enhance the well-being of their caregivers [2]. In addition, numerous studies have shown that mobile health (mHealth) apps can effectively reduce medical costs and improve quality of life for middle-aged and older adults, especially after COVID-19 [3,4].

The use of technology among older adults (aged >65 years) has triggered noteworthy transformations in health care provision [5]. An area where technology has proven especially valuable is in the realm of dementia management, with mHealth apps dominating the forefront of this field [6]. In addition, the UK government has shown support for the advancement of intelligent assistive technology for individuals with dementia [7]. This includes endorsing the development of mHealth apps specifically tailored to patients with early-stage dementia and their caregivers [8]. These apps are believed to have significant potential in aiding cognitive function and facilitating self-care among those living with dementia [9].

However, the constant emergence of mHealth apps has made it challenging for both patients with dementia and their caregivers across different categories. The second goal was to assess the quality of individual apps using the user version of the Mobile Application Rating Scale (uMARS). The third objective was to perform a comparative analysis of the highest- and lowest-quality dementia-related mHealth apps, with the broader goal of establishing guidelines to facilitate future app development. Finally, the study aimed to explore the correlation between app quality and downloads. This was done to help identify the gaps in the currently available dementia-related mHealth apps and to provide recommendations for patients with dementia and their caregivers on how to select high-quality apps.

Objective

This study had several goals. The first goal was to analyze the content of mobile apps for people with dementia and their caregivers across different categories. The second goal was to assess the quality of individual apps using the user version of the Mobile Application Rating Scale (uMARS). The third objective was to perform a comparative analysis of the highest- and lowest-quality dementia-related mHealth apps, with the broader goal of establishing guidelines to facilitate future app development. Finally, the study aimed to explore the correlation between app quality and downloads. This was done to help identify the gaps in the currently available dementia-related mHealth apps and to provide recommendations for patients with dementia and their caregivers on how to select high-quality apps.

Methods

Search Strategy and Inclusion Criteria

Apps were identified from the Taiwan Apple App Store and Google Play Store. Between July 2022 and November 2022, the following search terms (in Mandarin and English) were used in the app stores: dementia, cognitive dysfunction, dementia caregiver, Alzheimer disease, dementia care, cognitive games, and memory games. The screening criteria and process are illustrated in Figure 1.

Apps were included if they met all of the following inclusion criteria: (1) exists in the Google Play Store for Android mobile devices and the App Store for Apple mobile devices; (2) addresses daily-life topics related to neurocognitive disorders [17], and (3) was purposefully developed with the primary goal of supporting patients or caregivers (including health care workers) with the topic of mild cognitive impairment; (4) can be downloaded and used for free; (5) mainly uses Mandarin or the English version can be translated into Mandarin and is easy to understand; and (6) has been updated within the last 5 years.
Stratified Random Sampling of Apps by Average Download Numbers

In November 2022, searches were conducted on the two platforms to find apps that met the above criteria. Of the 407 apps found, 332 were deemed ineligible after screening (Figure 1). The remaining 75 apps were thoroughly screened, resulting in 52 apps included for preliminary evaluation. Since the length of time an app has been available on a platform can affect its number of downloads, we calculated the ratio of download numbers with respect to time on the platform. Additionally, to consider uneven allocation and lack of continuity in stratification, the apps were sorted according to the ratio of downloads relative to the number of days since the release date on the platform. Thus, the average number of downloads was calculated as the total number of downloads/number of days on platform since the release date. The apps were then ranked according to the average number of downloads in ascending order, and we randomly selected 1 out of every 3 apps for a total of 17 apps that were subject to detailed quality assessment and review.

General Characteristics and Classification

Each app was used by two authors (THC and WFM) independently. According to their content subcategory, the selected apps were categorized into four different types using the guidelines provided by the National Institute for Health and Care Excellence and the National Health Service in the United Kingdom [18,19]. Any conflicts in app classification were adjudicated by discussion between the two reviewers regarding each domain within the extraction form to reach consensus. Details on the main characteristics and comments of the included apps are provided in Multimedia Appendix 1.

mHealth App Quality Evaluation

The uMARS is a tool that can be used to evaluate the quality of mHealth apps, including four objective subdomains: engagement, functionality, esthetics, and information. There is also a domain for subjective quality and another for perceived impact. Stoyanov et al [20] developed the uMARS in 2016, which showed excellent internal consistency (Cronbach $\alpha=0.90$). The uMARS scores are rated on a 5-point Likert scale ranging from 1 (“strongly disagree”) to 5 (“strongly agree”).

The objective quality score is calculated as the average of the scores of the four dimensions. Engagement is defined as fun, interesting, customizable, interactive, and has prompts (eg, sends alerts, messages, reminders, feedback, allows sharing). Functionality refers to overall app functioning, easy to learn, navigation, flow logic, and gestural design of the app. Esthetics refers to the graphic design, overall visual appeal, color scheme, and stylistic consistency. Finally, the information domain assesses whether the app contains high-quality information (eg, text, feedback, measures, and references from a credible source). The subjective quality score reflects the rater’s personal interest in the app. The final uMARS subscale includes 6 items designed to assess the perceived impact of the app on the user’s awareness, knowledge, attitude, intention to change, help-seeking, and likelihood to change the target health behavior.
Reviewer Recruitment and Selection

Reviewers recruited for this study were required to have a professional background in clinical treatment, the health care industry, or information engineering. Additionally, they were required to have at least 3 years of work experience in elderly health care or health technology–related fields, as well as experience using digital mobile devices. Exclusion criteria included no relevant work experience in elderly health care or health technology–related fields in the past 5 years.

Five reviewers were recruited as an interdisciplinary group of experts. The initial reviewer possessed knowledge and had experience in creating a content management system for a dementia management app. The second reviewer was a health informatics researcher with sufficient training and expertise in the relevant health care technology fields focused on dementia. The third reviewer also had extensive experience in dementia and in the mHealth industry. The fourth reviewer was a psychiatric nurse with experience in caring for older adults along with clinical experience in dementia. The final reviewer was a nurse practitioner who has been providing care for older adults and patients with dementia for over a decade.

Evaluation Process

Each of the apps was assessed by the five reviewers and the evaluation process was conducted between December 17, 2022, and January 3, 2023. All 17 apps can be found on the Android platform; hence, the apps were reviewed when running on the same Android tablet. The experts were blinded to the download numbers, year, and country of development of the apps, and they were not allowed to discuss their assessments with each other to ensure independence in their ratings. We ensured an equal distribution of app assessments in each round by applying a ratio that took into account the download-to-time axis. Furthermore, each reviewer allocated a minimum of 30 minutes and a maximum of 1 hour to thoroughly evaluate the included apps.

Ethical Considerations

The study received ethical approval from the ethics committee of China Medical Hospital, Taiwan, on November 8, 2022 (approval number: CMUH111-REC2-151) and was conducted according to the guidelines of the Declaration of Helsinki.

The experts in this study were not compelled to take part and had the freedom to determine their involvement. Additionally, they possessed the ability to discontinue their participation at any juncture, without being required to supply a justification for their decision.

This study utilized legally obtained publicly available information, and it was ensured that the use of information aligns with its intended public knowledge purpose. Furthermore, data collected from research and expert evaluations are stored on a hard drive and encrypted. The evaluation process was fully anonymous, with no face-to-face interactions among experts, and the evaluation of the app was a non-nominal, noninteractive, and noninvasive study. Relevant original data regarding this research will be preserved for at least 3 years after the execution period, securely locked in the principal investigator’s office cabinet.

The clinical trial protocol developed by the research institute stipulates that in the event of adverse reactions resulting in damages, China Medical University Hospital is responsible for providing compensation. Nonetheless, adverse reactions explicitly disclosed in the informed consent form signed by the experts are not eligible for compensation. This study was not covered by liability insurance and the per-expert evaluation cost was US $170.

Statistical Analysis

The number and proportion of information displayed in the apps, including the country of app development, download number, and app type, were summarized using descriptive statistics. The uMARS scores, along with the scores for each domain and subscale, are presented as the mean and SD. The t test was used to examine the association between downloads and each domain of the uMARS. Statistical analyses were conducted using IBM SPSS Statistics v28 (IBM Corp). We considered \( P < .05 \) to indicate statistical significance in all analyses.

Results

App Attributes

The apps were primarily developed in the United States, and 11 out of the 17 dementia-related mobile apps were downloaded less than 5000 times. Among the 17 apps, 8 were classified as those designed to improve clinical outcomes from established treatment pathways through behavior change, and for enhancement of patient adherence and compliance with treatment; 5 were designed as standalone digital game therapeutics; 3 were classified for supporting clinical diagnosis and/or decision-making; and 1 app was primarily designed to provide disease-related education (Table 1).

App Quality Assessment by Interdisciplinary Experts

There was a notable level of agreement or correlation among the reviewers in their app evaluations, as indicated by the Kendall W statistic of 0.143, which was significant at P=.05.

Overall, the mean app quality score was 3.35 (SD 0.56), which ranged from 2.25 (worst-rated app) to 4.07 (best-rated app). For engagement, the mean score was 3.04 (SD 0.81). Furthermore, functionality had the highest mean score of 3.76 (SD 0.38) and showed the smallest variation in minimum and maximum scores among the apps evaluated. In other words, these apps were considered to have relatively high levels of functionality and usability by the interdisciplinary expert reviewers. The esthetic quality of the interface received a mean score of 3.45 (SD 0.65), indicating that visual design elements such as button size, icon clarity, and content arrangement were perceived as being well organized. Additionally, the information domain received a mean score of 3.14 (SD 0.88), suggesting that the presentation and accessibility of information on the screen could be improved. Multimedia Appendix 2 provides the complete details of app quality scores.

Top Three and Bottom Three Performers in App Quality Score

The apps ranked in the top three positions according to app quality scores included Memorad0 Brain Games, NeuroNation-Brain Training & Brain Games, and Brain Track. The common characteristic among these apps is that their interface consists of training games focused on memory, attention, concentration, calculation, and speed. Conversely, Alz Test, American Caregiver Association, and Dementia and Me ranked in the bottom three; these three apps performed poorly on both engagement and information.

The overall scores for each item for the top three and bottom three apps are provided in Table 2. The functionality domain received the highest average ratings, particularly for gestural design, navigation, and performance. The largest discrepancies in app quality ratings between the top three and bottom three apps were found in the areas of entertainment and interest, where the scores ranged from 1.4 (worst-rated app) to 5 (best-rated app). Similarly, in the subscale of perceived impact, there was
a significant difference in attitude, with ratings ranging from 1.2 (worst-rated app) to 4.2 (best-rated app).

Association Between Downloads and Quality of Mobile Apps

The Connectivity in Digital Health survey of global mHealth apps reported that 55% of the apps available on the Google Play store, Apple App Store, Windows Phone Store, Amazon Appstore, and Blackberry World had fewer than 5000 total downloads [21]. Therefore, the 17 apps included in our study were divided into two subgroups based on the total number of downloads. The first subset consisted of 6 apps with more than 5000 total downloads, representing 35.3% of all apps. The mean app quality score for this subgroup was significantly higher than that of the group of apps with less than 5000 downloads (Table 3). In addition, apps with more than 5000 downloads generally had higher scores for each domain. However, neither information nor perceived impact scores were significantly correlated with the number of downloads (Table 3).

Table 3. Independent-samples t test of the correlation of the scores of app quality with download numbers.

²uMARS: user version of the Mobile Application Rating Scale.

Discussion

Principal Findings

According to our results, there was only one included app that primarily focused on delivering dementia-related education. Furthermore, the top three quality apps were all classified as the main app type, as they all served as standalone digital game therapeutics. In general, the dementia-related mHealth apps were of moderate quality with a common characteristic of high functionality. Nonetheless, these apps exhibited poor performance in engagement and the credibility of information domain. Although we found a correlation between the number of downloads and app quality, this may not be a significant determinant of the information provided and the app’s perceived impact.

Comparison With Prior Work

mHealth apps offer a new way to support people with dementia and their caregivers [22]. However, previous studies have pointed out that the scientific literature on the design and evaluation of web- and mobile-based health apps remains scarce [23,24]. To address this issue, our study directly assessed the app type in a practical setting and found the lack of a dementia management app that delivers disease-related education. A randomized controlled trial indicated that mHealth apps can be of educational value to patients by providing structured disease and treatment-related education; therefore, future app developers can focus on increasing the availability of this app type with educational value [25].

A previous study suggested that research collaboration between health care and software engineering experts could help advance our knowledge of app functionality and effectiveness [16]. Therefore, we established a panel of experts to obtain accurate results on the quality of currently available dementia-related mHealth apps and further identified their subjective quality and perceived impact. The pattern of high functionality and low information quality is in accordance with the findings of other studies on mobile apps designed for older adults [26]. Additionally, the inadequacy of credibility was associated with several risks, particularly in the areas of self-diagnosis, prevention, and health promotion [27].

High-quality mHealth apps offer self-management features, relaxation, recreation, and trustworthy information [28,29]. The uMARS consists of elements of usability and a broader range of areas that are used in the assessment of mHealth apps with superior quality. Notably, a consensus was reached among the reviewers in both the engagement and esthetics domains. However, there was no correlation or similarity among reviewers with respect to assessments on functionality and information of the apps. This discrepancy may be due to the different backgrounds of the reviewers [30]; health care providers may perceive the app’s information as inadequate, whereas experienced developers of dementia apps may find its functionality to be lacking.

Currently, little is known about why some health apps become popular and others do not, and researchers have demonstrated that the number of downloads on app marketplaces does not correlate with clinical utility or validity for mental health apps [31]. A study from the Netherlands and Portugal identified the predictors that might influence the number of downloads for urology apps [32]. However, there is little research on the predictors of app downloads for dementia-related mHealth apps in the PubMed database. Hence, to gain a more comprehensive understanding, the apps were stratified using a random sampling
approach. Due to the different themes of mHealth apps, our study found a positive relationship between app quality and number of downloads. Finally, the download number does only seem to be a limited orientation aid for the selection of an mHealth app, and future studies should consider this aspect.

Limitations

This study has several limitations. Initially, the search for mobile apps was conducted within a limited time frame and focused on apps that had been updated within the last 5 years. As such, the study fell short with respect to establishing causal relationships. In addition, rapidly expanding and ever-changing mobile app marketplaces are facing significant challenges in keeping pace with the dynamic landscape; hence, some of the apps evaluated in this study may have since changed or new alternatives may have been developed. Furthermore, the search for mobile apps was confined to app stores in Taiwan, which may not accurately represent app offerings in other countries due to regional disparities in developers’ decisions regarding app availability.

Previous research indicated that the cost associated with using mHealth apps acts as a major obstacle for older individuals when it comes to embracing mobile technologies [9,33]. Furthermore, a recent study discovered that 96% of mHealth apps that are accessible on the Chinese market can be downloaded without cost [34]. Consequently, one-quarter of the apps would have been overlooked if they required payment. Nonetheless, it is possible that within this group of paid apps, there may have been some high-quality apps that were unintentionally excluded from consideration.

Additionally, the stratification method represents both less popular and highly downloaded apps, mirroring real-world data [21]. However, this method resulted in a smaller sample size, which could potentially lead to some superior apps being overlooked by chance. With only 17 apps remaining for evaluation, it is possible that there may not have been sufficient statistical power to establish a significant relationship between app quality and download frequency.

Finally, to ensure a rigorous evaluation of the app content, experts from different fields were recruited to review the apps. However, the limited number of reviewers could potentially influence the results of the study, and the degree of agreement may not be strong given that the reviewers are from different disciplines and the time they allocated to evaluate each app could potentially impact the reliability of agreement.

Despite these limitations, this study helps to fill the gap in the evaluation of dementia-related mobile apps. The results can still be used to guide the selection of such apps in Taiwan and possibly other regions with similar app marketplaces, while also highlighting the need for ongoing evaluation of mobile apps for dementia care.

Conclusions

This study set out to gain a better understanding of the characteristics, quality, and downloads of dementia-related mHealth apps. In particular, the top three quality apps were all offered as standalone digital game therapeutics, which scored well on both engagement and information quality, and received more than 5000 total downloads. Nevertheless, the findings of our investigation do not offer a comprehensive solution due to the restricted scale of the sample and the potential for overlooking extraordinary instances. Consequently, annual reviews and publicly available expert ratings of mobile apps could help people with dementia and their caregivers choose a high-quality mobile app.

Acknowledgments

The authors acknowledge all staff and participants for their contributions to the study. This study was supported by the Ministry of Science and Technology (MOST 110-2314-B-039-041-MY2; NSTC112-2314-B-039-015) and China Medical University (CMU111-MF-108), Taiwan. The funders reviewed the study as part of the grant application but had no further role in study design; data collection, analysis, and interpretation; manuscript preparation; and paper publication.

Data Availability

The study data are identified participant data. The data that support the findings of this study will be available beginning 12 months and ending 36 months following the article publication from the corresponding author (WFM) upon reasonable request.

Authors’ Contributions

THC and WFM designed the study and were responsible for data collection and analysis. THC, SDL, and WFM all contributed to manuscript preparation and critical revisions.

Conflicts of Interest

None declared.

Abstract

Background: Heightened stress and insufficient sleep are common in the transition to college, often co-occur, and have both been linked to negative health outcomes. A challenge concerns disentangling whether perceived stress precedes or succeeds changes in sleep. These day-to-day associations may vary across individuals, but short study periods and group-level analyses in prior research may have obscured person-specific phenotypes.

Objective: This study aims to obtain stable estimates of lead-lag associations between perceived stress and objective sleep duration in the individual, unbiased by the group, by developing an individual-level linear model that can leverage intensive longitudinal data while remaining parsimonious.

Methods: In total, 55 college students (n=6, 11% second-year students and n=49, 89% first-year students) volunteered to provide daily self-reports of perceived stress via a smartphone app and wore an actigraphy wristband for the estimation of daily sleep duration continuously throughout the academic year (median usable daily observations per participant: 178, IQR 65.5). The individual-level linear model, developed in a Bayesian framework, included the predictor and outcome of interest and a covariate for the day of the week to account for weekly patterns. We validated the model on the cohort of second-year students (n=6, used as a pilot sample) by applying it to variables expected to correlate positively within individuals: objective sleep duration and self-reported sleep quality. The model was then applied to the fully independent target sample of first-year students (n=49) for the examination of bidirectional associations between daily stress levels and sleep duration.

Results: Proof-of-concept analyses captured expected associations between objective sleep duration and subjective sleep quality in every pilot participant. Target analyses revealed negative associations between sleep duration and perceived stress in most of the participants (45/49, 92%), but their temporal association varied. Of the 49 participants, 19 (39%) showed a significant association (probability of direction>0.975): 8 (16%) showed elevated stress in the day associated with shorter sleep later that night, 5 (10%) showed shorter sleep associated with elevated stress the next day, and 6 (12%) showed both directions of association. Of note, when analyzed using a group-based multilevel model, individual estimates were systematically attenuated, and some even reversed sign.
Conclusions: The dynamic interplay of stress and sleep in daily life is likely person specific. Paired with intensive longitudinal data, our individual-level linear model provides a precision framework for the estimation of stable real-world behavioral and psychological dynamics and may support the personalized prioritization of intervention targets for health and well-being.

Introduction

Background

The transition to college is often accompanied by elevated stress and insufficient sleep [1-3], both of which have been found to impact daily functioning and, upon repeated exposure, to be associated with negative health outcomes ranging from internalizing disorders, including anxiety and depression, to cardiac and metabolic disease [4-9]. A better understanding of the dynamic day-to-day interplay between perceived stress and sleep duration could inform the mechanisms of their downstream impacts and the development of interventions to prevent or mitigate them [10-14]. Nevertheless, only a few studies have collected daily observations to evaluate within-person associations between stress responses and sleep duration, and their results are mixed: some studies report that heightened stress is followed by shorter sleep that night but not vice versa [15,16], others report that shorter sleep is followed by heightened stress the next day but not vice versa [17], and yet others report bidirectional relationships [18,19].

Inconsistent findings in stress-sleep associations might be at least partially explained by 2 interrelated methodological limitations, both of which are addressed by the individual-level modeling approach presented in this study. First, existing longitudinal studies have aggregated individual observations collected over short study periods of ≤14 days, thus limiting the estimation of stable associations that are robust to changing environmental demands (eg, first week of the semester vs final examinations period). Thanks to the adoption of digital phenotyping tools such as wearables and smartphones, research designs that sample individuals over much longer periods of time are increasingly feasible [20-22]. Sleep duration can now be passively tracked through continuous actigraphy sensing over months and even years, while perceived stress levels can be probed via brief daily smartphone-based surveys, with high compliance rates in student samples and small participant burden [23-25].

Moreover, the prevailing focus on group modeling and sample-level effects obscures the possibility that day-to-day associations between perceived stress and sleep duration may vary across individuals; for instance, it is possible that in certain individuals, getting less sleep than usual has no significant impact on stress levels the following day, but heightened stress during the day leads to shorter sleep duration later that night, while the opposite pattern might be true for others. Even when group-level models allow for individual-level estimates, such as in multilevel models with random effects, the degree to which the individual estimates are pulled toward the group (a shrinkage effect) is different for each individual based on the amount of data they provide, thus reducing the individual tailoring in a nonuniform manner [26].

Individual-level linear models (iLMs), which are fitted over a single individual’s intensive longitudinal observations, may offer a critical alternative to the estimation of stress-sleep associations. Compared to group-level approaches, iLMs provide estimates of phenotypes that are tailored to each person’s data and unbiased by the group [27-30]. They may also be more readily applicable in real-world contexts, where a clinician might use a precision health approach to evaluate and support each individual patient based on their personal data rather than on a hypothetical average patient [31-34]. Of note, individual-level approaches can also contribute to conclusions at the group or population level, such as by estimating the prevalence of each individually derived phenotype, rather than blurring across individuals, to arrive at a central tendency that might not accurately represent many of the included individuals.

Objectives

In this study, we introduce a novel iLM approach that leverages daily observations collected over a full academic year for the assessment of day-to-day associations between actigraphy-derived sleep duration and self-reported stress levels in first-year college students. Our aims were 2-fold. First, we used a pilot data set to develop and validate a parsimonious iLM that estimates concurrent or lagged associations between 2 daily variables of interest while accounting for the weekly structure in student behavior. We then leveraged this iLM for the target examination of bidirectional day-to-day associations between perceived stress and objective sleep duration in an independent data set of 49 first-year college students. We expected a negative association for most participants—such that higher stress levels are associated with shorter sleep—but we also anticipated that some participants might show positive or null associations. We further hypothesized that the lead-lag relationship between perceived stress and sleep duration (ie, which of the 2 temporally precedes the other) would vary across individuals such that, for some, elevated stress would associate with shorter sleep that night; for others, shorter sleep would associate with elevated stress the next day; and for still others, both directions of association would be identified.
Methods

Participants

Pilot Group

A total of 6 undergraduate students returning for their sophomore year volunteered for a year-long study (all aged 18-19 years; n=3, 50% women and n=3, 50% men). All had participated in a previous pilot study in our laboratory during their first year of college and were known to be compliant. These 6 pilot participants provided data to develop the statistical models that were then applied to the new group of target participants described in the next subsection. The pilot participants enrolled for this study during the first 2 weeks of their fall semester. As in the case of the target participants, they were required to be taking full-time classes and own a smartphone compatible with the study smartphone app, Beiwe, which is part of the open-source Beiwe platform for digital phenotyping [35]. Available and missing data information at the participant level is provided in Figure S1 in Multimedia Appendix 1. Given our focus on individual-level models where each person serves as their own baseline, and there is no aggregation across participants, students were not excluded for current or past psychiatric disorders or medication use, and nor were they excluded if they began treatment or medication for mental health issues during the study.

Target Group

In total, 49 undergraduate students beginning their first year of college volunteered for a year-long study (aged 18-19 years; mean age 18.1, SD 0.24 y; n=25, 51% women and n=24, 49% men). We have previously reported data from these participants [24]. Participants living on campus were recruited via flyers posted on campus boards and distributed via email lists and were enrolled during the first 2 weeks concurrently with the pilot participants. Enrollment criteria were the same as for the pilot participants other than the fact that the target first-year participants were all new to the university. Initially, 68 participants enrolled, of whom 19 (28%) were excluded based on issues with data acquisition, including early withdrawal from the study (n=7, 37%), technical failure of the actigraphy data (n=1, 5%), poor-quality actigraphy data (n=2, 11%), and completion of <50% of the daily surveys (n=9, 47%). Of the 49 participants in the final sample, 2 (4%) identified as American Indian, 5 (10%) as Asian, 7 (14%) as Black, 31 (63%) as White, and 2 (4%) as mixed race. Furthermore, 12% (6/49) reported prior diagnosis of a psychiatric disorder (including anxiety, depression, and attention-deficit/hyperactivity disorder), and 8% (4/49) maintained active diagnoses. The 49 first-year students had not yet declared their area of study, but they reported their desired future occupation to be medicine (n=15, 31%), business or finance (n=7, 14%), academia or other research (n=6, 12%), engineering (n=5, 10%), policy or government (n=5, 10%), law (n=4, 8%), and other or undecided (n=7, 14%). Of the 49 participants, 46 (94%) were iPhone users, whereas 3 (6%) used Android mobile phones.

Study Design

As previously reported in our study [24], this intensive longitudinal observational study collected passive and active data as participants engaged in their lives over a full academic year, extending a few days into the summer break. Both pilot and target participants completed smartphone-based daily surveys and a voice-recorded diary; wore an actigraphy wristband (GENEActiv Original; Activinsights Ltd) for continuous activity and sleep monitoring for the duration of the study; completed a battery of web-based questionnaires at the beginning, middle, and end of the study; and attended brief in-person check-ins every 3 to 4 weeks.

Ethical Considerations

Informed consent and all study procedures and methods were approved by the institutional review board of Harvard University (IRB16-1230). All participants completed an in-person informed consent session where study procedures were explained, and any questions were clarified. Participants were informed that they could withdraw their study participation at any time. Participants were compensated US $1 per each daily survey they submitted, US $1 per day for continuously wearing the actigraphy wristband, and US $20 per hour for web-based surveys and attending in-person visits. Milestone bonus payments for completing half of the study (US $100) and the full study (US $300) were also provided to compensate participants for their continued compliance.

Study data collected across devices were stored and automatically backed up in a secure data warehouse configured to automatically import data from various collection streams. All data were kept as securely as possible and were only accessible to study staff. Participants’ data were labeled with a randomly generated participant ID. Personally identifying information, such as names and contact information, were kept separate from all other collected data in a locked file cabinet (in a locked office, behind an ID card–secured suite during off-hours) and in a password-protected database.

Measures and Quality Control

Objective Sleep Duration

Daily sleep duration reflects the number of minutes between the estimated start and end of the day’s longest detected sleep episode. As redescribed from our original study [24], sleep duration was derived from the accelerometer data collected through the GENEActiv Original actigraphy wristband and analyzed via the deep phenotyping of sleep processing pipeline [36]. Participants wore the wristband on their nondominant wrist continuously, including during sleep and when bathing. Triaxial acceleration was collected with a sampling frequency of 30 Hz during the academic semesters and 10 Hz during the winter break (to extend battery life and memory while participants were away from campus). Participants were instructed to press the wristband’s button when they began trying to fall sleep at night and immediately after they awoke in the morning. Individuals exchanged their wristband for a fully charged one with reset memory at the in-person check-ins.
The deep phenotyping of sleep (DPSleep) processing pipeline was applied to the raw actigraphy data to detect the major sleep episode for each day [36]. The pipeline first converted the accelerometer data to minute-based activity estimates, removed the minutes when the individual was not wearing the device, and then estimated the major sleep episode based on a sliding window. Days where one of the boundaries of the sleep episode (ie, rises in relative activity both before and after a period of lower activity) could not be detected due to missing data were labeled as unusable. Two independent trained raters examined the automatically detected start and end times and the usability label of each sleep episode against the minute-based activity levels and the participant button presses when available. When necessary, they adjusted the automatic times and labels. Any disagreements between the 2 raters’ assessments were reviewed by the research team and resolved through discussion. A full description of the DPSleep processing pipelines applied to the actigraphy data, including quality control steps, can be found in the study by Rahimi-Eich et al [36].

All data that passed quality control were included in analysis, including days with no detected sleep episode (ie, with no extended periods of lower relative activity).

**Daily Telephone-Based Surveys**

Smartphone surveys were administered via the Beiwe app [35]. Each night before bed, participants completed a 46-item self-report survey related to their daily lives. As described originally in our study [24], the questions assessed a range of behaviors and internal states over the past 24 hours, including sleep quality, stress levels and sources, positive and negative affect, general physical health, daily consumption habits, studying behaviors, and sociability and support [24]. This paper reports analyses using 2 survey questions selected a priori that probed daily subjective sleep quality and perceived stress. The sleep quality question asked “How did you sleep last night?” and was answered on a 5-point scale (1 = terrible; little or no sleep, 2 = not so well: got some sleep but not enough, 3 = sufficient: got enough sleep to function, 4 = good: got a solid night’s sleep and felt well rested, and 5 = exceptional: one of my best nights of sleep). The perceived stress question asked “How much did you feel stressed over the past 24 hours?” and was also answered on a 5-point scale (1 = very slightly or not at all, 2 = a little, 3 = moderately, 4 = quite a bit, and 5 = extremely).

Surveys submitted between 5 PM (local time) on the day the survey opened and 6 AM the following day were considered to be on time. Surveys submitted after 6 AM the day after the survey was prompted were marked as missing. A participant was included in analysis if they were compliant with at least 100 daily surveys across the data collection period, and only on-time surveys from these participants were included.

**Analytical Approach**

**Development of the iLM**

An iLM was developed on the intensive day-level longitudinal data from the 6 pilot participants to test person-specific day-to-day behavioral associations. The iLM framework allows for individually tailored estimates by treating each day as the unit of observation and the individual as the population, as opposed to each individual as the unit of observation used to estimate the general population. An individual’s observed time series data can be understood as just one realization of a stochastic process whose data-generating process we are trying to model and understand [37], in this case through linear models. The intercept and slope estimates are unique to the individual, and we interpret them as a proxy for the individual’s phenotype. Of note, in this framework, each individual model can be interpreted as an independent test of the hypothesized association (eg, is shorter sleep than usual associated with heightened perceived stress the following day?).

The model was structured to be parsimonious while accounting for the nonindependence of the daily measures and the temporal structure imposed by the academic schedule. The day of the week was included as a categorical covariate to account for weekend versus weekday effects and other weekly structures imposed by the college schedule (eg, classes that meet on Monday-Wednesday-Friday vs those that meet on Tuesday-Thursday). In addition, because behavioral patterns during the semester vary substantially from those during the 5-week winter break (when students do not have classes and typically are away from campus), we decided a priori to only include in the model compliant data collected during the school semesters.

The final iLM took the following general form:

\[ y_t = \beta_0 + \beta_1 x_{\text{t-1}} + \beta_2 \text{DayOfWeek}_t + \epsilon_t \]

A daily observation on day \( t \) starts with the nighttime sleep episode and ends with the submission of the daily survey submitted in the evening before the next sleep episode. In the aforementioned formula, \( y_t \) is a single participant’s outcome variable (eg, sleep duration in min) at daily time point \( t \), \( \beta_0 \) is this participant’s individual intercept, \( x_t \) is the predictor variable (eg, sleep quality or stress measured on a 1-5 scale) at daily time point \( t \) or \( t-1 \) (depending on the lag of the tested association), \( \beta_1 \) is the participant’s individual slope for \( x_t \), and \( \epsilon_t \) is a normally distributed random error term.

All modeling was carried out in a Bayesian inference framework, which treats unknown parameters (eg, a slope) as random variables with a probability distribution rather than a discrete value; this distribution is updated based on the observed data (resulting in a posterior distribution) and serves as a measure of uncertainty around the parameter [38-40]. The Bayesian framework was favored for these analyses due to its flexibility in computing models with varied specifications (including complex random effect specifications in the multilevel models we fitted as part of our model validation process), robustness to sample data characteristics (eg, dispersion), and intuitive interpretation of the posterior distribution and 95% uncertainty interval (UI; ie, conditional on the data and the model, the probability that the parameter is contained in the interval is 0.95) [39,40]. For comparison, parallel iLMS fitted in a frequentist inference framework in the pilot validation stage yielded nearly identical point estimates.
to their Bayesian counterparts (refer to Figure S2 in Multimedia Appendix 1), suggesting that our model specification is robust across both statistical inference frameworks. All models were estimated in R (version 4.3.1: R Foundation for Statistical Computing) [41]. Bayesian models were estimated using the Stan modeling language [42] and the packages rstanarm (version 2.21.4 [43]), tidybayes (version 3.0.1 [44]), and bayesestR (version 0.13.1 [45]). Frequentist iLMs were estimated using the stats package included in base R [41].

Bayesian models were fit with default weakly informative priors specifying a gaussian distribution (mean 0, SD 2.5) to represent our diffuse prior knowledge. We estimated parameters using a Markov chain Monte Carlo (MCMC) approach. For each parameter, we sampled from 4 stationary Markov chains, each comprising 5000 sampling iterations, including a burn-in period of 2500 iterations that were discarded (for a total of 10,000 post–warm-up draws). Convergence of the 4 chains to a single stationary distribution was assessed quantitatively via the R-hat convergence diagnostic [46] (adequate convergence defined as R-hat <1.1) and qualitatively by visual inspection of trace plots showing the estimated parameter as a function of each chain’s iteration number (adequate convergence defined as the chains overlapping with each other throughout and a lack of structured patterns in each chain). Each model’s effective sample size (ESS) metric is reported. Each estimate in the MCMC process is serially correlated with the previous estimates: the higher the correlation, the more samples are needed to get to a stationary distribution. In the presence of nearly no autocorrelation, the ESS will be equal to the number of posterior draws requested (in this case, 10,000). Generally, the ESS should be at least 1000 to obtain stable estimates [38,47].

Adequacy of the model specification was assessed via 2 methods. First, posterior predictive checks entailed a visual comparison of the distribution of the observed outcome variable to the distribution of 100 simulated outcome data sets generated by applying 100 draws from the model parameters’ posterior distribution to our observed data set. Similarity in the distributions of the observed and model-generated outcomes suggests that the model specification captured the data well. Second, we inspected the model residuals against the model’s stationary distribution. In the presence of nearly no autocorrelation, the ESS will be equal to the number of posterior draws requested (in this case, 10,000). Generally, the ESS should be at least 1000 to obtain stable estimates [38,47].

We conducted model checks to evaluate the performance of the iLM framework. Posterior predictive checks (described earlier in this subsection) evaluated that a gaussian model specification captured the distribution of the data well. In addition, given the longitudinal design, we examined whether the model residuals lacked meaningful autocorrelation, which would suggest that our day-of-the-week covariate sufficiently captured the weekly structure of sleep duration. Finally, we compared the estimates obtained through the iLMs to the estimates obtained when the same data for the 6 pilot participants were fit within a single, group-based multilevel linear model (MLM), specifying fixed effects for intercepts and slopes and additional participant-level random intercepts and random slopes for the main predictor of interest (in this case, sleep quality). This comparison allowed us to assess our expectation that MLMs would provide individual estimates roughly comparable to those of the iLM, but with the critical difference that MLMs would systematically
attenuate these individual estimates, especially for individuals who deviate from the predominant association phenotype or when there is large heterogeneity in these phenotypes across individuals.

**Application of the iLM to the Novel Target Participants**

After developing the iLM and validating it extensively over the pilot data set, the modeling framework was then carried forward and applied to the independent target data set of first-year college students. All models were fit with a gaussian distribution. We first applied the same sanity check models as in the pilot data set. Subsequently, we used the iLM method to test a priori target hypotheses regarding the association between perceived daily stress and objective sleep duration.

Two target models were fit for each individual to examine bidirectional associations between sleep duration and perceived stress. A daily observation on day _t_ consists of last night’s sleep duration (ObjectiveSleepDuration, recorded passively via the actigraphy wristband) and the subjective rating of the present day’s overall stress levels (SubjectiveStressRating, reported by the participant in the evening). First, to test whether stress level during the day is related to sleep duration later that night (ie, a stress-then-sleep association), the model used the stress rating the day before sleep (day _t−1_ ) as the predictor of subsequent sleep duration (day _t_ ). Thus, the formula for this model was specified as follows:

\[
\text{ObjectiveSleepDuration}_t = \beta_0 + \beta_1 \text{SubjectiveStressRating}_{t-1} + \beta_2 \text{DayOfWeek}_t + \epsilon_t
\]

Next, to test whether sleep duration is related to stress levels the day after (ie, a sleep-then-stress association), the model used stress rating the day after sleep (day _t_ ) as predictor of the previous sleep duration (day _t−1_ , sleep duration last night):

\[
\text{ObjectiveSleepDuration}_t = \beta_0 + \beta_1 \text{SubjectiveStressRating}_t + \beta_2 \text{DayOfWeek}_t + \epsilon_t
\]

In this model, stress rating (predictor) is back-predicting sleep duration (outcome), which effectively tests the question “Is stress today associated with sleep last night?” As the objective sleep duration measure occurs temporally before the daily stress rating is submitted, results are interpreted as sleep duration being associated with increased or decreased stress the next day. Implementing the model in this way (rather than using sleep duration as the predictor and stress rating as the outcome) presented the advantage that the slope estimates across the 2 models are on equivalent units, namely, the change in the number of minutes in sleep duration per unit of change in stress rating. This allows us to directly compare the quantitative outputs for the models testing the questions “Is stress associated with subsequent sleep?” and “Is sleep associated with subsequent stress?”

As with the pilot data set, we conducted model checks to further evaluate the specification and performance of the iLM framework in our target data set, including posterior predictive checks; inspection of model residuals; and a comparison of the estimates obtained through the iLMs and the estimates obtained when the same data for the target sample were fit in a single, group-level MLM with random intercepts and random slopes per participant on the stress predictor. Additional inspection of model results against each participant’s raw time series data was conducted to complement our interpretation.

**Results**

**Participant-Level Descriptive Statistics**

Table 1 presents participant-level available data and summary statistics for sleep and stress variables used in analysis. The pilot participants provided a median of 178 (range 119-212 out of a total possible of 223) usable observations for modeling, that is, day-level observations collected during the school semesters with usable actigraphy and survey data. The target participants provided a median of 178 (range 84-214) usable observations. Participants’ total number of usable observations was not correlated with their mean sleep duration (r=0.09; _P_ =0.53) or mean stress levels (r=-0.11; _P_ =0.42). In addition, participants’ mean sleep duration did not differ on days with or without available actigraphy and survey data (paired 2-tailed _t_ test, _P_ =0.59), and participants’ mean stress levels did not differ on days with or without available actigraphy data (paired 2-tailed _t_ test, _P_ =0.70). These observations suggest that participants’ overall sleep and stress metrics did not introduce systematic missingness in the data (more details on participant-level missing data are presented in Figure S1 in Multimedia Appendix 1).

Sleep and Stress Fluctuate in Relation to the Academic Calendar in the Pilot Participants

There was a pattern of enhanced sleep and lower stress when students were released from the structured academic demands of the in-person school semesters. Participants were enrolled for a full academic year, including a fall semester and a spring semester (each lasting roughly 16 weeks), as well as a 5-week class-free winter break bridging the 2 semesters. During the winter break and weekends, pilot participants had longer objective (actigraphy-derived) sleep duration, better subjective sleep quality, and felt less stress compared to school semesters and weekdays (Figures 1A and 1B). The temporal structure of sleep and stress variables was further evidenced by their autocorrelation estimates. Autocorrelations were generally small (|r|<0.2; Figure 1C) but were strongest (highlighted with asterisks) at a 7-day lag (and again at a 14-day lag) for sleep duration, consistent with a weekly sleep schedule. By contrast, autocorrelations for stress were strongest at 1- and 2-day lags, suggesting that experiences of stress might come in chains of >1 day.

The school break and week-related changes observed in the data informed the design of the iLM seeking to capture stable person-level associations. Given that the winter break presents different environmental demands from the school semester, we decided a priori to exclude from the model the observations collected during this period. In addition, to account for weekly patterns in sleep behavior (outcome variable) within the school semesters, we added the day of the week as a covariate in the model.

iLMs Capture Day-to-Day Associations in the Pilot Participants

To test the viability of the iLM approach, a proof-of-concept model examined the association between objective sleep duration and subjective sleep quality in the pilot participants (Table 2 and Figure 2). This model allowed for a test of construct validity, given that the tested association was intuitive and expected. The model tested the association between sleep duration and sleep quality for the same sleep episode (ie, a concurrent association). All pilot participants showed the expected positive association: when participants slept for a shorter period than usual, they also subjectively rated these same sleep events as worse quality (shown in orange in Figure 2A). The effect size was large for all individuals, and the 95% UI lay outside of the ROPE for all models. These results provided preliminary evidence that the iLM is a valid framework to reliably detect relations between psychological variables (in this case, subjective sleep quality rating) and objective behaviors (sleep duration) at the individual participant level.

A second, exploratory iLM tested the association between sleep duration (on day \( t \)) and sleep quality the day before (on day \( t-1 \)). We expected this model to show significant but weaker effects compared to the first model, given that the variables were referring to lagged sleep events. Moreover, we expected negative associations such that worse sleep quality on one night would associate with longer sleep duration the next night, that is, a compensatory sleep rebound effect. Half of the participants (3/6, 50%; P1, P4, and P6) showed this expected pattern of association (pd>0.975; shown in blue in Figure 2). Of the 6 participants, 1 (17%; P2) showed a positive association such that worse subjective sleep quality experienced on the preceding night was associated with shorter sleep durations on the subsequent night. This participant might experience chains of poor sleep over multiple days (eg, reduced sleep days ahead of a deadline to accommodate increased workload), rather than a sleep rebound effect immediately the following night. In addition, of the 6 participants, 2 (33%; P3 and P5) showed a positive slope estimate but without reaching statistical significance (pd<0.975). We did not observe structured patterns of association between individual slope estimates and individuals’ mean sleep quality, mean sleep duration, or total number of daily observations (Figure 2B). This suggests that the estimated slopes were not systematically influenced by person-level characteristics of the psychological and behavioral phenomena of interest.
### Table 2. Pilot sample results of individual-level linear models assessing sleep duration associated with concurrent sleep quality and assessing sleep duration associated with sleep quality the day before (all models included the day of the week as a covariate, but the table only shows model parameters for the main predictor, sleep quality).

\(^a\)UI: uncertainty interval.  
\(^b\)pd: probability of direction.  
\(^c\)ROPE: region of practical equivalence.  
\(^d\)ESS: effective sample size.  
\(^e\)Statistically significant result.
Figure 2. Within-individual linear models capture real-world associations between objective sleep duration and subjective sleep quality. (A) Each row (from participant 1 [P1] to participant 6 [P6]) shows model results for an individual pilot participant. Individual-level models testing sleep duration associated with sleep quality the day before are displayed in blue; models testing sleep duration associated with concurrent sleep quality are displayed in orange. Column 1 shows the models’ estimated slopes (computed as the median of the posterior distribution) and uncertainty metrics. Symbol shading signifies statistically significant slopes. Error bars show 95% uncertainty intervals (UIs). Shaded density plots show the full posterior distributions of the slopes; gray shaded areas show the regions of practical equivalence (ROPEs). Column 2 shows the models’ predicted sleep duration as a function of sleep quality; shading around the lines indicates 95% UIs. Column 3 shows the participant-level distributions of sleep duration (in min) and sleep quality (1-5 Likert scale) across all daily observations used in analysis. (B) Slope estimates from column 1 in subpart A are plotted against participant-level estimates across the study period. Dur.: duration; n.s.: not statistically significant; pd: probability of direction; sig.: statistically significant.

Model Diagnostics Confirm Convergence and Adequate Specification

Both visual and quantitative MCMC diagnostic checks revealed that all iLMs converged successfully (Figure 3). Trace plots (Figure 3, column 1) revealed no structured pattern in the estimated slopes across sampling iterations. R-hat values were <1.1, and ESSs were >1000 for the estimated slopes of all models (Table 2). Posterior predictive checks comparing the observed distribution of the outcome variable (sleep duration) to 100 randomly sampled simulated data sets from the posterior predictive distribution confirmed that a gaussian model specification captured the observed data well (Figure 3, column 2). Inspection of the model residuals against the model’s predicted values confirmed homoscedasticity, with no structured pattern in the plots (Figure 3, columns 3 and 4). Finally, residual autocorrelation was generally low (|r|<0.2) for all models (Figure 3, column 5), suggesting that the model specification was able to account for the temporal structure in the data.
Figure 3. Within-individual model diagnostics suggest adequate convergence and specification. Each row (from participant 1 [P1] to participant 6 [P6]) shows model diagnostics for an individual pilot participant. Diagnostics for the models assessing the association between sleep duration and sleep quality the day before are displayed in blue; models assessing the association between sleep duration and concurrent sleep quality are displayed in orange. Column 1’s trace plots display time series of each Markov chain’s estimated slope (y-axis) as a function of postwarmup iterations (x-axis). Column 2 shows posterior predictive checks; black density lines show the observed distributions of the outcome (sleep duration), and the thin colored density lines show 100 replicated outcome distributions generated based on random samples from the models’ parameters’ posterior distributions. Columns 3 and 4 show the models’ predicted values (x-axis) against the models’ residuals (y-axis). Column 5 shows autocorrelation plots of model residuals.

iLMs Yield Similar, but Not Identical, Estimates to a Group-Based Multilevel Model

The slopes estimated from the iLM are similar to those obtained through a MLM testing the same associations between concurrent objective sleep duration and subjective sleep quality (Figure 4). This suggests that the individually tailored slopes obtained from our iLM are comparable to more traditional group-based approaches. Of note, although the estimates are similar, they are not identical. Comparison of the 2 models suggested attenuation of the individual-level estimates in the group models (refer to the part of Figure 4 highlighted with an asterisk). Even with random effects by participant, in the MLM, these estimates are, by design, biased by the group and may underestimate individual-level effects, especially for uncommon phenotypes [20]. As will be revealed later in the results from the larger sample of target participants, group-based estimation can even result in the reversal of the sign of the association for some individuals.
The iLM Is a Valid Framework to Identify Individual-Level Associations

Proof-of-concept analyses of the pilot data demonstrated that the iLM successfully captures expected associations between objective behavior and psychological variables, has an adequate model specification, and captures individual-level estimates unbiased by the group. Moreover, point estimates obtained with our Bayesian iLMs are nearly identical to those obtained through iLMs fitted with a frequentist inference framework (refer to Figure S2 in Multimedia Appendix 1), suggesting that our individual-level modeling approach is robust across both major statistical inference frameworks. In sum, the iLM is a valid framework to identify individual-level associations, which justified carrying over the model to test target hypotheses regarding the association between perceived stress and objective sleep duration in the independent target data set of first-year students (n=49).

Sleep and Stress Fluctuate With the Academic Calendar in the Target Participants

As with the pilot participants, during winter break and weekends, participants had longer objective sleep duration, better subjective sleep quality, and felt less stressed compared to the fall and spring semesters (columns 1 and 2 in Figure S3 in Multimedia Appendix 1). We replicated the autocorrelation pattern seen in the pilot data set: sleep duration showed the greatest autocorrelation at a 7-day lag (and then again at a 14-day lag), indicating that sleep patterns are tied to a weekly schedule, while stress showed the greatest autocorrelation at 1-day and 2-day lags, indicating that experiences of stress might come in chains of a few days (column 3 in Figure S3 in Multimedia Appendix 1). These school break– and week-related dynamics confirm that our target data set captured real-life dynamics associated with college life and reinforce our individual-level modeling decisions regarding the exclusion of winter break data and the addition of the day of the week as a covariate.

Shorter Objective Sleep Duration Is Associated With Worse Subjective Sleep Quality in the Target Participants

All participants showed a positive slope estimate for the association between concurrent sleep duration and sleep quality, and this effect was statistically significant in 46 (94%) of the 49 target participants (pd>0.975; Table 3 and Figure 5A, in orange). In other words, for only 10% of participants, sleep rated as worse quality was consistently followed by longer sleep the following night, suggesting that sleep rebound effects are perhaps less common or reliable than anticipated. Among these participants, a 1-point decrease in a 5-point sleep quality scale was associated with a subsequent sleep episode that was also longer by a median 59 (range 16-119) minutes, a substantial increase in sleep duration for most participants considering that the average sleep duration in the sample was 432 minutes (7.2 h; SD 34 min).

For the exploratory lagged model, the expected negative association between sleep duration and sleep quality the day before reached statistical significance in only 5 (10%) of the 49 participants (pd>0.975; Table 4 and Figure 5A, in blue). In other words, for only 10% of participants, sleep rated as worse quality was consistently followed by longer sleep the following night, suggesting that sleep rebound effects are perhaps less common or reliable than anticipated. Among these participants, a 1-point decrease in a 5-point sleep quality scale was associated with a subsequent sleep episode that was also longer by a median 18 (range 15-22) minutes across participants, a much smaller effect compared to the concurrent model. We did not observe structured patterns of association between individual slope estimates and individuals’ mean sleep quality, mean sleep duration, or total number of daily observations, suggesting that the model results were not systematically influenced by person-level aggregates of the variables that went into the model (Figure 5B).
Table 3. Target sample results of individual-level linear models assessing sleep duration associated with concurrent sleep quality (all individual-level models included the day of the week as a covariate, but the table only shows model parameters for the main predictor, sleep quality).

</table>
Higher Subjective Stress Is Associated With Shorter Objective Sleep Duration in Most Target Participants, but the Direction of the Temporal Association Varies

The slope estimate for the association between stress and sleep duration was negative in 86% of all iLMs fitted such that an increase in stress was associated with a decrease in sleep duration (Tables 5 and 6; Figure 6A). This association between stress and sleep duration reached statistical significance in 19 (39%) of the 49 participants (pd>0.975); of these 19 participants, 18 (95%) showed a negative association. Of note, the only participant who showed a significant positive association (T15, for the association between sleep duration and stress the day after) also had no usable actigraphy data over the full spring semester due to a technical issue with their wristband, and their estimated positive slope should therefore be interpreted with caution considering the structured missingness in their data. No other participant in the target sample showed this kind of systematic missingness in either the actigraphy or survey data streams (refer to Figure S1 in Multimedia Appendix 1).

Of the 19 participants who showed a statistically significant relationship between stress and sleep duration, 8 (42%) showed only the stress-then-sleep phenotype, that is, days with shorter sleep durations were preceded by higher stress the day before (Figure 6, in green) but not vice versa; 5 (26%) showed only the sleep-then-stress phenotype, that is, nights with shorter sleep duration were followed by increased stress the day after (Figure 6, in purple); and 6 (32%) showed bidirectional effects such that nights with shorter sleep duration were preceded by increased stress the day before as well as followed by increased stress the day after. Among participants who showed a significant association between today’s stress levels and sleep duration later that night (14/49, 29%), a 1-point increase in a 5-point perceived stress scale was associated with shorter subsequent sleep duration of a median 17 (range 11-33) minutes across participants. Among participants who showed a significant association between today’s stress levels and last night’s sleep duration (11/49, 22%), a 1-point increase in a 5-point perceived stress scale was associated with shorter previous sleep duration of a median 18 (range 10-38) minutes across participants. These effects would compound to more substantial reductions in sleep duration with greater increases in daily stress.

Individual slope estimates of the association between sleep duration and stress showed no clear pattern of association with individuals’ mean sleep duration or the number of daily observations that went into the model (see Figure 6B for mean sleep duration and number of daily observations). Individuals with higher mean stress tended to have a larger absolute slope estimate (see Figure 6B for mean stress), perhaps because participants with very low stress levels have little variance to be modeled.

**Figure 6.** Higher subjective stress associates with shorter objective sleep duration in most individuals. (A) Estimated slopes (corresponding to the median of the posterior distribution) from the individual-level models that assess sleep duration associated with stress the day before (triangles) and with stress the day after (circles) are plotted along the y-axis ordered by participant (x-axis). Statistically significant slope estimates are shaded green (day before) or purple (concurrent). Error bars show 95% uncertainty intervals, and shaded density plots show the full posterior distributions of the slopes. (B) Slope estimates from subpart A are plotted against each participant-level estimate across the study period.

**Person-Specific Estimates Get Attenuated in Group-Based Modeling**

A comparison of the estimates obtained through the iLM and those of an MLM demonstrates that individual-level estimates get systematically attenuated in a group-based approach when there is between-person heterogeneity in the effects (Figure 7). When there was a strong effect and small between-person variability in the tested associations, as with the association between sleep duration and concurrent sleep quality, the iLMs provided slope estimates nearly identical to those estimated through an MLM (Figure 7A). However, for associations that showed a weaker effect and greater degree of between-person variability, group-level approaches systematically flatten individually tailored effect sizes or even reverse the sign of the association (Figure 7B). We observed this in the lead-lag associations between stress and sleep duration (as highlighted with asterisks in Figure 7) and to some degree in the lagged association between sleep quality and sleep duration.
Examining Raw Within-Individual Data Informs the iLM Results

A closer look at individual participants’ data reveals important considerations for the application and interpretation of the iLMs (Figure 8). As with other statistical models, the iLM is unlikely to detect stable associations for participants with too little variability in their data; for instance, participant T45 had consistently low stress levels over the course of the year, with occasional, small increases in stress tied to periods with increased academic demands (eg, ahead of midterm and final examinations periods). This participant’s individual linear models showed null results for both directions of stress-sleep associations (pd<0.975). Meanwhile, participant T29 also had low baseline stress levels, but they presented more frequent and substantial rises in stress throughout the year. Participant T29’s iLMs showed bidirectional negative associations between stress and sleep duration (pd>0.975).

While variability in daily observations over time is necessary to detect linear associations within the iLM, variability alone is not sufficient. Participant T10 showed substantial fluctuations in stress and sleep duration throughout the year, and their iLMs found bidirectional negative associations between stress and sleep duration (pds>0.975). Meanwhile, participant T16 also presented substantial variability in stress and sleep duration, and while their iLM detected a significant association between sleep duration and stress the day after (pd=1.00), no association was detected in the opposite direction (pd=0.65).
Figure 8. Intensive within-individual longitudinal data reveal differences among individuals. Results are shown for individual-level models testing the association between sleep duration and stress the day before (green) and between sleep duration and stress the day after (purple). Column 1 shows the models’ estimated slopes (computed as the median of the posterior distribution) and uncertainty metrics. Symbol shading signifies statistically significant slopes. Error bars show 95% uncertainty intervals (UIs). Shaded density plots show the full posterior distributions of the slopes; gray shaded areas show the regions of practical equivalence (ROPEs). Column 2 shows the models’ predicted sleep duration as a function of stress; shading around the lines indicates 95% UIs. Shaded density plots show the full posterior distributions of the slopes; gray shaded areas show the regions of practical equivalence (ROPEs). Column 3 shows daily observations of actigraphy-derived sleep duration and survey-based perceived stress. Gray dashed lines show the participant’s mean value across the study period. Vertical lines indicate landmark events (labeled) in the academic calendar. Gray shading indicates missing data during the school terms or the winter break, which were excluded from the individual-level linear models. Dur.: duration; E: examinations period; n.s.: not statistically significant; pd: probability of direction; R: reading period; SB: spring break; sig.: statistically significant; TB: Thanksgiving break; WB: winter break.

Discussion

Principal Findings

Stress levels and sleep duration interact in an individual’s daily life, but research has yielded mixed findings regarding the temporal directionality of their associations, with changes in stress preceding changes in sleep, changes in sleep preceding changes in stress, or both. Here, we leveraged a novel individual-level linear regression modeling iLM framework to obtain precision estimates of day-to-day associations between self-reported stress levels and actigraphy-derived sleep duration in a sample of first-year college students studied continuously for a full academic year. While most of the participants (45/49, 92%) showed a negative association between daily stress levels and sleep duration, the temporal direction of the association varied, with all types of lead-lag association previously reported at the group level present within distinct individuals in our sample.

In agreement with prior literature, our results within individuals confirm that stress levels and sleep duration are closely and inversely related in daily life [10-19]. Nearly four-tenths (19/49, 39%) of the participants—each considered an independent test of the association—showed a negative association between daily stress levels and sleep duration, the temporal direction of the association varied, with all types of lead-lag association previously reported at the group level present within distinct individuals in our sample.

Our precision approach further revealed that the temporal directionality of the association between stress and sleep duration varied from person to person, representing all patterns of results reported by prior, group-level studies. For some of the participants (8/49, 16%), heightened stress during the day associated with shorter sleep later that night but not vice versa, in agreement with group results reported in the studies by Marcusson-Clavertz et al [15] and Slavish et al [16]; for others
(5/49, 10%), shorter sleep associated with heightened stress the next day but not vice versa, in agreement with group results in the study by Sin et al [17]; and yet others (6/49, 12%) showed both directions of association, in agreement with group results in the studies by Doane and Thurston [18] and Yap et al [19]. Daily psychological and behavioral experiences such as perceived stress and sleep duration thus seem to interact in person-specific ways, rather than being uniform across the population.

For individuals showing the stress–then–reduced-sleep phenotype, experiences of heightened stress (eg, due to an impending final examination or social conflict) might elicit hyperarousal and rumination [13,51-53], as well as behaviors aimed at mitigating the source of stress (eg, studying or socializing with friends late into the night), all of which can delay sleep and reduce its overall duration. Moreover, for those showing the reduced-sleep–then–stress phenotype, shortened sleep durations might enhance their sensitivity to (and undermine their ability to cope with) academic, interpersonal, or other stressors and thus make them more likely to experience heightened stress levels [10,54,55]. For some individuals, both patterns of effect might occur, with changes in stress levels and sleep duration reinforcing one another and resulting in chains of days with heightened stress and nights of short sleep that succeed one another.

Critically, our results suggest that group-level studies might report inconsistent findings, at least partly, because the dynamic interaction between daily stress levels and sleep duration varies from person to person. When data are aggregated at the group level, individual phenotypes might be obscured, and the resulting group-level estimates are suggestive of generalized effects when in fact they might only apply to a fraction of the sample. Even when hierarchical group models allow for fitting individual estimates, these are biased by the group and tend to attenuate (or shrink) the estimation of individual effects [26]. A comparison of individual slope estimates of stress-sleep associations derived from our iLMs and those derived from an MLM with random intercepts and slopes starkly demonstrated this group bias: the group MLM estimated individual slopes that were systematically attenuated or even reversed sign compared to those estimated by our iLMs.

These results demonstrate the utility of individual-level modeling for characterizing real-world behavioral and psychological dynamics [27-29,34]. Our approach leverages mobile and wearable technology and provides a fit-for-purpose methodology that can turn these devices’ large-scale longitudinal measurements into meaningful insights. The iLM’s model specification is parsimonious by design and easy to interpret, including a single linear term for the main predictor of interest and a day-of-the-week covariate to account for the weekly structure in the outcome variable. Diagnostic checks confirmed that this simple model specification was powerful enough to capture real-world, stable linear associations between psychological phenomena and objective behaviors, while accounting for the time-related dependencies in the daily observations. Individual tailoring is achieved by fitting only 1 person’s data within a model, but the model specification remains identical across individuals, allowing for direct between-person comparisons of results, including estimating the relative prevalence of different phenotypes in the group.

The iLM framework is readily applied to a single individual’s data, making it useful for multiple real-world purposes beyond fundamental research that are increasingly gaining interest in the fields of consumer health informatics and digital health [21,31,32]. The iLM can be applied to data collected through personal devices for self-monitoring as well as for precision approaches in health care settings, where clinicians might use a patient’s data to triage intervention plans. Taking these results as an example, stress management interventions might be first prioritized among individuals for whom heightened stress precedes shortened sleep, while sleep interventions might be prioritized among individuals for whom shortened sleep precedes heightened stress. Moreover, this work might inform a growing body of research and products combining multiple data streams from wearables and smartphones along with machine learning techniques to predict experiences of stress [36,57]. Although prediction was not the focus of our work, understanding the person-specific association between stress and sleep duration, as well as the weekly behavioral patterns revealed by our actigraphy and survey data and individualized approach, could potentially contribute to the identification of periods when individuals are more likely to experience stress so that timely interventions can be offered.

The iLM offers a simple yet powerful precision framework for the estimation of real-world psychological and behavioral associations within the individual, but the results should be interpreted carefully in light of its assumptions and limitations. First, the iLM’s assumptions of linear, stable associations between the predictor and outcome variables are a deliberate attempt to simplify real-world behavioral and psychological dynamics that are highly complex. In the context of this study, these features allowed us to estimate college students’ day-to-day stress-sleep associations that are stable across the fluctuating demands on students within the school semesters as well as straightforward to interpret. However, it is possible that the association between stress and sleep duration is context dependent, varying as a function of the specific source of stress experienced by the individual (eg, academic vs interpersonal) and the broader seasonal demands (eg, whether school is in session). In fact, given the possibility of the latter, we decided a priori to exclude data collected during the winter break from our models. Future research could examine how these contextual demands influence stress-sleep associations, as well as explore nonlinear associations or cumulative effects over time.

Our analyses leveraged leading and lagging patterns in each individual’s time series of stress and sleep duration measures to ascertain the temporal directionality of their association (eg, stress during the day as a predictor of subsequent sleep duration later that night), but we did not implement a controlled experimental manipulation and cannot establish a causal relationship. While our use of intensive longitudinal data collected in the real world grants our results ecological validity, it also exposes them to confounders; for example, it is possible that a significant association between short sleep and higher stress the next day could be explained by the anticipated demands of the next day, such as an examination. Rather than
short sleep duration causing higher stress the next day, the examination might be the primary cause behind both the short sleep (staying up late to prepare) and the stress reported the next day (heightened stress during test taking).

While our current intensive longitudinal data set and individual-level modeling framework passed sanity checks and diagnostics that confirmed data quality and adequate model specification, researchers applying our framework to other data sets and research questions should scrutinize the appropriateness of the data and the model before interpreting the results. Mobile and wearable technologies enable the collection of large behavioral data sets over time, but quantity does not guarantee quality, and long study periods require extra vigilance to ensure that participants remain compliant over time. Quality checks should confirm that the data collected are capturing expected real-world behavior (eg, as suggested by the intuitive changes we observed in students’ behavior between school terms and breaks as well as between weekdays and weekends). Even if the available data are substantial, and participant compliance is high, small variability in the metrics under study could still impede obtaining meaningful estimates of their associations, as demonstrated by participants with minimal fluctuations in stress levels over the course of the academic year. Moreover, investigators should be careful to identify appropriate uses, sanity checks, and interpretations of the iLM for their population of study; for example, part of our iLM validation process included testing the expected positive association between objective sleep duration (measured via the actigraphy wristband) and the participant’s subjective rating for the same sleep event (reported via a daily smartphone survey). While we expect that generally healthy participants will tend to rate nights of shorter-than-usual sleep duration as lower quality, it might not always be advisable to assume a simple linear association between objective sleep duration and subjective sleep quality, especially when modeling data from patients with sleep and psychiatric disorders.

**Conclusions**

Our novel iLM framework leveraged intensive longitudinal data from mobile and wearable devices to obtain individually tailored estimates of day-to-day associations between subjective stress levels and objective sleep duration. While stress and sleep duration were inversely related in most of the participants (45/49, 92%), the iLM revealed that the temporal direction of these associations is person specific, identifying a variety of individual phenotypes that may account for the diverse group-level findings reported in prior literature. Our results demonstrate the utility of individual-level modeling approaches for the assessment of behavioral and psychological associations in the real world. An individualized approach offers a foundation for the characterization of life dynamics at both the individual and group levels, as well as for the development of precision health and well-being interventions tailored to the individual.

Abstract

Background: Obesity is a prevalent and serious chronic condition associated with abnormal or excessive fat buildup that poses significant health risks. The rates of overweight and obesity in adults and children continue to rise, with global rates of children with overweight or obesity aged 5-19 years growing from 4% to 18% between 1975 and 2016. Furthermore, in 2017, nearly 4 million people died due to complications arising from being overweight or obese.

Objective: This study aims to investigate the potential impact of the mobile app Heia Meg on promoting healthier lifestyle choices regarding nutrition and physical activity.

Methods: A prospective longitudinal study was conducted in collaboration with the Norwegian Directorate of Health. Participants were recruited through the Heia Meg app and were asked to complete a questionnaire before and after using the app. A total of 199 responses were included in the first (preintervention) questionnaire, while 99 valid responses were obtained in the second (postintervention) questionnaire.

Results: The majority (159/199, 79.9%) of participants were female, and their age ranged from 18 years to 70 years and older. The results show a reduction in BMI after the digital intervention. However, some variables influence the BMI reduction effect: sex, age, education, and smoking. The group that obtained the most benefit from the intervention consisted of those who were male, aged 30-39 years, highly educated, and nonsmokers. Although positive, some of the findings are slightly above the statistical significance threshold and therefore should be interpreted carefully.

Conclusions: Our study found weak evidence to support the effectiveness of the Heia Meg app in promoting healthier lifestyle choices. However, limitations and confounding factors suggest that further research in different populations with larger sample sizes is needed to confirm or disprove our findings.

Introduction

Overview

Consumers have benefited from the internet’s transformation in information access about a decade ago [1]. Smartphones allow people to access information with a single touch. Smartphones offer a vast variety of health apps that users can download (for free or not). Many offer reference, monitoring, and calculator tools and address a wide range of health-related concerns. Apps count calories and nutrition, calculate BMI, monitor diabetes, handle emergencies, and improve workouts.

Mobile health (mHealth) technology and consumer health informatics research have increased in recent years [1]. A survey by Sarcona et al [2] indicated that mHealth app users had significantly better eating behavior inventory scores or reported more positive eating behavior than nonusers. Fry and Neff [3] found that periodic reminders can aid in behavior improvement. These findings can be used to improve periodic quick interventions, leading to increased effectiveness, positive behavior change, and better health [3].

Health psychology models were used to design the experiment. Most social-cognitive theories presume that the desire to change predicts actual change, yet people rarely act on their intentions [4]. Heia Meg, which in Norwegian means the people’s conviction in their own capacities to produce predetermined levels of performance, influences the circumstances that affect their conduct. Belief in mastery influences people’s thoughts, feelings, motivation, and conduct. Cognitive, motivational, emotional, and selection processes generate this belief.

The health belief model (HBM) was devised in the 1950s to explain why so many people do not participate in disease prevention and detection programs [5]. The HBM is one of the most often used conceptual frameworks in health behavior research since 1950, “both to explain change and maintenance of health-related behaviors and as a guiding framework for health behavior treatments” [5,6]. If individuals regard themselves as susceptible to a condition, believing it could have serious consequences, while believing a course of action could reduce their susceptibility to or severity of the condition, and believing that the anticipated benefits of taking action outweigh the costs, this could increase the likelihood to act [5].

Perceived susceptibility refers to people’s health risks. Perceived severity refers to feelings about the seriousness of developing a disease or leaving it untreated, including medical and clinical implications (such as disability, death, and pain) and possible social consequences (such as effects on work, family life, and social relations) [5,7,8]. The individual’s thoughts regarding the perceived advantage of the potential activities for reducing the threat of illness can influence whether this perception leads to behavior change [5,7]. Other nonhealth factors, such as money savings from quitting smoking or pleasing a family member, may also influence behavior. Individuals with ideal views on susceptibility and severity are unlikely to choose a health intervention unless they believe it can lessen the threat. Perceived barriers are anticipated unfavorable outcomes of a health action. They may prevent people from engaging in the suggested activities. Individuals balance the action’s projected advantages against perceived barriers in an unconscious cost-benefit analysis. Consequently, “susceptibility and severity offer the energy or force to act, and benefits (without barriers) provide a preferred course of action” [5]. Cues to action are inputs that can trigger behaviors and were incorporated in previous HBM formulations. Hochbaum [9] argued that other aspects, such as physical occurrences or media attention, may only increase readiness to act (perceived susceptibility and perceived rewards).

Self-efficacy refers to having faith in one’s own strengths when presented with challenging activities and situations [10]. To attain mastery, one must learn from fresh hurdle situations and practice. A self-efficacy approach was implemented in the app messages as well. Through Heia Meg, messages are delivered as little challenges such as “Try something new, what about a walk before bedtime? Bring a headlamp, use the stairs, and take a 20-minute walk today” or sentences such as “You don’t like hills, yet they have something great to offer. Hills increase heart rate and health. So, imagine a top goal line and go for it.” These messages contain encouraging sentiments that may help people complete the challenge. The second most important source of self-efficacy is what we observe others do or accomplish.

Positive role models can help develop positive self-beliefs and can include family, friends, teachers, coaches, or employers. The third most important source of self-efficacy is social persuasion—receiving positive feedback while executing a difficult task might persuade a person, as they might start considering that they have the abilities and potential to succeed. The Heia Meg app’s daily messages have a positive tone, with statements such as “something is better than nothing.” or “The best session is the one you finish:)” or “A week has passed. Many people find it hard to start, so keep going. Cheers!” Since emotional and physiological factors might affect how someone feels about their ability, the app’s motivational sentences include “Good company helps when motivation fades.” “Know somebody who wants to get in shape? You can request a group activity.” “Before turning, take a 5-minute walk.” or “The first obstacle is often the hardest, but you can continue.”

The I-Change model was developed by Hein de Vries to explain health behavior and motivation [11]. I-Change combines aspects of the theory of planned behavior, the transtheoretical model for health behavior change, the social cognitive theory, the goal-setting theory, and the HBM to create a motivation and behavior change model. Motivation or intention determines behavior. Attitudes, social pressures, and self-efficacy affect motivation. Attitudes are the cognitive and emotional beliefs and costs of an activity. Social modeling, social norms, and social support from others are examples of social influences on a person. New research suggests multiple types of self-efficacy, including stress-, social-, routine-, and skills-based self-efficacy. The I-Change model believes information and antecedent circumstances affect communication results—motivation, awareness, action, and behavior (Figure 1). Preparing and executing detailed plans to achieve the intended behavior increases the likelihood of intentions becoming actions, while barriers decrease these chances [11,12]. Attitudes, social pressures, and self-efficacy expectations all affect a person’s motivation.

https://formative.jmir.org/2024/1/e48185
Overweight and Obesity

According to the World Health Organization, the number of 5- to 19-year-olds with overweight or obesity quadrupled between 1975 and 2016, and overweight and obesity cause more deaths than underweight [13]. We are also seeing a rise in overweight and obesity in Norway, largely due to an energy intake or consumption imbalance [14]. According to the Norwegian Directorate of Health, this increase is linked to increased inactivity, which can lead to various diseases over time, including increased mortality and increased risk of heart attack, stroke, high blood pressure, type 2 diabetes, several cancers, musculoskeletal disorders, and mental disorders. Another US study indicated that physical inactivity is the primary cause of increased mortality and morbidity in adults who are overweight (with a BMI up to 35 kg/m$^2$), but that good physical shape can minimize the risk of weight-related diseases [15]. Increasing weight and obesity have health and economic effects, such as weight-related health problems accounting for 2% to 6% of overall health costs [16].

mHealth

mHealth is a new sector with the potential to reach a large portion of the population cost-effectively. It is a branch of eHealth that uses technology to improve people’s health. Research shows that 2.9% of Google Play apps and 8.8% of Apple App Store apps support healthy behaviors [17]. Cost-effective technologies that record a user’s behavior are gaining prominence. Despite apps’ potential to alter health behavior, there is no proof of their health theory foundation [17]. According to Antezana et al [17], health apps have low levels of theory of behavior change strategies, and improved implementation could lead to more user engagement and better interventions. Mateo et al [18] compared a mobile app to other weight-loss and exercise strategies. In their review of 12 studies, using a mobile app positively affected body weight, but not physical activity.

Heia Meg

The Heia Meg app was developed by the Norwegian Directorate of Health with inspiration from the United Kingdom’s “One You” and a previous Norwegian app called “Slutta” or “Quit” [19]. The project is nondirectly supportive and based on the idea that motivation changes behavior. The “Quit” app is a popular tool for Norwegians trying to quit smoking. Due to the “Quit” app’s success, self-efficacy and positive psychology were also used in Heia Meg.

Heia Meg self-efficacy examples include inspiring health alternatives, push-notification support, and push warnings preventing temptation. The pursuit of happiness is one of the humanities’ most persistent movements [20]. Positive psychology aims to answer the question “What is happiness?” The Heia Meg app uses positive psychology by focusing on stress management and by pushing alerts encouraging users.

Push alerts are regular and scheduled. After downloading the app, users must agree to its terms before choosing 2 of 5 themes to focus on. Users can choose between (1) exercise, (2) mental health, (3) alcohol, (4) sleep habits, and (5) dietary intake. After choosing the 2 themes, the app will send notifications on a regular basis. The notifications include encouragements, theme facts, challenges, and recommendations. The texts are short and written in Norwegian, with no emojis or abbreviations.

The National Institute of Public Health (NIPH) national public health survey presented a report of results on diet, self-reported weight, and weight development in the Norwegian population in 2020 [21]. The report showed that over two-thirds of people wished to reduce weight or had tried to maintain their weight, as well as a large proportion of the population being overweight or obese. According to the findings of the public health survey on body weight and development, male individuals’ average weight, height, and BMI were 86.6 kg, 180.7 cm, and 26.5 kg/m$^2$, respectively [21]. The percentage of male individuals who were overweight or obese (BMI ≥25 kg/m$^2$) was 59%, while the percentage of male individuals who were underweight (BMI <18.5 kg/m$^2$) was 0.8%. On the other hand, the average weight, height, and BMI for female individuals were 86.6 kg, 180.7 cm, and 26.5 kg/m$^2$, respectively [21]. The number of female individuals who were overweight or obese (BMI ≥25 kg/m$^2$) was 47%, while the proportion of female individuals who were underweight was 2.7%. Overall, 16% of female and male individuals had a BMI ≥30 kg/m$^2$. The project is nondirectly supportive and based on the idea that motivation changes behavior. The “Quit” app is a popular tool for Norwegians trying to quit smoking. Due to the “Quit” app’s success, self-efficacy and positive psychology were also used in Heia Meg.

The National Institute of Public Health (NIPH) national public health survey presented a report of results on diet, self-reported weight, and weight development in the Norwegian population in 2020 [21]. The report showed that over two-thirds of people wished to reduce weight or had tried to maintain their weight, as well as a large proportion of the population being overweight or obese. According to the findings of the public health survey on body weight and development, male individuals’ average weight, height, and BMI were 86.6 kg, 180.7 cm, and 26.5 kg/m$^2$, respectively [21]. The percentage of male individuals who were overweight or obese (BMI ≥25 kg/m$^2$) was 59%, while the percentage of male individuals who were underweight (BMI <18.5 kg/m$^2$) was 0.8%. On the other hand, the average weight, height, and BMI for female individuals were 86.6 kg, 180.7 cm, and 26.5 kg/m$^2$, respectively [21]. The number of female individuals who were overweight or obese (BMI ≥25 kg/m$^2$) was 47%, while the proportion of female individuals who were underweight was 2.7%. Overall, 16% of female and male individuals had a BMI ≥30 kg/m$^2$.
of 30 kg/m$^2$ or higher, which indicates obesity [21]. The average person consumed 2 servings of fruits and vegetables each day, including juice, and according to the survey, only 2.3% reported that they consume at least 5 servings each day. Furthermore, the report stated that 43% of the participants ate fish 2-3 times per week, whereas 7% rarely or never ate fish. Approximately 30% said they ate sweets frequently (at least 3 times per week), while 10% reported eating snacks and 11% reported eating sweet pastries at least 3 times per week [21]. A large percentage of people reported using soft fat or a combination of soft and hard fat types or none for bread, and 61% reported using soft fat, oil, or nonfat for frying. Further, when looking at sugary soft drinks, juices, and soda, 13% reported drinking them 3 times a week or more, with the proportion being highest among younger male individuals and among the least educated. Dietary changes were also mentioned, with 5.4% following a low-carb diet, 3.8% following a calorie-reduced diet, and 3.3% fasting on a regular basis [21].

The survey revealed that Norway’s population needs and wants to improve its lifestyle regarding nutrition and weight loss. Therefore, the aim of this study was to test whether the Heia Meg app can help achieve this goal. Therefore, the following research question was formulated: “Is Heia Meg, a smartphone app, effective in helping users to make healthier lifestyle decisions about nutrition and physical activity?”

**Methods**

**Overview**

Based on past observations using the app and its structure and functioning, we anticipated that it could improve the physical activity behavior and eating habits of users. To test the assumption, we used a prospective longitudinal design. All statistical analyses were conducted using SPSS Statistics (version 26; IBM Corp).

**Recruitment Procedure**

In collaboration with the Norwegian Directorate of Health, we added a link to the questionnaire within the Heia Meg app. This was only accessible to Heia Meg app users with internet connectivity enabled. Besides the in-app advertisement, posters were put on Facebook, Instagram, and Snapchat to foster recruitment. A poster was affixed to the wall of a neighboring fitness center, which contained complete information about the study and how to participate. Because the app and survey were written in Norwegian, so were the posters.

**Participants**

The Heia Meg app was the only channel for the registration of study participants. The sample consisted of users who downloaded the app and agreed to take part in the study.

Everyone who downloaded the app between October 4, 2021, and November 5, 2021, received a message the day after downloading it asking whether they were interested in joining a research study. Participants had to read and sign a consent form confirming that they were 18 years of age or older and that they consented to participate. Participants were asked to provide their email address because that is what was used to send the follow-up survey.

**Materials**

This project’s questionnaire was based on Harris’s [22] NIPH study, “Social circumstances and health: a twin study.” The form was modified for this investigation, and it contains 12 health-related items.

The 12 items response alternative were all defined as a Likert scale, so they could be graded from 1 to 4, with 1 being the worst and 4 being the best. The replies to the 12 items would be used to compute a health score. The score is the sum of the participants’ responses, with a minimum of 12 points (scoring 1 on all 12 questions) and a maximum of 48 points (scoring 4 on all 12 questions). This study took place during the COVID-19 pandemic, which may have affected people’s health, lifestyle, eating, drinking, and mental health.

**Ethical Considerations**

An application, containing the project plan and the questionnaire, was submitted to the Norwegian Center for Research Data (NSD) and the regional ethics committee. As no health or sensitive data were going to be processed, the regional ethics committee confirmed that the project is approved without a formal assessment (application 284804).

Participants had to read and sign a consent form confirming that they were 18 years of age or older and that they consented to participate.

Most of the ethical considerations concern the gathering of personal data and how to organize, implement, and complete it in line with legislative requirements and ethical norms. The Health Research Act, the Health Register Act, laws on population-based health assessments, and the Privacy Ordinance and Personal Data Act offer a comprehensive foundation for medical and health research [23]. For this consent-based research project, the duty to disclose information is accomplished through Netskjem. All personal information was to be anonymized for data processing; hence, a participant identification number was required. Due to participants using their email, their answers were not anonymous; nonetheless, the data were secured, anonymized, and held until the manuscript was submitted, following which they were deleted.

NSD approved the study in relation to the processing of personal data (approval 385157).

No compensation was given to the participants; they volunteered to take part in the study.

**Results**

**Overview**

We received 365 responses, but some did not meet the criteria and were eliminated. In the preintervention questionnaire, 5 people were removed for being 17 years of age or younger, 9 for refusing informed consent, and 20 for answering the questionnaire twice or more. Two people, aged younger than 18 years and 31 years, respectively, had repeated responses, which were eliminated from the postintervention questionnaire.
This study included 298 replies in total: 66.78% (n=199) in the preintervention group and 33.22% (n=99) in the postintervention group.

**Descriptive Statistics**

As depicted in Table 1, female individuals participated more than male individuals. Participants ranged in age from 18 years to 70 years and older, with the majority between 40-49 years (54/199, 27.1%) and 18-29 years of age (43/199, 21.6%). Most participants (63/199, 31.7%) had 4 or more years of college or university. Many (54/199, 27.1%) possessed high school diplomas or apprenticeship certificates. Male individuals have a higher BMI; the mean BMI for female individuals (29.33 kg/m²) falls under the overweight category, while male individuals (31.22 kg/m²) fall under the grade I obesity category. Furthermore, when looking at health score by sex, education, smoking, lifestyle change reason, and BMI, male individuals had a higher health score than female, while female individuals had a higher SD. The group of 30- to 39-year-olds had the highest health score, followed by those over 70 years old. The group of 60- to 69-year-olds had the lowest health score. Higher-educated people got better health scores than individuals with less education. Smokers had a poorer health score than nonsmokers. Comparing BMI and health score, those with the lowest BMI had the highest health score.

Table 2 displays the characteristics of respondents to the postintervention questionnaire. Again, female individuals were more represented than male individuals (76/99, 76% vs 23/99, 23%), and the age groups of 40- to 49-year-olds (22/99, 22%) and 18- to 29-year-olds (21/99, 21%) had the most respondents. We observed that some participants belonging to the 70 years or older age group were still using the app and continued to take part in the study. Male and female individuals’ mean BMI after 1 month with the app show that male individuals have a marginally higher BMI than female, while female individuals have a higher SD. People who were 70 years of age or older had the highest health score; however, there were only 5 participants in this group, and therefore precaution is needed in interpreting this result. Interestingly, the participant group of 18- to 29-year-olds had the lowest health score. People with higher education had a better health score than those with lower education. Nonsmokers had better health score than smokers.

The health score scale’s Cronbach α was .92, indicating good reliability.

For the following phase, we focus on pre-post analyses. We matched respondents from both the pre- and postintervention surveys, leaving us with a sample of 74 participants.

A paired sample 2-tailed t test examined BMI and health score pre-post differences. Results are presented in Table 3 below. The data indicate that the BMI and the health score before intervention were higher than after intervention. More specifically, the differences between the pre- and postintervention groups were 0.284 for the BMI and 0.797 for the health score, as displayed in Table 4 below.

However, the results of the paired sample t test of the BMI and health score before and after intervention were not statistically significant (P=.07 for the BMI and P=.24 for the health score).
Table 1. Preintervention descriptive statistics of the participants recruited through Heia Meg: sex, age group, education, BMI, smoking status, reason for lifestyle change.

Discussion

Participants

The majority of study participants were female, 79.9% (159/199) before intervention and 77% (76/99) after intervention. Is it because female individuals are more interested in improving their health or have more faith in health-related apps or the app’s design? This is a question that deserves further investigation. Another intriguing observation was the high percentage of participants aged 40-69 years (116/199, 58.3% for the preintervention questionnaire and 56/99, 57% for the postintervention questionnaire), as well as the participation of people aged 70 years and older (8/199, 4% and 5/99, 5%, respectively). When the questionnaire was delivered through Heia Meg, it was assumed that younger people would use it. Instead, we believe that for older individuals, the fact that the app was produced and sponsored by the Norwegian Directorate of Health was reassuring and trustworthy. The relatively small sample size in our study does not allow us to generalize these findings.

Most of the study participants had a higher education (113/199, 56.8% in the preintervention group and 63/99, 64% in the postintervention group). The link between the degree of education and health literacy and the engagement of individuals in their health, including participation in research studies such as ours, is worth discussing further. Furnée et al [24] conducted a meta-analysis to determine the marginal impact of education on self-reported health, while Nummela et al [25] examined the relationship between self-reported health and 3 variables of social economic position (disposable household income, self-reported education, and adequacy of income) and 3 categories of communities (rural areas, highly or sparsely papillated areas, and urban areas) among male and female individuals in southern Finland. The adequacy of income had the strongest positive connection with self-reported health in metropolitan locations among all age groups, demonstrating that while real income is a powerful predictor of health, the adequacy of income is even greater [25]. Furnée et al [24] found that a year of education added 0.036 quality-adjusted life-years. Preliminary calculations show that investing in education improves health.

Individuals with high health literacy may make better decisions regarding their health and well-being [26]. Environmental needs and available resources affect health literacy, highlighting the need to enhance it in schools and communities [27]. Individually, health literacy efforts in schools should focus on teaching meta-cognitive abilities such as critical thinking, self-awareness, and citizenship. Health literacy education should include socioeconomic determinants of health and societal processes that lead to health inequities [27].

Most of our study participants wished to improve their diet and fitness. Male individuals’ mean BMI was higher than female individual’s (31.2 kg/m² vs 28.6 kg/m² preintervention and 29.3 kg/m² vs 28.5 kg/m² postintervention). Respondents in the preintervention group had mostly type I obesity, while female individuals were overweight. The intervention proved beneficial in lowering the mean BMI of study participants. Male individuals’ mean BMI decreased more than female individual’s, and in the postintervention survey, both sexes were overweight. After intervention, both sexes ended up in the overweight category as a mean BMI; several participants were within the BMI category of normal weight; none of the participants were underweight; 10 participants were overweight; and 7 had obesity (group III).

Male individuals had a higher health score than female individuals, both in the preintervention observation (36.9 vs 35.09) and in the postintervention questionnaire (33.1 vs 32.25). Interestingly, both sexes experienced a reduction in their health scores between the pre- and postintervention questionnaires. One possible interpretation of this result is that participants gained self-awareness between the 2 questionnaires, and their replies in the postintervention phase were more realistic than preintervention. Moreover, this study was conducted during the COVID-19 pandemic, and society was locked down and reopened numerous times. We foresee the possibility that the fact that Norwegian society was more open when the study began (October 4, 2021) than when the postintervention questionnaire was sent out (November 25, 2021) could have impacted our results. We all experienced changes in our behavior during the lockdown times of the COVID-19 pandemic, and the same could be true for the participants in this study. In a study conducted during the COVID-19 pandemic, Flanagan et al [28] found that eating behavior altered significantly. Cooking at home rose from 4.49 to 5.18 times per week (P<0.001), while eating out fell from 1.98 to 1.08 (P<0.001). Fast-eating assessments improved from 0.04 to 0.81 (P<0.001), indicating a healthier diet. A total of 35.6% of the participants ate unhealthier food in general, and 43.5% ate more unhealthy snacks [28]. Those who ate poorly had a more sedentary lifestyle, less physical exercise, did not go to bed or sleep later, and reported almost doubling in anxiety [28].

When looking at the health score stratified by age, the group of 30- to 39-year-olds had the highest health score before intervention but one of the lowest after interventions. For those 70 years of age and older, their preintervention health score was 36 and 41.40 after intervention. This age group has more stability in their lives, which influences their perceived health, diet, and exercise habits. However, we must highlight that this age group accounted for less than 5% (13/298) of the study sample; therefore, the findings are not generalizable, and further research is needed to confirm these findings or not.

As anticipated within our research group based on existing evidence, we found that those with the lowest level of education also had the lowest health score, while those with the highest level of education had the highest health score. Smokers have poorer health scores than nonsmokers, and this finding is not unexpected considering available evidence. Tobacco use has long been linked to life-threatening diseases [29], and it is one of the top 10 practices that cause global sickness [5,29].

In most low-income nations, socioeconomic status creates health disparities between persons of different income levels. Chronic diseases and behavioral risk factors are more widespread in low-income and low-educated people [30]. Tobacco, sedentary...
habits, poor diets, and alcohol cause 1 million deaths per year in the United States alone, and changing health behaviors is our best hope for reducing global disease and death [5]. Socioeconomic causes and reducing health disparities should be prioritized by public health officers and policy makers [30].

We presented in the Results section the difference in BMI and health score before and after using the app. We saw that the mean preintervention BMI was higher than the mean postintervention BMI, even though the difference was not statistically significant (P = .07). Given the positive change observed in the BMI, while being aware that there are multiple factors beyond the app that could have influenced this change (eg, motivation), we encourage further research extended to larger samples to investigate the effectiveness of similar apps on the BMI.

This project’s goal was to contribute to digital health app research. Over 200 people joined the study through the app, and a response rate of 49.7% (99/199) was observed in the postintervention questionnaire. Participants were given the possibility of making suggestions about the design and functionality of the app. Some of their feedback messages are similar to the following: “Should have been more specific tips”; “I only get push alerts from Heia Meg, not alerts with a visible note, that’s what I need to get motivated from the app”; “Make it clear, what extreme progression you get when first starting a lifestyle change as physical activity, as well as how these progression values for everyday life”; “It’s motivating to motivate others, and some counsel is too simplistic”; or “It’s great, simple, and uncomplicated.” We used the feedback and reported it to the Norwegian Directorate of Health, which used it as a quality improvement tool.

Although the positive effects we observed were not statistically significant, we cannot exclude that this was due to an insufficient statistical power obtained from our relatively small sample and therefore encourage more research from other scholars who have access to other pools of participants.

When a program or intervention is motivated by a health behavior theory, individuals and communities benefit [5]. Never before have health education and behavior change workers had so many possibilities. Mobile phones, laptops, and smartphone apps have the potential to help people improve their lifestyles. Digital interventions can improve awareness of dangers or benefits, provide cues or reminders for healthy habits, and provide encouragement or training to boost confidence. Digital interventions can help increase self-efficacy through mastery and vicarious experiences, as well as social persuasion, emotional, and physiological factors with sending prompts and challenges for engaging in healthy behaviors, as well as the opportunity to follow friends, family, or a role model.

**Limitations**

When recruiting participants, the survey’s inadequacies harmed the data’s validity and dependability. Several participants modified their behavior aim between the first and second questionnaires, reducing the number of participants for a 2-tailed paired t test. In other cases, people filled out the questionnaire multiple times, giving different ages, education levels, and themes. The questionnaire was not sent out until the day after the app was downloaded, but the recruitment of participants pulled in individuals who were truly using the app, as they had to read the message and click the link to the questionnaire. Our recruitment strategy yielded more female than male individuals, while a more balanced sample could have been more generalizable to the general public. Our sample seems skewed toward higher education, and as for sex, a more balanced sample would make it easier to extend our finding to the general public.

The study’s shortcomings include a lack of a control group to determine the cause and effect of the Heia Meg app, as several confounding factors may have influenced our results (eg, the motivation of each participant and all the exogenous factors). Voluntary participation and a restricted number of participants may risk the study’s external validity, as volunteers may have different opinions than the general public.

**Conclusions**

This research project attempted to investigate the effectiveness of the lifestyle app Heia Meg, developed by the Norwegian Directorate of Health, in helping individuals make healthier lifestyle decisions about nutrition and physical activity. Although we did observe some positive effects, the differences were not statistically significant, and therefore we conclude that from our study, it does not appear that the app intervention leads to better nutrition and physical activity choices. This result could be affected by the limitations and confounding factors described above, and further research is needed to confirm, or not confirm, this conclusion.

**Data Availability**

The data sets generated and analyzed during this study are not publicly available due to the requirements of the Norwegian Center for Research Data to delete the data as soon as the processing is over. However, an anonymized version of the data set is available from the corresponding author on reasonable request.

Abstract

Background: Digital health technologies offer the potential to improve the daily lives of older adults, maintain their health efficiently, and allow aging in place. Despite increasing evidence of benefits and advantages, readiness for adopting digital interventions among older people remains underexplored.

Objective: This study aims to explore the relationships between sociodemographic-, health-, and lifestyle-related factors and technology use in everyday life and community-dwelling older adults’ readiness to adopt telemedicine, smartphones with texting apps, wearables, and robotics.

Methods: This was a cross-sectional, population-based survey study with a stratified probabilistic sample of adults aged 75 years or older living in South Tyrol (autonomous province of Bolzano/Bozen, Italy). A random sample of 3600 community-dwelling older adults living at home was invited to complete a questionnaire including single items (older adults’ readiness to use health technology) and scales (PRISMA-7; Program of Research on Integration of Services for the Maintenance of Autonomy). Descriptive and logistic regression analyses were performed to analyze the data.

Results: In total, 1695 community-dwelling older adults completed the survey (for a response rate of 47%). In terms of potential digital health technology adoption, wearable devices were favored by 33.7% (n=571), telemedicine by 30.1% (n=510), smartphones and texting apps by 24.5% (n=416), and assistant robots by 13.7% (n=232). Sociodemographic-, health- and lifestyle-related factors, as well as the use of technology in everyday life, played a significant role in explaining readiness to adopt digital health technologies. For telemedicine, age ≥85 years (odds ratio [OR] 0.74, 95% CI 0.56-0.96), financial constraints (OR 0.68, 95% CI 0.49-0.95), and less than 2 hours of physical activity per week (OR 0.75, 95% CI 0.58-0.98) were associated with nonreadiness, while Italian-speaking participants (OR 1.54, 95% CI 1.16-2.05) and those regularly using computers (OR 1.74, 95% CI 1.16-2.60), smartphones (OR 1.69, 95% CI 1.22-2.35), and the internet (OR 2.26, 95% CI 1.47-3.49) reported readiness for adoption.

Conclusions: Community-dwelling older adults display varied readiness toward the adoption of digital health technologies, influenced by age, mother tongue, living situation, financial resources, physical activity, and current use of technology. The findings underscore the need for tailored interventions and educational programs to boost digital health technology adoption among community-dwelling older adults.

Introduction

As global populations age, health care systems worldwide grapple with the challenge of providing personalized, efficient, and integrated care for an increasing proportion of older adults, with the ultimate goal of facilitating "healthy ageing-in-place" [1]. Digital health technologies offer potential advancements to improve various older adults' health outcomes and access to health care services [2]. There is increasing evidence of the benefits of digital health interventions for community-dwelling older adults in terms of physical function, cognitive performance, depression, behavioral and psychological symptoms of dementia, and overall quality of life [3-6]. Digital health technologies, such as smartphone-based mobile apps or wearables, allow the measurement and tracking of clinical parameters, such as pain, fatigue, fever, arrhythmias, slower walking speed, and insufficient physical activity to prevent or improve the management of chronic diseases, frailty, morbidity, and mortality [7]. For instance, in older adults with type 2 diabetes mellitus, digital health interventions (i.e., mHealth) have been shown to be effective in improving cardiometabolic outcomes [8].

Despite technological advancements and the benefits of digital interventions, the adoption of digital health technologies remains low and inconsistent among older persons, suggesting that underlying factors influence their acceptance, adoption, and use [9]. For example, older adults’ adoption of new digital health technologies, such as social robots to combat social isolation and loneliness [10], depends on multiple factors related to technology, psychological, social and personal aspects, costs, and the environment [11]. Personal factors, including life satisfaction, social relationships, self-perception of health, and everyday activities, are integral facets of an individual’s life, especially in their senior years. These aspects not only shape their overall well-being but also their openness to embracing and readiness to adopt and use potentially beneficial digital health technologies [12]. As the intersections of these domains with digital health adoption have been underexplored, particular attention needs to be given to studying the antecedents of digital health technology adoption, including older adults’ readiness [11]. In Italy, a potential digital health gap among older adults due to infrastructural issues and the lack of digital skills have been described, with differences between age groups and educational levels [13]. In a cross-sectional survey study, less than half of the 1002 respondents were aware of telemedicine services in their region [14]. According to health care professionals, some groups of patients experience difficulties in accessing and using digital health technologies due to sociocultural factors, technological and linguistic challenges, and the absence of caregivers [15]. Yet, little is known about the adoption and use of digital health technologies by community-dwelling older adults. In this study, we aimed to explore the relationships between sociodemographics, health- and lifestyle-related factors, and technology use in their everyday life and community-dwelling older adults’ readiness to adopt digital health technologies, that is, telemedicine, smartphones with texting apps, wearables, and robotics. A deeper understanding of these intersections can inform the design, implementation, and evaluation of digital health technology interventions that resonate closely with the needs and preferences of older adults. Such insights can catalyze the development of more target group-oriented digital health strategies, ensuring not only better health outcomes but also improved quality of life for community-dwelling older adults in the digital age.

Methods

Study Design

This cross-sectional, population-based survey study was conducted jointly by the Provincial Institute of Statistics-ASTAT (Istituto Provinciale di Statistica – Landesinstitut für Statistik) and the Institute of General Medicine and Public Health in the Autonomous Province of Bolzano, South Tyrol between March 1 and May 30, 2023.

Setting and Sample

South Tyrol, the autonomous province of Bolzano, is part of the Trentino–Alto Adige region in Italy, next to Austria (total population: 534,912), with approximately 70% German-speaking, 25% Italian-speaking, and 5% other languages. The target population of the survey comprised approximately 51,000 individuals residing in South Tyrol aged 75 years and older. A stratified probabilistic sampling method was used in this study. The ASTAT randomly selected 3600 community-dwelling adults aged ≥75 years, stratified by age (75-84 years, 85 years and older), sex (male and female), and residency (municipalities), from the register of the current resident population in the whole province. To ensure an adequate level of precision, the sampling of the 3600 individuals considered the distribution of and variation between the strata.

Excluded from the survey were individuals permanently residing in senior living facilities and those who, due to health reasons, were unable to complete the questionnaire independently or with the aid of a family member.

Participant Survey

The participant survey was designed collaboratively by the ASTAT and the Institute of General Medicine and Public Health, based on a similar survey study conducted in 2013 [16] and the INSPIRE population survey applied in Switzerland [17]. The German and Italian language versions, translated from the ASTAT, were reviewed for language equity by the research group at the Institute for General Medicine and Public Health. The final versions were checked and approved by the local health and social authorities. As the survey questionnaire included instruments and items previously used (in 2013 edition of the survey and INSPIRE population survey), we conducted pretesting with 10 older adults aged 75 years and older. These participants were invited to complete the questionnaire and to provide oral feedback regarding the clarity of questions,
difficulty of completion, and the technical functionality of the web-based survey to the research group by phone.

Older adults’ readiness for adoption of digital health technologies was assessed using single items, asking to rate on a 5-point Likert scale (yes/maybe/no/I do not understand what this means/I am already using it) the following four technologies: (1) telemedicine, that is, communicating with your doctor via video or smartphone; (2) smartphone with text messaging apps, that is, reminding you of your clinical condition or taking medications, providing information on how to manage your condition; (3) wearable devices, that is, monitoring your heart rate, blood glucose, physical activity, or SOS device; and (4) assistive robots, that is, supporting you at home for taking medications, or recognizing emergencies.

Participants’ sociodemographics included age (birth year), sex (male/female), native tongue (German/Italian/Ladin/Others), citizenship (Italy/other country), educational level (Below Highschool/Highschool or higher), community and region of origin (rural/urban), living situation (alone/with spouse or family member), children (yes/no), financial resources (excellent or good/adequate/insufficient or low), and overall optimism (yes/no).

Health- and lifestyle-related factors included self-reported health status (poor or moderate/good or very good), frailty (no=0-3 points/yes=4-7 points on PRISMA-7 [Program of Research on Integration of Services for the Maintenance of Autonomy], [18]), physical activity (2 hours or more a week/ less than 2 hours a week/ never), use of home care assistance (eg, from family, nursing team, or private family assistant; yes/no).

Technology use in everyday life was assessed by asking participants if they had already used computers, tablets (yes/no), smartphones (yes/no), or the internet (yes/no).

**Data Collection**

Letters were mailed from the ASTAT to the randomly sampled participants to inform them about the study and to invite them to voluntarily participate by completing the survey alone or with the aid of a family member. Completion of the survey was possible by one of the following: (1) web-based self-completion, (2) paper-based self-completion, or (3) telephonic interviews with collaborators from the ASTAT. One month after the first letter, a second letter was sent to inform them about the study and invite them to participate. The web-based survey was created using LimeSurvey [19].

**Ethical Considerations**

Ethical approval was obtained from the institutional board of the Institute of General Practice and Public Health, Bolzano, Italy (reference number: 03/2023). All study procedures were in accordance with the 1964 Helsinki Declaration and its amendments, European Union General Data Protection Regulation (679/2016), and Italian Data Protection Law (196/2003). Before filling out the online questionnaire, participants were explicitly asked to provide informed consent. Filling out the paper questionnaire and sending it back by post was considered as participants’ informed consent. Participation was voluntary. All data of the study participants were anonymized to protect their identities.

**Statistical Analysis**

Only fully completed questionnaires were included in the statistical analysis, resulting in the exclusion of 73 partially filled-out questionnaires. Descriptive statistics (eg, frequency) were calculated to describe the measured variables. To explore differences between the characteristics of older adults and their readiness to adopt digital health technologies (yes and maybe vs no), we used Fisher exact test. Four binary logistic regression models were used to explore the association between each digital health technology, that is, telemedicine, smartphone and texting apps, wearables and robotics (dependent variables), sociodemographics, health- and lifestyle-related factors, and use of technology in everyday life (independent variable). All analyses were performed using R (version 4.3.1; R Foundation for Statistical Computing) and RStudio (version 2023.6.2.561) with the packages tidyr [20] and lme4 [21]. A P value of less than .05 was considered significant.

**Results**

**Sample Characteristics**

In total, 1695 community-dwelling older adults completed the survey, reflecting a response rate of 47%. As described in *Table 1*, the majority of participants were female (880/1695, 51.9%), aged between 75 and 84 years (1005/1695, 59.3%), living with partners or family (1179/1695, 69.6%), had at least 1 child (79.3%), and had an educational level below high school (1319/1695, 77.8%). Health status was reported in more than half as poor or moderate (1012/1695, 59.7%), not frail (999/1695, 58.9%), yet receiving home care assistance from family, nursing team, or a private family assistant (1121/1695, 66.1%). Approximately 1 in 3 older adults mentioned using a computer or tablet (524/1695, 30.9%), smartphone (678/1695, 40%), and the internet (656/1695, 38.7%) in their everyday lives.

Group Differences in Older Adults’ Readiness for Adopting Digital Health Technologies

The tables in Multimedia Appendix 1 present the sociodemographics of the participants and highlight group differences between those who are ready to adopt digital health technology (either responded “Yes” or “Maybe”) and those who responded “No”. In summary, age, educational level, living situation, financial resources, physical activity, and technology use in everyday life significantly influenced older adults’ readiness to integrate various digital health technologies into their lives.

Age plays a key role in digital health technology adoption readiness. In particular, 72.4% (n=697) of older adults between the ages of 75 and 84 years showed readiness to adopt wearables. Living arrangements also had an impact on digital health technology adoption, with individuals living with a partner or family showing higher readiness to integrate all forms of digital health technologies than their counterparts living alone. Similarly, older adults with an educational level of high school or higher; those reporting having adequate financial resources; being physically active; and older adults already using computers, tablets, smartphones, and the internet reported higher readiness to adopt all 4 digital health technologies. In terms of gender differences, except for robotics, more than half of the men reported being ready to adopt digital health technologies and higher readiness than women to use telemedicine and smartphones. Italian-speaking adults living in urban areas who were more optimistic about the future, with good or very good health status, and were not frail, were more likely to adopt 2 out of 4 digital health technologies, namely telemedicine and smartphones with texting apps. Regarding frailty as assessed by PRISMA-7, we observed that nonfrail individuals reported higher readiness to adopt telemedicine, as well as smartphone and texting apps compared with frail individuals.
Factors Influencing Older Adults’ Readiness for Adopting Digital Health Technologies

Tables 3 and 4 present the results of multiple logistic regression analyses examining the association between older people’s readiness to use 4 digital health technologies (telemedicine, smartphone with texting app, wearables, and assistant robot) and various sociodemographic, health- and lifestyle-related factors, and use of technology in everyday life.

Table 3. Multiple logistic regression analyses between older people’s readiness to use telemedicine, smartphones with texting apps and sociodemographics, health- and lifestyle-related factors, and use of technology in everyday life (n=1521).

^OR: odds ratio.

As reported in Table 3, higher age and insufficient financial resources were associated with lower readiness to adopt telemedicine, as well as being active for less than 2 hours a week. Italian-speaking older adults and everyday users of computers or tablets, smartphones, and internet reported significantly higher readiness to adopt telemedicine.

For smartphones with texting apps, adults aged ≥85 years with no physical activity at all were reported to be less likely to adopt this technology, while users of computers, tablets, smartphones, and the internet reported significantly higher readiness to adopt telemedicine.

Living alone, never performing physical activity, and being in need of home care assistance were all associated with lower readiness to adopt wearables. Regarding assistant robots, older adults aged aged ≥85 years and those already receiving home care assistance were less likely to adopt this digital health technology.

Discussion

Principal Findings

The integration of digital health technologies in health care has gained increasing prominence in recent years to improve access to and delivery of services, especially among older adults, who often face unique health care needs. With this cross-sectional, population-based survey study, we aimed to investigate the readiness of community-dwelling older adults in South Tyrol, Italy, to adopt 4 types of digital health technologies. Our study revealed that more than half of the older adults reported readiness to adopt telemedicine and wearable devices. However, a large portion responded with nonreadiness to adopt digital health technologies, that is, smartphones with texting apps or assistant robots. Sociodemographic, health- and lifestyle-related factors, and the use of technology in everyday life played a significant role in explaining older adults’ readiness to adopt digital health technologies.
Our finding on community-dwelling older adults’ readiness to adopt digital health technologies in South Tyrol aligns with a growing body of literature that highlights the increasing acceptance and willingness of older adults to embrace digital health care solutions [22]. In this context, it is evident that readiness to adopt digital health technologies, as observed in South Tyrol’s older population, is part of a more extensive global shift toward digital health technology use. This shift in attitude may be attributed to various factors, including the greater accessibility and user-friendliness of digital devices and health care apps as well as the increasing emphasis on and necessity to use technological solutions during the COVID-19 pandemic [23]. As the use of technology has increasingly become a crucial element of everyday life, older adults seem to embrace the potential benefits of digital health technologies to meet their health care needs, such as improved access to services, enhanced convenience, and better management of chronic conditions, thus playing a crucial role in fostering healthy aging, enhancing social inclusion, and facilitating independent living [24].

Our study revealed a higher adoption readiness for wearables and telemedicine compared with smartphones, texting apps, and assistant robots. One possible explanation for this is the perceived direct health benefits and simplicity associated with wearables and telemedicine. Telemedicine directly addresses the challenges of physical mobility, frequent clinic visits, and waiting times, thereby offering a convenient alternative [23]. Wearables, often designed with user-friendly interfaces, provide real-time health monitoring and a sense of security to older people. In contrast, texting apps may seem less intuitive to a generation that is less accustomed to digital communication, with the added layer of concerns about miscommunication or misunderstanding medical advice. Moreover, older adults are cautious about sharing health-related information online because of privacy and security concerns [25]. Assistant robots, being relatively newer innovations, might invoke apprehensions regarding complexity, safety, and potential dependency. While older adults acknowledge the future potential, readiness to adopt assistant robots is still low because of perceived barriers, such as mismatch between needs and solutions offered by the robots, usability factors, and lack of experience with technology [26].

Our results demonstrate that sociodemographics, health- and lifestyle-related factors, and the use of technology in everyday life play a significant role in shaping older adults’ readiness to adopt digital health technologies. While several sociodemographic, health, and lifestyle-related factors showed significant relationships in simple regression models, their associations were often attenuated or eliminated in multiple regression models. For instance, lower age (below 85 years) was the most consistent sociodemographic factor explaining higher readiness to adopt 3 out of 4 digital health technologies, while higher education or financial resources played a less important role. In our study, Italian-speaking older adults were more inclined to adopt telemedicine, which might be related to higher awareness or potentially more available Italian-language information and campaigns, for example, in television, promoting digital health technology. As language mirrors cultural, societal, and regional differences within South Tyrol, it may play an important role in the acceptance and use of digital health technologies. Recognizing the influence of linguistic and cultural differences on digital health technology adoption can guide future interventions by emphasizing multilingual support and culturally tailored educational and outreach programs.

The association between technology use in everyday life (ie, computer/tablet, smartphone, and internet) and older adults’ readiness to adopt digital health technologies emphasizes the importance of technology literacy, that is, the ability to use, comprehend, manage, and analyze technology safely, effectively, and responsibly. The pronounced readiness among “tech users” in the older age underscores the importance of technological familiarity. Recent research from China has revealed that overcoming technology anxiety is essential in enhancing the adoption and continued use of wearable health technologies among older adults [27]. While developing credible digital health apps that require minimal internet navigation skills, patient education, and collaborative efforts to address access and affordability are urgently warranted [28], tailored training sessions or workshops on basic technology use could substantially bridge the readiness gap. Similarly, health care professionals need to be prepared for the adoption and use of digital health technologies. A recent survey among clinical and nonclinical staff in general practice in South England revealed a significant difference between the self-reported competence in using digital health technologies, with the lowest readiness for using clinical apps and wearables [29].

**Future Implications**

Collaboration between all stakeholders, that is, health care providers, technology developers, policymakers, and the older population, is essential to promote the successful integration of digital health technologies into the health care system for older adults in South Tyrol and beyond. Policymakers and health care providers should consider disparities when designing and implementing digital health interventions, and ensure that technologies, including telemedicine, are accessible and affordable to all older adults to avoid health inequities with inequality in the distribution of health care resources among different populations [30]. Moreover, the use of sensors and wearables for remote monitoring as a source of information for chronic disease management needs to be integrated into primary health care processes so that information with clinical value is not lost along the way and by ensuring data protection [31]. Design adaptations and well-thought-out blended alternatives (ie, combining telemedicine with face-to-face support) may be potential solutions to improve older adults’ user engagement with digital health technologies [32].

While our study aimed to describe and explore more in-depth the experiences of individuals aged 75 years and above, future research should focus on evaluating readiness, actual adoption, and use of digital health technologies among older adults of different ages (eg, 55 years and above) over time. Qualitative research is needed to gain an in-depth understanding of the potential facilitators and barriers to adopting and using digital health technologies, which can guide health care providers, technology developers, and policymakers in creating more targeted and user-friendly digital health technology solutions.
for older adults, ensuring higher adoption rates and beneficial health outcomes. Education and awareness campaigns should address the concerns of older adults, such as safeguards in place to protect their data. Addressing these concerns is crucial for building trust in digital health technologies.

**Limitations**
This study has some limitations that need to be considered. First, its cross-sectional design limits our ability to establish causality or track changes in readiness over time. Longitudinal studies are needed to better understand how attitudes toward digital health technologies evolve among older adults. Additionally, the survey was conducted in South Tyrol, Italy, which may limit the generalizability of our findings to other regions or countries with different health care systems and sociocultural contexts. The participants primarily came from a specific age group, predominantly aged 75-84 years. This narrow age range does not offer a comprehensive picture of the general population’s attitudes across a broader age spectrum. We excluded older adults living in residential care facilities as they are more care-dependent and receive 24/7 institutional care, which might limit their readiness, ability, and need to use digital health technologies. Although the response rate (47%) can be considered excellent, this implies that over half of the potential participants did not respond. There could be systematic reasons for nonresponses, which might have introduced bias. Although we aimed to capture a wide range of community-dwelling older adults, we acknowledge that the findings may not be fully representative, as older adults less inclined or unable to embrace technology might not have participated in this study. Finally, the results are quantitative, which, while providing clear metrics, might not explore deeper reasons or barriers behind older adults’ hesitations or willingness to adopt digital health technologies.

**Conclusion**
This cross-sectional survey study sheds light on the readiness of community-dwelling older adults aged 75 years or older in South Tyrol, Italy, to adopt digital health technologies. While older adults reported being open to embracing these technologies, readiness to adopt telemedicine or wearables was higher than readiness to adopt smartphones with texting apps or assistant robots. Readiness to adopt digital health technologies among older adults was explained by sociodemographic, health-related, and lifestyle factors, with higher age consistently associated with less willingness to adopt digital health technologies, particularly among individuals aged 85 years and older. The use of computers, smartphones, and the internet in everyday life appears to be the most significant driver of readiness to adopt digital health technologies. Key stakeholders, including health care providers, technology developers, and policymakers, require a nuanced understanding of the readiness of older adults for digital health technologies. Among older people, tailored approaches addressing the needs of diverse demographic segments could further enhance the adoption rates. Collaborative initiatives, blending technological innovation with elder-friendly interfaces, and protective policies are vital for the seamless integration of digital health technologies into the lives of older people. Further, longitudinal studies are needed to explore how attitudes toward and the use of digital health technologies evolve among older adults over time. Qualitative research is necessary to gain a deeper understanding of the differential adoption readiness of older adults, including their language differences.

Abstract

Background: Indigenous communities often have poorer health outcomes and services under traditional models of care. In New Zealand, this holds true for Māori people who are tūanga whenua (the indigenous people). Several barriers exist that decrease the likelihood of indigenous communities often have poorer health outcomes and poor service fit under traditional models of care, including access issues, systemic and provider racism, and a lack of culturally safe and responsive services. Web-based interventions (WBIs) have been shown to be effective in supporting mental health and well-being and can overcome some of these barriers. Despite the large number of WBIs developed, more investigation is needed to know how well WBIs fit with an indigenous worldview and how they meet the needs of indigenous communities so that a digitally based future does not drive social and health inequities.

Objective: This study aims to explore the goodness-of-fit of WBIs of Māori individuals, the indigenous people of Aotearoa/New Zealand.

Methods: We used interviews (n=3) and focus groups (n=5) with 30 Māori participants to explore their views about WBIs. Interviews were analyzed using reflexive thematic analysis by members of the research team.

Results: Overall, there was a perception that the design of WBIs did not align with the Māori worldview, which centers around people, relationships, spirituality, and holistic views of well-being. A total of 4 key themes and several subthemes emerged, indicating that WBIs were generally considered a poor fit for Māori. Specifically, the themes were as follows: (1) WBIs are disconnected from the core values of te ao Māori (the Māori worldview), (2) WBIs could be helpful in the right context, (3) there are significant barriers that may make it harder for Māori to use WBIs than other groups, and (4) ways to improve WBIs to help engagement with Māori.

Conclusions: While WBIs are often considered a way to reduce barriers to care, they may not meet the needs of Māori when used as a stand-alone intervention. If WBIs are continued to be offered, developers and researchers need to consider how to develop WBIs that are responsive and engaging to the needs of indigenous communities rather than driving inequities. Ideally, WBIs should be developed by the people they are intended for to fit with those populations’ world views.

Introduction

Background

Web-based interventions (WBIs) are therapeutic interventions delivered over technological means such as mobile phones or the internet to facilitate behavior change to improve health or well-being. Over the past 2 decades, the explosion in the number of WBIs has paralleled the growth and increased access to technology worldwide. This growth is driven by the potential of WBIs to reach more people at a lower cost than comparable face-to-face therapies. Several reviews now report that WBIs are as effective as face-to-face interventions [1-4], making WBIs a viable alternative to conventional therapies.

Indigenous communities often face more significant barriers to accessing health care than the dominant cultural group [5-9]. The barriers include systemic racism [10-14], negative attitudes held by health care professionals about indigenous people and traditional methods of healing [14-17], a lack of culturally responsive and safe services [18-20], and significant psychosocial barriers that make even getting to appointments difficult [21]. Due to these barriers and the social inequities created by colonization [22-24], indigenous people often experience worse health and social, psychological, and mortality outcomes. Given the potential benefits of WBIs to overcome some of these barriers, WBIs are increasingly being developed for the hard to reach or engage groups [25-27], such as indigenous communities.

However, one of the reasons that traditional health care underserves indigenous communities is that the care delivery model is often driven by a Western or dominant cultural paradigm [17], which often does not fit with the values and worldview of the indigenous community [28,29]. Thus, existing Western and biomedical models may further perpetuate health inequities [30]. For example, many indigenous communities such as Māori (the indigenous people of New Zealand) [31] hold a collectivist worldview rather than the individualized view prevalent in Western medicine [31,32]. In te ao Māori (the Māori worldview), the relationship and generational history between 2 people are paramount and influence engagement with others. Similarly, wairua (spirituality), Mauri (life force), whakapapa (history), and tikanga (ways of doing things) are paramount in all interactions. These factors are often deprioritized in the medical model, where an adequate patient-clinician relationship is assumed. Similarly, there is often a belief that this relationship will progress within what is largely superficial, impersonal and not responsive to the patient’s cultural needs nor recognizes the history and impact of colonization [33].

As the uptake and persistence of WBIs are often considered low, particularly on a long-term basis [34,35], it is essential to understand the views of potential users to inform the design and determine if WBIs are the best form of intervention. This has been frequently explored with nonindigenous populations, which found that time constraints and lack of perceived worth of the WBI were key reasons for stopping using WBIs [35]. In indigenous communities, uptake of WBIs has been found to be variable and can be affected by intervention characteristics [36,37]. In addition to this, many indigenous communities have poor access to technology and technological infrastructure [38], which can create further barriers to accessing WBIs. Understanding barriers to uptake can help researchers, developers, and policy makers consider how to improve WBIs for indigenous populations or if WBIs are even an appropriate intervention strategy for indigenous communities—because without this understanding, investment in technology may further drive health inequities.

Objective

Currently, there is limited research exploring the views of Māori adults about WBIs and the fit of WBIs with te ao Māori. Given this, this study sought to understand the views of Māori adults about WBIs using a qualitative design and reflexive thematic analysis of interviews and focus groups.

Methods

Overview

This study used a qualitative methodology using a mix of web-based videoconferencing interviews, face-to-face interviews, and focus groups. All interviews were facilitated by MCBP, who also recruited participants using snowball recruitment and social media advertising.

Participants

People were recruited into the study if they identified as Māori, were aged >18 years, and could consent to participation either orally or in a written format. There were no exclusion criteria for this study.

Recruitment

Participants were recruited through a range of recruitment methods using convenience sampling. Participants for 1 focus group (n=8) were recruited through Te Kete Pounamu, a nationally based organization for Māori with lived experience of mental distress and addiction. The remainder of the participants were recruited via the researchers’ professional and personal networks, web-based advertisements, and through relationships formed in the community by research team members.

Procedure

The participants were offered a choice of participating in an individual interview or a focus group discussion. During the initial stages of the meeting with the participants, the interviewer (MBP) opened the session with karakia (prayer) if the participants wished for this to happen. The interviewer then engaged with participants in whanaungatanga (building relationships through shared connection). The participants were then reoriented to the study, and consent was obtained in a written or recorded verbal format. The participants then confirmed that they were happy to be recorded, and the interview or focus group commenced.

Interviews initially started by providing the participants with a definition of WBIs and then asking participants about their views of WBIs. If needed, the participants were prompted to talk about why they felt WBIs did or did not fit with their...
worldview. A specific example of an existing WBI was used as a talking stimulus by demonstrating the WBI if required. At the end of the session, participants were thanked for their time, and the session was closed with karakia if it was opened with one.

Data Gathering

Given that Māori have a strong oral history and prefer to engage kanohi-ki-te-kanohi (face-to-face), interviews and focus groups were used. Combining both methods meant that participants could be part of a group to share their views or talk individually. Consultation with Te Kete Pounamu indicated that their tāngata whaiora (people seeing health) would likely prefer to engage in a focus group. Thus, focus groups were offered to allow this. Individual interviews were offered to enable flexibility in interview times at a time and place that suited individuals. Group interviews were complete kanohi-ki-te-kanohi, while individual interviews were a mix of kanohi-ki-te-kanohi and on the web. Both interviews and group interviews used the same semistructured interview guide with questions to facilitate reflective discussion. Examples of questions used were as follows: “What are your views on digital interventions to support mental health and well-being?” “What do you think has led to you developing these views?” “How does the use of digital interventions fit your background and culture?”

A total of 8 transcripts were produced, consisting of 3 individual interviews and 5 interviews with >2 participants. A total of 30 people were interviewed as part of the study. The interviews were manually transcribed (by HW); checked (by LD); and coded using inductive reflexive thematic analysis by Clarke et al [39] by 2 members (LD and MCBP) of the research team individually and following a 6-step process of familiarization, coding, generating themes, reviewing themes, defining and naming themes, and writing up. Reflexive thematic analysis was chosen as an appropriate methodology for this study as it is aligned with recent projects seeking to understand the views of Māori [40-43] as tāngata whaiora (those seeking health).

The transcripts were not returned to the participants for review. Any disagreements in coding between LD and MCBP were resolved by discussion between LD, MCBP, and PH. Codes, subthemes, and themes were combined on the web for review. The wider team (LD, MCBP, HW, and PH) was chosen as an appropriate methodology for this study as it is aligned with recent projects seeking to understand the views of Māori [40-43] as tāngata whaiora (those seeking health).

The participants had the option to provide scanned copies of the signed consent form to the interviewer if they preferred this method over video consent.

Ethical Considerations

Ethics approval for the study was received from the Auckland Health Research Ethics Committee (AHREC AH23110; expiry October 18, 2024).

Written consent was provided by all participants who completed face-to-face interviews or focus groups following a review of the participant information sheet. In web-based interviews, an oral consent protocol was followed where participants were video recorded giving their consent. The researchers then completed the consent forms based on participant responses, and consents were electronically provided to the participants. The participants had the option to provide scanned copies of the signed consent form to the interviewer if they preferred this method over video consent.

One participant completed their interview or focus group, the recordings were transcribed (completed by MCBP or HW), and all identifying information was removed from the transcript. The deidentified transcripts were provided to the wider research team for review. LD led the review process with MCBP. Codes and themes were discussed with HW, AHYC, and PH once coding was complete. The original recordings were stored separately from the transcripts in a secure manner on a password-protected university-managed research drive aligned with the data management plan.

During the research process, Koha (a gift acknowledging the time spent by participants and sharing their knowledge) in the form of NZ $20 (US $11.87) supermarket vouchers and kai (food) were provided to participants.

Results

Participants

A total of 30 participants participated in this research across 5 group interviews and 3 individual interviews (Table 1).

In terms of participants, ages ranged from 18 to 74 years, with the mean participant age being 41.3 (SD 19.6) years. Of the 30 participants, 11 (37%) identified as a man, 12 (40%) as a woman, 6 (20%) did not specify their gender, and 1 (3%) identified as nonbinary. The participants lived in a mix of main urban centers, such as Auckland and Hamilton, and in more urban areas, such as Northland and Rotorua.

Findings

The participants were largely aligned with their views on WBIs. Although they often offered a critical perspective on WBIs, they also quickly indicated that others might find WBIs helpful even though they did not believe that WBIs would be useful for themselves. Through the analysis of the transcripts, 4 themes emerged, as listed in Table 2.

These themes and subthemes are discussed in more detail in the subsequent sections.

\(^a\)WBI: web-based intervention.

WBIs Are Disconnected From the Core Values of Te Ao Māori

Overview

Te ao Māori (the world view of Māori) and Māori culture are built around relationships, collectivism, and a shared connection. Considering the collective is vital, and a treatment model focused on the individual’s pathology alone without connection or relationships is at odds with Māori beliefs and values. The participants felt that WBIs may not understand and replicate the critical relational aspect, which is crucial in all aspects of life for Māori. Therefore, most participants did not consider WBIs as something that would fit with Māori culture or worldview. A participant said the following:

*Because you are not face to face...and as Māori’s, we are...like, unless we know you and love you, we’ll never be as open though. No way! Ah, it’s, it’s, I don’t know...it just is* [Group 5]

Another participant stated the following:

*I definitely think doing something online definitely lacks whanaungatanga [relationships/the process of forming relationships] and that kind of personal relationships with your doctor or your medical provider* [Group 5]

Many of the older participants struggled to conceptualize what an automated program such as a chatbot would look like and how this could be used to support well-being, as this was removed from the concept of relationships, which are key to wellness and healing. Even when considering web-based therapy delivery, this had significant barriers to developing whanaungatanga. For some, there was a perception that without a real in-person connection with others, it would be easy to mask true feelings and intentions, which would further limit the benefits of the WBI. Others felt that people might inadvertently disclose more than they wanted to due to the WBI not seeming like a relationship (and more like a diary), and this could be harmful due to mistrust in how this information would be used. The overall message is that a person’s absence meant the absence of connection and healing. A participant said the following:

*For healing purposes, people are necessary in our culture* [Group 1]

Another participant stated the following:

*I know people, they would like the online thing because they don’t feel like they are disclosing much about themselves. They are, but they don’t feel like they are* [Interview 2]

Another participant said the following:

*At the same time, when its online you can kind of feel some like you’re wearing a mask. So, it’s not really you* [Interview 3]

The perceived lack of connection for users with WBIs hindered honesty and information sharing. This ultimately limited the benefits and healing that could be obtained when exclusively using WBIs. For some participants, there was the belief that WBIs and the digital world contributed to poor health as people became more disconnected from others; lost their ability to communicate; and tended to live in a digital world that was disconnected from their whakapapa (family history or genealogy), whenua (land), atua (gods or spiritual beings), and...
values. Some perceived turning to a digital world for help as a lack of personal responsibility for healing, which would further exacerbate long-term difficulties and have implications for future generations. This was particularly emphasized for automated interventions with a lack of relationship and accountability. A participant stated the following:

I do I think there is a whole generation, like the younger generation, who will know nothing else but digital stuff and like babies who now are growing up seeing nothing but masks on people’s faces. It’s the same kind of thing they won’t know how to relate unless it’s seen, or read it, or hear it. You know, tap into it online. You know? Their connections might be doing the de-de-de finger scrolling online, whatever online that might be their connection. But for me, I’m old school. I like people [Group 1]

Te Ao Māori Is About Wairua and WBIs Cannot Replicate This

When Māori connect, they do so with an energy transfer between 2 people, which conveys many things, including meaning to nuanced words. As such, te ao Māori is about wairua (spirituality) and Mauri (energy or life force), which respondents felt could not be conveyed by a digital tool. The 1D nature of the WBIs often felt empty to participants, robotic, and therefore not healing. For some, there was a perception that turning to WBIs would further drive participants away from te ao Māori and may worsen the underlying illness mechanism. A participant in stated the following:

We need that human connection. But it’s not just physical connection. It’s the frequency, it's the energy, it’s the Wairua [Group 1]

A participant stated the following:

Well-being for Māori comes from connection. I think well-being, particularly in terms of Māori well-being, you know? The energy and frequency that comes with healing...um...is can be misinterpreted; can be absent [Group 2]

Another participant stated the following:

The last thing you want is for people to be dependent on digital apps for their well-being. That would be disastrous when people don’t know how to go to other people in a group and don’t be empowered enough to heal themselves [Group 1]

Māori Models of Health Are Holistic, Whereas WBIs Are Singular in Focus

Many participants reflected on Māori models of healing as being holistic and considering all areas of well-being. Specifically, one was unlikely to become well or heal from illness by just considering 1 facet of treatment (eg, thinking styles), when being well also included good physical health, strong connections to wānau (family) and whenua (the land), whanaungatanga (relationships), a connection to a higher purpose and meaning, and spirituality, all of which were considered essential for people to flourish. The approach of WBIs was largely seen to be singular in focus and did not fit with te ao Māori views of what was needed for healing. It was recognized that the perceived approach of WBIs was not aligned with Māori models of health and was more aligned with traditional Western models of treatment, such as psychological therapy or a medical model.

The common themes demonstrating the desire for a holistic approach included being able to meet the needs of wānau through accessing food, forming relationships, and recognizing that conversations about Mauri and spirituality were absent. Even when WBIs incorporate te reo Māori (the Māori language), the use of kupu (words) are often perceived as tokenistic, with poor translation that fails to capture the nuances of te reo Māori.

WBIs Could Be a Strand in the Weaving of a Well-Being Kete

Despite the belief that WBIs were unlikely to meet the ideal delivery of an intervention to support the well-being of Māori, many participants were open to considering using a WBI. Specifically, there was a perception that WBIs could be used as an adjunct to a treatment or therapeutic intervention already underway, particularly when there was already a strong relationship with the therapist or the care team. A participant stated the following:

I feel like I could get the information I need to do more. Cause, obviously, an app can only go so far, and your mental health is really...you know? You’re paddling that waka [boat]...People can help you, but you’re the main navigator of that boat...I think it will help start it will help you build the waka and get it onto the water, um, but then yeah...I am guessing that you would have to put in the work yourself to go find other resources [Interview 3]

Another participant stated the following:

Am just not sure we would be able to actually heal people properly, but it could help at least getting them toward the resources they need [Group 3]

WBIs Could Be Helpful in the Right Context

Overview

The participants noted several strengths of WBIs and were open to WBIs being a tool that might benefit some people more than others. Context was important, as was the support around the WBI. Specifically, there was a view that while WBIs might be good for some people, using them in isolation, without connection to people, might actually exacerbate issues.

WBIs Could Be Useful for People Who “Moved With the Times”

There was a perception that WBIs might suit those that have moved away from traditional modes of healing, such as the younger generations, but those groups did not always support this view. Many participants reported that they felt “older,” meaning they were more likely to struggle with WBIs than younger generations. There was a strong sense that rangatahi (young people) would be more inclined to use WBIs than kūmātua (elders), who were less confident with technology. This was observed in this study by the difficulty many kūmātua...
experienced accessing the stimulus WBI and the confusion around what the application was asking. The participants often indicated that they did not believe they could learn new technology and tended to avoid using it. As such, the perceived stress of using the WBIs outweighed the potential benefits. A participant stated the following:

I think the young Māori people might have embraced it, but the older ones, we say, “It’s pākehā! [non-Māori].” They won’t; they won’t switch onto it. Could you imagine your mother doing it? [Interview 2]

Younger participants tended to voice more concerns about functionality and technological issues with WBIs and less about the values disconnection expressed by the older participants. While open to using WBIs, the younger participants still had reluctance to do so. A low tolerance for poor functionality was indicated, with participants highlighting that the complicated log-in processes or errors would lead to them feeling frustrated and uninstalling an application. This indicated that significant barriers to use were complicated sign-up or sign-in processes and outdated or faulty technology. A participant stated the following:

I feel like I would probably uninstall it. I mean, I don’t really have the patience for broken web pages and things...I don’t think most people do. Especially on phones and your meant to be doing a million things at once [Group 3]

The younger participants also supported the views of the older participants around holistic care and the desire for a face-to-face connection. Thus, the assumption that WBIs were embraced by rangatahi was not necessarily true. The younger participants wanted interpersonal connection and did not think WBIs could meet this. WBIs were instead seen as a source of information but unlikely to be considered for therapeutic intervention or connection with others.

**Apps Could Be a Tool but Not the Solution: a Blended Care Approach Is Needed**

Many participants felt that they would be more open to using a WBI when integrated in the context of an existing, trusted relationship. The perception was that the role of the relationship would be to facilitate healing, while the WBI could serve for monitoring, support, providing information, promptly answering questions, and potentially facilitating connections to others beyond the primary relationship. The relationship would center around wairua, whanaungatanga, and whānau, while the WBI might provide exercises, reminders, and ways to keep track of important things. Relaxation and mindfulness recordings were specifically noted as something that could be provided or used by participants in WBIs. Contacting a trusted support or therapist through the WBI was also seen as a way to increase whanaungatanga and healing if used in a timely and appropriate manner.

**Barriers to Using WBIs for Māori**

There were several barriers to using WBIs for participants, and many participants shared that they believed other Māori would also experience some of these challenges.
or that the person using the WBIs would not be a priority. A participant stated the following:

I share something you share something you know that kind of kōrero or that I don’t know if they’re listening. I mean, while I’m talking, what are they doing? Emailing somebody? [Group 1]

The participants raised further concerns about the confidentiality of information shared with WBIs and how this would be used, particularly with regard to information potentially being shared with government agencies and the potential negative impact this could have on the participant and their whānau. This mistrust was not limited to WBI but to the researchers, the institutions, and the groups that supported it. A participant stated the following:

What puts me off is that there is nothing that comes across as Māori. This is a pākehā app for pākehā, pākehā solutions, pākehā reference pākehā, you know? And I think that’s one of the, um, big issues of today, um, well-being solutions is that pākehā are trying to form solutions using methodologies that aren’t Māori, you know? [Group 1]

Many participants reported struggling with interventions that Pākehā developed as they lacked the depth of understanding about the historical impact of colonization on Māori and how this may impact the person is seeking help. Many felt that interventions and Pākehā therapists and WBIs could not address this as they did not have these lived experiences. A participant stated the following:

I would want someone who can understand what lived experience is... [Group 2]

Another participant stated the following:

I prefer to speak with people, real people. And when it comes to, um, some of my historical stuff, then I would want someone who can understand what lived experience is. You know, email doesn’t cut it either, you know, again who is this person that I’m emailing? [Group 1]

Mistrust was further exacerbated by the perception that Māori did not design many WBIs for that were reportedly for Māori. This was not only due to the WBI being perceived as a poor fit for te ao Māori but also due to Pākehā ultimately designing many WBIs for Pākehā (or the dominant paradigm) and then adapting (often poorly) these for Māori. Therefore, very few interventions were specifically designed for Māori, and even fewer were created by Māori. A participant said the following:

There’s no Māori kupa in here. Not even a “kia ora,” welcome [Group 1]

Another participant said the following:

They had a real photo, but, um...whoever created didn’t look at the photo properly and it had somebody poking their tongue. So what time was given to that? I felt it was lacking big time cause if I’m not in a great space and I see someone poking their tongues, saying, you know? I’m feel challenged! What’s up with that? [Group 1]

The participants were also wary of research teams that used a Māori interviewer but did not involve Māori in key decision-making. Questions were raised around the motivations of the teams and whether they came from genuine caring and a desire to reduce inequities (it was noted that the interviewer was challenged about this on >1 occasion). There was a belief that these teams that did not have genuine motivation would create solutions that were unlikely to resonate with Māori. A participant stated the following:

You know, they’re not using Māori or mātauranga Māori [knowledge] or Māori methodologies to create Māori solutions or do the research. You know they have got a brown face here, but I mean, who’s behind it and why they behind it? You know? [Group 4]

Ways to Improve WBIs to Help Engagement With Māori

Despite reservations about WBI, the participants provided several recommendations that could make WBIs more engaging for Māori. These were specifically about features of WBIs that would make them more engaging for Māori who may be interested in using WBIs.

Māori Imagery Is Key for Māori to Connect

The most common subtheme was that the participants wanted to see themselves reflected in the WBI. Imagery was important, and the participants wanted to see a mix of images, including pictures of Māori people, whānau (families), and hapu (communities). This imagery also included other key things such as bodies of water, native bush, maunga (mountains), Māori art and carvings, and buildings easily identified as Māori (eg, wharenui—meeting houses). This range of imagery tied back to a sense of holistic approaches to well-being, including the connection to people, to whenua (land), and to key important spiritual sites.

The participants also highlighted that Māori are diverse people and that not just 1 image connects with all Māori. Images depicting kapa haka or individuals performing a pukana (facial expression) were frequently viewed as oversimplified and occasionally offensive, simplifying the complexity of Māori culture. Instead, the participants would be drawn to WBIs that used a range of imagery of people showing the diversity of Māori. A participant stated the following:

A diverse range of Māori women. Um...sizes, ages...um, you know, skin tone. You know? Just like everything [Interview 3]

This was considered important by almost all participants, particularly as some participants identified that Māori are a strongly oral and visual culture with images of kowhaiwhai (weaving), whakairo (carving), and taonga (treasured items) drawing the eye and creating connection. For participants, many WBIs still mimicked clinical rooms in terms of the colors used and simple pages, which further created a sense of depersonalization and disconnection. A participant stated the following:

It seems very like clinical in a way, um, because of the coloring. Like, it’s all blue, like, it kind of just
makes me think of, like, the doctors, um, like, it’s very formal I think [Group 3]

Māori Models of Well-Being Should Be at the Heart of All Interventions

Several participants noted that if WBIs interventions could be constructed around Māori models of well-being, WBIs would be likely be more engaging for Māori. The key model suggested was Te Whare Tapa Whā [45]. While other participants did not explicitly outline a model, they articulated the need for a holistic approach to care that supported all aspects of wellness, including connection to culture as a path for healing. A participant stated the following:

Inclusive of the mental effort, you know the spiritual and all that stuff and the physical but so is this are they talking about holistic well-being or are they just talking about mental well-being because you can’t have one it’s, like, Te Whare Tapa Whā thing, ah, you can’t just focus on the one when you are expecting others to fall into place you have to work on the whole lot [Group 1]

Another participant said the following:

There needs to be some sort of cultural, um, tool that helps...that grounds people. I guess whakapapa was one of those things [Group 1]

Improved Integration of the Te Reo Māori Language Would Make WBIs More Appealing

The participants agreed that correct and appropriate use of te reo Māori was important if WBIs were to engage Māori. Recognizing that the fluency of te reo varied, the participants wanted WBIs to be able to be modified based on the user’s fluency (such as entirely in te reo Māori or with only a few words). Even for those only beginning their te reo journey, keywords such as a greeting should be used meaningfully. The participants also noted that, based on past experiences, simply translating a few words into te reo lost the nuances of the language and could lead to misunderstanding and, at times, felt tokenistic. There was an emphasis on the correct use of Māori words, which often carry contextual meanings. Tokenistic inclusion of these words can lead to misunderstandings or, at worst, be offensive. Therefore, people developing WBIs for Māori needed someone fluent in te reo Māori working on the content rather than using simplified translation tools.

By Māori for Māori

A strong theme that came through was that WBIs, interventions, and tools that were developed by Māori for Māori resonated more strongly with Māori participants and were more likely to be engaging and used. Trusted institutions and sites tended to result in resources that were more readily used. A participant said the following:

I have searched through...through Te Ora [website] you know to find out stuff I think because it’s a Māori organization there’s a sense of connection being a Māori organization [Group 1]

A clear understanding of the whakapapa (history and origin) of the research project and the research team was deemed crucial, ideally with the project being designed and led by Māori for Māori. In addition, there was discussion about incorporating key models of health and acknowledging the influence of significant Māori figures in the project’s development.

Discussion

Principal Findings

This study is one of the first to explore the views of Māori, the indigenous people population of New Zealand, about WBIs. Although participants could see the potential benefits of WBIs when used in the context of a strong existing relationship, there were concerns that a digital tool would not be able to facilitate healing due to the perception of WBIs being 1D in their focus rather than holistic, the potential to drive people further away from te ao Māori, and the lack of genuine connection that could be made on the web. Significant barriers to using WBIs were highlighted, including the impact of social inequities, which hindered access to the technology needed to engage with WBIs. Educational disadvantage also contributed to difficulties, particularly with text-heavy platforms. In addition, concerns about confidentiality and mistrust in the motivations of researchers (and government) due to experiences of colonization were clear.

This study makes a unique contribution to understanding WBIs, how they fit with the view of Māori as the indigenous people of New Zealand, and how indigenous communities may perceive and respond to WBIs. Our findings are in contrast with previous studies that explored uptake and engagement with WBIs in indigenous populations and ethnic minority groups. A recent scoping review exploring the use and uptake of web-based therapeutic interventions among indigenous populations in Australia, New Zealand, the United States, and Canada found moderate uptake of WBIs and potentially improved health outcomes associated with them [36]. Of the 31 studies, 9 (29%) were from New Zealand, with 3 (10%) relating to 1 web-based cognitive behavior therapy–based intervention (Smart, Positive, Active, Realistic, X-factor thoughts), 1 (3%) relating to minimizing risky alcohol use, and others (n=5, 16%) on specific noncommunicable diseases. The review findings reported a more positive experience with WBIs, possibly because of the younger age of participants and the way the WBIs were implemented, for example, delivered in school-based settings or with significant input and coproduction with Māori. Similar to our findings, the review highlighted the importance of tailoring content and presentation formats to ensure cultural relevance; appropriateness; and a customizable, easy-to-use interface. Another systematic review looking at the use of digital technologies to improve the mental health and well-being of indigenous people reported 27 studies that generally support the effectiveness of digital technologies in aiding the provision of mental health services but acknowledged that decolonizing and culturally appropriate approaches are needed [46].

The studies in these reviews generally do not examine the user experience of using the WBIs in depth. The review was limited in the degree to which it could explore barriers to accessing
WBIs resulting from cultural and linguistic diversity, low health literacy, limited digital capabilities, and infrastructural and resource limitations for individuals and communities in different geographic locations—concepts that our participants expressed as potential barriers to WBI use. Similarly, a recent rapid review examining the use of web-based care in indigenous populations highlighted several barriers to engagement with web-based care—cost, accessibility, digital literacy, and language [47]—which align with our findings. The review emphasized the importance of building relationships and trust and ensuring the infrastructure is present to support technology navigation with indigenous populations, echoing our findings. Our study builds on these reviews by being one of a few studies to examine the views of Māori using qualitative methodology, which may explain the more in-depth findings articulated by respondents.

Limitations

Several limitations for this study exist. First, although the sample size was large for a qualitative study, Māori, like all indigenous people, are diverse; therefore, the views reflected in this study may not apply to all Māori. These views can likely be beneficial in shaping the development of WBIs. However, an effective WBI should be developed by Māori with the understanding that one intervention will not fit everyone. Instead, WBIs need to be developed with Māori models of well-being being central for use alongside a strong kanohi-ki-te-kanohi (face-to-face) therapeutic relationship. Previous reviews [36] recognize that the definitions of health often used are less holistic and relational than indigenous models of health and well-being, which may affect the interpretation of published studies in this area or result in studies appearing to be more effective than what would be perceived from a more holistic framework.

Second, this study explored the views of WBIs and used an existing intervention as an example for participants. This means that interventions that may have a different development process (eg, Māori developed) may have resulted in different views by the participants around the acceptability and usability of WBIs. The views of the participants may also be affected by the stimulus chosen as the example.

Finally, while most of the research team were Māori, the researchers varied in the strength of their connection to te ao Māori and their knowledge of this. This means that the analysis of the transcripts and subsequent findings may have varied if other people with different understandings and connections were to analyze the transcripts.

Reflections

One challenge for the research team was to avoid replicating some of the concerns and barriers regarding WBIs that were raised by the participants. Specifically, one aspect was the composition of the research team, where the individual conducting participant interviews was Māori, while the senior authors of the paper were not Māori. For context, this project is 1 part of a 2-part study designed from the onset with a diverse team in consultation with a Kaupapa Māori nongovernment organization. MCBP was involved in early discussions with the research team about the project and was brought into the team in recognition of the mātauranga Māori (knowledge unique to Māori) that she brings. MCBP was supported to be an active and equal member of the research, including being provided with support to upskill in qualitative methodologies. PH and HW were engaged in reviewing the themes to ensure interpretation and understanding were correct and to add to the richness of the interpretation, as the research team did not want to assume understanding and acknowledged their limitations around the lived experiences of Māori. Author order was decided among the team (MCBP, HW, PH, LD, and AYHC) based on roles in the project, with the decision to make MCBP and LD joint lead authors in recognition of the different roles in the project. We recognize that Māori should ideally lead projects exploring the view of Māori, and the experience that MCBP has within this project has meant that she has been able to colead a subsequent project and is beginning to develop her own research pathway as a Māori researcher with lived experience.

Conclusions

Through in-depth qualitative interviews and focus groups with Māori (indigenous people of New Zealand), WBIs were found to be generally considered a poor fit for Māori as the design of WBIs did not align with the Māori worldview or concepts of well-being. This contrasts with previous findings, where WBIs have been shown to be effective in supporting mental health and well-being and can overcome some of the traditional barriers to help seeking. With the large number of WBIs being developed, these findings are important in highlighting key considerations for WBIs to promote engagement with Māori, particularly considering how well WBIs fit with the indigenous worldview and how they meet the needs of indigenous communities in a culturally appropriate manner. While WBIs may have a place in supporting the well-being of Māori, WBIs alone are unlikely to achieve the same benefits expected for a non-Māori population and may further drive health inequities if not properly implemented and supported.

Acknowledgments

The authors would like to acknowledge the participants who contributed to this study and Te Kete Pounamu for their support, advice, and help with recruitment for this project. In addition, funding was provided by Chorus and Oakley Mental Health Foundation.
**Data Availability**

The data sets generated and analyzed during this study are not publicly available due to participants not consenting to the sharing of data beyond the research team with consent given for publication.

**Authors' Contributions**

LD is a health and clinical psychologist and researcher of New Zealand European descent who works in the area of digital interventions. LD was involved in the design of the project, ethics application, recruitment, overseeing interviews and supporting MCBP to complete the interviews, checking the transcripts, overseeing data analysis including supporting MCBP to upskill in thematic analysis, coding and generation of themes, and writing the manuscript. MCBP is a Mōari (Ngāti Whakaue and Te Arawa) and a research assistant for this project. MCBP was involved in the recruitment, facilitated interviews, and focus groups as well as the checking of transcripts, coding of interview data, and generation of themes. HW is a Mōari (Ngāti Tahu) and a PhD candidate at the University of Auckland. HW was involved in the project as a transcriber of the interviews. HW was also involved in discussions with the wider research team about the themes uncovered in the data. PH is a Mōari (Ngāti Porou, Ngapuhi, Te Whānau-a-Apanui) psychologist and an academic who is completing her PhD. PH was involved in the discussion where there was disagreement in the coding of the transcripts and was involved in the wider team discussion about the generated codes. AHYC is an academic clinical pharmacist with Asian heritage. She has particular expertise in digital health, big data, and behavioral medicine. AHYC was involved in the project development, reviewing the themes from the interviews, and contributing to the manuscript.

WBI: web-based intervention
Abstract

Background: Poor sleep quality can elevate stress levels and diminish overall well-being. Japanese individuals often experience sleep deprivation, and workers have high levels of stress. Nevertheless, research examining the connection between objective sleep assessments and stress levels, as well as overall well-being, among Japanese workers is lacking.

Objective: This study aims to investigate the correlation between physiological data, including sleep duration and heart rate variability (HRV), objectively measured through wearable devices, and 3 states (sleepiness, mood, and energy) assessed through ecological momentary assessment (EMA) and use of rating scales for stress and well-being.

Methods: A total of 40 office workers (female, 20/40, 50%; mean age 40.4 years, SD 11.8 years) participated in the study. Participants were asked to wear a wearable wristband device for 8 consecutive weeks. EMA regarding sleepiness, mood, and energy levels was conducted via email messages sent by participants 4 times daily, with each session spaced 3 hours apart. This assessment occurred on 8 designated days within the 8-week timeframe. Participants’ stress levels and perception of well-being were assessed using respective self-rating questionnaires. Subsequently, participants were categorized into quartiles based on their stress and well-being scores, and the sleep patterns and HRV indices recorded by the Fitbit Inspire 2 were compared among these groups. The Mann-Whitney U test was used to assess differences between the quartiles, with adjustments made for multiple comparisons using the Bonferroni correction. Furthermore, EMA results and the sleep and HRV indices were subjected to multilevel analysis for a comprehensive evaluation.
Results: The EMA achieved a total response rate of 87.3%, while the Fitbit Inspire 2 wear rate reached 88.0%. When participants were grouped based on quartiles of well-being and stress-related scores, significant differences emerged. Specifically, individuals in the lowest stress quartile or highest subjective satisfaction quartile retired to bed earlier (β<0.001 and P=0.01, respectively), whereas those in the highest stress quartile exhibited greater variation in the midpoint of sleep (P<0.001). A multilevel analysis unveiled notable relationships: intraindividual variability analysis indicated that higher energy levels were associated with lower deviation of heart rate during sleep on the preceding day (β=-0.12, P<0.001), and decreased sleepiness was observed on days following longer sleep durations (β=-0.10, P<0.001). Furthermore, interindividual variability analysis revealed that individuals with earlier midpoints of sleep tended to exhibit higher energy levels (β=-0.26, P=0.04).

Conclusions: Increased sleep variabilities, characterized by unstable bedtime or midpoint of sleep, were correlated with elevated stress levels and diminished well-being. Conversely, improved sleep indices (eg, lower heart rate during sleep and earlier average bedtime) were associated with heightened daytime energy levels. Further research with a larger sample size using these methodologies, particularly focusing on specific phenomena such as social jet lag, has the potential to yield valuable insights.

Introduction

Sleep is one of the most important health behaviors for human beings, and a lack of it affects both physical and mental health [1,2]. Furthermore, subjective stress and well-being are closely related to sleep quality [3-5]. Subjective methods for evaluating sleep quality are the Consensus Sleep Diary [6] and Pittsburgh Sleep Quality Index [7]; however, their results sometimes differ from those of objective assessments [7,8]. Therefore, objective sleep evaluation methods have been developed, and research using these methods is ongoing.

Polysomnography is the gold standard for objective sleep assessment methods [9], but it is expensive and physically demanding. Hence, wearable devices have emerged as recent alternatives for sleep assessment, offering less burdensome options compared with polysomnography [10]. For example, commercially available devices such as Fitbit (Fitbit Inc.) can measure motion, heart rate variability (HRV), and respiratory rate, and based on these measurements, sleep quality can be measured with reasonable accuracy [11]. Furthermore, HRV, a quantitative biomarker of autonomic activity [12], has been reported to be useful for the quantitative assessment of stress [13] and is highly associated with subjective well-being [14,15]. In addition, self-administered questionnaires such as the Epworth Sleepiness Scale have been used [16]; however, they do not capture diurnal variations in sleepiness. One method to capture symptom variability is ecological momentary assessment (EMA), which is a prospective, repeated sampling of symptoms in real time in the participants’ natural environment, with minimal burden on respondents [17]. EMA has been widely used to accurately assess respondents’ mood and stress levels during the day [18]. Moreover, several studies have examined sleep conditions and their relationship to daytime sleepiness using EMA [19-23]. In recent years, studies have combined objective sleep assessments, such as those obtained by wearables, with EMA-based assessments [24-26]. It has long been reported that, on average, Japanese people go to bed later and sleep for shorter durations than people in other countries [27,28]. A survey of 13 countries in 2020 and 2021 also reported that Japan had the lowest subjective satisfaction with sleep for 2 consecutive years [29]. In Japan, the number of individuals with work-related mental health problems continues to increase annually [30]; furthermore, in a 2023 survey on workers’ health and well-being, Japan ranked last among 30 countries [31]. However, only a few studies have evaluated the relationship between sleep and stress and well-being among Japanese workers using a combination of objective sleep assessments and EMA. This study investigated the relationship between sleep and stress and well-being among Japanese workers. We evaluated the relationship between sleep quality/daytime sleepiness and stress levels/perception of well-being (hereinafter, stress/well-being) by combining the assessment of sleep quality using wearable devices with real-time monitoring of daytime sleepiness and mental status using EMA. In particular, we examined the relationships between objectively measured sleep indices and HRV using Fitbit Inspire 2 (Fitbit Inc.) and the participants’ subjective conditions or feelings to verify the following hypotheses: (1) people with short total sleep time and late bedtime have high stress levels and low perceived well-being; (2) people with high sleep quality have high energy and good mood during the day.

Methods

Study Design

The study was designed to explore the correlations between physiological and behavioral data (eg, sleep, daytime activity, HRV, and blood glucose) objectively measured by wearable devices, and the participants’ perception of well-being, stress levels, daily mood, energy, and sleepiness assessed through questionnaires and EMA. The participants were asked to wear 2 wearable devices, namely, the Fitbit Inspire 2 and the FreeStyle Libre (Abbott Diabetes Care) for acquiring the physiological/behavioral data and 24-hour blood glucose data.
respectively. In this study, our focus was on examining the relationships between sleep and HRV indices measured using the Fitbit Inspire 2, alongside the concurrent assessment of participants’ psychological status through EMA and stress/well-being questionnaires. Other aspects of the study will be reported separately.

The detailed study design consists of recruiting a total of 40 participants, comprising individuals with impaired glucose tolerance (not meeting the diagnostic criteria for diabetes mellitus) and healthy participants. Initially, participants completed a questionnaire aimed at evaluating their eating behaviors and stress/well-being. Following this, they were instructed to wear the Fitbit Inspire 2 continuously for 8 consecutive weeks. In addition, during the initial 2 weeks of the study, participants were instructed to wear the FreeStyle Libre continuously during the day. After the completion of this 2-week period, participants were asked to once again complete the questionnaire assessing their eating behaviors. Furthermore, they received guidance on eating behaviors from a dietitian. Following the initial 4 weeks of wearing the Fitbit Inspire 2 device, participants were requested to wear the FreeStyle Libre once more for a duration of 2 weeks. This period coincided with the final 2 weeks of the 8-week Fitbit Inspire 2 wearing period. Subsequently, upon concluding the 8-week duration of wearing both devices, participants were once again asked to complete the questionnaires assessing their eating behaviors, as well as another questionnaire aimed at evaluating their stress/well-being. Furthermore, EMA was conducted to evaluate sleepiness, mood, and energy levels. This assessment involved participants sending emails 4 times a day, with each email sent 3 hours apart. This process occurred on 8 designated days throughout the 8-week study period.

Participants

The inclusion and exclusion criteria for participants are detailed in Textbox 1. Eligible participants were adults, defined as individuals at least 20 years old (the age of adulthood in Japan at the time of recruitment), who possessed a smartphone (either Android or iOS). The study aimed to investigate the correlation between sleep, HRV, 24-hour blood glucose levels, and various psychological factors including sleepiness, energy, mood, and stress/well-being. Therefore, inclusion criteria encompassed individuals expected to exhibit high blood glucose variability, alongside normal participants. Specifically, participants with abnormal glucose tolerance (hemoglobin A\textsubscript{1c} (HbA\textsubscript{1c}) levels ranging from 5.8 to <6.5) who did not meet the criteria for diabetes mellitus were considered eligible. Psychiatric disorders were neither inclusion nor exclusion criteria for participant selection. Recruitment for the study occurred in February 2022, with participants recruited at a 1:1 male-to-female ratio.

Textbox 1. Inclusion and exclusion criteria.

1. **Inclusion criteria**
   - Patients with hemoglobin A\textsubscript{1c} (HbA\textsubscript{1c}) values of 5.8 ≤ HbA\textsubscript{1c} <6.5 at the most recent physical examination undergone within the previous year, or healthy participants with no glucose intolerance.
   - Adults aged 20 years or older at the time of consent acquisition.
   - Smartphone users who owned and used a smartphone that was compatible with the app used in this study.

2. **Exclusion criteria**
   - Patients who had been diagnosed and treated for diabetes mellitus in the past.
   - Patients with comorbidities that could affect the data measured by the wearable wristband device, such as paralysis of the upper limbs.
   - Others who were deemed as being inappropriate participants for the study by the principal researcher or coresearchers.

Data Collection

The data collected in this study are outlined comprehensively in Textbox 2. Further, the data collection schedule is presented in Table 1. Data collection occurred between February 2022 and April 2022. The Perceived Stress Scale (PSS) [32] was used for the assessment of subjective stress. For the assessment of subjective well-being, we used the Satisfaction With Life Scale (SWLS) [33], the Japanese version of the Scale of Positive and Negative Experience (SPANe-J) [34], and the Japanese version of the Flourishing Scale (FS-J) [34]. To evaluate sleepiness, the Japanese version of the Epworth Sleepiness Scale (JESS) [35] was used.
Textbox 2. Data collected in this study.

1. Background information (results of company medical checkup)
   - Gender, age, and preexisting medical conditions
   - Results of the most recent medical checkup undergone within the previous year

2. Questionnaire
   - Brief-Type Self-Administered Diet History Questionnaire (BDHQ) [36]
   - Eating Behavior Questionnaire (EBQ) [37]
   - Perceived Stress Scale (PSS) [32]
   - Satisfaction With Life Scale (SWLS) [33]
   - The Japanese version of the Scale of Positive and Negative Experience (SPANE-J) [34]
   - The Japanese version of the Flourishing Scale (FS-J) [34]
   - The Japanese version of the Epworth Sleepiness Scale (JESS) [35]

3. Ecological momentary assessment
   - Sleepiness (Visual Analog Scale [VAS] format): scores range from 0=not sleepy at all to 100=very sleepy (maximum sleepiness imaginable).
   - Mood (VAS format): scores range from 0=negative mood (lowest mood imaginable) to 100=positive mood (best mood imaginable).
   - Energy (VAS format): scores range from 0=no energy at all to 100=full of energy (greatest state of energy imaginable).

4. Wearable Devices
   - Fitbit Inspire 2 data (eg, sleep, heart rate variability, and body movements)
   - FreeStyle Libre data (24-hour blood glucose)

Fitbit Inspire 2 data were collected continuously throughout the 8-week study period. FreeStyle Libre data and EMA data were collected 2 weeks after baseline and 2 weeks before the final evaluation. Data collection was facilitated through electronic patient-reported outcomes, a self-administered instrument completed by participants independently. Electronic patient-reported outcome response links were disseminated via
email and accessed by participants through their smartphones. An identical method was used for EMA.

As previously noted, not all data from this study are presented within this paper. The results of the assessment of eating behaviors and blood glucose–related data, along with the corresponding analyses, were reported elsewhere [38,39].

**EMA**

In the EMA, participants were prompted to respond to questions regarding 3 states: sleepiness (ranging from “not sleepy at all” to “very sleepy [maximum sleepiness imaginable]”), mood (ranging from “negative mood [lowest mood imaginable]” to “positive mood [maximum mood imaginable]”), and energy (ranging from “no energy at all” to “full of energy [greatest state of energy imaginable]”). These responses were provided using the Visual Analog Scale (VAS) format. The design of these VAS items was informed by previous studies that combined EMA with the VAS [40,41].

Throughout the study period, the questions were administered 2 times a week on weekdays, occurring on 2 consecutive days (such as Tuesday and Thursday or Wednesday and Friday). These questions were delivered at defined times of the day, spaced 3 hours apart. Specifically, the questions were presented at 9 AM, noon, 3 PM, and 6 PM. Participants were then requested to respond to the questions during the following time intervals: 9 AM to noon, noon to 3 PM, 3 PM to 6 PM, and after 6 PM, respectively.

The EMA score data collected on the same day as the email was sent were used in the analysis. Fitbit Inspire 2 activity indicators, including heart rate, number of steps, and metabolic equivalents (METs), were aggregated within the 1-hour time window immediately preceding the EMA response time. Each EMA response is collected as time-stamped data, and the analysis is conducted retrospectively from the time stamp, specifically 1 hour before the EMA response time. Sleep indices were compiled from Fitbit Inspire 2 sleep records where the waking time fell within the time window from 6 PM on the day preceding the EMA response date to 9 AM on the EMA response date. In instances where multiple sleep records were present within this timeframe, the sleep periods were consolidated, and sleep indices were recalculated accordingly.

**Fitbit Inspire 2**

Fitbit Inspire 2 is a commercially available device equipped with a triaxial acceleration sensor, which allows for the calculation of body movement, sleep patterns, and other related metrics. In addition, it features a pulse sensor that collects data for each heartbeat using the photoelectric pulse wave method. Participants were instructed to wear the Fitbit Inspire 2 device, distributed at the outset of the study, continuously for a designated period (8 weeks). Participants were permitted to temporarily remove the Fitbit Inspire 2 device for short durations, such as during bathing or when recharging the device. As the Fitbit Inspire 2 has a data storage capacity of approximately 7 days, participants were requested to periodically transmit the collected data to the cloud using their smartphones.

Fitbit Inspire 2 records were considered valid record days if at least 80% of the day was recorded. When matching against EMA data, only participants with a wear rate exceeding 80% in the hour preceding the most recent hour of EMA activity were included. For investigations into the relationship between EMA results and sleep, only participants with a wearing rate of 80% or greater between 6 PM on the day before the response date and 9 AM on the day of the response were included in the analysis.

**Statistical Analysis**

All data collected during the study were incorporated into the analysis. We adopted an exploratory analysis approach, thoroughly examining the various relationships among the data obtained from the wearable devices, EMA, and assessments of stress/well-being.

The Fitbit Inspire 2 device provides data on time in bed (TIB), mid-wake time, and sleep duration. Using this information, we computed bedtime, midpoint of sleep, and sleep efficiency (calculated as 100 × sleep duration/TIB) for the analyses conducted in this study. However, we chose not to include sleep stage estimates provided by the device in our analyses because of concerns regarding their validation. Therefore, this parameter was excluded from our analysis. Based on the pulse data obtained from the Fitbit Inspire 2, we calculated the SD of the NN intervals (SDNN) to assess HRV. In analyzing the SDNN, we used a 15-minute time window. This decision was made considering that the pulse was measured once every 5 seconds. Using a shorter time window, such as 5 minutes, might lead to less reliable values because of the limited amount of data available. Although SDNN is typically calculated based on each pulse interval, the Fitbit Inspire 2 reports pulse rate data every 5 seconds. Therefore, in this study, the SDNN was calculated based on the pulse rate provided at 5-second intervals.

The participants were stratified into quartiles based on their scores on the stress/well-being questionnaires. We then compared the sleep and HRV indices measured by the Fitbit Inspire 2 between the groups with scores in the lowest and highest quartiles. To assess the differences between these 2 groups, we used the Mann–Whitney U test. Given the multiple comparisons conducted, we applied the Bonferroni correction to adjust for potential type I errors.

The study also investigated the relationships between the sleep and HRV indices measured by the Fitbit Inspire 2 and the daily mood, energy levels, and sleepiness assessed by EMA.

In the multilevel analysis, 3 types of multilevel models were constructed, with the EMA scores for energy, mood, and drowsiness serving as the dependent variables. The independent variables were selected through forward stepwise selection using the Akaike information criterion as the evaluation index. The sleep index, sleep heart rate, and sleep HRV index measured by the Fitbit Inspire 2 were considered potential candidates for the independent variables in the models. In addition to the main predictors, control variables such as age, sex, response time, and MET time were included in the analysis. However, to mitigate the influence of activity immediately preceding the response on the EMA score, the aggregate value of the MET...
time from 1 hour before the response to the time of the response was used. Sleep indices were separated into 2 components: the mean value across all participants (interindividual), such as average bedtime among participants, and within-participant deviations (intraindividual), such as bedtime deviations for each participant. These components were then used as explanatory variables in the analysis. The statistical analyses described above were performed using either Python (Python Foundation) or R (R Foundation) programming languages.

**Ethical Consideration**
This study was carried out with the approval of the Keio University School of Medicine Ethics Committee (ID 20211103). Before enrollment, all participants provided written informed consent. All collected information was anonymized and used solely for the purpose of the study. Participants did not receive any monetary compensation; however, they were provided with feedback on their own data collected during the study.

**Results**

**Participant Characteristics**
A cohort of 40 eligible participants, comprising office workers from a real estate company, was enrolled in this study in February 2022. All participants successfully completed the entire study protocol. It is noteworthy that participants were required to work from their respective offices throughout the study duration, and none took extended vacations or engaged in remote work for prolonged periods during the study period. The demographic characteristics of the participants are summarized in Table 2. The mean age of the participants was 40.4 (SD 11.8) years, and the male-to-female ratio was 1:1. No individuals were excluded from participation due to meeting the exclusion criteria at the time of recruitment. Responses to the background information questionnaire revealed that none of the participants were currently undergoing treatment for psychiatric disorders. Furthermore, no serious adverse events, including instances of COVID-19 infection, were reported throughout the study duration. Histograms displaying the distribution of scores on the stress/well-being questionnaire within each quartile group are provided in Figures S1-S6 in Multimedia Appendix 1.

**EMA and Fitbit Inspire 2 Adherence**
All participants successfully completed the program without dropping out. The overall response rate for EMA was 87.34% (1118/1280). Regarding the difference between EMA transmission time and response time, the median (IQR) was 11.8 (3.2-42.4) minutes. However, 1 participant was unaware of receiving emails until midway through the study period because the emails had been inadvertently sorted into the spam folder. The mean daily wear time for all Fitbit Inspire 2 users was 1214 (SD 374) minutes. In addition, the Fitbit Inspire 2 data recovery rate during the study period was 87.98% (2,837,881 minutes/3,225,600 minutes).

**Bedtime, TIB, Midpoint of Sleep, and Psychological State**
In terms of the relationship with JESS scores, compared with the group with high daytime sleepiness (third quartile to maximum; high-score group), the group with low daytime sleepiness (minimum to first quartile; low-score group) exhibited significantly earlier bedtime and midpoint of sleep (r=0.24, P<.001 and r=0.25, P<.001, respectively) (Figures 1 and 2). In the low JESS group, the median bedtime and midpoint of sleep were 11:21 PM and 2:36 AM, respectively. By contrast, in the high JESS group, the median bedtime and midpoint of sleep were 12:12 AM and 3:54 AM, respectively.
Figure 1. Box plot showing the distribution of bedtime in the low- and high-score groups of the JESS score. The dashed line in the box plot refers to the mean value and the whiskers refer to the minimum and maximum values within the IQR 1.5 range (same for subsequent figures). JESS: The Japanese version of the Epworth Sleepiness Scale.

Figure 2. Box plot showing the distribution of the midpoint of sleep in the low- and high-score groups of the JESS score. JESS: The Japanese version of the Epworth Sleepiness Scale.

Regarding subjective stress, the median bedtime was 11:30 PM in the low PSS group and 12:45 AM in the high PSS group. Notably, the median bedtime was significantly earlier in the low PSS group ($r=0.226$, $P<.001$; Figure 3).
In terms of well-being scores, the group with high SWLS scores and low SPANE-J negative experience (SPANE-N) scores exhibited significantly earlier bedtime ($r = -0.23$, $P = 0.01$ and $r = 0.23$, $P < .001$, respectively; Figures 4 and 5). Specifically, the median bedtime was 11:48 PM and 11:24 PM in the high SWLS group and the low SPANE-N group, respectively. Conversely, in the low SWLS group and the high SPANE-N group, the median bedtime was 12:51 AM and 12:54 AM, respectively.

**Figure 3.** Box plot showing the distribution of bedtime in the low and high score groups of the PSS score. PSS: Perceived Stress Scale.

**Figure 4.** Box plot showing the distribution of bedtime in the low- and high-score groups of the SWLS. SWLS: Satisfaction With Life Scale.
Variability in the Midpoint of Sleep and Psychological State

The SD of the midpoint of sleep per week was significantly larger (|Hedge g|>0.5) in the group with low scores on the well-being scales, namely, the FS-J and the SPANE-J positive experience (SPANE-P), compared with the group with high scores (r=−0.11, P=.006 and r=−0.3, P<.001, respectively). Concerning the FS-J, the average SD of the midpoint of sleep per week was 75 minutes in the low-score group compared with 44 minutes in the high-score group. Similarly, based on the SPANE-P, the average SD was 67 minutes in the low-scoring group versus 37 minutes in the high-scoring group (Figures 6 and 7).
Similarly, the SD of the midpoint of sleep was significantly greater in the group with high subjective stress as measured by the PSS compared with the group with low subjective stress ($r=0.3$, $P<.001$). Specifically, on the PSS, the median SD of the midpoint of sleep was 33 minutes in the low-score group versus 66 minutes in the high-score group (Figure 8).

**Figure 6.** Box plot showing the distribution of variability in the midpoint of sleep in the low and high score groups of the FS-J. FS-J: The Japanese version of the Flourishing Scale.

**Figure 7.** Box plot showing the distribution of variability in the midpoint of sleep in the low- and high-score groups of the SPANE-P. SPANE-J: The Japanese version of the Scale of Positive and Negative Experience; SPANE-P: SPANE-J positive experience.
Sleep Duration, Sleep Efficiency, and Psychological State

There was no significant relationship between sleep duration and psychological state. However, the sleep efficiency was higher in the group with high scores on the PSS compared with the group with low scores ($r=0.25, P=.006$).

HRV

HRV was assessed separately during daytime and bedtime. HRV during sleep, specifically the SDNN, was significantly higher in the high SWLS group compared with the low SWLS group ($P=.003$).

EMA Response and Data Obtained From Fitbit Inspire 2

The intraclass correlation coefficients for the EMAs performed in this study were as follows: energy, 0.407; mood, 0.4075; and sleepiness, 0.3286.

The results of the multilevel analysis for the EMA response and data obtained from the Fitbit Inspire 2 are presented in Tables 3-5. Regarding intraindividual variability, energy levels tended to be higher when the deviation of heart rate during sleep on the previous day was lower ($\beta=-.12, P<.001$; Table 3). Furthermore, sleepiness levels tended to be lower on days with a higher deviation of time in bed (TIB; $\beta=-.10, P<.001$; Table 5).

Based on the interindividual evaluation of the relationships, participants with a lower deviation of the midpoint of sleep tended to have relatively higher energy ($\beta=-0.26, P=.04$; Table 3).

Discussion

Principal Findings

In this study, we investigated the relationships between sleep indices and HRV, measured through the use of wearable devices, and the daily sleepiness, energy, and mood status assessed by EMA, along with stress and well-being questionnaires, in a cohort of 40 participants. The response rate of the participants was relatively high, and several significant associations were observed: greater variability of the midpoint of sleep was linked to lower well-being and higher stress levels, later bedtimes were associated with increased sleepiness and higher stress levels, and greater HRV during sleep was correlated with higher well-being.

The intraclass correlation coefficients of the EMA performed in this study exceeded 0.1 (energy, 0.4071; mood, 0.4075; and sleepiness, 0.3286). Hence, it can be concluded that the EMA VAS scores in this study captured not only within-individual (within-participant) variation but also psychological differences.
between individuals. The findings regarding the relationship between psychological state and sleep were consistent with previous studies, suggesting that wearable devices and EMA are valuable methods for quantifying both sleep and psychological state.

The results regarding mood and sleepiness were impacted by the level of activity around the response time, highlighting the importance of considering real-time information, including waking time, collected by both EMA and wearable devices when investigating the relationship between psychological state and sleep.

Comparison With Prior Work

Regarding participation rates in studies using EMA, a meta-analysis on EMA compliance reported a typical response rate of 78%. Specifically, the average response rate was 92% for prompts 2-3 times per day for nonclinical participants, and 74% for prompts 3-4 times per day [42]. Therefore, we consider the EMA response rate in this study (1118/1280, 87.34%) to be within a reasonable range. Although not extensively detailed in this paper, it is noteworthy that this study also involved participants wearing the FreeStyle Libre in parallel. Therefore, it was significant that responses were collected without dropouts, despite participants likely having additional tasks compared with a typical study.

The results of this study revealed significantly higher HRV during sleep in individuals with higher scores on the SWLS. It is established that HRV is greater during high-quality sleep and that sleep-related HRV is compromised in individuals with sleep disorders and mental health conditions [43,44]. The findings of this study align with prior research indicating a relationship between sleep quality and well-being [3-5]. Moreover, the results demonstrated that individuals with earlier bedtimes exhibited lower levels of sleepiness, as measured by the JESS, and lower stress levels, as measured by the PSS. Previous studies have suggested that late bedtime is associated with daytime sleepiness and that sleep deprivation can impact daytime stress [27,45], which is consistent with our findings.

Furthermore, our study revealed that the SD of the midpoint of sleep was correlated with stress and well-being. In recent years, the issue of social jetlag—referring to the misalignment between an individual’s internal circadian rhythm and external social demands, often due to work and other societal factors—has gained recognition, particularly among urban office workers. This phenomenon has been noted in Japan as well [46,47]. Social jetlag has been increasingly associated with stress and well-being [48,49]. Our study findings among urban office workers similarly demonstrated a link between disruptions in sleep rhythm and stress/well-being, consistent with previous research on social jetlag. To our knowledge, there have been no studies investigating social jetlag in Japanese individuals using wearable devices or similar tools for objective assessment of sleep. This presents a promising area for future research, offering the opportunity to explore the relationship between social jetlag, sleep patterns, and various health outcomes in this population.

In this study, sleep efficiency was higher among participants reporting higher subjective stress. Typically, it is understood that when subjective stress is high, sleep efficiency and quality are lower [50,51]. However, the reasons for these results in our study remain unclear and warrant further investigation. It is plausible that the group reporting higher subjective stress may have experienced fatigue from work, leading them to fall asleep earlier. However, this is a hypothesis that requires further investigation in future studies.

Regarding the results of the EMA, later bedtimes were correlated with lower energy levels and mood. Previous research has indicated that poor sleep quality can impact positive emotions throughout the day [52], and the findings of our EMA analysis corroborate this trend [23]. Thus, the results of this study are consistent with prior findings in the literature.

Limitations

This study had several limitations. First, as this was an exploratory study, formal power calculations were not conducted, and a practical sample size was adopted. A larger sample size might have enabled the detection of additional findings. Second, the study recruited a small number of participants from a single company in Japan. Given the presumably similar working environment of the participants, the generalizability of the results may be limited. For instance, sleep habits are likely to vary by occupation, as job stress and working hours are known to influence habitual sleep duration and quality [53]. To enhance the generalizability of the study results, it would be necessary to recruit participants from a diverse range of occupations with various lifestyles. Further, the study relied on the Fitbit Inspire 2 for the measurement using wearable devices, which may have limitations compared with more advanced monitoring technologies. Despite providing thorough instructions to participants before the study and conducting regular checks for defective products throughout the study period, intrinsic limitations such as device performance were unavoidable. Moreover, in this study, HRV was calculated from heart rate measurements with a sampling time of 5 seconds, which may be less accurate compared with using methods such as electrocardiography. Finally, the EMA in this study entailed participants answering questions 2 times a week, 4 times a day, to avoid placing excessive burdens on them. However, for instance, if evaluating social jetlag, it would be important to compare weekends and weekdays. Including additional days of the week could potentially yield more meaningful results. It is worth noting that Japanese individuals often tend to select the week could potentially yield more meaningful results. It is worth noting that Japanese individuals often tend to select answers that fall in the midpoint of the range in surveys [54]. This conservative response tendency might have limited their ability to reflect subtle differences in their condition from one day to the next in their EMA responses. Given the limited number of studies using EMA in healthy Japanese adults, it would be beneficial in future research to investigate the potential presence of a response tendency in this population. Furthermore, our EMA design had its limitations. Recognizing that all participants in this study were full-time workers who might often have difficulty responding immediately, we set the EMA notification time as a fixed time but provided a range of response deadlines. Indeed, a randomly scheduled EMA is preferable for evaluating highly variable psychological states. However, the
accuracy of the EMA in this study is limited because of the use of scheduled EMAs, which can lead to participant learning and anticipation. In our study, analysis was conducted based on response time rather than the sending time of the EMA. This approach ensured that regardless of any significant discrepancy between the sending and response times, the answers were elicited at the time of the response. However, it is important to note that this approach can introduce bias by only collecting data when participants choose to respond. Nevertheless, considering that the median difference between the sending and response times was 11.8 minutes, we believe that this issue was not significant in our study.

Conclusions
In this study, the combination of objective assessment of sleep using a wrist-worn device worn by participants, along with subjective symptom assessment through EMA, provided valuable insights into the relationship between sleep and stress/well-being, particularly considering daily variations in sleep patterns. For example, increased sleep variability, characterized by unstable bedtime or midpoint of sleep, was linked to elevated stress levels and diminished well-being. Furthermore, improved sleep metrics, such as lower heart rate during sleep and earlier average bedtime, correlated with enhanced daytime energy levels. Conducting broader-scale studies, such as those on social jetlag, using a methodology akin to that of this study and encompassing a wider array of occupations, could provide valuable insights.

Acknowledgments
We thank all the participants who made this study possible and the members of the Wellness Promotion Department at Mori Building Co., Ltd who helped with the recruitment of the study participants.

Data Availability
All data generated and analyzed are included in this article and a previously published article [38,39]. Raw data sets analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: Face-to-face hearing voices peer support groups (HVGs), a survivor-led initiative that enables individuals who hear voices to engage with the support of peers, have a long-standing history in community settings. HVGs are premised on the notion that forming authentic, mutual relationships enables the exploration of one’s voice hearing experiences and, in turn, reduces subjective distress. As such, group cohesion is assumed to be a central mechanism of change in HVGs. The rise of digital mental health support, coupled with the COVID-19 pandemic, has resulted in many HVGs adapting to online delivery. However, to date no studies have examined the implementation of these online groups and the adaptations necessary to foster cohesion.

Objective: This study aims to understand the experience of group cohesion among HVG facilitators in online groups compared with face-to-face groups. Specifically, we examined the ways in which the medium through which groups run (online or face-to-face) impacts group cohesion and how facilitators adapted HVGs to foster group cohesion online.

Methods: Semistructured qualitative interviews were conducted with 11 facilitators with varied experience of facilitating online and face-to-face HVGs. Data were analyzed using reflexive thematic analysis.

Results: The findings are organized into 3 themes and associated subthemes: nonverbal challenges to cohesion (lack of differentiation, transitional space, inability to see the whole picture, and expressions of empathy); discursive challenges to cohesion (topic-based conversation and depth of disclosure); and necessary adaptations for online groups (fostering shared experience and using the unique context to demonstrate investment in others). Despite challenges in both the setting and content of online groups, facilitators felt that group cohesion was still possible to achieve online but that it had to be facilitated intentionally.

Conclusions: This study is the first to specifically investigate group cohesion in online HVGs. Participants noted numerous challenges to group cohesion when adapting groups to run online, including the unnaturally linear narrative flow of dialogue in online settings; lack of transitional spaces, and associated small talk before and after the session; ease of disengagement online; inhibited sharing; and absence of shared physical presence online. Although these challenges were significant, facilitators nevertheless emphasized that the benefits provided by the accessibility of online groups outweighed these challenges. Necessary adaptations for cultivating group cohesion online are outlined and include capitalizing on moments of humor and spontaneity, using group activities, encouraging information sharing between participants using the chat and screen-sharing features, and using objects from participants’ environments to gain deeper insight into their subjective worlds.
Introduction

Background

Hearing voices peer support groups (HVGs) have a long-standing history within the community [1]. The establishment of HVGs is one of the primary objectives of the Hearing Voices Movement (HVM), an international, survivor-led coalition of voice hearers and their allies, which strives to shift professional and public attitudes toward voice hearing away from biogenetic, pathology-based models toward understandings that locate voice hearing as a complex psychological experience imbued with subjective meaning (eg, psychosocial, cultural, or spiritual) [1]. HVGs are premised on the notion that forming genuine, mutual relationships between group members can support individuals to safely explore their voice hearing experiences and, as such, may result in positive psychosocial change [2-11]. As a result, group cohesion is posited to be of central importance in HVGs [7,9].

The concept of group cohesion arises from group psychotherapy literature and refers to participants’ feelings of connectedness to one another and to the group as a whole [12]. Group cohesion is believed to be the foundational feature upon which all other therapeutic work takes place [12]. Although their distinct ideologies mean theories of group psychotherapy cannot be uncritically applied to peer support groups [13], it may nevertheless be instructive to further investigate the role of group cohesion in HVGs.

Although peer support is an established aspect of mental health provision, a more recent development concerns their online delivery; a process largely expedited by the COVID-19 pandemic, wherein many forms of support, including HVGs, were forced to be held remotely. As a result, there has been growing interest in understanding if and how group cohesion can form in online groups [14-16]. The literature on online group cohesion has been largely theoretical and anecdotal but suggests that although group cohesion does occur, there are various challenges to its achievement, including the ease of disengagement and the lack of embodied presence of both the participants and therapist [14]. Given that online peer support represents a potentially accessible and scalable form of support that can be implemented in multiple contexts globally, it is necessary to further investigate the development of group cohesion in online spaces. This type of investigation is particularly important to HVGs as they are an existing resource that exist internationally and can provide vital support to individuals who may otherwise be insufficiently supported by mental health services [17,18].

Study Objectives

This study aims to understand HVG facilitators’ experience of group cohesion in online groups compared to face-to-face groups. Specifically, the following issues were examined: (1) How does the medium through which groups run (online vs face-to-face) impact group cohesion? and (2) How do facilitators adapt HVGs to foster group cohesion online?

Methods

Design

Semistructured qualitative interviews were conducted with 11 HVG facilitators. Data were analyzed using a hybrid of deductive and inductive reflexive thematic analysis (RTA), a flexible approach that recognizes the centrality of the researcher’s subjectivity as an analytical tool and emphasizes reflective engagement with theory, data, and interpretation [19]. The study was further underpinned by a critical realist epistemological position, which acknowledges the existence of an objective social world while recognizing that one’s understanding of that social world is shaped by one’s experiences within it [20]. The subjective realities of both participants and researchers were acknowledged while still aiming to understand and explain experiences that exist beyond the study sample [21].

Topic guides were developed by AB in consultation with patient and public involvement and engagement (PPIE) experts with relevant experience of HVG facilitation or membership. Specifically, topic guides were informed by the supposition by Yalom [12] that group cohesion is the foundation for effective groups; as such, the interviews focused on facilitators’ experiences of if and how group cohesion was cultivated in both face-to-face and online settings. Topic guides were further informed by previous literature on the proposed mechanisms of action in HVGs [6] as well as the lived experience of AB and PPIE representatives as HVG facilitators. All questions were piloted with PPIE experts before commencing recruitment, with topic guides revised based on PPIE feedback. Questions were open ended and sequencing was determined based on the flow of conversation. Probes were used throughout to elaborate on relevant topics. Topic guides were iterative, with specific questions being added or emphasized as preliminary themes began to be constructed. Reflective logs were kept throughout data collection and analysis. The COREQ (Consolidated Criteria for Reporting Qualitative Research) were consulted in reporting this research (Multimedia Appendix 1) [22].

Participants

Participants in this study comprised an international sample of HVG facilitators, who were recruited using convenience and snowball sampling methods through the HVM (Figure 1). Adults who spoke English and had at least 3 months of experience facilitating HVGs were eligible for interview. The sample size was determined through information power [23] and thematic sufficiency [19], with the former referring to the degree in which participants hold information to address the research question and the latter referring to the point at which data collection is sufficiently complete as to meaningfully answer the research questions. This approach to data completeness was chosen over
the more common idea of data saturation, which is subjective in nature and theoretically incompatible with RTA [24].

**Ethical Considerations**

Ethics approval was received from the University of Manchester Research Ethics Committee (2022-13944-22907), and all participants provided written informed consent. Participants received a participant information sheet outlining the parameters of study involvement and were given a minimum of 24 hours to decide whether they wanted to take part. The voluntary nature of the research was emphasized throughout, including during the qualitative interviews. All interviews were confidential, and transcripts were pseudonymized with any other identifiable information removed. Due to resource constraints, no compensation was offered for study participation. Furthermore, due to the potentially identifiable nature of the data, interview transcripts were not made available via public data repositories, and the data were not shared outside the research team.

**Procedure**

Potential participants contacted AB via email to express their interest in the study. Interviews were conducted by AB, a researcher with lived experience of voice hearing and HVG group facilitation, between April and June 2022. Participants were aware of AB’s background as an HVG facilitator. All interviews were conducted online via Zoom (Zoom Video Communications, Inc) [25] and were audio recorded using Zoom’s built-in encrypted recording software. Interviews were then transcribed verbatim. Participants were assigned a pseudonym, and identifying information was removed from the transcripts. The median interview length was 58 minutes 42 seconds (range 38 min 7 s to 89 min 20 s).

**Analysis**

A predominantly inductive approach to data analysis was adopted. Data were open coded, and preliminary codes were inductively generated based on participants’ responses. However, given that the topic guide was framed on the theoretical assumption that group cohesion was crucial for both face-to-face and online HVGs, deductive analysis was also used to allow for the identification of codes that could meaningfully answer the research question. As such, both latent and semantic codes were generated. The iterative approach to data analysis by Braun and Clarke [19] was followed: (1) data familiarization through repeated reading of transcripts, (2) generating initial codes, (3) generating initial themes, (4) reviewing initial themes, (5) defining and naming themes, and (6) producing the report.

The final thematic structure was derived by AB in consultation with EL, SB, APM, and FV. Data analysis took place using NVivo (version 12; QSR International) [26]. No attempt was made to establish interrater reliability as it is antithetical to the philosophical position of RTA [27]; however, sense checking among the research team, the use of reflective notes and memos, and the 20-point guide by Braun and Clarke [27] for the assessment of RTA research quality were used to enhance the trustworthiness of the data. Furthermore, validation of the thematic structure was sought from all study participants, all of whom consented to member checking, as well as from PPIE representatives.

**Reflexivity**

All the researchers in this study hold perspectives on voice hearing that align with those of the HVM; specifically, that voice hearing is an inherently meaningful psychological experience that is worthy of ongoing exploration. AB is a PhD-level researcher; EL is an academic psychologist; and SB, APM, and FV are academic clinical psychologists; all of whom have experience supporting and developing interventions, including digital interventions, for individuals who hear voices. All researchers had extensive experience conducting and analyzing qualitative data. AB and EL have similarly been members and facilitators of HVGs (AB has experience with online and face-to-face HVGs, and EL has experience with face-to-face HVGs). The background of the research team, particularly their commitment to developing various forms of psychosocial support for voice hearers, influenced the generation and interpretation of the data. To maintain transparency around how the researchers’ backgrounds were interacting with the data, AB kept reflective logs to record impressions about interviews and emergent themes and document ways in which findings paralleled or differed from her lived experience as a facilitator. Emphasis was placed on ensuring that divergent views were represented within both analysis and reporting.

**Results**

**Overview**

A total of 11 participants consented to take part in the study. Facilitators ranged in age from 25 to 52 (mean 41.27, SD 7.40) years with most participants identifying as male (7/11, 64%) and White (10/11, 91%). Participants had between 1 and 10 (mean 5.45, SD 3.06) years of experience facilitating HVGs.
Key participant characteristics are presented in Table 1, with a table of full participant characteristics available in Multimedia Appendix 2.

Results were organized into three themes and associated subthemes: (1) nonverbal barriers to cohesion (lack of differentiation, transitional space, inability to see the whole picture, and expressions of empathy), (2) discursive barriers to cohesion (topic-based conversation and depth of disclosure), and (3) necessary adaptations for online groups (fostering shared experiences and using the unique context to demonstrate investment in others). The findings from the first 2 themes informed the necessary adaptations presented in the third theme. A thematic map of the findings is presented in Figure 2.

Figure 2. Thematic map depicting the relationships between themes and subthemes.

Nonverbal Barriers to Cohesion

Groups that took place online lacked many of the nonverbal elements of communication that were previously relied upon to create a cohesive space. These nonverbal elements included both the group setting and cues between HVG participants.

Lack of Differentiation

HVGs were often described as “unique” (Lex) and “different” (Rachel) spaces, whose ethos of curiosity, openness, and nonjudgmental approaches toward voice hearing were intentionally cultivated and led to connections that could not be fostered elsewhere:

It wasn’t ever said...but we all picked up that describing these sorts of [voice hearing] experiences wasn’t welcomed in other groups. So we participated in other groups on another level. But have these [voice hearing] experiences close to our chest. So when you have this space to talk about it and then realize “oh I’m so far from alone in this” that you have all these different individuals... and all of a sudden it’s kind of like, “oh you share this with me as well.” And it feels very opposite of being alone. Like, it was really connected. [Annika]

In turn, many facilitators took great care to create a soothing environment that reflected the distinctness of the groups:
We had always put a lot of emphasis on making a nice atmosphere. Much more than in our [other] groups. We turned off the industrial lights; we had candles; we sat in a circle. You don’t even need to sit on a chair if you don’t want to. We had like yoga meditation chairs. And some people sat on the floor. And it was so different... We were really thinking of the atmosphere. And then when we moved online it’s just, uh, the screen and the face and you couldn’t really make this atmosphere in the same way. [Annika]

In contrast, online meetings tended to feel indistinct from both other mental health groups, as well as other online gatherings, wherein participants were often sitting in the same place regardless of whether they were joining the HVG, a family event, or a work meeting. In this regard, this lack of differentiation resulted in grief as it felt some HVGs lost the distinctiveness they had in the face-to-face setting. Groups such as Annika’s, which adhered very strongly to the ethos of the HVM, particularly struggled with the transition online because the truly distinct nature of the space was largely lost.

Transitional Space

Facilitators spoke to the importance of transitional space, or the “before and after” (Lex) of the group, where participants could “walk together to the bus stop” (Lex) or meet in the doorway over tea and coffee to enjoy small talk and forge “potential relationships outside of this room” (Annika). The social energy likewise made its way into the meeting, as described by Sabina: “Often there’s coffee or cookies or something like that and so often a conversation...it starts with...’the coffee is stronger this time than last time’.” As such, entering a group without a transitional space could potentially feel lonelier and more jarring, especially for new members:

Whereas with online groups, particularly if you’ve never been before, it really is, it’s that all or nothing: “I’m in the waiting room by myself and now I’m with all of these people that I don’t know. And there’s not that, there’s no clear etiquette about how I’m supposed to behave because every group is completely different.” [Annika]

Similarly, facilitators also reported how a lack of intentional time for small talk could inhibit members’ subsequent willingness to share, given that they no longer had initial opportunities to connect on less vulnerable topics.

Inability to See the Whole Picture

As described by facilitators, online groups posed a unique visual context: that rather than sitting in a circle, as is customary with face-to-face groups, participants were instead confined to small, 2D screens online, if their cameras were even on at all. As such, the information and input participants received from and about one another was diminished, which could make individuals feel less connected. As Lex described, “some people get their camera off. Only audio...that makes a whole different dynamic,” whereas Michail noted how “on Zoom it’s just so much easier to hide.” Even in cases where participants had their cameras on, engagement could still be difficult to assess, as it was impossible to tell, for example, if “you’re busy playing with your phone” offscreen (Arjun).

In this regard, one clear impact of meeting online was the ease with which participants could disengage with the group. As Michail reported, “it’s just so much easier to be distracted on Zoom.” Although seeing members in their own home enabled them to join the group from an environment that felt safe and comfortable, at times this could also be taken to the extreme when participants visibly engaged in other activities during the meeting:

[Group member] sat there and poured himself a glass of beer. And drank it during the group. And it’s like, that would have never happened if we were sitting together in a circle because it’s just, it doesn’t work like that. [Isabella]

Not all facilitators felt it was problematic if group members engaged in other activities during the group, especially if doing so made it easier for them to participate. However, it did highlight the importance of discussing expectations about engagement with their respective members in a way that was unnecessary in face-to-face groups. Annika described having to create group agreements online that had not previously existed: “we had to have rules like, ‘you have to be dressed, you’re going to a meeting’ and ‘please do not be doing something else’.”

The ability to disengage could also pose unique challenges within the online context. Disagreement between members could be particularly troublesome in this regard, as abruptly leaving could prevent disagreements from being resolved within the group space: “One time there was sort of a heated discussion, one of the guys just hung up...but that was hard and kind of a bummer. So it’s easier to check out in that way” (Michail).

Facilitators further noted that at times it could be difficult to navigate confidentiality online, not least because many participants did not have access to truly private spaces. As Annika described, “Like they had the computer in the kitchen and a parent could just walk by whenever. It didn’t really feel as confidential.” This, in turn, could impact the trust that group members were able to develop with one another. Annika noted that this was particularly pronounced for group members who had not been a part of her group before it transitioned to being held online, stating, “I don’t remember somebody starting to trust online rather than in person.”

Expressions of Empathy

One of the greatest challenges posed by online groups was the lack of proximity between group participants. This resulted in participants’ needs not always being responded to in a way that felt appropriately compassionate:

I had a couple instances where I’d get on and somebody looks like they’re in trouble...they’re way over there. I can’t help them way over there. But if they’re in front of me, you can try and do something you know...If they’re definitely in front of you, you can try to give them a hug if it comes to it. [Patrick]
Other facilitators spoke of how being in the same space and seeing and hearing the same things in one’s surroundings naturally fostered a sense of connection. As described by Lex, “there’s also the nonverbal part and being in the same place and seeing the same sun or rain outside when you’re having a break… I think that’s really powerful.”

The importance of physical contact, such as “you shake each other’s hand or a sometimes a hug” (Lex) was important not just for expressing social bonds, but for conveying empathy and understanding toward participants who were distressed. Isabella compared the experiences in her online and face-to-face group in the following way:

Whereas online we had as well that people were like distressed or crying and there isn’t that same level of connection or compassion if that makes sense. Somehow, because there is this distance. There is this distance of not being in the, in the same room together. [Isabella]

Facilitators described it as “natural” (Patrick) to interact in person, and that one could achieve a richer, more embodied experience wherein nonverbal cues provided important communicative information: “You know, just being in person, being in the presence of other people, the body language and just you know, you forget how much you get out of sitting with someone” (Michail).

**Discursive Barriers to Engagement**

Without the nonverbal cues present in face-to-face meetings, facilitators noted that there were changes in both the style and content of verbal communication in online groups.

**Topic-Based Conversation**

Facilitators noted how the group medium could have a distinct impact on the flow of conversation. For example, a defining feature of face-to-face groups was topic-based conversations, or conversations that were centered on a particular issue to which everyone contributed, regardless of whether it was particularly relevant to them at the time. These conversations were marked by a “free flow” (Annika) of “collaborative interrupting” (Noah), where “you go to something and it leads to something else” (Arjun). “There’s no uncomfortable silences [and] everybody gets to speak” (Sean) and “[participants] really bounced off each other and related to each other on experiences that you wouldn’t imagine that anybody could relate on” (Rachel):

If it was running well, we really didn’t need to facilitate much…And maybe someone came in wanting to start with a, with a topic or, that they kind of added to another person’s story, but really like, it flowed. [Annika]

These kinds of interactions reduced the reliance on the facilitator to keep the discussion going, with participants instead empowered to carry on the conversation themselves:

It seemed like it was definitely a running machine when everybody did kind of play a role. It definitely lessened any outlook on me as some kind of authority figure for everyone to see…And I think it made everybody feel a bit more of a sense of connection. Like it was a little community and that they all were really relating to each other. [Rachel]

This “natural” (Patrick) conversation allowed discussions to deepen in a way that felt appropriate and engaging: “they respond to each other. Sometimes asking questions, deepening questions to each other” (Noah).

In contrast to face-to-face meetings, the physical distance between participants in online groups made topic-based conversation more difficult. In the absence of nonverbal cues typically present in face-to-face meeting, Isabella noted that it was difficult for participants to know when to speak next:

They have to lift the hand and say, “can I say something”…because sometimes they don’t know like, “is it my turn to speak?” “Can I speak?” Because you don’t have that connection.

This was true even in groups that transitioned to being online and where the participants had previously connected face-to-face. The resultant flow was markedly more sequential, with individuals tending to bring up a topic that was relevant to them, and the topic then shifting when the next person spoke: “Yeah, in the online setting there was, ok this topic was talked about. Now I bring this topic for new conversation” (Sabina). Thus, when stories were shared as isolated silos, participants were not connecting with each other as intimately as they would when face-to-face:

It’s more like one says something and then the other one then tells her story, the other one then tells his story and then the next one. There’s not really like interaction as much as when we were in a room together. [Isabella]

**Depth of Disclosure**

Some facilitators felt that conversation could be “flattened” (Michail) online, that there was more hesitation sharing “intimate” (Sabina) details of one’s life, and that, in general, “you don’t go too heavy in the group” (Patrick). As a result, conversations sometimes lacked the depth that was often felt in face-to-face meetings. This, in turn, could hinder the development of trusting relationships because participants felt neither open enough to talk about vulnerable subjects nor secure enough to connect over day-to-day experiences. Sabina described one such situation:

In [in-person groups, the conversation is deeper but also could often go to more lighter topics, like their favorite TV series or something like that. And in online setting it wasn’t as deep, but it wasn’t also as light. And I had the feeling like [the participant[s], they didn’t feel secure enough to put this light things. So, they feel “ok this topic about TV series is too dumb or too, um, superficial or too, yeah whatever;” And in [in-person group[s] they, after deep topic, they went after the connecting together; they feel secure enough to put also this more superficial [topic]. And it brings, brings a little bit of lightness and cosiness in the group setting.
Necessary Adaptations for Online Groups

Despite the challenges posed by the online medium, many facilitators were still able to run cohesive and successful groups. This theme outlines the specific ways in which cohesion between members was cultivated online.

Fostering Shared Experience

Creating and building on shared experiences was a central feature of forming cohesion within online groups and was achieved in 2 primary ways: the first being capitalizing on spontaneity, and the second through group activities. In terms of the former, moments of spontaneity served as the online corollary to infectious laughter in face-to-face spaces; indeed, the fact that participants were not in a shared space could, at times, enhance the experience as they had access to objects that would not have been available within in-person groups:

A couple of times this spontaneous thing happened where one group member was wearing a new hat and he was telling us about his hat. And everybody in the group went off and got a hat. And it was so funny and fun and he still will talk about that day. And we laughed so much that day...And I remember feeling like, “it feels so good to laugh like this.” And we’ll laugh about that day still. And he wears the hat all the time and sometimes he’ll say, “c’mon guys, where are your hats? You know it’s our group. Where are your hats guys? C’mon?” You know this sort of spontaneous thing that couldn’t really happen in person. [Michail]

In this respect, spontaneous, shared moments provided a sense of continuity between groups and served as a crucial moment that could be repeatedly referred to, ultimately enhancing the sense of group identity. Following this experience, Michail wondered if similar occurrences should be fostered more deliberately: “Boy I wonder if it’s nice to have an ice breaker activity where you actually share something from your space.” Similarly, such moments also enabled group members to connect with one another over other topics of mutual interest, experience, or “personal things like music” (Lex), which left facilitators feeling like they were having “a co-human kind of experience” (Lex).

Although valuable, facilitators of online HVGs also noted that moments of spontaneous humor could be few and far between. However, when this was the case, the second means of fostering shared experience could be used, namely group activities. These could range from voice-related work, such as introducing members to the Maastricht interview [28], a technique used to explore voices’ characteristics, origins, and emotional impacts; practices such as reiki; or “playing music” (Patrick) and “watching videos together” (Lex). These activities could provide a starting point for conversation: “we’ll play [Beyond Possible: How the Hearing Voices Movement Transforms Lives [29]] and it really brings up a lot of stuff to talk about” (Michail), whereas at other times, participating in the activity was a shared experience in and of itself:

Sometimes...we’ll have something like...something more structured [co-facilitator will] bring somebody in to talk about reiki or have a guest speaker for meditation or something. Um, or tapping [as described by the emotional freedom technique] and stuff like that. [Callum]

The ease with which information could be shared online was an asset that offered individuals a novel way of participating in the group and sharing their experiences or interests. The chat and screen-sharing feature allowed ideas to be shared in real time, which enabled the entire group to have access to the same information. In turn, such information could be informative (“maybe if someone was sharing a visual aid or like ‘I was listening to something. Here is the link.’ It would go in the chat” [Annika]) or humorous (“if there was a funny video or something that was much easier to share in the online group” [Sabina]).

Using the Unique Context to Demonstrate Investment in Others

Facilitators emphasized the fact that group members were equally able to foster intimacy online as they did in face-to-face settings, but that the manner of achieving this was necessarily different. For example, seeing people in their own homes provided “an extra possibility to show an interest in their world” (Lex). At times, facilitators could gain a more contextualized sense of who a person was and what their life was like outside the group when they were able to see them in their home environments:

We had someone who wasn’t comfortable speaking, but he would attend, and he would write in the chat. And we would ask “is it okay if we read from the chat to the group” um, and, and he was okay with that. But he was doing that because he was concerned about who around him could hear. [Michail]

Online groups also offered an additional level of accessibility, thus enabling individuals to take part who either did not feel comfortable participating in or did not have access to face-to-face groups. For some members, joining a group online was “a lower bar to participation” wherein “it makes it a little easier for folks who are reticent to just kind of try it” (Michail). The online medium also provided voice hearers with the opportunity to engage with the group in a way that worked best for them. For some members, this opened up new channels of communication: “if you’re not confident to speak...you can type. You’ll be able to type [in the chat]” (Callum). For others, it enabled them to engage in a way that felt safe to them:

We’ve had [participants] say “can I join and not show my face? Is that ok?” And we say...”sure, as long as it’s ok with the group, as long as the group doesn’t feel weird about it but we want you to participate as fully as you can. Or in a way that feels right for you.”...It gives a different set of opportunities for modulating engagement. [Michail]

The distance and anonymity of online groups was additionally advantageous for some members, making it easier to disclose personal experiences precisely because they could talk about them in a “safe space” (Lex) that felt very distant and removed from the rest of their lives: “I would say you can very [easily]
communicate stuff on Zoom you probably wouldn’t do it the person was living down the road...[online] it’s like, it’s not like it’s gonna walk out of the room” (Patrick).

Discussion

Principal Findings

This study is the first to explore how the medium through which HVGs are delivered impacts cohesion within the group. It is similarly the first to analyze the specific adaptations necessary to cultivate group cohesion in online peer support settings. In terms of building group cohesion, facilitators identified several nonverbal and discursive barriers to running groups online. The primary nonverbal barriers included the lack of differentiation between HVGs and other online spaces; the lack of transitional space online; the reduced visual input online, which prevented individuals from fully seeing what was going on in one another’s environment; and the inability to express and receive empathy nonverbally to the same extent as in face-to-face settings. These barriers, in turn, impacted discursive communication within the group, with online groups having an overprescriptive flow of dialogue where only one person could share at a time, thus resulting in discussions that tended to build less naturally on a single topic and where participants were discouraged from sharing as deeply. However, despite these challenges, facilitators were able to adapt to running cohesive groups online by (1) capitalizing on moments of spontaneity and using group activities to build a shared experience and (2) bringing members’ subjective environments into the group space.

These findings largely correspond with previous literature outlining how nonverbal elements of the group, both in terms of group setting and nonverbal communication between members, strongly influence group cohesion. For example, Weinberg [15] described how one of the tasks of group therapists was creating a “holding space” in which therapeutic work can take place, including deliberately choosing and arranging furniture, lighting, and objects in the room in such a way as to further therapeutic aims. Indeed, Payne et al [9] described one of the main benefits of HVGs as creating a “containing” environment in which anomalous experiences and intense emotions can be shared and processed. Similarly, facilitators in this study often took great care to create a soothing and inviting atmosphere that reflected the distinct values of HVGs; however, in the absence of this control, they could subsequently struggle to create an environment that felt sufficiently safe and containing to encourage disclosure and cohesion between members.

In turn, Weinberg [15] further noted how the opportunity for small talk before, during, and after meetings was necessary for establishing group cohesion. HVG facilitators similarly described how a lack of transitional space into and out of the group inhibited this small talk and acted as a barrier to connection. This is perhaps surprising given previous research on HVGs, which suggests that members primarily connect over the shared experience of voice hearing [4,7,30]. Future online HVGs, and online peer support groups more broadly, may therefore benefit from prioritizing time for these more informal, “co-human” (Lex) connections. This may be achieved by intentionally building in transitional space: for example, by opening the online room early and allowing participants to stay for several minutes after the group ends, encouraging small talk between participants, and having refreshment breaks during the group.

The flattening of visual cues online has similarly been demonstrated to be a barrier to cohesion. Within individual therapeutic settings, Grondin et al [31] argued that empathy and, by extension, alliance (the individual corollary to cohesion), are established through an iterative cycle of producing and perceiving cues that enable the interpretation of others’ emotional states. Although these cues can be verbal [32], they are very often nonverbal and include signals such as facial expression [33], body posture [34], and eye contact [35]. In online settings, these cues tend to be diminished [15], especially in instances where participants have their cameras off and thus, visual cues are neither sent nor received. This lack of visual cues can result in individuals feeling as though they are not being sufficiently empathically received by others [31,35], as well as having the potential to undermine trust and disclosure through reduced awareness as to whether other members are in a truly confidential space [15]. This study is largely consistent with these findings, with facilitators additionally noting the importance of overt nonverbal interactions, such as handshakes or hugs, in the establishment of cohesion. Interestingly, these barriers were still present in HVGs that transitioned from face-to-face during the COVID-19 pandemic, with facilitators often describing highly cohesive groups that subsequently struggled online, despite being composed of largely the same people. This can perhaps be explained by a sense of loss that accompanied the online transition [15], particularly for groups that adhered strongly to the ethos of the HVM and placed great emphasis on creating a distinct, user-led environment. Although not a replacement for nonverbal cues, future online groups may benefit from verbalizing the nonverbal; for example, by emphasizing the distinct values at the start of each group, acknowledging when a nongroup member appears in the background, or expressing that one wishes they could give another member a hug.

The distinct discursive elements of online groups were similarly consistent with previous research. For example, Weinberg [15] contended that there can be an unnaturally linear flow of dialogue in online psychotherapy groups because participants are in their own “boxes” and less able to pick up on nonverbal cues that indicate when the next person can speak. Similarly, facilitators in this study found that not only did discussions tend to focus on one person at a time rather than flow naturally between participants but disclosure was also not always as personal as in the face-to-face groups. This is a potentially important barrier to cohesion, and previous research suggests that facilitators can overcome this challenge by verbalizing statements and emotions, which previously would have remained nonverbal as a means of enhancing the continuity of dialogue between participants [35].

Although facilitators often noted significant challenges to group cohesion, many were nonetheless able to run successful and cohesive HVGs online. While previous research recommends acknowledging members’ subjective environment in moments...
where the space is disturbed (eg, a parent walks into the room during the group [15]). HVG facilitators went further and highlighted the utility of using each member’s individual space as a way of proactively showing interest and investment in their world. Given their open structure [30] and nonmanualized approach, HVGs may be particularly well-suited for this endeavor, as aspects of a member’s home environment can be incorporated more seamlessly and spontaneously into group discussion. Furthermore, previous literature recommends the use of “ice breaker” activities at the beginning of the group to help individuals ease into the space and connect with one another [36]. Sharing items from one’s home may serve as way of having less vulnerable conversations while still enabling members to connect with one another and gain unique insight into their subjective worlds. Similarly, HVG facilitators note that either planned (eg, sharing a video on voice hearing) or spontaneous activities (eg, members making music together) can be a useful tool in establishing cohesion. In this respect, facilitators in this study also emphasized the importance of capitalizing on moments of humor and spontaneity as a means of fostering shared experience between members. Although previous research has supported an association between humor and therapeutic alliance [37], this is the first study to specifically outline its utility in peer support groups and highlight how the unshared environment may lend itself more easily to these spontaneous moments. When moments of humor or spontaneity do arise, future groups should therefore purposefully use these moments to strengthen connections between members.

Mental health services may face particular challenges in providing adequate support to individuals who hear voices [17,18]. Therefore, despite the challenges outlined, caution should be taken in either interpreting online HVGs as inferior forms of support or in minimizing the value of their accessibility. Specifically, online groups allow members to engage more easily in ways that felt comfortable for them, as well as offering support to those who cannot access face-to-face groups. Furthermore, it was notable that facilitators did not mention voices and associated experiences (eg, paranoid beliefs, particularly those about being surveilled by technology) as being a major barrier to either group cohesion or to individuals successfully accessing the online space.

A significant strength of this study is its international scope, being the first of its kind to recruit participants throughout Europe and North America in a single group. Furthermore, none of the findings were region specific, meaning facilitators from across the global north may potentially benefit from implementing the strategies recommended below. Although HVGs are distinct in their ethos, the findings and recommendations may also be applicable to other forms of online support (although in non-HVG spaces, care should be taken to emphasize how the latter may be distinct from other types of mental health support groups). However, it should also be noted that the findings cannot be uncritically applied to groups facilitated in the global south, where norms and expectations about relational dynamics in peer support spaces may differ [38] and further research would be required.

Finally, the study must be interpreted in view of its limitations. Although previous research has highlighted the centrality of group relationships to the successful running of HVGs [6,7,9], the concept of group cohesion arises from psychotherapy literature rather than the peer support literature, and therefore cannot be uncritically applied [13]. Furthermore, the sample was racially homogeneous, with most participants identifying as White. Given the global spread of HVGs, future studies would be greatly enhanced by recruiting a more ethnically representative sample. Furthermore, 87% (7/8) of the facilitators with online experience had to adapt a face-to-face group to an online platform following the COVID-19 pandemic, and additional research should focus on delineating the development of cohesion in groups that started online compared to those that had to transition into being so. Finally, although efforts were made to member check results with all participants, responses were only received from 2 individuals (who suggested no substantial changes), and future research would be strengthened from incorporating a wider range of reflections into the analysis.

Conclusions

In conclusion, it is possible to overcome the distinct challenges inherent to the medium to deliver cohesive HVGs online. Facilitators should be mindful that there are both nonverbal and discursive barriers to cohesion, many of which originate from the distance and detachment inherent in the online space. However, group cohesion may be enhanced by highlighting the distinct nature of the group, creating transitional space, verbalizing the nonverbal, capitalizing on spontaneity, and using participants’ unique environments to foster intimacy. Recommendations for promoting cohesive groups online can be found in Textbox 1, and it is hoped such forums may continue to prove an accessible and implementable form of support not only for individuals who hear voices but also for anyone who may benefit from peer engagement.

Abstract

Background: The Apple Watch (AW) Series 1 provides energy expenditure (EE) for wheelchair users but was found to be inaccurate with an error of approximately 30%, and the corresponding error for heart rate (HR) provided by the Fitbit Charge 2 was approximately 10% to 20%. Improved accuracy of estimated EE and HR is expected with newer editions of these smart watches (SWs).

Objective: This study aims to assess the accuracy of the AW Series 4 (wheelchair-specific setting) and the Fitbit Versa (treadmill running mode) for estimating EE and HR during wheelchair propulsion at different intensities.

Methods: Data from 20 manual wheelchair users (male: n=11, female: n=9; body mass: mean 75, SD 19 kg) and 20 people without a disability (male: n=11, female: n=9; body mass: mean 75, SD 11 kg) were included. Three 4-minute wheelchair propulsion stages at increasing speed were performed on 3 separate test days (0.5%, 2.5%, or 5% incline), while EE and HR were collected by criterion devices and the AW or Fitbit. The mean absolute percentage error (MAPE) was used to indicate the absolute agreement between the criterion device and SWs for EE and HR. Additionally, linear mixed model analyses assessed the effect of exercise intensity, sex, and group on the SW error. Interclass correlation coefficients were used to assess relative agreement between criterion devices and SWs.

Results: The AW underestimated EE with MAPEs of 29.2% (SD 22%) in wheelchair users and 30% (SD 12%) in people without a disability. The Fitbit overestimated EE with MAPEs of 73.9% (SD 7%) in wheelchair users and 44.7% (SD 38%) in people without a disability. Both SWs underestimated HR. The device error for EE and HR increased with intensity for both SWs (all comparisons: P<.001), and the only significant difference between groups was found for HR in the AW (~5.27 beats/min for wheelchair users; P=.02). There was a significant effect of sex on the estimation error in EE, with worse accuracy for the AW (~0.69 kcal/min; P<.001) and better accuracy for the Fitbit (~2.08 kcal/min; P<.001) in female participants. For HR, sex differences were found only for the AW, with a smaller error in female participants (5.23 beats/min; P=.02). Interclass correlation coefficients showed poor to moderate relative agreement for both SWs apart from 2 stage-incline combinations (AW: 0.12-0.57 for EE and 0.11-0.86 for HR; Fitbit: 0.06-0.85 for EE and 0.03-0.29 for HR).

Conclusions: Neither the AW nor Fitbit were sufficiently accurate for estimating EE or HR during wheelchair propulsion. The AW underestimated EE and the Fitbit overestimated EE, and both SWs underestimated HR. Caution is hence required when using SWs as a tool for training intensity regulation and energy balance or imbalance in wheelchair users.

Introduction

Wheelchair users are generally less active than people without a disability, which increases their risk of developing noncommunicable diseases such as cardiovascular disease, type 2 diabetes, and obesity [1-4]. In fact, the prevalence of obesity is 2.5 times greater in wheelchair users compared to people without a disability [5]. This is related to an energy intake that exceeds their energy expenditure (EE), which is approximately 5% to 40% lower in wheelchair users compared to people without a disability [6-8].

Total EE in people without a disability is approximately 1900 to 2900 kcal/day and comprised of 3 components: 60% to 75% attributed to resting EE (REE), 10% to diet-induced thermogenesis, and 15% to 30% to physical activity EE (PAEE) [9,10]. The lower total EE of wheelchair users is mainly related to reduced REE and PAEE [11-13]. Wheelchair users with a spinal cord injury (SCI) have a 14% to 27% lower REE due to reduced fat-free mass and sympathetic nervous system activity [11]. Furthermore, wheelchair users have lower PAEE due to a smaller amount of active muscle mass during upper-body exercise compared to what ambulatory people without a disability expend during walking or running [14,15]. Also, PAEE typically ranges between 6% and 36% of the total daily EE in wheelchair users with a SCI [16,17] and is the most modifiable of the 3 components. Therefore, PAEE may be particularly useful for obtaining a balance between EE and energy intake.

Criterion devices for measuring EE, such as direct or indirect calorimetry, are restricted to the laboratory setting and expensive to use. Therefore, more accessible devices that accurately estimate EE within the population of wheelchair users are needed. Smart watches (SWs) are widely used to provide feedback on estimated EE and monitor physical activity intensity (eg, through monitoring heart rate [HR]) [14,18-20]. If sufficiently accurate, the feedback provided by SWs may serve as a tool to counteract obesity and promote physical activity in wheelchair users.

Commonly used cutoffs for acceptable accuracy of parameters provided by wearable devices are ±10% in free-living settings and ±3% in standardized settings [18,21]. However, even in standardized settings, SWs often estimate HR and EE values outside of this range in both wheelchair users and people without a disability [18-22]. Additionally, the development of wheelchair user–specific estimation algorithms for EE and HR is especially challenging because of the high heterogeneity and disability-related differences in physiological functioning in this population. Currently, the only study that evaluated the accuracy of estimated HR with a commercially available SW (Fitbit Charge 2 [Fitbit Inc]) found lower accuracy for wheelchair users (mean absolute percentage errors [MAPE] of approximately 10%-20% dependent on level of SCI) compared to people without a disability (approximately 8% MAPE) [23]. Furthermore, the sole study that assessed the accuracy of the estimated EE in the commercially available Apple Watch (AW) Series 1 (Apple Inc) with a wheelchair-specific setting reported a MAPE of 29% [24]. Notably, both studies report that the measurement error for estimating HR and EE increased with higher-intensity exercise [23,24]. While follow-up studies have not yet been conducted, one would expect companies to further improve the accuracy of their HR and EE estimation algorithms.

Therefore, the aim of this study was to assess the accuracy of the AW Series 4 (in the wheelchair-specific setting “outdoor push walking pace”) and the Fitbit Versa (in the treadmill running mode) for estimating EE and HR during wheelchair propulsion at different intensities. We decided to include both wheelchair users and a control group consisting of people without a disability to investigate if the wheelchair setting was specifically adjusted for wheelchair users.

Methods

Participants

A total of 20 wheelchair users and 20 people without a disability were included in the study. Both groups consisted of 11 male participants and 9 female participants and had similar demographic characteristics (Table 1). Participants were included if they were aged between 18 and 60 years and without injury or other health issues that could be aggravated by physical exertion. Included in the wheelchair user group were individuals that used a manual wheelchair as a main form of transport or were ambulatory wheelchair users. The wheelchair user group was comprised of individuals with SCI (n=11), spina bifida (n=2), and cerebral palsy (n=2). A total of 5 participants had other neurological, musculoskeletal, or joint impairments. Participants were recruited from sports associations and organizations for people with disabilities in Norway and social media.

**Study Protocol**

Three test days of wheelchair propulsion with different treadmill incline-speed combinations were conducted within 2 consecutive weeks. A minimum of 24 hours separated each test day, and sessions occurred at approximately the same time of day to account for diurnal variations. All test days started with a 5-minute warmup at a 0.5% incline at a self-chosen speed that corresponded to a rating of perceived exertion of 7-9 on the Borg scale [25]. Then, 3 standardized 4-minute stages were performed at a predetermined incline for the day (either 0.5%, 2.5%, or 5%) with increasing speed across the stages. The order of the test days was counterbalanced. The speed at each incline was established through pilot testing and determined to be manageable for the participants (Table 2). Anthropometric data (age and sex) were collected before testing, and body mass and height were collected on the first test day. Participants were instructed to avoid high intensity training and alcohol consumption 24 hours before testing, avoid caffeine on the day of testing, and fast for at least 2 hours before testing.

Table 2. Overview of the standardized speeds for the 3 test days (0.5%, 2.5%, or 5% incline) for male participants (without tetraplegia) and female participants or male tetraplegic wheelchair users.

**Equipment**

Participants’ body mass was measured using a Kistler force plate (Kistler 9286BA; Kistler Instruments AG) before the first test day. Body mass was determined for participants in the wheelchair user group while seated in their own wheelchair and obtained by subtracting the mass of the individual wheelchair (range 6.5-18.2 kg). All people without a disability were weighed while standing without any equipment. Participants wore a facemask (7450 V2 Series; Hans Rudolph Inc), which was connected to a Vyntus CPX ergospirometer with a mixing chamber (Vyaire, Medical GmbH) to measure gas exchange as 10-second averages, from which the criterion device EE was calculated. The Vyntus CPX was calibrated against a known gas mixture of 15% O₂ and 5% CO₂ before every test. Participants were fitted with a Polar HR monitor (version M400; Polar Electro Oy) and a Polar chest strap (version H10; Polar Electro Oy), which served as the criterion device for HR.

Participants wore 2 SWs on their nondominant wrist: an AW Series 4 software version OS 7.3.3 and a Fitbit Versa (2017) software version OS 5.0. The SWs tracked HR using...
photoplethysmography, and both SWs had a built-in accelerometer and gyroscope. The SW placement (closest to the wrist) was counterbalanced. Participant characteristics were entered in the devices, and the activity settings of “outdoor push walking pace” (AW) and “treadmill running” (Fitbit) were used throughout testing. “Treadmill running” was chosen for the Fitbit in the absence of a wheelchair-specific setting. Wheelchair users used their personal wheelchair, and people without a disability used a standardized wheelchair (Küschall K-Series Attract; Invacare; mass 11.7 kg). The wheelchairs were secured on a motorized 5x3 m treadmill (Forcelink Technology) with a mobile traverse bar attached to side rails (Figure 1). The side rails were equipped with safety stoppers to prevent participants from rolling off the back of the treadmill.

Figure 1. Test setup on the treadmill with the manual wheelchair attached to the traverse safety bar.

Blood lactate concentrations (mmol/L) were measured in a rested state and after every stage from a 20-μl blood sample obtained from the participants earlobe [26]. Concentrations were analyzed using the Biosen C-Line Sport lactate measurement system (EKF Industrial Electronics). Rating of perceived exertion was obtained for muscular, respiratory, and total effort on the 6-20 Borg scale after each stage [25].

Data Analysis
The criterion EE was calculated for every 10-second average VO₂ and VCO₂ values using the Weir formula [27]:

\[
EE \text{ (kcal/min)} = 3.941 \times VO_2 \text{ (L/min)} + 1.106 \times VCO_2 \text{ (L/min)}
\]

An average over the entire 4-minute period (as opposed to a steady-state average) was calculated for EE and HR for each stage of the criterion device. This was done since the SWs displayed an estimated average EE and HR for each entire stage. It was not possible to retrieve data with a higher time resolution from the SWs. The EE values provided by the criterion device and SWs were converted to kcal/min for comparison. Lastly, incomplete 4-minute stages were excluded from the analyses.

Missing Data
In total, 20 of the 360 performed stages were incomplete and excluded from the analyses. Incomplete stages mostly occurred at the highest speeds and often at the 5% incline, which was due to a combination of an age- or disability-related lack of physical fitness or upper-body strength. Additionally, equipment failure or human error contributed to the following missing data: incorrect activity setting (AW, n=2), no HR recorded after activity (AW, n=32), and a lost HR signal (criterion, n=1).

Statistical Analysis
Statistical analyses were conducted, and visualizations created in R Studio (version 4.2.1; R Core Team) [28]. Descriptive statistics were calculated for EE and HR for criterion devices, AW, and Fitbit and visualized with box plots using the R Studio package ggplot2 (Multimedia Appendix 1).

Absolute Agreement
The MAPE was used to establish the difference between criterion devices and SWs for both EE and HR during each stage:

\[
MAPE = \frac{1}{n} \sum \frac{|C_p - SW_p|}{|C_p|} \times 100
\]

where criterion devices are represented by \(C\), smart watches as \(SW\), participants as \(p\), and the total number of participants that completed the respective stage as \(n\). In addition to the separate MAPEs visualized in a figure, an overall MAPE is provided in text, with the mean and SD being calculated across all participants and stages. The MAPE was categorized based on commonly used accuracy cutoffs for measuring EE, HR, and steps with wearable devices, with an acceptable error of ±10% in free living settings and ±3% in standardized settings [18,21].
Our categorization for the MAPE was therefore as follows: poor (>20%), moderate (10.1%-20%), good (3.1%-10%) and excellent (0%-3%).

The results of linear mixed model analyses are presented in our main results, in addition to Bland-Altman plots in the Multimedia Appendix 2. The main reason for choosing linear mixed model analyses as our main analyses was the repeated-measures design of our data collection with corresponding dependency in data [29], since all participants conducted several stages. The linear mixed model analyses were used to assess if there was a significant difference in EE and HR between criterion devices and SWs and to investigate the effect of group and sex as well as the increase in intensity on these device differences. Speed and incline were not adjusted for in the mixed model analyses, as we were interested in the estimation error of the SWs across all intensities and not within each speed-incline combination. As such, we also did not need to adjust for multiple comparisons. Participant ID was included as a random-intercept effect in these models to account for dependency in the data. An α value of .05 was used to indicate statistical significance. There was no deviation of the residuals from normality (checked by visual inspection of Q-Q plots) and no violation of the assumption of homoscedasticity (checked by plotting the fitted values against the residuals; plot_model function, R sjPlot package). The inclusion or exclusion of outliers did not change the results of the mixed model analyses. We therefore decided to include the analyses with outliers, as they represent the actual estimation errors of the AW.

### Results

#### Absolute Agreement

For the EE reported by the AW Series 4, the MAPE (with all inclines and stages combined) was 27.4% (SD 16.7%) in wheelchair users and 32.1% (SD 14.4%) in people without a disability. The EE provided by the Fitbit Versa had a MAPE of 73.9% (SD 57.2%) in wheelchair users and 44.7% (SD 37.8%) in people without a disability. Absolute agreement based on the MAPE for each incline-stage combination was mostly poor (Figure 2).

For HR, the MAPE with all stages and inclines combined was 8.5 (SD 10.4%) in wheelchair users and 8.1 (SD 13.6%) in people without a disability for the AW, and 17.4 (SD 12.4%) in wheelchair users and 14.3 (SD 10.7%) in people without a disability for the Fitbit. The absolute agreement for HR in each incline-stage combination was moderate-good for the AW and poor-moderate for the Fitbit (Figure 2).

The mixed model analyses indicated that EE was underestimated by the AW and overestimated by the Fitbit, while both SWs underestimated HR (Figure 3). Additionally, the differences between criterion and comparison devices increased negatively with higher exercise intensity for EE and HR (all comparisons, P < .001; Figure 3 and Multimedia Appendix 2). This led to reduced accuracy in the AW (larger underestimation) and improved accuracy in the Fitbit (lower overestimation) with increased intensity. EE and HR differences between SWs and criterion devices were not significantly different in wheelchair users compared to people without a disability in most comparisons (P > .06), with the exception of the HR reported by the AW (~5.27 beats/min; P = .02). Furthermore, for EE, the differences were significantly larger in female participants for the AW (~0.69 kcal/min; P = .02). For HR, the only sex difference was found for the AW, with smaller differences between the AW and criterion device in female participants (5.23 beats/min; P = .02).

#### Relative Agreement

Interclass correlation coefficients (ICCs) were used to quantify relative agreement between criterion devices and SWs for both EE and HR. The ICCs were calculated using the 2-way random effects model with absolute agreement by using the icc function from the irr package. ICCs were categorized based on widely used cutoff points into poor (<0.5), moderate (0.5-0.75), good (0.75-0.9), and excellent relative agreement (>0.9) [30,31].

#### Ethical Considerations

The data collection and processing were approved by the Norwegian Centre for Research Data (216680) and conducted in accordance with the Declaration of Helsinki. All participants were informed of the study purpose, design, potential risks, and the possibility to withdraw without penalty before signing the consent form. Participation was voluntary and without financial compensation beyond insight into the individual’s collected data. The collected data were deidentified.
Figure 2. Mean absolute percentage error (MAPE) between criterion devices and smart watches for energy expenditure and heart rate on all 3 test days (0.5%, 2.5%, and 5% incline) and stages with increasing speed. Values are presented separately for wheelchair users and people without a disability. MAPEs were categorized as poor (>20%), moderate (10.1%-20%), good (3.1%-10%), and excellent (0%-3%).
Figure 3. Regression lines (with shaded 95% CIs) separated by groups for the differences in energy expenditure (EE) and heart rate (HR) between smart watches (SWs) and criterion devices based on linear mixed model analyses: (A) EE: Apple-Vyntus; (B) EE: Fitbit-Vyntus; (C) HR: Apple-Polar; and (D): HR: Fitbit-Polar. The x-axis shows the criterion device values, while the y-axis shows the absolute difference between SWs and criterion devices. A regression line below zero indicates underestimation of SWs compared to criterion devices, while 1 above zero indicates overestimation.

Relative Agreement
Apart from 1 EE (Figure 4; a 5% incline for stage 3) and 1 HR ICC (Figure 4; a 0.5% incline for stage 2), all remaining ICCs indicate poor to moderate relative agreement between the criterion devices and SWs (Figure 4). The ICCs for each incline-stage combination for the AW had a range from 0.12 to 0.57 for EE and from 0.11 to 0.86 for HR. For the Fitbit, the corresponding ranges were from 0.06 to 0.85 for EE and from 0.03 to 0.29 for HR.
Figure 4. Interclass correlation coefficients (ICCs) between criterion devices and smart watches (SWs) for wheelchair users and people without a disability on all 3 test days (0.5%, 2.5%, and 5% incline) and stages with increasing speed. ICCs were categorized as poor (<0.5), moderate (0.5-0.75), good (0.76-0.9), and excellent (>0.9) for energy expenditure and heart rate.

Discussion

Summary

The aim of this study was to assess the accuracy of the AW Series 4 and the Fitbit Versa for estimating EE and HR during wheelchair propulsion at different intensities. The AW underestimated EE and the Fitbit overestimated EE, suggesting that neither of the SWs are accurate enough for estimating EE in wheelchair users. Furthermore, both the AW and Fitbit underestimated HR. Lastly, the differences in HR and EE between SWs and criterion devices increased with increasing intensity, and they mostly did not differ between groups.
EE Findings

The MAPE of approximately 30% and poor to moderate ICCs of the AW Series 4 are similar to the ones reported by Moreno et al [24] for the AW Series 1. Since the participant characteristics were similar those in this study, there seems to be no improvement in the AW’s EE estimation algorithms. The SW algorithms are proprietary technology, and it cannot therefore be determined why the AW underestimates EE for all participants. A plausible explanation is that Apple intentionally chose to report lower values for the sake of obesity prevention. Another possible explanation is that the data for developing the AW algorithms were collected from wheelchair users with lower training status or higher levels of SCI, who have a lower EE compared to the wheelchair users tested in this study. If the latter is the case, injury and fitness levels are important factors to consider when estimating the EE of wheelchair propulsion.

In this study, the AW was found to be equally inaccurate when estimating EE for wheelchair users and people without a disability, a finding that also aligns with Moreno et al [24]. Since the AW does not request user information on, for example, impairment levels, this finding indicates that the watch’s software is not capable of identifying these types of individual characteristics from other factors such as movement patterns or HR responses. In contrast, sex could be inputted into the AW settings, and we found a significantly better estimated EE for male participants. Preliminary evidence [32] indicates that algorithms for wearable devices are developed mostly based on reference data from male participants and may therefore be less accurate for female participants.

The AW’s underestimation of EE increased with intensity, which contradicts findings from previous AW studies [24,33]. While Pope et al [33] reported lower accuracy at moderate compared to low and high intensity during running, Moreno et al [24] reported consistent accuracy across wheelchair propulsion stages with an increasing stroke rate. The test protocol with the standardized stroke rate increases in Moreno et al [24] might more closely resemble the way the AW estimation algorithm works. Possibly, the AW uses the accelerometry data to determine how much exercise intensity, and thereby EE, has increased. In contrast, in this study, intensity increased with higher speeds at a given incline, with the steeper incline days being more physiologically taxing with a larger anaerobic contribution than the flatter incline days. Furthermore, it is possible that the AW EE estimation algorithms were developed mostly based on low-intensity data or without a physiological intensity measure (eg, HR) since wheelchair users spend most of their day at or below low-intensity exercise levels. In line with this, preliminary findings of our research group [34] indicate that estimation algorithms developed for wheelchair users perform less well on high-intensity data if they are only developed based on low- to moderate-intensity data.

The Fitbit did, in contrast to the AW and other SW studies on EE [24,33], show a systematic decrease in the error with higher intensities for both groups, which resulted in lower overestimations. This finding was most likely related to using the “treadmill running mode” in the absence of a wheelchair-specific setting. This setting leads the estimation algorithm to expect a weight-bearing and leg-dependent activity with higher muscle activation. However, wheelchair propulsion is a non–weight-bearing activity that allows longer rest between cycles, especially at lower speeds and inclines. The reduction of the Fitbit error at higher intensities might therefore be a result of more active muscle mass, faster cycle rates, and longer cycle lengths with increased incline or speed. As such, the physiological effort of wheelchair propulsion may be more similar to running at higher intensities. Although the Fitbit displayed improved accuracy at higher intensities, the MAPEs were far greater than the ±3% acceptable accuracy cutoff, and the Fitbit should therefore not be used to estimate EE in wheelchair users.

HR Findings

Both SWs showed better accuracy for HR compared to EE. However, only the AW had a MAPE below the arbitrary cutoff of ±10% that is commonly used for acceptable accuracy in free-living activities, with no values below the ±3% cutoff for standardized settings [18,21]. Both SWs additionally showed reduced accuracy at the highest intensities, which is in agreement with previous findings of HR measured from wrist-worn devices during running [22]. Furthermore, wheelchair users were found to have a larger underestimation of HR (ie, −5 beats/min) compared to people without a disability. While the reasons for this are somewhat unclear, it seems like this is due to more negative outliers in wheelchair users. Overall, the high MAPE variance and mostly poor to moderate (AW) and poor (Fitbit) ICCs indicate a high risk of individual inaccuracy when monitoring HR from these wrist-worn SWs during wheelchair propulsion.

Methodological and Future Considerations

Two main factors need to be addressed for better EE and HR estimation algorithms in wrist-worn SWs: (1) the sensor hardware (eg, Apple Watch) and (2) the sensor software (estimation algorithm).

The sensor hardware of current wrist-worn technology is not capable of reporting precise or consistent HR signals during activity, which was partly highlighted by the missing data in this study. With regard to further improving the estimation algorithms, an assessment is needed on the impact and relative importance of factors such as personal characteristics (sex, age, body mass, training status, etc) or more wheelchair users–specific aspects such as type and level of impairment. These additional factors may increase estimation accuracy and reduce variation within the highly heterogeneous wheelchair user group, even without hardware improvements.

Furthermore, investigation into appropriate cutoffs for acceptable accuracy of EE and HR provided by SWs is needed. The commonly used cutoffs (±3% in standardized and ±10% in free-living settings) are based on previous research assessing step count during walking [35-38] or pushes during wheelchair propulsion [39]. It may be plausible to establish higher cutoffs for EE or HR, especially when testing a heterogeneous wheelchair user group during an upper-body activity. However, a standardized low cutoff is essential to avoid differentiating acceptable accuracy between parameters in both controlled and free-living settings. Accurate estimates are also crucial for various populations, for example, to address an imbalance...
between energy intake and expenditure in athletes trying to regulate nutrition for performance purposes or in wheelchair users attempting to prevent or counteract obesity. Therefore, it is likely the ±10% error cutoff for free-living activities is too high.

Lastly, the effect of filtering done by the AW and Fitbit on the EE or HR data deserves mentioning. The AW removed many average HR values, which is likely attributed to a low number of data points. Comparatively, Fitbit reported data for all activities, although with lower accuracy. For now, we advise the use of HR belts for increased accuracy of the parameters investigated.

**Conclusion**

Neither the wrist-worn AW nor Fitbit were sufficiently accurate for estimating EE or HR during wheelchair propulsion. The AW underestimated EE while the Fitbit overestimated the EE across all incline-stage combinations. The underestimation of the AW increased and the overestimation of the Fitbit decreased with higher intensities, suggesting that neither watch sufficiently adjusts for the change in intensity. Additionally, both SWs underestimated HR. High MAPEs were found for both SWs and parameters (ie, EE and HR), in addition to the poor relative agreement indicated by low ICCs. Furthermore, neither the wheelchair-specific algorithm for estimating EE nor its ability to differentiate between wheelchair users and people without a disability have been improved for the AW Series 4 as compared to the previously investigated AW Series 1. Overall, our findings suggest that caution is required when using SWs as a tool for training intensity regulation and energy balance or imbalance in wheelchair users.

**Acknowledgments**

Testing was performed with the laboratory facilities and equipment from NeXt Move, the Norwegian University of Science and Technology, the Faculty of Medicine at the Norwegian University of Science and Technology, and the Central Norway Regional Health Authority. We appreciate the work of everyone involved in “the digital wheelchair” project, in particular Cecilia Severin and Roy Mulder for contributions previously and during data collection, in addition to all the colleagues and master students assisting in the laboratory. This study was financed by strategic funding from the Faculty of Medicine and Health Science at the Norwegian University of Science and Technology, an innovation scholarship, and Discovery funding at the same university. The funding bodies had no role in the design of this study, its execution, analyses, interpretation of the data, or decision to submit results.

Abstract

Background: Telemedicine is an important option for rural older adults who often must travel far distances to clinics or forgo essential care. In 2014, the Geriatric Research, Education, and Clinical Centers (GRECC) of the US Veterans Health Administration (VA) established a national telemedicine network called GRECC Connect. This network increased access to geriatric specialty care for the 1.4 million rural VA-enrolled veterans aged 65 years or older. The use of telemedicine skyrocketed during the COVID-19 pandemic, which disproportionately impacted older adults, exacerbating disparities in specialty care access as overburdened systems shut down in-person services. This surge presented a unique opportunity to study the supports necessary for those who would forgo telemedicine if in-person care were available.

Objective: In spring 2021, we interviewed veterans and their informal caregivers to (1) elicit their experiences attempting to prepare for a video visit with a GRECC Connect geriatric specialist and (2) explore facilitators and barriers to successful engagement in a telemedicine visit.

Methods: We conducted a cross-sectional qualitative evaluation with patients and their caregivers who agreed to participate in at least 1 GRECC Connect telemedicine visit in the previous 3 months. A total of 30 participants from 6 geographically diverse GRECC Connect hub sites agreed to participate. Semistructured interviews were conducted through telephone or the VA’s videoconference platform for home telemedicine visits (VA Video Connect) per participant preference. We observed challenges and, when needed, provided real-time technical support to facilitate VA Video Connect use for interviews. All interviews were recorded with permission and professionally transcribed. A team of 5 researchers experienced in qualitative research analyzed interview transcripts using rapid qualitative analysis.

Results: From 30 participant interviews, we identified the following 4 categories of supports participants described regarding successful engagement in telemedicine, as defined by visit completion, satisfaction, and willingness to engage in telemedicine
in the future: (1) caregiver presence to facilitate technology setup and communication; (2) flexibility in visit modality (eg, video from home or a clinic or telephone); (3) technology support (eg, determining device compatibility or providing instruction and on-demand assistance); and (4) assurance of comfort with web-based communication, including orientation to features like closed captioning. Supports were needed at multiple points before the visit, and participants stressed the importance of eliciting the varying needs and preferences of each patient-caregiver dyad. Though many initially agreed to a telemedicine visit because of pandemic-related clinic closures, participants were satisfied with telemedicine and willing to use it for other types of health care visits.

Conclusions: To close gaps in telemedicine use among rural older adults, supports must be tailored to individuals, accounting for technology availability and comfort, as well as availability of and need for caregiver involvement. Comprehensive scaffolding of support starts well before the first telemedicine visit.

Introduction

Not all older adults have the means or willingness to successfully participate in telemedicine visits. In a survey of medically high-need, high-risk older US veterans, approximately half of respondents were unwilling to engage in video visits. A quarter of those willing lacked the needed technology, and these individuals were more likely to be older, less health literate, or living in more socioeconomically disadvantaged areas [1]. Concerns persist about technology access and use among older adults for telemedicine, such as those who lack broadband access, and common age-associated communication challenges related to sight, hearing, and cognitive limitations [2,3].

However, when telemedicine is successful, its advantages may be especially critical for older, rural adults and their caregivers [4]. Compared to in-person appointments, telemedicine has been shown to have similar, and sometimes better, clinical outcomes [5-8]. It has similar quality, including for visits related to cognitive decline [9], has high levels of patient satisfaction, and is associated with timely access to specialty care [10] which can help support patients with mobility or transportation issues [11,12]. Telemedicine cuts down on travel complications [13], bridging far distances to clinics for older adults living in rural areas [14] and reduces patient and caregiver stress [15]. Further, telemedicine improves care continuity and decreases missed care opportunities [16], including in dementia clinic settings [10].

Those who are older, lower-income, or living in rural areas have historically been less likely to engage in telemedicine visits [17], disparities that worsened during the COVID-19 pandemic. The pandemic disproportionately impacted older adults (World Health Organization) [18], exacerbating disparities in specialty care access as overburdened care systems shut down nonessential in-person services. Even as the overall use of telemedicine soared, gaps among rural patients and those in the oldest age groups widened [19,20]. Yet, the forced pivot to telemedicine provided a unique opportunity to study the support needs of rural, older adults who may not have otherwise used these services.

The US Veterans Health Administration (VA) serves as an optimal setting in which to explore factors influencing successful engagement in telemedicine for rural older patients. More than half of the 2.8 million rural veterans receiving VA services are aged 65 years or older [21]. The VA has been a leading force in telemedicine for 20 years [22,23] in its efforts to expand access to health care services to all veterans, recently celebrating the milestone of 20 years of providing telemedicine services. In 2014, the VA's Office of Rural Health funded GRECC Connect to use telemedicine to expand access to geriatric specialty care for rural, older veterans with multiple chronic conditions and complex care needs. Geriatric specialists from urban centers of excellence called Geriatric Research, Education, and Clinical Centers (GRECCs) focused on aging worked to build partnerships with rural clinicians to serve older adults living in rural areas through clinic-to-clinic or clinic-to-home visits [24,25].

In spring 2021, we interviewed older adults and their caregivers as part of an evaluation of GRECC Connect’s national network of geriatric telemedicine specialty services. We conducted interviews using the same VA videoconferencing platform used for clinical visits, enabling us to observe and interact with participants as they navigated technological and communication challenges and, if needed, provide necessary technical support or instruction. While other studies have examined satisfaction with telemedicine in older adults [9,10] and competencies of providers, including previsit preparation [26], few studies have looked in-depth at the experiences of older patients inexperienced in telemedicine as they prepare to engage in visits. We sought to (1) elicit patient and caregiver experiences attempting to participate in a video visit with a GRECC Connect geriatric specialist, and (2) explore facilitators and barriers to successful engagement in a telemedicine visit among this group. In this paper, we relay lessons learned from the experiences of these rural older adults and their caregivers, as well as the study team, highlighting the kinds of supports needed for successful engagement in telemedicine among older rural adults and caregivers.

Methods

Study Design

We conducted a cross-sectional qualitative evaluation with patients and, when appropriate, their informal caregivers, who...
had agreed to participate in at least 1 VA GRECC Connect telemedicine visit in the previous 3 months. The study team, led by an anthropologist and health services researcher, was experienced in qualitative research. Throughout the evaluation, the team consulted with an advisory group composed of GRECC Connect leaders, clinicians with expertise in geriatrics, neurology, and primary care, health services researchers, and a veteran consultant. The VA Bedford Healthcare System’s Institutional Review Board determined this evaluation of GRECC Connect services to be nonresearch.

Setting

In December 2020, we sent letters to clinical leads at 7 of the 15 GRECC Connect hub sites, interdisciplinary geriatric specialty teams who partner with rural community-based outpatient clinics (CBOCs), to assess their willingness to serve as recruitment sites. Potential sites were chosen based on their diverse geographic location across regions of the United States and high volume of telemedicine visits performed during fiscal year 2020.

Participants

Interviewees were recruited from lists of patients who agreed to participate in a GRECC Connect telemedicine visit at 1 of the 7 hub sites from December 2020 to March 2021. Inclusion criteria included age of ≥65 years and residential rurality (rural-urban commuting area code >1, in line with VA practice). We defined telemedicine as (1) video visits conducted between a remote geriatric specialist and a patient located at home (VA Video Connect; VVC) or at a rural VA CBOC (clinical video telemedicine; CVT) or (2) telephone visits conducted between a remote geriatrics specialist and a patient. Some participants had agreed to a video visit but, for various reasons, only completed a phone call with the clinician. We reviewed the electronic health record to exclude potential participants who passed away or were currently hospitalized or in hospice.

Recruitment

We sent patients a recruitment letter detailing the goals of the evaluation and inviting them to participate in an interview. Overall, 1 of 3 team members (CA, JHB, and JC) conducted a brief phone screening with the patients and, in some instances, caregivers who agreed to participate to confirm recall of the GRECC Connect index appointment—a recent GRECC Connect telemedicine appointment around which to ground the interview. During the screening call, a staff member administered a technology questionnaire to gauge participant comfort with and access to technology (Multimedia Appendix 1).

Data Collection

We asked participants about their preference for completing the interview through VVC videoconference or telephone. Members of the study team (CA, JHB, JC, and EMD) conducted semistructured qualitative interviews using participants’ preferred modality. In cases where patient participants had some degree of cognitive impairment (eg, dementia) or communication challenges (uncorrected hearing loss), we interviewed the patient-caregiver dyad. Based on needs identified through the technology questionnaire administered during initial screening phone calls, interviewers sometimes began the interview appointments early to provide instruction for initiating and connecting through the videoconference application. We documented technical support needs in interview notes, which offered additional context for the experiences participants shared. Interview questions were drafted by a subset of the study team, shared with the advisory group for feedback, piloted with 2 different older patients, and then finalized. The guide focused on the support received to engage the dyad in telemedicine, what worked and did not, preferences for medical visit modality, satisfaction, and recommendations for improving the telemedicine experience and available support.

Analysis

Interviews were audio-recorded and professionally transcribed verbatim. The study team (CA, JHB, JC, EMD, and MAK) analyzed interviews using rapid qualitative analysis [27,28]. Analysts summarized individual interviews using a structured template organized by key conceptual categories or domains. We met regularly to develop consensus about the template domains, which included a priori and emergent domains from the interview guide and content of interviews, respectively. To achieve consensus in the content and application of the template used to organize salient aspects of interview transcripts, 2 evaluators summarized 2 initial transcripts. Other members of the evaluation team reviewed this work. We then summarized 10 additional interviews in pairs, or triads, to maintain consistency in applying the template. The remaining transcripts were summarized individually. The team met to resolve uncertainties and refine content domains as needed. Summary templates were condensed into a single matrix where each row contained data for an individual transcript and each column represented a domain. This matrix allowed us to discern and distill patterns in the data within and across domains. We shared key themes and illustrative quotes with the advisory group, who used their expertise to help interpret the findings.

Ethical Considerations

The VA Bedford Healthcare System Institutional Review Board determined this work was undertaken to inform VA operations as part of program evaluation and quality improvement activities and was not human subjects research.

Results

Participants

We interviewed 30 patients and 26 caregivers who had agreed to participate in at least 1 telemedicine visit in the previous 3 months at 7 geographically diverse GRECC Connect hubs (2 in the Midwest, 1 in the Northeast, 2 in the West, and 2 in the South). Table 1 provides a summary of participant and index-visit characteristics as determined from electronic health record data and interview responses. Patient participants were all male, 93% (28/30) non-Hispanic and White, with a mean age of 76 years. Interviewed caregivers (some had additional caregivers) were most often the patient’s spouse (20/26, 77%) and thus were often older adults themselves. A total of 13% (4/30) of the patients we interviewed did not have a known caregiver. During interviews, sometimes the caregiver was the main respondent in cases where the patient experienced

(page number not for citation purposes)
cognitive or communication challenges. Indeed, 87% (26/30) of index telemedicine visits with geriatrics specialists were related to the patient’s cognitive challenges.

**Modality of Index Visit**

At least two-thirds of participants’ index appointments (specific, recent GRECC Connect appointments used to identify participants and ground interviews) were conducted using a video modality (Table 1). Some had agreed to a video appointment but either missed it or were unable to initiate it through the home videoconference application. Of these, some visits were performed by phone instead. A total of 90% (27/30) of index visits were not the patient’s first telemedicine encounter, though many had only begun telemedicine visits during the COVID-19 pandemic.

needed or desired supports
Participants described supports they experienced or would recommend before a video visit. They noted that such support should be provided at multiple points between appointment scheduling and the time of the appointment to ensure success. Supports (available, desired, or recommended) fell into the following 4 categories: (1) presence of a caregiver; (2) choice and flexibility in visit modality (eg, video visit or phone); (3) technology support, including assurance of compatible devices, instruction, and provision of on-demand assistance; and (4) assurance of comfort with web-based communication, orientation to features of the videoconferencing platform.

presence of a caregiver
Patients relied on caregivers for assistance with technology and communication, as needed, to successfully participate in telemedicine visits. Among those who successfully initiated the video visit, caregivers were frequently responsible for setting up in-home technology. Ease of connecting, thanks to the presence of a family caregiver, led to favorable views on telemedicine. As per 1 caregiver,

I know that older people that aren’t computer savvy or want to be on the computer. They can get a little intimidated and I know that’s a challenge for some.... I go in and I make sure it’s set up and make sure that he’s connected like we did today with you.... It’s been a very easy process to work with him to work with the telehealth and set it up and to go with it.

However, not all caregivers were comfortable with the technology. One said, “I’ve been known to push the wrong buttons sometimes and cause errors, so. Other than my hesitation or lack of confidence in electronics, there really wasn’t [any issues].”

Further, caregivers often supported the patient in communication, liaising between the patient and the clinician, especially for patients with hearing challenges or cognitive impairment. One patient told us during his video interview, “This is my memory here, over my shoulder,” referring to his spouse. However, caregivers cautioned that the clinician should be cognizant of including the patient in communication rather than just relying on the caregiver.

choice and flexibility in visit modality
Participants seldom felt that the telemedicine modality had been a choice. Rather, sometimes telemedicine was the only option available due to pandemic-related clinic closures, and the patient or dyad was informed of visit modality at or after appointment scheduling. Other reasons for telemedicine use and location (home or clinic) included patient or caregiver concern about COVID-19, distance from the specialty clinic, and other logistical concerns. One caregiver said, “We were told it was to be done over the telephone because of COVID-19. [The patient] wasn’t vaccinated then and he had a lot of health issues... Especially breathing issues and stuff so, I don’t think they even wanted like to try to take that attempt with him.”

Some said that having options, when possible, would make them more comfortable with telemedicine. For example, a caregiver recalled that the staff member scheduling the patient’s appointment assured her that telemedicine was appropriate for her father’s evaluation but that alternatives were available if the dyad was unsatisfied with the visit’s quality:

I thought [telemedicine] seemed like a good idea, but I was a little bit uncertain as to how effective it would be for the type of evaluation that needed to be done.... I mentioned it to the person that I spoke to when I scheduled the visit for Dad and she was very clear that if it did not seem to go well, that if it didn’t seem to work well that they would, of course, schedule an in-person visit, so I was fine to go ahead and start with the telehealth visit after she said that.

A patient shared the experience of repeatedly being scheduled for CVT appointments from the rural CBOC, even though he would have preferred to do telemedicine appointments from his home. After several visits, he talked to his doctor to have it changed: “I’d rather do it at home here and talk to [the clinician]. And, you know, finally I just told Dr X, I said, you know, I don’t think I need to have all these nurses standin’ around here listening to our call.”

The telephone enabled additional flexibility for telemedicine encounters. Having the ability to switch from video to the telephone if technical issues arose allowed patients and caregivers to continue the appointments and participants to continue interviews. The phone also afforded caregivers the opportunity to join patients’ visits when they were unable to attend in-person. One caregiver, the patient’s child, who lives in another state, explained, “I wasn’t there, but they call me, or my dad calls me on his cell phone so I can overhear the conversation. They put me on speaker, and we’ve done this twice now and it has been wonderful.”

technology support
Participants stressed that having a positive experience with the technology is critical to successful telemedicine engagement. The ability to connect to video appointments varied, with many experiencing roadblocks such as poor internet connectivity and uncertainty about how to connect to the video software, especially from home. One patient who agreed to try but was unable to complete his visit over video said, “They told me I could try [VVC] and I tried it a couple days before and I still couldn’t do it, so I just got frustrated with it.”

Some participants experienced technology challenges due to incompatibility between their equipment and the VA’s videoconferencing platform. While the VA has the capability to offer free, internet-connected tablets to patients who don’t have their own devices, we found participants at 5 out of the 6 VA hub sites had not been offered a device by anyone in the VA. When the availability of these VA-owned devices was raised in interviews, many showed interest in a VA-issued device. One caregiver remarked, “With the tablet, we could walk outside if it gets, like I can’t [go] outside with my [landline] phone so I just thought like a tablet would be great because we could go sit on the bench.... That would be perfect for him.”
Participants desired more formal instruction before the video appointment date, such as test calls or group education for older adults and caregivers. Some preferred printed and mailed materials, while others found it easier to keep track of digital resources and were overwhelmed by receiving too much written information. Appointment reminders sent through electronic mail were 1 channel participants identified for receiving such instructions. A few recalled receiving in-depth instructions to test audio and video before the appointment. Our experience preparing participants for video interviews corroborated this need. As I participant said, “(For) telemedicine, if I know how to get on there and if I know how to, you know, set everything up...like today, my wife was able to set it up because you gave her the instructions, and that was great.” One patient who had struggled to connect to the VA videoconferencing platform before the interview said he wished he had received instruction sooner:

I would just say [to VA employees], “Hey, if you don’t get it to work, tell them to scroll down and hit ‘Start.’” Cause, you know, if I would’ve known that. Of course, they probably figure, “Well, you can see that,” and I mentioned earlier, I’m sure that that’s why nothing ever went through because, you know, I never seen the “Start” ’til [I received live instruction] today.

We observed that some dyads needed more than 1 round of instruction to support successful engagement. Those who performed test calls typically found it helpful and stressed its importance, but some, like the patient previously mentioned, had challenges with test calls but did not know how to reach anyone for live technical support. One participant recommended, “If [the patient is] not connected with the internet and knows a little bit...there could be somebody provided through the VA that would help them.”

Those who participated in CVT visits from a local rural outpatient clinic benefited from additional technology support from a nurse or technician who was present during setup. Participants who experienced this additional help found it valuable. One patient received hearing aids from the telemedicine nurse. When asked if he would recommend CVT to others, another patient said, “Oh heck yeah! Even the lady setting up stuff like this [is] helpful and everything.”

Comfort With Web-Based Communication

Participants described and displayed variability in comfort with and preferences for telemedicine visits. For CVT appointments from rural community outpatient clinics, in particular, preferences for having staff in the room during the appointment session varied. In a previous example highlighted earlier in this paper, a patient disliked having extra staff in the room for privacy reasons. Another patient we interviewed had positive feedback about a CVT call where the staff member left after setting up the technology and ensuring that the patient and caregiver were comfortable: “Whoever the person was that, you know, got the doctor on the TV and, you know, made us comfortable. Yeah, it worked very well.... I really liked the fact that she left us—the person that set it up left us alone with the doctor so we had privacy. I liked that part of it.” However, another participant liked having a nurse in the room who could ask the clinician questions on his behalf if he needed help with web-based communication. Another participant was unaware of the optional closed captioning feature of the VA’s videoconferencing platform and recommended that this should be promoted for patients with hearing difficulties.

“More Than Just COVID-19”

Participants were typically satisfied with their telemedicine experience, and many said they were interested in continuing using telemedicine for at least some appointments. One participant said, “I totally agreed to [the telemedicine visit] and the only reason was because of COVID. But then, after we’d done it a couple of times, it was—it’s so much more than COVID. I mean, I think [the VA] should continue doing it all the time.” Some still preferred or would like to at least keep some in-person appointments.

“They May Surprise You With What They Know”; A Note on Tailoring Supports

Overall, patients and their caregivers desired options tailored to their preferences and needs. Participants noted that not all older adults have the same technological abilities. One participant acknowledged that “[technology is] a great mystery to some [older adults],” but said they personally had “[not] really hesitated to use what they [the VA] offer tech-wise” and that other older patients “may surprise you with what they know.” Still, not all patients or their caregivers were tech-savvy. Some who formerly felt confident in their technological literacy had lost abilities due to aging or cognitive decline, leading to feelings of frustration or shame. One patient, who engineered military jets before his retirement, explained how he went from being among the top in his technical field to relying on his spouse to set up his computer and the effect it had on his confidence:

I’ve worked all over the world. I’ve worked on the F-18s, the design of it, and worked on all the missiles and all this and I was considered one of the top techs or engineers or directors.... Now, when I had a problem, I would invite my wife on my computer. I could probably work on it, but she’s faster and she does it, you know, better or she’ll say, “Remember, you had to do this,” and I didn’t remember that, so I kind of shied away from it, you know?

Discussion

Principal Results

Patient and caregiver participants identified supports critical to the successful initiation of video visits. These included an explanation of options (from local clinic vs from home), instruction and test calls, on-demand technology support, and orientation to video communication norms and features, including sensitivity to privacy preferences. Supports desired spanned multiple points in time between when a patient is offered a telemedicine appointment and the appointment itself, suggesting that ongoing support may be needed to adequately prepare patients and their caregivers.
Our work contributes to the research on telemedicine in several ways. Unlike other studies, we provided an in-depth look at the preappointment preparation experiences of a group of older adults inexperienced in telemedicine. Our methods in this study allowed a uniquely intimate perspective on the telemedicine experiences of our participants. By conducting qualitative interviews using the same technology used in these appointments, we were able to solicit participants’ nuanced accounts of their experiences and recommendations, observe some of the challenges they described, and embody a support role to facilitate engagement in real time. Assisting patients in connecting to the video visit through phone or troubleshooting issues using the chat feature, a previously identified support [29], was often helpful and valued by participants. Table 2 shows recommended strategies to support older telemedicine participants and their caregivers based on patient and caregiver experiences, interviewer observations, and input from our advisory group stakeholders.

Proactively assessing the needs of older adults and their caregivers and discussing available supports is needed. While the VA provides some of the supports participants desired, such as on-demand assistance, closed captioning, and 4G-enabled tablets, many participants were not aware of these resources. System-level interventions may be needed to extend tablet services to more VA patients. A recent evaluation of the tablet program to date found that the VA distributed tablets to more than 7000 patients with access needs in more than 850 inpatient settings, mostly for mental health but increasingly for specialty appointments, though broadband has been a challenge [30]. As in other studies [1,31], we identified a segment of older adults who are interested in participating in telemedicine but who lack the appropriate technology. Offering alternatives to these patients, such as conducting the visit from a local clinic, receiving a clinic-issued device, or suggesting borrowing a device from a family member or friend, may enable engagement in video visits [31]. Patients and their caregivers desired more tailored training for video visit technology use. A study done by Hawley et al [31] showed that trainings for older adults tailored to telemedicine interest level and capability and informed by an initial needs assessment reduce barriers to engagement in video visits.

Patients’ physical and psychological comfort should be addressed to ensure a positive experience that respects patient beneficence and autonomy. Other studies have identified previsit preparation as an important clinician competency domain for video telemedicine with older adult patients, including optimizing the clinician environment for audibility and visibility and identifying who should be included in the visit and their roles in the patient’s care [26]. Our results echo privacy concerns in the telemedicine community regarding the sharing of sensitive information and diagnoses with care partners or others who happen to be in the appointment environment, which in some situations can pose distress to patients or caregivers [32,33]. Mishkin and colleagues [32] recommend multilevel strategies to address these challenges, including system-level patient reminders that encourage patients to ensure privacy before joining appointments, provider discretion in the appropriateness of telemedicine for sensitive appointments, and partnering with local clinics to provide private spaces to see distant providers, as the VA does in its GRECC Connect clinical video visits. Greater attention may be needed to respect patient autonomy by eliciting preferences about the presence of staff and care partners during these appointments.

Social and technological needs are not one-size-fits-all and should be approached with compassion and supportive solutions. This may be especially pertinent for appointments with patients being seen for memory loss and other cognitive challenges whose needs and abilities may be rapidly changing as disease progresses, but is important to consider with all older adults, who have a range of technical aptitude. Studies have shown that clinicians anticipate that older adults will have trouble with remote technology [34]. Yet even within what may appear to be a homogeneous group, we saw variation in what supports were wanted and needed.

Many participants did need help successfully engaging in video visits. Caregivers and staff at CBOCs were key supports for setting up the technology, troubleshooting issues, and getting logged into appointments. Numerous studies have found that the presence of a caregiver facilitates engagement in video visits for older adults, particularly for setting up technology and for patients with dementia [13,14,29,35]. Additionally, we found that participants with hearing or cognitive challenges relied on caregivers for communication with clinicians.
Table 2. Recommended strategies to support older telemedicine participants and their caregivers based on patient and caregiver experiences from telemedicine appointments between December 2020 and March 2021, interviewer observations from phone and videoconference interviews, and input from our advisory group stakeholders.

Limitations

We interviewed patients who agreed to a telemedicine visit and to an interview through phone or video, so there may be unexplored prohibitive barriers for this population among those who declined either. However, many of our participants were not offered in-person visit alternatives because of pandemic closures. Further, while we gained insights into the VVC experience through observation through our interview method, we were not able to observe the CVT experience from a VA clinic. Participants reported far fewer technical challenges in these instances, likely because they had on-site technicians who were responsible for establishing the video connection to the hub site specialists. While our study population reflects the demographics of older, rural veterans and their caregivers, it is important to note that our participants were predominantly White and male and typically had female caregivers who were spouses. Future qualitative studies about the experiences of older, rural adults should explore the social and technological needs of those with different ethnic, racial, gender, or sexual identities, including identity-discordant patient-caregiver dyads. Several studies conducted over the same time frame found that patients who are Black and living in lower-income areas are more likely to engage in telephone visits while patients who are White and living in higher-income areas are more likely to engage in video visits [36-38].

Conclusions

Telemedicine has the potential to expand access to specialty health care services for rural older adults. Yet widening gaps in use following the COVID-19 pandemic surge show that this population needs more support to engage in telemedicine successfully. Older adults and their caregivers may need ongoing support over various touch points to ensure successful engagement in video telemedicine. Supports are not one-size-fits-all and should instead be tailored to individual older patients, considering their access to and comfort with videoconferencing technology, comfort with the clinician, and availability of and need for caregiver involvement. Technology continues to be a barrier for many, in part due to gaps in broadband access in rural areas. If we do not address these barriers, we are increasing the inequity for this most vulnerable population.

Acknowledgments

The authors wish to thank Robert Bruno, a veteran consultant on our project team, for providing valuable input and feedback on our work. This work was supported by funding from the US Department of Veterans Affairs, Office of Rural Health, and Veteran
Rural Health Resource Center-Salt Lake City for portfolio project FY21-16035. Data Availability
Data sharing is not applicable to this article as the qualitative interview data contains participants’ sensitive information. More information is available from the corresponding author.

Conflicts of Interest
None declared.

Multimedia Appendix 1
During screening calls for interviews with veterans and caregivers who participated in a telemedicine visit between October 2020 and March 2021, qualitative research team members administered a technology questionnaire to gauge participant comfort with and access to technology. This questionnaire was used to help determine interview modality (telephone or videoconference) and anticipate interview technology challenges.

Abstract

Background: There is increasing interest in using patient-generated health data (PGHD) to improve patient-centered care during pregnancy. However, little research has examined the perspectives of patients and providers as they report, collect, and use PGHD to inform obstetric care.

Objective: This study aims to explore the perspectives of patients and providers about the use of PGHD during pregnancy, including the benefits and challenges of reporting, collecting, and using these data, as well as considerations for expanding the use of PGHD to improve obstetric care.

Methods: We conducted one-on-one interviews with 30 pregnant or postpartum patients and 14 health care providers from 2 obstetrics clinics associated with an academic medical center. Semistructured interview guides included questions for patients about their experience and preferences for sharing PGHD and questions for providers about current processes for collecting PGHD, opportunities to improve or expand the collection of PGHD, and challenges faced when collecting and using this information. Interviews were conducted by phone or videoconference and were audio recorded, transcribed verbatim, and deidentified. Interview transcripts were analyzed deductively and inductively to characterize and explore themes in the data.

Results: Patients and providers described how PGHD, including physiologic measurements and experience of symptoms, were currently collected during and between in-person clinic visits for obstetric care. Both patients and providers reported positive perceptions about the collection and use of PGHD during pregnancy. Reported benefits of collecting PGHD included the potential to use data to directly inform patient care (eg, identify issues and adjust medication) and to encourage ongoing patient involvement in their care (eg, increase patient attention to their health). Patients and providers had suggestions for expanding the collection and use of PGHD during pregnancy, and providers also shared considerations about strategies that could be used to expand PGHD collection and use. These strategies included considering the roles of both patients and providers in reporting and interpreting PGHD. Providers also noted the need to consider the unintended consequences of using PGHD that should be anticipated and addressed.

Conclusions: Acknowledging the challenges, suggestions, and considerations voiced by patients and providers can inform the development and implementation of strategies to effectively collect and use PGHD to support patient-centered care during pregnancy.
Introduction

Patient-centered care can improve health outcomes by addressing each patient’s individual needs, increasing patients’ ownership of their health decisions, and improving patient-physician relationships [1-4]. In obstetrics, patient-centered care is recognized as important, yet providing this care during pregnancy remains challenging [5-8] as providers need to gather information from patients about their health and well-being throughout their pregnancies. To facilitate the gathering of person-centered information, there is increasing interest in the role of patients in reporting health-related data to their providers to inform patient-centered care.

Patient-generated health data (PGHD) is any health-related information that is gathered from or recorded directly by patients [9-11]. These data include self-reported symptoms, health behaviors, and physiologic measurements. While PGHD is frequently gathered during in-person appointments, opportunities also exist to collect these data between visits. To date, the collection of PGHD between in-person appointments to inform patient care has largely focused on physiologic measurement data, such as blood glucose levels and blood pressure [12-18]. The collection of these measurements is of particular interest during pregnancy, as diabetes and hypertension present common and serious risks to both mothers and their babies [19-27]. Although other aspects of patient-reported health status have been identified as important to informing patient care during pregnancy, such as quality of life, pain, and mental health status [28], limited evidence exists about the collection of these data between in-person appointments, or about the use of this information to inform patient care.

Patient sharing of PGHD between in-person appointments has been shown to improve patient-provider communication [29], enhance patients’ involvement in their clinical visits [30], and increase insight into patients’ health between clinical visits [31]. While evidence is building to understand if and how the use of PGHD can improve health outcomes [32], it is largely understudied in the context of pregnancy [33,34]. The use of PGHD may be particularly beneficial to improve obstetric care, as pregnancy encompasses a period during which many individuals experience frequent changes in their health status, and there are potentially serious complications that can occur that can impact maternal and infant health outcomes.

While there is growing interest in implementing strategies to collect PGHD, there has been little exploration of the experiences of patients and providers as they share and receive these data [35]. When implementing strategies to collect and use PGHD to inform patient care, technological considerations, such as integration of data into the electronic health record [12-14], have been at the forefront of research efforts. Less attention has been paid to the experiences of patients and providers as they collect and report PGHD, their perceptions of the impact of using PGHD, and the practical considerations that are critical to the implementation of strategies to expand the collection and use of these data. Exploring the perspectives of both patients and providers is, therefore, critical to improving our understanding of their needs and preferences, many of which should be acknowledged and addressed in clinical guidelines, reimbursement strategies, policy, and rules of engagement for the collection and use of PGHD [35].

This study aims to explore the perspectives of pregnant patients about sharing PGHD and the perspectives of obstetric providers about collecting and using PGHD for clinical decision-making during pregnancy. We were interested in understanding the benefits of using PGHD, as perceived by patients and providers, as well as the challenges that each group noted. Finally, we sought to gather patients’ and providers’ suggestions for ways to improve or expand the collection and use of PGHD during pregnancy.

Methods

Study Design and Setting

This exploratory qualitative study was guided by a constructivist and interpretivist research paradigm [36]. Through one-on-one interviews, we sought to explore the perspectives of our study participants within the unique contexts of their roles and experiences. We recognize the reflexivity of our research team in our data collection and the interpretation of our study findings, where research team members included bachelor-trained and doctoral-trained health services researchers. The reporting of our findings is guided by the Standards for Reporting Qualitative Research checklist [37].

We conducted one-on-one interviews with patients and providers from 2 obstetrics and gynecology ambulatory care clinics at The Ohio State University Wexner Medical Center, an academic medical center (AMC), between September 2020 and January 2021. Patients who were 18 years or older, pregnant or up to 90 days postpartum, and spoke English were eligible to participate. Eligible providers included physicians and nurses who worked in either or both clinics. Purposeful sampling was used to recruit patients to the study by telephone call inviting their participation, while providers were recruited by email. Emails sent to providers included a Qualtrics survey link to indicate their interest in participating and their preference for a telephone or videoconference interview.

Data Collection

Separate semistructured interview guides were used to support data collection from patients and providers (Multimedia Appendices 1 and 2). These interview guides were developed by 3 members of the research team (ASM, SRM, and NF) who worked in either or both clinics. Purposeful sampling was used to recruit patients to the study by telephone call inviting their participation, while providers were recruited by email. Emails sent to providers included a Qualtrics survey link to indicate their interest in participating and their preference for a telephone or videoconference interview.
symptoms and physiologic measures. The patient interview guide was tested with 2 individuals—1 pregnant and 1 postpartum—before finalizing the interview questions. Provider interviews asked about current strategies for collecting patient-generated information, opportunities to implement new strategies to collect this information in the future, and potential challenges faced when collecting this information.

Patient interviews were conducted by 2 female members of the research team who were either doctoral-trained or bachelor-trained (SRM and Abigail Petrecca). Patients did not know their interviewer prior to their interview. Patients were contacted by telephone and were given the option to complete the interview at the time of the call or schedule their interview at another time that was convenient for them.

Providers who were interested in participating in the study from the initial recruitment email provided a preferred time to schedule either a phone or videoconference (ie, Zoom) interview. Provider interviews were completed by 2 members of the research team, 1 female and 1 male, who were both doctoral trained (SRM and NF). Most providers did not know their interviewer prior to their interview; however, some providers had met their interviewer in a professional capacity prior to their interview. All interviews were audio-recorded and transcribed verbatim to permit rigorous qualitative analysis.

Data Analysis
We used thematic analysis to code the transcripts from all interviews [38]. First, we created separate preliminary coding dictionaries for the patient and provider interview transcripts based on questions from the semistructured interview guides (Multimedia Appendix 3). Three doctoral-trained or bachelor-trained members of the research team (SRM, NF, and Holly Heffer) then coded 2 patient transcripts and 2 provider transcripts using these preliminary coding dictionaries. The coders met to discuss discrepancies in initial coding and refined the coding dictionary. Two of the initial coders (SRM and Holly Heffer) individually coded the remaining transcripts using the refined coding dictionary, meeting frequently to ensure consistency between the coders. After this deductive coding, the 2 coders met to discuss emergent subthemes they identified during the coding process and inductively developed subcodes that were added to the coding dictionary. One coder (Holly Heffer) then applied these subcodes to all the transcripts. The coding team reached thematic saturation based on consensus among coders that themes fully covered emergent topics across transcripts [39]. ATLAS.ti software (ATLAS.ti Scientific Software Development GmbH) was used to support the coding and analysis process.

Ethical Considerations
The Ohio State University’s institutional review board approved this study (2020B0038). Participation was voluntary and all participants provided verbal informed consent. Interview transcripts were deidentified to protect participant privacy and confidentiality. Patients and nonphysician participants received a US $25 gift card in appreciation for their participation.

Results
Participant Characteristics
Interviews were conducted with 30 patients and 14 providers. Patients had a mean age of 30 years and included 22 pregnant individuals (mean gestational age: 28.6 weeks) and 8 postpartum individuals (mean weeks postpartum: 6.3). Providers included 9 physicians and 5 nurses. Patient interviews lasted an average of 16 minutes, while provider interviews lasted an average of 26 minutes.

Thematic Analysis
Overview
Three themes were identified across patient and provider interviews: (1) current collection of PGHD during pregnancy, (2) suggestions for reporting PGHD during pregnancy, and (3) the impact of reporting PGHD during pregnancy. A fourth theme was identified only from provider comments: (4) considerations for expanding the collection of PGHD during pregnancy. Themes and their respective subthemes are discussed below and summarized in Table 1.

\(^a\)PGHD: patient-generated health data.
Current Collection of PGHD During Pregnancy

Patients and providers described the current collection, reporting, and use of PGHD during pregnancy. Patients and providers reported that the majority of PGHD were collected or reported during in-person appointments. It was noted to be less common for patients to report PGHD or for providers to collect PGHD between their appointments.

Providers described collecting PGHD related to symptoms, as well as self-reported physiologic measurements including blood pressure and blood glucose values, and noted using these data to direct patient care. Although information about symptoms was predominantly collected in person, providers reported informing patients to call the AMC if they experienced any concerning or worsening symptoms between visits. For example, 1 provider described:

I tell patients to keep a log [of fetal kicks] if they feel like, you know, to get a basis for what their babies do, because some babies are more active and some are less active. So, typically we're not like reviewing those logs. I just tell them to keep that information so if they noticed that it's less frequent, they can, you know, let us know. [provider 3]

Providers commented that they asked some patients to regularly measure their blood pressure at home between appointments and contact their provider if their blood pressure exceeded a certain limit. Providers also reported that they asked patients with diabetes to track their blood sugar levels at home (taking between 4 and 8 daily measurements) and share those values with them each week. Patients most frequently reported sharing blood sugar values with a clinic nurse via email.

Suggestions for Reporting PGHD During Pregnancy

Patients and providers described several opportunities to improve or expand the collection of PGHD between in-person appointments.

Use Patient Portal for PGHD Collection

For physiologic measurements that were already being reported between appointments to monitor hypertension and diabetes (ie, self-reported blood pressure and blood glucose measurements), patients suggested that it might be better to report this information in the AMC’s patient portal, where the data could be stored and available for the whole care team to view. One patient suggested:

I think I’d rather have it in the patient portal because then it’s like recorded. It’s logged, everyone has access to it. So, it’s not just one person has an email, you know, the whole staff team could have availability of it and then you have it. [patient 13]

Use Reminders to Collect PGHD

Patients and providers also commented that reminders might improve adherence to taking and reporting these measurements. As 1 provider suggested:

We probably could be better about being sure that patients are potentially even sent reminders about like how often they should be checking their blood pressures ...whether it be morning and night or just one time during the day. You know, it’s sending a reminder to them to be like, “Hey, can you enter your blood pressure for the day?” [provider 9]

Collect Information About Symptoms

For patients with diabetes or hypertension, providers suggested collecting additional information about symptoms between in-person appointments; for example, asking about complications among patients with diabetes, as 1 provider suggested: “With the diabetic patients, I think it would be helpful to know, are you having anything that could be signs and symptoms of ketoacidosis” (provider 5). Another provider suggested asking about symptoms of pre-eclampsia: “I think certainly if we have a patient who has preeclampsia, asking them for symptoms like headache, change in vision, things like that would be important” (provider 8).

Expand Collection of PGHD to Health Concerns That Are Currently Only Assessed in Person

Patients and providers also proposed that it could be useful to collect PGHD between appointments related to health concerns that were currently only assessed in person, including changes in fetal movement and evaluating mental health status. One provider described the opportunities to collect information about fetal movement:

With like you mentioned earlier, fetal movement, there’s no formalized way that we do that except, you know, talk to people in office visits. But if you want to collect data, that would be a good thing to do if patients could just weekly send them something saying, yes fetal movement has been the same, or fetal movement has been less, or things like that. [provider 5]

With regard to evaluating mental health status, 1 patient recommended:

Maybe the postpartum depression, stuff like that, maybe have them look more into that. Because the only time I’ve done the questionnaire for that was when I took my twins to the pediatrician. [patient 11]

A provider echoed this suggestion:

I think if there could be some sort of system where it tracks people’s mood and then if it was really bad, you know some certain threshold, that it sent a notification to the provider. I think that would be good, especially for postpartum depression. [provider 2]

Impact of Reporting PGHD During Pregnancy Between In-Person Appointments

Patients and providers also noted the positive impacts of reporting PGHD during pregnancy, including that sharing PGHD helped to inform patient care and helped to encourage patients’ involvement in their care.

Informs Patient Care

First, providers commented that reporting PGHD allowed them to identify issues and adjust patient care between clinical visits.
For example, collecting blood sugar values allowed providers to adjust diabetes medication, as 1 patient with pregestational diabetes described, “It [reporting blood sugar values] helped, it definitely helped regulate. It helped them to figure out how to adjust my [insulin] pump to regulate my diabetes in general” (patient 23). One provider described how having information between in-person visits helped them make health care decisions for their patients:

- I think that they empower you to feel like you're making the right decision and care for the patient. I mean, I know when I have, when I have the information documented and I have it to work off of, I think two ways in which I think it’s helpful: one, it gives me the comfort level as the provider that I’m making an informed decision about their care. I think, in particular, about the diabetic patients and the hypertensive patients, it’s good to have that information so that you know that you can make changes to their care that feel appropriate and safe. [provider 3]

Providers also noted that knowing PGHD between in-person appointments could help them adjust patient care in a timely manner:

- The blood pressure, blood sugars, you know, in between visits, if we knew that we were having issues, you know, we would be able to assist them quicker than you know, waiting until the next appointment. Or even with postpartum depression, or, you know, fetal movement counts. You know, those things we would be able to address quicker if we did it in between visits. If we were able to track it in between visits. [provider 15]

**Encourages Patient Involvement in Their Care**

Patients and providers also reflected that reporting PGHD could encourage patients’ involvement in their care. One patient explained their increased attention to their health when asked to report information between in-person appointments:

- I just feel like you’re more aware of things and pay more attention to things if you are like sending that information in between appointments...sometimes you wait till you almost have your appointment and then you start paying attention to things. Where if you’re doing it like every week or throughout, then you’re just more aware, and you’re basically paying more attention to what’s going on. [patient 28]

Another patient described their increased sense of control in their health care with regard to reporting their blood glucose levels: “With what I have done with the insulin and some concerns with the gestational diabetes at the beginning, it does make me feel more in control, and it does make me feel like I have more say in my care” (patient 29). A provider’s comment echoed this perspective: “I do think it will give patients more ownership of their care” (provider 5).

Providers also expressed that collecting PGHD could help them understand patients better and potentially strengthen the patient-provider relationship, which might similarly encourage patients’ involvement in their care: “I think it would just allow for a more like solid or strengthened patient-doctor relationship that you know, hopefully the patient would feel that I'm more involved and checking in on her, and kind of aware of what's going on in between visits” (provider 4).

**Considerations for Expanding the Collection of PGHD During Pregnancy Between In-Person Appointments**

Finally, providers mentioned several considerations when discussing opportunities to expand the collection of PGHD to support obstetric care. These fell into the following categories: considerations for the patient role, considerations for the provider role, and considerations for unintended consequences.

**Considerations for the Patient Role**

With respect to patients’ roles in reporting PGHD, providers noted the importance of targeting and tailoring instruments (eg, questionnaires) to collect this information. Providers stressed that PGHD collection from each patient should be personalized to that patient’s individual clinical needs. As 1 provider described:

- Linking certain diagnoses to it and certain conditions to it, it makes them much more targeted and tailored approaches rather than just kind of a “here’s everything you could possibly answer.” And that would be completely overwhelming to people and completely turn them off. [provider 9]

Providers also commented about the need for guidance when asking patients to report information that may be hard to quantify, including the perceived severity of symptoms that are subjective. One provider described this challenge in the context of nausea:

- I think nausea is hard because I think so many women also experience nausea. And we try to manage those women as an outpatient as best as we can. And I think sometimes it’s patient perspective that helps. You know, you can have someone who’s really nauseous and vomits all the time and they’re able to manage that at home with medications. ...And then you have other women who vomit but they feel like their amount of nausea is something they need to be seen for. Their amount of nausea and their amount of vomiting objectively may be less than someone else who’s controlling symptoms at home. So, I think that would be a little tricky. [provider 2]

In another example, a provider explained this consideration in the context of bleeding:

- You know, bleeding is a little bit harder because that’s a little bit, so subjective. But it can be, I think there’s ways to potentially quantify that to people's satisfaction, such that they would feel okay with it. Like in the sense of you know, if you have spotting on your tissue, okay, you know, did you see it again? Or like, check again with like another wipe or in like another like two hours, if it's still there come in. Or if it’s fully filling the tissue paper or even like a panty liner come in, those types of things. [provider 9]
Considerations for the Provider Role

With regard to the provider’s role in reviewing and responding to PGHD, providers stressed the importance of how the data would need to be presented to them. Providers reflected that, depending on the type of PGHD, they may not need to review every value or data point, but rather the data should be presented in a way to alert them to abnormal values that would be cause for concern. One provider gave the example:

I mean some things we need to know, like blood sugars. We have to know every single blood sugar. But you know, perhaps something like a fetal movement count, we don’t really need to know about that until it’s abnormal. [provider 12]

Providers also commented on the importance of presenting the data in a way that could help them understand trends over time (eg, tables or charts), rather than going through data presented as text alone: “If we have a formalized portal, that would be great, that would come up with a you know, a graph or a table rather than have to wade through a bunch of texts” (provider 5).

Additionally, providers identified the importance of assigning roles and responsibilities among the care team to ensure that PGHD was collected appropriately, promptly reviewed, and acted upon by the care team. One provider explained these considerations:

I’d say there’s the systemic issue of you know, who is responsible for making sure that information is read? When is it supposed to be read? And what ways are we supposed to respond to it? Who’s supposed to be responding to it? How frequently are they supposed to be checking? [provider 13]

Considering roles and responsibilities was critical due to the additional workload these processes presented to the health care team, as 1 provider commented:

During pregnancy, my concern with collecting all the information would be about who is assessing it. So, if we are sending out text messages once a week or every day, making sure that there’s a nurse who’s going to be really thoughtful about looking at it so that the concerns, symptoms, complaints are not automatically pushed to the physician to review and look at. I think there’s already a lot of work being done and physician burnout, and so my concern would be that with all this extra data, is that overwhelming the physician’s already limited time and brain capacity during the day to kind of review all that information? [provider 8]

Considerations for Unintended Consequences

Finally, providers described considerations regarding the potential unintended consequences of collecting PGHD. First, providers noted the need to identify and react to emergencies as indicated by patients’ responses. One provider gave an example in the context of a patient reporting changes in fetal movement:

If there was a way for the system to automatically tell the patient if she said, “I’m not feeling the baby move, I have decreased fetal movement,” then there should be no delay. It should be like an automatic response to come to the hospital and get evaluated. That is the only thing. I feel like there’s some liability there if a rare event or something would happen. [provider 4]

Another provider described how processes might be designed to help identify emergencies in the context of identifying pre-eclampsia:

We have the potential for automation to kind of play a factor in the sense that you know, if you have certain triggering blood pressure thresholds that would, you know, rapidly bring that to the attention of somebody, or more specifically guide a patient through, okay you have this blood pressure, is this a second blood pressure you’ve already checked because it was elevated before? If not, you know, re-check it in 15 minutes after you’ve sat down, relaxed, all that thing. Or if this blood pressure is still severely elevated above this level after 15 minutes, you know, please, you know, report to the like emergency room or, you know, call this number specifically so we can get you in touch with the provider and guide you through the care process. [provider 9]

In addition to identifying and reacting to emergencies, providers also expressed consideration that the collection of PGHD may increase the number of nonemergent concerns being reported during pregnancy. One provider explained their consideration:

I think my biggest concern would just be with, with extra data comes up with extra medical intervention. That would be my biggest concern. I think them reporting it would be fine. But would we be more apt to bring people into the hospital then, to assess these symptoms? More testing? When ultimately maybe they were, you know, most of them were fine. [provider 8]

Some providers questioned whether reporting PGHD would result in patients reporting a greater number of concerns, which could also potentially increase medical costs and cause extra work for clinic staff:

I’d be a little bit worried that we would get a lot of responses that we would be following up on that wouldn’t necessarily amount to anything. And that would be a lot of extra work for the staff in bringing those patients in and tracking those outcomes on so many patients that we have. [provider 2]

Discussion

Principal Results

Our qualitative analysis provides insight into patients’ and providers’ perspectives on the value and challenges of collecting and using PGHD to inform obstetric patient care. While the use of PGHD during pregnancy has most commonly been reported for objective physiologic measurements (eg, blood glucose and blood pressure) [40,41], our patient and provider participants...
also expressed interest in the collection of subjective measurements including anxiety, depression, and symptoms indicative of pregnancy complications. Recognizing the interest in PGHD beyond physiologic measurements is important, as studies have demonstrated that the collection of a range of different types of PGHD can improve understanding of the unique context of each patient’s pregnancy. For example, pregnant women with heart disease identified general well-being, mental health, fatigue, and quality of life as important topics for which PGHD, in addition to clinical outcomes specific to cardiac function, may be critical information to share with their providers [42]. Similarly, in a study of pregnant women with gestational diabetes, the collection of PGHD including patient perspectives of anxiety, self-knowledge about diabetes, and social support has been proposed to provide a more comprehensive picture of the patient that helps explain why some patients experience challenges with blood glucose management [43]. Increasing holistic awareness of the patient through the collection of PGHD may also help providers target interventions (e.g., education) as a means to improve maternal health outcomes [44].

The growing emphasis on patient-centered care during pregnancy has brought to light the potential of PGHD as an important factor that can enhance the delivery of value-based care [23,28,45-47]. Evidence is growing surrounding the use and effectiveness of strategies for using PGHD to inform obstetric care. For example, uploading self-reported measures of blood glucose to a patient portal has been associated with improvements in glycemic control in a sample of pregnant and nonpregnant patients [13], and continuous monitoring of blood glucose has been associated with improved neonatal outcomes [46,48]. Evidence will continue to grow from several ongoing clinical trials on this topic, with the greatest focus of these studies on patient-generated physiologic measurements [49,50].

Despite interest in expanding the use of PGHD during pregnancy, little work has investigated the perspectives of stakeholders in the use of PGHD, including those of pregnant individuals providing this information and the providers receiving and using this information to improve obstetric care. While patients and providers in our study commented about the clinical benefits of using PGHD, for which there is a mixture of evidence in the literature [15,51,52], they also suggested the additional benefit of improving patients’ involvement in their care through the collection of PGHD. In nonpregnant populations, the collection of PGHD has been recognized to create an opportunity for self-reflection among patients that can encourage patient-provider communication, which, in turn, increases provider awareness of patient concerns [53]. Similarly, others have suggested additional benefits of using PGHD beyond their impact on health outcomes, such as improved patient satisfaction with care as a result of improved patient-provider communication [29,45,54].

In imagining the expanded use of PGHD to inform obstetric care, providers in our study explained several considerations in the practical implementation of strategies to collect and use this information. These considerations included questions surrounding the patient’s role in reporting PGHD, the provider’s role in using PGHD, and the potential unintended consequences of collecting PGHD. These considerations bring to light how challenging it can be to introduce PGHD into clinical practice. Furthermore, it will be important to evaluate these considerations within the unique context of the multiple ways in which PGHD can be collected, synthesized, and displayed. Examples of methods in operation or development for these purposes include the use of electronic health records and patient portals [12], automated SMS text messages [55-57], mobile health apps [29], wearable devices [58,59], and remote patient monitoring systems [60,61].

While interest in expanding the use of PGHD during pregnancy was expressed by providers in our study, there is little guidance on the collection of PGHD and a paucity of research on using PGHD in this patient population [33,34]. Furthermore, the infrastructure to measure and synthesize PGHD is not extensive in the United States [45]. For example, challenges noted in the literature include how PGHD can be collected, how to best interpret PGHD, and how meaningful thresholds of PGHD are indicative of an action required by the patient or provider [62-64]. Notably, many of the approaches to address these challenges will be specific to providers, their health care systems, and the patient populations they serve.

One mechanism to increase our collective knowledge surrounding the collection and use of PGHD in pregnancy is through the existing call to action for randomized controlled trials in maternal health to standardize the selection, collection, and reporting of outcomes based on PGHD that reflect the perspectives of study participants [65]. Such an endeavor could facilitate the translation of research into clinical practice for PGHD collection and use while increasing contextual knowledge about patient health and health care experiences that can be used to improve the patient-centeredness of obstetric care. Future research should focus on the evaluation of methods for using PGHD in obstetric care to begin to build evidence and inform implementation strategies for this practice.

**Limitations**

One limitation of our study is that the participant population was drawn from a single AMC. Our findings, therefore, represent perspectives specific to the patient and provider populations at our clinical sites. In addition, while our study population included both patients and providers, our analytical approach was not designed to identify convergence or divergence of perspectives across groups. Future research that explicitly assesses similarities and differences in the perspectives of patients and providers on these topics is important to inform interventions for PGHD collection and reporting that meet the needs and preferences of both stakeholder groups. We conducted this study during the COVID-19 pandemic, a period during which pregnant individuals may have experienced changes in their clinical care due to the many impacts of the pandemic. Due to restrictions on in-person research at this time, study participants were recruited by phone or email, which may have influenced their willingness to participate. The remote nature of the interviews, conducted by phone or videoconference, may have also impacted the sharing of information, as compared with an in-person interview. Furthermore, changes in care experienced due to social distancing and other restrictions may...
have increased interest in remote communications, including those that involved the collection of PGHD. Finally, we did not systematically collect participant clinical characteristics, such as pregnancy complications, that could impact participants’ perspectives about PGHD. Including the collection of these data in future studies may be important to understand the perspectives of individuals based on their specific clinical needs.

**Conclusions**

Our qualitative analysis presents patient and provider perspectives on the collection of PGHD and its use during pregnancy. Participant responses collectively supported the use of PGHD to improve obstetric care. While several opportunities to expand the use of PGHD during pregnancy were mentioned, many considerations for implementing strategies to use PGHD were also noted, shedding light on the challenging nature of collecting and using this information in clinical practice.

Abstract

Background: Open-system electronic cigarette (EC) product features, such as battery capacity, maximum output wattage, and so forth, are major components that drive product costs and may influence use patterns. Moreover, continued innovation and monitoring of product features and prices will provide critical information for designing appropriate taxation policies and product regulations.

Objective: This study will examine how product features are associated with the prices of devices sold in web-based vape shops.

Methods: We draw samples from 5 popular, US-based, web-based vape shops from April to August 2022 to examine starter kits, device-only products, and e-liquid container–only products. We implemented a linear regression model with a store-fixed effect to examine the association between device attributes and prices.

Results: EC starter kits or devices vary significantly by type, with mod prices being much higher than pod and vape pen prices. The prices of mod starter kits were even lower than those of mod devices, suggesting that mod starter kits are discounted in web-based vape shops. The price of mod kits, mod device–only products, and pod kits increased as the battery capacity and output wattage increased. For vape pens, the price was positively associated with the volume size of the e-liquid container. On the other hand, the price of pod kits was positively associated with the number of containers.

Conclusions: A unit-based specific tax, therefore, will impose a higher tax burden on lower-priced devices such as vape pens or pod systems and a lower tax burden on mod devices. A volume- or capacity-based specific tax on devices will impose a higher tax burden on vape pens with a larger container size. Meanwhile, ad valorem taxes pegged to wholesale or retail prices would apply evenly across device types, meaning those with advanced features such as higher battery capacities and output wattage would face higher rates. Therefore, policy makers could manipulate tax rates by device type to discourage the use of certain device products.

Introduction

The electronic cigarette (EC) market has experienced a surge in growth, especially among adolescents and young adults in the United States, which prompted a series of government regulatory actions such as flavor product restrictions and e-cigarette taxes at various government levels [1]. Although ECs pose addiction risks among adolescents and young adults, they also have the potential to help people who smoke combustible tobacco to quit smoking [2], making EC regulations challenging and controversial. Nonetheless, effective EC regulations require that policy makers weigh the benefits and risks of ECs [3,4].

One important feature distinguishing ECs from cigarettes is the wide range of EC models, ranging from basic disposable models to more complex rechargeable devices, which may affect product appeal, use patterns, and health consequences. The use of certain EC devices such as mods and pods may be associated with more frequent EC use and nicotine dependence symptoms [5-7]. The majority of adolescent and young adult EC users report using rechargeable pods (eg, JUUL) [7-11], while smokers who successfully quit smoking are more likely to use open-tank systems or mods [12,13]. The choices of models are further associated with the frequency of EC use and nicotine dependence, making EC devices or models an important product attribute for policy makers to regulate [5-7].

In addition to regulating product attributes by implementing product standards, policy makers could also impose taxes on ECs, including devices, to change their appeal. To attract new users, many EC retailers offer starter kits at discounted prices [14,15], which typically include a rechargeable device and replaceable e-liquid tanks or pods [16,17]. Therefore, taxes and promotion restrictions may be needed to decrease the affordability or appeal of these starter kits to prevent youth initiation. On the other hand, the perceived cost of the devices may make ECs seem expensive compared to traditional tobacco products, which may prevent people from switching from cigarettes to ECs [18,19]. Therefore, monitoring EC device prices and attributes associated with price differences is crucial for policy makers and public health officials to make informed decisions about EC taxation and other pricing policies [5,6].

Rapid advancements in technology have resulted in an increasing number of EC devices being offered in the market, making it challenging to monitor the market and keep track of pricing trends. The existing surveillance data also have the limitation of only providing information on brands sold in brick-and-mortar stores and missing the products sold in other retail channels such as vape shops and web-based stores. Prior studies examining web-based EC stores or vendors revealed that the prices offered digitally were much cheaper than physical stores and few collected sales taxes in their state of business or based on shipping addresses [20,21]. Web-based retail websites engage in a variety of promotional strategies, such as promo or discounts, customer rewards, loyalty programs, and so forth [20,21]. Moreover, they use multiple marketing techniques such as linking their websites to social media platforms, using celebrity endorsement, posing misleading messages about ECs (eg, ECs are healthier, cleaner, and effective as a cessation aid), and so forth, to attract younger population [22-24]. As the US Food and Drug Administration (FDA) issued denial orders to approximately 1 million EC-flavored products in 2020, how this will shift the marketplace and product features remains unknown. It is therefore critical to conduct comprehensive and rapid surveillance on EC devices.

Finally, a growing literature suggests that EC taxes and prices are effective in reducing EC use, with a 10% increase in prices associated with an 11.5% decrease in sales or purchases [25]. However, it is also shown that the current tax bases for ECs vary significantly by state; some states adopt specific taxes, whereas others adopt ad valorem taxes. Given that ECs have a wide range of configurations and features, different tax bases may lead to different tax burdens on different EC types (eg, vape pens vs disposables) [26]. The taxation policies also differ by state regarding whether to tax devices, which are the more durable components compared to refillable cartridges or e-liquid in open-system ECs. A better understanding of EC devices and their costs is needed to guide taxation policies for devices.

In response to these research needs, this study aims to bridge the gap in the literature by analyzing EC device data from popular web-based retailers to evaluate the distribution of device prices and features and investigate the associations between device characteristics and prices in the marketplace using a hedonic pricing model [27]. The results of this study will provide insights to policy makers considering product standards and taxation policies for ECs.

Methods

Data Sources

After conducting extensive research through a combination of Google searches and Reddit discussions in 2021, we curated a list of 5 popular web-based vaping shops. Using the latest information available, we prioritized the top results from Google searches and Reddit threads. Specifically, we focused on the top 3 results without physical addresses from Google and identified 2 highly regarded shops without physical addresses from a Reddit discussion dated in 2020. This comprehensive approach ensured that our selection process was thorough and reflective of the most current and popular web-based vape shops available.

From April to August 2022, we conducted a study on open-system EC device products sold from these 5 web-based vape shops. In total, we identified 1166 reusable products after charging or changing batteries. These products include starter kits, device-only products, and container-only products. Starter kits refer to products that include both the heating device and containers, such as mod kits, pod kits, and vape pens. Device-only products only include the heating devices, such as mod and pod devices. Container-only products are just replacement tanks or pods and contain no liquid or solutions. To examine the relationship between prices and device attributes, we focused our analysis on starter kits and device-only products as replacement tanks or pods are components instead of devices.
Outcome Variable

The outcome variable in our analysis was the log-transformed effective price (ie, after discounts) in US dollars, extracted from the store web pages.

Explanatory Variables

The following product attributes were selected for regression analysis: the number of containers (ie, tanks or pods or cartridges), container volume size (ie, maximum e-liquid capacity per tank, pod, or cartridge in mL), maximum output wattage (divided into 3 groups with each group comprising approximately one-third of the total observations: 5-39 W, 40-85 W, and more than 85 W), and battery capacity (divided into 3 groups: less than 900 mAh, 900-1499 mAh, and 1500 mAh and more). For the products with missing battery capacity (n=488) or missing wattage information (n=91), we manually checked each product web page. We found that the missing battery capacity in mod kits (n=273) or mod device–only products (n=209) was due to their use of 18,650- or 21,700 mAh–sized batteries and a lack of inclusion in the kits or devices. The missing battery capacity information on other products (n=6) and missing wattage information were purely due to a lack of information on the product web pages. To fully use the sample that we collected for the analysis, a missing category was added for output wattage and battery capacity. In addition to these attributes, the number of coils, rings, cables, chargers, batteries, glasses, and chips were included as control variables.

Statistical Methods

We used a 3-step approach to investigate pricing patterns and product attributes of EC devices sold in web-based vape shops. First, we computed the price distribution for all EC device products and identified the respective brands. Second, we examined the battery capacity and maximum output wattage features of products for starter kits and device-only products. Finally, we analyzed a linear regression model to examine the association between device prices and product attributes using a hedonic pricing model [27], controlling for store-specific unobservable factors using store-fixed effect and stratified by device types (mod kit, mod devices only, pod kits, and vape pens). Pod device–only products were excluded from the analysis because of the small sample size (n=8). SEs were clustered at the store level to account for intertemporal correlations among products sold in the same store. As the outcome variable was the log form of device price, our estimates reflect the percentage change in price due to a 1-unit change in a continuous independent variable. In the case of a categorical independent variable, our estimates indicate the percentage change in price for being in a certain category compared to the comparison category.

Given that our sample comprises a large number of brands (93 brands) and many brands (59/93, 63% brands) have fewer than 5 products, we did not control for brand-fixed effects. Nonetheless, we conducted sensitivity analysis and estimated alternative models where brand effects are controlled using random effects and generalized estimating equations.

Ethical Considerations

In this study, we collected data from 5 US-based, web-based vape shops. Thus, no human subjects were involved, and the determination of no human subjects was approved by the Ohio State University institutional review board (study 2020E1328).

Results

Table 1 shows the summary statistics of EC device products. We identified 1166 products from 93 unique brands, including 427 mod kits, 348 pod kits, 50 vape pens, 229 mod device–only products, 8 pod device–only products, and 104 replacement tanks or pods. Among starter kits, mod kits have a mean price of US $51.46 (SD US $24.23), which is significantly higher (P<.001) compared to pod kits (US $24.72, SD US $8.78) and vape pens (US $29.50, SD US $15.60). The mean price of mod kits is significantly lower (P<.001) than that of mod device–only products (US $58.93, SD US $41.98). In addition, the median price of mod starter kits is about US $6 cheaper than the sum of individual mod device and e-liquid container prices (US $44.99 and US $8.99, respectively), suggesting that mod kit prices are heavily discounted.

aEC: electronic cigarette.
The price distribution for all devices except pod kits, which follow a normal distribution, is positively skewed (i.e., having high prices; Figures 1-4). Few pod device–only products (n=8) were identified, and they were significantly less expensive than pod kits. This reveals that web-based stores are more likely to sell pod devices in starter kits instead of individual products. The price distributions of vape pens and pod kits are similar: the lower quartile and median prices for vape pens and pod kits are almost identical.

**Figure 1.** Price distribution of mod products from 5 US-based popular vape shops from April to August 2022 (mod device: n=229, mod kit: n=427).

**Figure 2.** Price distribution of pod products from 5 US-based popular vape shops from April to August 2022 (pod device: n=8, pod kit: n=348).
Table 2 displays the distribution of product attributes based on the device type. Pod kits tend to have more replacement tanks or pods included in the kits than mod kits and vape pens. However, the volume size of the containers in mod kits is significantly larger than that in pod kits and vape pens. Most mod kits (396/427, 92.74%) have a battery capacity above 1500 mAh (123/427, 28.81%) or high-end 18,650- and 21,700 mAh–sized batteries (273/427, 63.93%), which are not included in the kits. On the other hand, most pod kits (282/348, 81.04%) have a battery capacity below 900 mAh (152/348, 43.68%) or between 900 mAh and 1500 mAh (130/348, 37.36%). This is probably because these products also typically have much higher concentrations of nicotine so they can still deliver high doses of nicotine with lower wattage and therefore do not need the
same battery power. Of the 50 vape pens, 21 (42%), 14 (28%),
and 12 (24%) have a battery capacity above 1500 mAh, between
900 mAh and 1500 mAh, and below 900 mAh, respectively.
Additionally, 90.63% (387/427) of mod kits have output wattage
between 40 W and 85 W (194/427, 45.43%) or above 85 W
(193/427, 45.2%), while the majority of pod kits (293/348,
84.2%) have output wattage less than 40 W (216/348, 62.07%) or
between 40 W and 85 W (77/348, 22.13%). Most vape pens
(21/50, 42%) have output wattage below 40 W. The majority
of the mod device–only products (209/229, 91.27%) are sold
without including batteries (18,650 or 21,700 mAh) in
web-based vape shops. More than half (154/229, 67.25%) of
the mod device–only products have output wattage greater than
85 W. These findings suggest that mod kits and mod
device–only products are distinct from pod kits and vape pens
in terms of battery capacity, output wattage, and volume size.

Table 3 illustrates the association between device prices and
product attributes, stratified by device types (mod kit, mod
device–only products, pod kits, and vape pens). We found that
the price of mod kits is not significantly associated with the
number of tanks or pods ($P_{.84}$) included or with the volume
size of the container ($P_{.07}$). Mod kits with advanced battery
sizes (18,650 or 21,700 mAh) are priced 21.5% higher than
those with less than 900 mAh batteries, even though the battery
is not included in the kit. Mod kits with output wattage over 85
W are priced 27.3% higher than those with less than 40-W
output. Similarly, the prices of mod device–only products are
higher when they have greater battery capacity or output wattage.

On average, the price of pod kits is 10% higher as the number
of tanks or pods increases. However, the price of pod kits is not
significantly associated with the volume size of tanks or pods
($P_{.60}$). Furthermore, the price of pod kits is positively
associated with battery capacity, with a capacity between 900
mAh and 1500 mAh and greater than 1500 mAh being 16%
and 23.9% higher, respectively, than those with less than 900
mAh battery. The price of pod kits with output wattage between
40 W and 85 W is 12.5% higher compared to those with output
wattage less than 40 W.

Unlike mod and pod devices that can be sold as part of a starter
kit or as individual devices, vape pens are rechargeable devices
sold exclusively as starter kits. The price of vape pens is
positively associated with volume sizes, with every 1-mL
increase in volume size associated with 3.7% higher prices. In
addition, compared to vape pens with a battery capacity below
900 mAh, those with a battery capacity above 1500 mAh are
priced 11.9% higher. Output wattage is not significantly
associated with the prices of vape pens.

The sensitivity analysis using a random effect model or
generalized estimating equations to account for brand effects
is reported in Multimedia Appendix 1. The results are very
similar to our main findings using ordinary least square
regressions.

Discussion

Using unique data gathered from 5 web-based stores that sell nationally, this study examines the pricing of rechargeable EC starter kits and devices. The findings reveal that the prices of mod devices and starter kits are on average US $59 to US $51, respectively, approximately twice as high as those of pod starter kits (US $25) and vape pens (US $30). Moreover, all rechargeable devices are much more expensive than disposable devices (cost about US $8) [28]. The average price of mod starter kits (US $51) from the 5 stores is similar to the price reported in a 2016 study (US $56) [20], which evaluated starter kit costs from 44 web-based vendors. Therefore, consumers considering using ECs, especially mod products, can expect relatively high initial costs. This supports previous findings suggesting that consumers tend to choose more affordable disposable options when first experimenting with ECs [29].

Furthermore, we discovered that the price distribution of both mods (starter kits and devices) and vape pens are positively skewed, suggesting that certain products are priced much higher than their average counterparts. This finding is consistent with prior studies based on web-based vendors and studies using the Standardized Tobacco Assessment for Retail Settings: Vape Shops surveillance tool to document prices that found that advanced mod products are priced much higher than regular mods [30,31].

The price analysis of EC devices further illustrates that greater battery capacity and output wattages are associated with higher device or kit prices. This is not surprising given that battery capacity and output wattage are key factors that determine nicotine delivery and user behaviors [21,32,33]. Studies have shown that tank ECs (eg, mod devices) can achieve much higher blood nicotine levels over a longer duration [34]. Survey data also suggest that smokers who successfully quit cigarette smoking using ECs are more likely to use tanks or mod devices [12,13]. It is possible that the higher output wattage and battery capacity, which ensure longer use before needing to be charged and reduce the risk of unexpected power outages, lead to more frequent e-cigarette use and may have assisted in transitions from smoking to vaping. However, greater battery capacity and output wattages could also attract youth and young adult users who report often trying or using multiple devices. Nonetheless, higher output wattage could also expose users to higher toxicant emissions and exposure to higher amounts of particulate matter, which may be harmful to human health [35,36]. The FDA and policy makers may need to take all of the factors (eg, product appeals in youth vs adult smokers) into consideration when setting product standards for batteries and volume sizes.

Our findings provide several key insights about designing EC pricing policies (eg, taxes) for devices. While there is growing literature that increasing EC taxes and prices reduces consumption, there is a lack of evidence that distinguishes between EC types and components, such as devices versus consumables such as e-liquid and cartridges. As a growing number of states start to tax ECs, not all EC-taxing states impose excise taxes on devices. Moreover, there is no clear guidance on how best to tax devices such as choosing tax rates and bases. Our findings suggest that EC starter kits or devices vary significantly by type, with mod prices being much higher than pod and vape pen prices. A unit-based specific tax therefore will impose a higher tax burden on lower-priced devices such as vape pens or pod systems and a lower tax burden on mod devices. A volume- or capacity-based specific tax on devices will impose a higher tax burden on vape pens with large container sizes. On the other hand, ad valorem taxes based on wholesale or retail prices will impose uniform tax burdens across all device types and consequently tax devices with higher battery capacities and output wattage at a higher rate. Therefore, policy makers could manipulate tax rates by device type to discourage the use of certain device products according to the health literature on the relative harms of ECs. For example, if cheap devices are preferred by smokers who are considering ECs, ad valorem tax may be preferred over specific taxes as the former imposed lower taxes on lower-priced products. In contrast, if the goal is to prevent youth from trying ECs and youth are more interested in cheap devices, a specific tax will be more favorable than ad valorem taxes in raising the prices of cheap devices.

In addition to taxation policies, our findings also highlight the importance of promotion restrictions. In web-based stores, the prices of mod starter kits are even lower than those of mod devices, suggesting mod starter kits are discounted. If mod products are mostly used by adult smokers to quit and the initial costs of ECs are a barrier to completely transitioning from cigarettes to ECs, such discounts should be allowed. However, if mods are found to attract youth and young adults, promotion restrictions may be needed to reduce their affordability.
Finally, we used data collected from 5 web-based stores that sell nationally. Although these data are not representative of the US web-based EC marketplace, they provide valuable information on device attributes and costs. It is also important to acknowledge that web-based stores or sales lead to challenges for regulations, including low prices and low compliance with state taxes [21,37]. A prior study further shows that there are international sites that sell ECs to the United States and these sites did not have age verification and detectable health warnings [38]. Future research is needed to understand how international markets in the web-based space may impact use behaviors, price minimization, and policy effectiveness.

There are some limitations of this study. First, we have very limited data on pod devices sold as stand-alone products and therefore do not have sufficient statistical power to conclude the pricing differences between pod starter kits and pod devices. Future studies are needed to address this gap. Second, we did not control for all the factors that affect prices because many factors are either not available or not measurable, such as production costs, consumer preferences, and so forth. Future studies may address this limitation. Nonetheless, we assessed all attributes that are presented on the web-based store web page, which arguably contains all the information that consumers see when they make purchasing decisions. Finally, the US FDA has approved a limited list of EC products. Many e-liquid products have or will become illegal for either failing to submit a premarket approval application or having their applications denied. Therefore, the demand for open-system devices could be significantly reduced as a result. However, given that many e-liquid products remain available in the marketplace and devices could still be used with 0-nicotine e-liquid, we consider monitoring device features continuing to be an important endeavor.

In summary, we provide the first assessment of how product features are associated with device or starter kit prices for the following distinct device types sold in the US digital market: mods, vape pens, and pods. The results can be used to design EC product standards and pricing policies by policy makers.

Abstract

Background: Common interventions for musculoskeletal pain disorders either lack evidence to support their use or have small to modest or short-term effects. Given the heterogeneity of patients with musculoskeletal pain disorders, treatment guidelines and systematic reviews have limited transferability to clinical practice. A problem-solving method in artificial intelligence, case-based reasoning (CBR), where new problems are solved based on experiences from past similar problems, might offer guidance in such situations.

Objective: This study aims to use CBR to build a decision support system for patients with musculoskeletal pain disorders seeking physiotherapy care. This study describes the development of the CBR system SupportPrim PT and demonstrates its ability to identify similar patients.

Methods: Data from physiotherapy patients in primary care in Norway were collected to build a case base for SupportPrim PT. We used the local-global principle in CBR to identify similar patients. The global similarity measures are attributes used to identify similar patients and consisted of prognostic attributes. They were weighted in terms of prognostic importance and choice of treatment, where the weighting represents the relevance of the different attributes. For the local similarity measures, the degree of similarity within each attribute was based on minimal clinically important differences and expert knowledge. The SupportPrim PT’s ability to identify similar patients was assessed by comparing the similarity scores of all patients in the case base with the scores on an established screening tool (the short form Örebro Musculoskeletal Pain Screening Questionnaire [ÖMSPQ]) and an outcome measure (the Musculoskeletal Health Questionnaire [MSK-HQ]) used in musculoskeletal pain. We also assessed the same in a more extensive case base.

Results: The original case base contained 105 patients with musculoskeletal pain (mean age 46, SD 15 years; 77/105, 73.3% women). The SupportPrim PT consisted of 29 weighted attributes with local similarities. When comparing the similarity scores for all patients in the case base, one at a time, with the ÖMSPQ and MSK-HQ, the most similar patients had a mean absolute difference from the query patient of 9.3 (95% CI 8.0–10.6) points on the ÖMSPQ and a mean absolute difference of 5.6 (95% CI 4.6–6.6) points on the MSK-HQ. For both ÖMSPQ and MSK-HQ, the absolute score difference increased as the rank of most similar patients decreased. Patients retrieved from a more extensive case base (N=486) had a higher mean similarity score and were slightly more similar to the query patients in ÖMSPQ and MSK-HQ compared with the original smaller case base.

Conclusions: This study describes the development of a CBR system, SupportPrim PT, for musculoskeletal pain in primary care. The SupportPrim PT identified similar patients according to an established screening tool and an outcome measure for patients with musculoskeletal pain.

**Introduction**

**Background**

Musculoskeletal pain conditions are the leading cause of disability and a major societal burden worldwide [1]. Common interventions for musculoskeletal pain either lack evidence to support their use or, at best, have modest or only short-term effects [2,3]. Treatment guidelines are based on randomized controlled trials considering effects on the group level with little or no consideration for the huge variation in patient stories and individual symptoms, even within more narrowly defined diagnostic entities, for example, low back pain. Thus, applying group-level evidence to individual patients and the relevance of one-size-fits-all treatment guidelines have been questioned [4]. In addition, the highly selected patients in most clinical trials do not match clinical settings where patients often present with comorbidities and large variations in symptoms and clinical history. Thus, clinicians are at unease with and often do not follow evidence-based guidelines [5]. Different attempts at subgrouping patients have been explored [6,7], but most attempts of subgrouping patients according to symptoms and clinical characteristics, and offering matched treatments (stratified care), have yet to demonstrate superior treatment outcomes [8].

It has been argued to focus less on diagnostic classification in musculoskeletal pain and more on prognostic factors to inform treatment decisions and improve treatment outcomes [9]. Factors influencing patients’ course and treatment outcomes are many, making decisions on the best treatment approach challenging for clinicians. In this situation, artificial intelligence (AI) may add decision support [10]. An intriguing AI method relevant to musculoskeletal pain disorders is case-based reasoning (CBR), where experiences from past problems and their solutions are used to solve new problems [11]. CBR may advance decision-making for musculoskeletal pain disorders and improve patient care and outcomes by providing information for tailoring the treatment. CBR has been used in fields such as the oil industry [12]; weather prediction [13]; and different aspects of health care [14], for example, kidney functioning in an intensive unit setting [15]; assessment and diagnosis of depression in palliative care [16], follow-up of patients who underwent stem cell transplantation [17], and diabetes management [18]. More recent studies have used CBR in diagnostics [19] and promoting self-management [20,21]. Yin et al [19] developed a CBR-based decision support system capable of differentiating between 2 types of probable primary headaches challenging for physicians in clinical care. The system was found to have high accuracy and differentiated probable migraine and probable tension-type headache much better than a guideline-based system. In a previous study from our research group, CBR was used to capture patient experiences and find the best treatment advice for patients by evaluating how to carry out a similarity-based retrieval [22]. This was further used for tailoring self-management support for patients with low back pain through a smartphone app. The app was provided as an adjunct to usual care and compared to usual care only in a randomized controlled trial. The patients in the intervention group reported a larger improvement in disability compared to those receiving usual care only [20]. The effect of the app has recently also been tested in a 3-armed randomized controlled trial among patients with neck and back pain in the specialist care. The authors reported no differences in effects among use of the app, a web-based nontailored self-management support tool, or usual care alone [21].

**Objective**

In this study, we used CBR to build a system for decision support in patients with musculoskeletal pain seeking physiotherapy care. This study describes the development of the system and demonstrates the system’s ability to identify similar patients.

**Methods**

The CBR Cycle Versus Physiotherapy Way of Solving a Problem

CBR has been described as a 4-step process, known as the CBR cycle: retrieve, reuse, revise, and retain (Figure 1) [11]. The most similar case or cases are retrieved from the collection of previous cases (stored in the case base), where a case is a set of data that represents a problem with its solution from the past. Knowledge of the CBR model (eg, adaptation rules) is applied to fit a new problem to an existing solution (reuse). The solution for the new case is tested for success and revised if necessary. The system learns as useful experiences of the new case are retained for future problem-solving, such that the case base is continuously updated with new or modified cases. Building and refining the collection of cases, the case base, is an important step in the CBR process [23]. The CBR methodology assumes that similar problems have similar solutions. Translated to medical terms, the problem is defined by a detailed description of the patient’s characteristics, signs, and symptoms, and the solution is defined by the treatment leading to a successful outcome. New patients are matched to previous similar patients (problems) with a successful outcome, and their treatment is used to inform treatment for the new patient (solution).
Figure 1. The case-based reasoning cycle, adapted from the study by Aamodt and Plaza [11].

An important reason for choosing CBR as the AI method of choice in this study (Figure 1) was its logic and resemblance with how physiotherapists approach new patients in clinical care (Figure 2). When a new patient consults a physiotherapist (Figure 2), the physiotherapist collects information about the patients’ symptoms, performs a clinical examination, and then tries to recall his experiences with similar patients from the past (ie, Retrieve in Figure 2). Knowledge and experience with previous similar patients with a successful outcome are used to guide treatment for the new patient (ie, Reuse in Figure 2), and the treatment is adapted and revised if necessary to fit the new patient. The physiotherapist gains experience with the new patient and may thus increase their knowledge of treatment leading to a successful outcome (ie, Retain in Figure 2). This process resembles the structure of the CBR cycle. The main difference in problem-solving between a physiotherapist and a CBR system is that the physiotherapist is limited by his memory and experiences, while a CBR system can use experiences from many different physiotherapists and thus use a much larger case base for decision support.
Development of the CBR System, SupportPrim PT, in Musculoskeletal Pain

In this study, we focus on the retrieval phase of CBR. We demonstrate the CBR system, SupportPrim PT, for musculoskeletal pain in two steps: (1) how similar patients were identified and (2) an evaluation of SupportPrim PT’s ability to identify similar patients. The system also displays solutions (ie, treatment suggestions) for new patients based on previous successful cases, but this part will only be described briefly. The medical community is the target audience for this study, and we have, therefore, used nontechnical language.

Patient Similarity Measures

The SupportPrim PT was built using myCBR (myCBR v3 and its rest API v2), which leverages patient data from the past to identify the most similar patients to advise management [24]. We used the local-global principle in CBR to identify similar patients, where similarity is calculated by a weighted sum function [25]. Global similarity measures are attributes used to identify similar patients, where an example of an attribute is a patient’s age or pain intensity. The weighting of these attributes (ie, global weighting) represents the relevance of the different attributes for the identification of similar patients, in our case, in terms of prognostic importance and choice of treatment, while local measures weight similarities between different values for the same attribute.

For the development of global weights, we first created a baseline CBR system by assigning equal weights to all the attributes, a second system with assigned weights based on a data-driven approach [49], and then a CBR system that used expert knowledge. We decided to use the expert knowledge approach to emphasize evidence of prognostic factors across different musculoskeletal conditions. We validated the weighting of the attributes in an iterative process using a sample of 14 patients representing 5 distinct phenotypes of musculoskeletal complaints [50], ranging from good to poor prognosis for a successful outcome [51]. The validation aimed to retrieve the most similar patient from the same phenotype as the queried patient, which is the new patient. In addition, we weighted attributes we believed were important for choosing adequate physiotherapy treatment higher (eg, mental distress, insomnia, and work ability; Multimedia Appendix 1).

For the local similarity measures, we decided the degree of similarity between values within each attribute from 0 (not similar at all) to 1 (full conformity between scores; Multimedia Appendix 1). To guide this work, we used knowledge about minimal clinically important difference, which is the smallest difference that is clinically important for the patient. For instance, this could be 2 points in the numeric rating scale for
pain intensity [52], which means that values within this range were regarded as completely similar. For attributes where information about minimal clinically important difference were lacking, we determined this by consensus within the study group. We did not always assume a linear relationship between scores on an attribute in the local similarity measure, where the local similarity for the same absolute difference in score could differ if the score was at the upper or lower end of the scale (eg, physical activity, where we defined full conformity—1.0 similar—between 5 and 6 to 7 days, while 0 versus 1 day were defined as only 0.4 similar).

**How to Find a Similar Patient**

The SupportPrim PT calculates a similarity score to find similar patients. A similarity score is the weighted sum of all the local similarity scores divided by the total possible weighting (Table 1), giving a similarity score between 0 and 1. Calculation of the similarity score between a query patient (Q) and the most similar patient in the case base (C) is shown in equation 1, earlier described by Bergman [25], where “w” is the weight of the attribute “i.” For each attribute “i,” the local similarity is defined as “sim_i(q, c),” where “q” is the value of the attribute for the query patient and “c” is the value of that respective attribute for the patient case from the case base. Finding the most similar patient is the result of the retrieval process where all patients are compared to the query patient, and the most similar patients are returned. The patient with the highest similarity score will be the most similar to the query patient.

**Equation 1** shows the calculation of the similarity score between a query patient (Q) and the most similar patient in the case base (C).

**Calculations (Table 1).** A similarity score is the weighted sum of all the local similarity scores divided by the total possible weighting (Table 1), giving a similarity score between 0 and 1. Calculation of the similarity score between a query patient (Q) and the most similar patient in the case base (C) is shown in equation 1, earlier described by Bergman [25].

**Table 1.** A similarity score is the weighted sum of all the local similarity scores divided by the total possible weighting (Table 1), giving a similarity score between 0 and 1. Calculation of the similarity score between a query patient (Q) and the most similar patient in the case base (C) is shown in equation 1, earlier described by Bergman [25].

<sup>a</sup> The attributes used to identify similar patients.

<sup>b</sup> The relevance of the different attributes for the identification of similar patients, ranging from 1 to 8, where higher weights represent higher relevance.

<sup>c</sup> Total score Similarity score<sup>c</sup> calculated as: [((attribute 1 weight × attribute 1 local sim)+((attribute 2 weight × attribute 2 local sim))+...+(attribute n weight × attribute n local sim))/attribute 1 weight + attribute 2 weight +...+ attribute n weight] = Similarity score. Patient A: [(8×0.8)+(4×1.0)+(2×1.0)+(4×1.0)+(4×1.0)]/(8+4+2+4+4)=0.93.

<sup>d</sup> The degree of similarity between values within each attribute. Ranges from 0 to 1, where 0 means not similar at all and 1 means full conformity between scores.

<sup>e</sup> N/A: not applicable.

In Table 1, we show a query patient with its 4 most similar patients ranked according to the similarity score (patient A, B, C, and D). We exemplify the calculations of the similarity score by showing 5 of the 29 global measures (ie, attributes) used to represent cases in the CBR system. Patient A will be the most similar, B second most similar, C third most similar, and D the fourth most similar. Furthermore, which is beyond the scope of this study, important patient information and treatment description from the most similar patients having successful outcome will be displayed for the physiotherapist in a clinical dashboard.

To populate the case base for the SupportPrim PT, we systematically collected data from patients and physiotherapists in primary care of Norway. The case base consists of data on patient characteristics, prognostic factors, description of treatments, and outcomes from patients aged ≥18 years with musculoskeletal pain in any of these areas: shoulder, neck, upper or low back, hip, knee, or with complex pain as primary contact reason. Classification of complex pain was at the discretion of the treating physiotherapist based on a combination of the overall severity of symptoms, the number of pain sites, the clinical examination, and the patient history.

**System’s Ability to Identify Similar Patients**

To explore how the SupportPrim PT performs in finding similar patients, we assessed the similarity score of all patients in the case base, ranked from the most similar to the least similar patients, with the scores on the short form Örebro Musculoskeletal Pain Screening Questionnaire (ÖMSPQ) [53] and the Musculoskeletal Health Questionnaire (MSK-HQ) [54].

For similarity scores, each patient was compared with all other patients in the case base and ranked similarly for all patients to attain a rank order of most similar patients for all patients in the case base. Both questionnaires are used across different musculoskeletal pain conditions. ÖMSPQ is an established...
prognostic tool for long-term disability and failure of return to work, with a total score of 0 to 100, where higher scores indicate a worse long-term disability. The ÖMSPQ questionnaire emphasizes biopsychosocial variables related to future disability—similar to the global measures in the CBR system. The ÖMSPQ includes pain, self-perceived function, distress, return to work expectancy, and fear avoidance beliefs. The MSK-HQ is a generic musculoskeletal outcome measure that can be used for different musculoskeletal conditions. It contains 14 key items: severity of pain or stiffness, physical function or activity, work or daily activities, symptoms interference, independence, sleep, fatigue or low-energy levels, emotional well-being, understanding of condition and treatment, confidence in being able to manage symptoms, and overall symptom impact. The total score range is 0 to 56, with higher scores indicating better musculoskeletal health.

Assessing the similarity scores with the 2 established instruments was done with the case base used to build the SupportPrim PT (n=105) and then repeated in a larger case base (n=486). For the latter, we imported additional patients in the case base from another study to assess the performance of the similarity scores in a larger case base.

For patients with musculoskeletal problems, there is rarely 1 ideal solution. Different treatments could lead to a satisfactory outcome and, thus, work as solutions to the problem. In the final CBR system, after identifying similar patients using the local-global principle, similar previous successful patients were filtered, and the description of their treatment was displayed to inform treatment for the new patient (“solution”). The criterion for a successful outcome was a combination of pain intensity and function measured at baseline and at 3-month follow-up, where also the change score on MSK-HQ and the patient’s global perceived effect were included in the combined outcome measure. Details of our definition of a successful outcome are described in Multimedia Appendix 2 [53-56].

Ethical Considerations
The Regional Committee for Medical and Health Research Ethics in mid-Norway approved the study (51566/2019 and 49308/2020). All patients provided written informed consent to participate in the study. Patients did not receive any compensation for participating. Study data are deidentified, and no identification of individual participants is possible.

Results

Descriptive Characteristics of Patients in the Case Base
The original case base consisted of 105 patients, with complete data gathered from 22 physiotherapists in primary care collected from January 2020 to January 2021. The patients’ mean age was 46 (SD 15) years, the majority were women (77/105, 73.3%), and pain duration was >3 months for most patients (87/105, 82.9%; Table 2).

### The System’s Ability to Identify Similar Patients

The SupportPrim PT built to use for decision support in patients with musculoskeletal pain consisted of 29 weighted attributes, each having a defined local similarity measure to identify similar patients. To demonstrate the system’s ability to identify the most similar patients, all patients in the case base were compared to each other, that is, each patient was queried against the rest of the patients, and this was repeated for all patients. Rank 1 thus represents the average similarity score for the most similar patient (“best match”) to the query patient for all patients in the case base. The ranks from the most similar to least similar were then plotted against each rank’s absolute difference on the ÖMSPQ (Figure 3) and MSK-HQ (Figure 4) scores. The most similar patients had a mean absolute difference from the query patient of 9.3 (95% CI 8.0-10.6) points on the ÖMSPQ and a mean absolute difference of 5.6 (95% CI 4.6-6.6) points on the MSK-HQ. For both ÖMSPQ and MSK-HQ, the absolute score difference increased as the rank of most similar patients decreased (Figures 3 and 4).
To assess the performance of the similarity scores in a larger case base, we imported additional patients into the case base, resulting in a case base of 486 patients. When we compare the mean similarity score for the most similar patients for the 2 case bases, we see that the patients retrieved from the larger case base had a slightly higher mean similarity score (Figure 5). We compared the ranks of most similar patients for all patients in both case bases with the ÖMSPQ (Figure 6 and Table 3) and MSK-HQ (Figure 7 and Table 4). The results showed that the larger case base identified slightly more similar patients with a smaller absolute mean difference on ÖMSPQ and MSK-HQ for the ranks compared to the original case base.

Discussion

Principal Findings

This study describes the development of the CBR system, SupportPrim PT, using the local-global principle to identify similar patients with musculoskeletal pain disorders. The SupportPrim PT successfully identified similar patients.

When comparing the similarity scores from the SupportPrim PT and their rankings with ÖMSPQ and MSK-HQ scores, we found that the SupportPrim PT successfully identified the most similar patients to the queried patients across the musculoskeletal pain conditions (Figures 3 and 4). The mean score differences on the questionnaires between the queried and the most similar patients increased linearly or curvilinearly with increasing rank order (less similar patients). These results are not unexpected as SupportPrim PT contains 29 mainly prognostic attributes partly overlapping with items on the ÖMSPQ and MSK-HQ. Mean differences between queried patients and best matches of 9.3 points on ÖMSPQ and 5.6 points on the MSK-HQ are also expected. The SupportPrim PT uses a larger number of attributes for patient similarity.
comparisons, possibly making the system more comprehensive in mapping patients’ symptoms and prognostic factors than the shorter comparative questionnaires. Using a larger case base, the SupportPrim PT yielded patients with slightly higher mean similarity scores and lower absolute mean difference between the queried patients and the most similar patients on the ÖMSPQ and MSK-HQ. This may indicate that a larger case base may improve the performance of the system [57]. The case base of 105 patients is nevertheless representative of primary physiotherapy care in Norway, with descriptive data being consistent with data from a large longitudinal observational study [58].

Key challenges when developing a CBR system are definition of the case representation, similarity measure development, and retrieval strategy. Attribute selection and weighting could be dependent on expert knowledge and limited by the number, type, and quality of the attributes included. We selected attributes based on their prognostic value or potential to influence treatment choice. There is good documentation for prognostic factors being similar across musculoskeletal diagnostic groups [42-46]. Classifying patients according to similar prognostic factors rather than diagnosis may be more fruitful in improving care [9]. To base interventions on diagnoses is relevant if a causal pathway between diagnosis and choice of treatment is established. However, a clear understanding of causal pathways is often lacking in musculoskeletal pain complaints. Thus, physiotherapy interventions are commonly directed toward symptom alleviation, for example, advice, reassurance, self-management, exercise, and manual therapy. Therefore, patients may best be treated within a prognostic framework with more emphasis on specific prognostic factors on the individual level [43].

Definition of global weights in CBR is challenging. We used expert knowledge instead of data-driven methods [49]. Among the attributes selected, the sum score of Hopkins Symptom Checklist 10-item, with questions about anxiety, depression, and somatization, was weighted highest, as emotional distress is an important mediating factor for the treatment effect [59] and also potentially modifiable by physiotherapy interventions [60]. Decisions were based on consensus between the authors with different backgrounds and extensive experience both from research and clinical work.

Limitations
Instead of attribute selection based on expert knowledge, automated data-driven attribute selection methods [61] could have been used. We acknowledge that other attributes not included in our system could have improved the process of identifying similar patients. A limitation of the study is that the process of assigning weights of the global measures did not follow a formal consensus method. This could have resulted in different weighting of the attributes. In addition, comparative studies of data-driven and expert-driven approaches to decide the weighting of different attributes should be explored in future work.

Conclusions
Advising treatment for new patients using previous similar patients with successful outcome represents a move toward more individualized treatment rather than relying on the best evidence of average effects in clinical trials. It is important to acknowledge that the SupportPrim PT is not built to replace the clinical expertise and experience of the therapist but to work as a decision support. Furthermore, AI might create an uncomfortable situation for clinicians and patients, not having complete control and being uncertain, not understanding what is in the system, not having the possibility to tell which attributes are used in the model, and thus not trusting the system [10]. We believe CBR can address this uncertainty by being an easy-to-understand and explainable AI method [62], with expert and domain knowledge being an integrated part of the system, which increases the likelihood for clinicians to trust it. This study describes the development of a CBR system, SupportPrim PT, for musculoskeletal pain in primary care. It demonstrates the system’s ability to identify similar patients on an established screening tool and an outcome measure used for patients with musculoskeletal pain disorders. The SupportPrim PT will be integrated into a clinical decision support system and tested in a full-scale randomized controlled trial in primary health care to evaluate its effectiveness among physiotherapists and their patients. The SupportPrim PT was developed for decision support for physiotherapists in managing patients with musculoskeletal pain disorders, but we think such an explainable system could be applicable to other health care personnel for patients where decision support is needed.

Acknowledgments
The authors are grateful to Anita Formo Bones for administration and support, Paola Marin Veites for technical help, Danielle van der Windt for inputs to the manuscript, and all physiotherapists and patients for participating in the data collection. The project was funded by The Norwegian Research Council and The Norwegian Fund for Post-Graduate Training in Physiotherapy.

Data Availability
The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors’ Contributions
All authors contributed to the design of the study. KB and AJ had the main responsibility for the technical parts. FG, IM, and OV completed the data collection and analysis. FG drafted the manuscript. All authors discussed the results, revised the manuscript, and approved the final version.

Abstract

Background: Training in acute care, such as emergency medicine (EM), where exposure to critically ill and injured patients is high, impacts the well-being of trainees and contributes to burnout. Investigating how, and if, trainees prepare for these situations is necessary to ensure they are supported.

Objective: This study aimed to evaluate medical students’ perspectives and emotional preparedness for handling acute care and trauma.

Methods: We conducted a pilot investigation using a remote digital survey of medical students during their EM clerkship at a large, urban academic institution. The primary outcome of interest was student-reported preparedness and comfort in handling trauma and critical care patient encounters. Secondary outcomes included awareness of well-being resources and comfort in accessing digital well-being resources.

Results: A total of 57 medical students completed the voluntary digital survey, and half of the students (n=28, 49%) reported having witnessed the care of a critically ill or a penetrating trauma patient (eg, a victim of gun violence). A majority (n=40, 70%) had thought about how these events may impact them, and over half felt unprepared to identify the emotional impact these cases may have on them (n=31, 54%) or address the emotional or mental health impact (n=36, 63%). Less than a quarter (n=14, 25%) were aware of digital mental health resources, and 58% (n=33) did not feel fully comfortable connecting with resources if needed. Students who had previously witnessed critical care were significantly more likely to report feeling well prepared in identifying the emotional impact and addressing this impact.

Conclusions: In this cross-sectional survey, students did not feel fully prepared to identify or address the emotional impact of working in EM. Additionally, they lacked awareness of or comfort with accessing digital institutional resources meant to support their well-being, such as a large web-based platform. These findings can help inform and guide interventions by educational and academic leaders. The aim would be to create and promote environments that empower students with tools to identify their own emotions and connect to well-being resources.

Introduction

Health care–associated burnout persists in medicine and can be identified early in medical training [1-4]. This syndrome has negative impacts at the individual level, and it also affects patient care and the health care system by contributing to more medical errors, lower patient satisfaction, reduced productivity, poor clinical teaching and role modeling for trainees, increased cost, and increased physician attrition and ultimately contributes to physician suicide [5-8]. Physicians have a higher risk for suicide than the general population, and these mental health risks have been labeled as known “occupational hazards” [9,10]. Notably, the rate of US physicians annually completing suicide is estimated to be equivalent to the number of students in 3 graduating medical school classes [11,12].

Studies have demonstrated that the impacts of burnout and mental health symptoms, such as depression and anxiety, begin early in medical education and are found in medical students, residents, and physicians in training [2,13-15]. Studies have also found that rates of depression are higher for medical students than other trainees, suggesting this group may be particularly in need of interventions to support well-being and prevent burnout [11,14]. The strain and emotional toll of working in health care emerges early in training. For students, investigating how one identifies, processes, and copes with feelings of anxiety, sadness, depression, or stress related to their clinical experiences within clerkships remains understudied [16]. Emergency medicine (EM) physicians consistently report some of the highest rates of burnout, with EM often being referred to as the “center” of burnout [6,17]. EM physicians are 3 times more likely to be burned out compared to non-EM physicians [4].

Investing in strategies to help trainees identify their own emotions related to providing care, how to cope, and how to sustain well-being is critical for the future of the workforce [18]. Rather than awaiting burnout to evolve, examining how prepared these students feel is necessary to ensure that health systems and medical schools adequately support and proactively maintain medical students' well-being. This is especially important given the rise of mental health symptoms and burnout in health care within the backdrop of the COVID-19 pandemic and social unrest related to racial injustice and rising gun violence.

The goal of this study was to assess medical students’ preparation during their EM rotation to understand how students self-identify their capacity to deal with emotionally charged clinical settings (eg, critical care cases or trauma).

Methods

Ethical Considerations

This pilot investigation used an electronic voluntary survey administered to second- and third-year medical students at the University of Pennsylvania in Philadelphia during their EM clerkship at a large, urban academic institution. The study was approved by the University of Pennsylvania Institutional Review Board (849318). All research methods, consent, and activities were performed in accordance with the university guidelines and regulations.

Eligible Participants and Study Type

Inclusion criteria consisted of students in their second (preclerkship or M2) or third (clerkship or M3) year of medical school. This study was cross-sectional, and a voluntary response sample was used. There were no specific exclusion criteria, as other students were not invited to the survey.

Recruitment Procedures

Participants were invited via email, completed informed consent, and were not compensated for participating. Data were collected and aggregated for analysis. The students at this medical school are routinely surveyed, and questions from this study were incorporated into the preexisting and ongoing school surveying. In total, the survey was sent to 161 students in their preclerkship (M2) and 153 students in their clerkship (M3) during the final week of classes in December 2021.

Approach and Analysis

This cross-sectional pilot study was developed by the research team, with expertise in medical education (authors ST and DA), qualitative methods (AKA and RG), and clinician well-being (AKA). No previous instrument, to the knowledge of the study team, exists; thus, the instrument was developed and pilot-tested in this study. All answers were anonymous, and no demographic information was collected. The primary outcome of interest was student-reported preparedness and comfort in handling trauma and critical care patient encounters. Secondary outcomes included awareness of well-being resources available to them during their clerkship, feelings of preparedness, and comfort in accessing well-being resources. Comparisons were done using chi-square tests in Stata IC 16.1 (StataCorp), and a P<.05 was considered statistically significant.

Results

A total of 57 medical students completed the voluntary survey; 26 (46%) of them were M2 students, and 31 (54%) were M3 students. Almost half (n=28, 49%) of the students reported having witnessed the care of a critically ill or injured patient (defined as a victim of gun violence). Most (n=40, 70%) students had thought about how these events may impact them, but most did not feel fully prepared to identify the emotional impact these cases may have on them (n=31, 55%) or prepared to address this emotional or mental health impact (n=36, 63%). Although resources are widely available to support students’ well-being at this institution, only 25% (n=14) were aware of these institutional resources to help them cope with the emotions involved with care, and 58% (n=33) did not feel fully comfortable connecting with resources if needed (Table 1).

Differences were identified between those students who had witnessed the care of a critically ill or injured patient and those who had not (Table 2). Students who had witnessed such care were more likely to feel well prepared in identifying the emotional impact of these cases (n=7, 25% vs n=0, 0%; P=.007) and in addressing this impact (n=9, 32% vs n=0, 0%; P=.001). No significant differences were found in student awareness of...
resources and their comfort in connecting with these resources to cope with the emotions involved with care.

Discussion

Principal Findings

Given EM’s high rates of burnout and the vulnerable role medical students hold as trainees, medical students undergoing their EM clerkship are at high risk of emotional strain and stress [15]. The rising focus on physician mental health extends to those in training [8]. There is a gap in understanding how prepared medical students feel in identifying and addressing their emotional response and the impact experiences in EM may have upon them. This study assessed medical students’ preparation to better understand their needs and guide interventions toward key priority areas of focus.

This study found that, regardless of whether students had already witnessed the care of a critically ill patient, most students did not feel prepared to identify or address the emotional impact associated with these situations. This highlights the need to train students early and normalize the emotional impact of working in medicine [19,20]. The stigma associated with mental health in health care has pervaded the classroom and hospitals, and to build structures to prevent burnout, we must begin early to help trainees identify feelings of anxiety, depression, or stress as they experience them [13,21-23]. A proactive approach would provide students with the tools and resources they need to adequately identify their emotions and connect to appropriate resources when needed.

It is essential for institutions not only to have resources available to support students’ well-being and mental health but also to make these resources readily accessible and easy to navigate. Our findings reveal that even in an environment where resources are present, students may be unaware of these resources or may not be comfortable accessing them. The University of Pennsylvania School of Medicine has a robust infrastructure within the medical school, a separate web-based mental health...
and well-being platform, accessible to the entire health system community [24]. However, students in this study remained unaware of their availability or accessibility. Institutions must work to incorporate these resources into the clinical and teaching environments to reduce the stigma that may prevent students from accessing them.

Finally, the significant differences in feelings of preparedness between those students who had and those who had not witnessed the care of critical care patients suggest that students do not feel prepared to identify the emotional impact such experience may have until it has happened. It is important to act proactively to prepare students to experience the care of critical patients. EM provides an ideal environment to do so, as the likelihood that students will be placed in an emotionally charged setting is high [17,25]. Venues such as critical care, pediatrics, obstetrics and gynecology, as well as surgery provide other opportune areas for schools to think about deploying focused interventions to where students may need them most.

Limitations
This study has some limitations. First, to protect confidentiality and privacy, we did not collect demographic information. This prevented us from analyzing how these findings might differ by age, race, or ethnicity. Second, as medical students self-selected to participate, selection bias may play a role. The participants surveyed here may not accurately represent the experiences of all medical students in the clerkship program. Additionally, this study was performed at a single urban, academic program and may not be applicable to all medical students at other various institutions. We are also limited by a sample of 56 students, which may further limit our ability to generalize these findings.

Conclusions
Similar to other roles in health care, medical students do not feel fully prepared to identify or address the emotional impact of working in acute care. Additionally, they lack awareness of or comfort with accessing institutional resources designed to support their well-being. Medical students who have not witnessed the care of a critically ill or injured patient were more likely to feel unprepared in identifying or addressing the emotional impact such an event might have on them. These findings can help inform and guide interventions by educational and academic leaders. The aim would be to create and promote training environments that empower students with tools to identify their own emotions and connect to well-being resources. We need to normalize the conversation around mental health in the health care workforce and reduce stigma early in medicine, beginning with our medical students.

Acknowledgments
We would like to acknowledge the students and staff of the University of Pennsylvania Department of Emergency Medicine.

Abstract

Background: Parents of children with cleft lip with or without cleft palate (CL/P) often face stigmatization, which has a significant impact on their quality of life and mental health. However, to date, there is a lack of comprehensive, multicenter empirical research on parents of children with CL/P in China, particularly those with large-scale samples.

Objective: This study aimed to identify major factors that contribute to the perception of stigma experienced by parents of children with CL/P.

Methods: A cross-sectional survey was conducted. A total of 104 parents of children diagnosed with CL/P in 2 hospitals were selected by convenience sampling. Demographics and disease information, the Chinese Perception of Stigma Questionnaire, the Center for Epidemiological Studies Depression Scale, and the Social Anxiety Scale were used in this study. Descriptive statistics, t-tests, and one-way ANOVA were used to compare the differences between participants’ demographic information and perception of stigma. Multivariable linear regression was performed to assess associations between demographic factors, social anxiety, depression, and perception of stigma.

Results: The mean scores for the dimensions of perception of stigma, depression, and social anxiety were 22.97 (SD 9.21), 38.34 (SD 8.25), and 22.86 (SD 6.69), respectively. Depression and social anxiety were positively associated with discrimination, while surgery status was a negatively associated variable. Parents with a college education or higher had significantly lower levels of perceived stigma compared to parents with a junior high school education (all P values <.05). These 4 factors explained 40.4% of the total model variance (F₈=9.726; P<.001; R²=0.450; adjusted R²=0.404).

Conclusions: Our findings highlight a concerning trend of diminished quality of life among parents of children with CL/P. Factors such as parents’ education level, surgery status, depression, and social anxiety are shown to influence the level of stigma experienced. Implementing comprehensive nursing care and providing presurgical support are effective strategies for alleviating parents’ social anxiety, reducing perceived stigma, and preventing depression.

KEYWORDS
stigma; social anxiety; depression; parents of children with cleft lip and palate; cleft lip; cleft palate; cross-sectional study
Introduction

Cleft lip with or without palate (CL/P) is a common congenital developmental malformation affecting the oral and maxillofacial region [1], with a global prevalence of about 1.62%–1.82% [2], and the highest prevalence in Asian countries [3]. There are 35,000 babies born with CL/P in China each year [4]. Palate repair surgery is usually done when babies are 10 to 24 months old, while lip surgery is generally performed at the age of 6 months [3]. The management of CL/P is long-term, beginning from birth and continuing into the late teenage years. Children born with CL/P not only face a visible facial disfigurement but also have other challenges related to the cleft, such as feeding difficulties, speech impediments, hearing issues, and psychological problems, which may compromise their ability to communicate effectively [5].

Children with CL/P are vulnerable to external discrimination because of the malformation. A child with CL/P is subjected to bullying, rejection, and social isolation, sometimes even from their own family [6]. The discrimination can have devastating health and well-being impacts, not only on children affected but also on people associated with the discriminated person. Having a baby with CL/P has variable psychological impacts on the parents [7]. Parents are often concerned about whether their children will be accepted as they grow up, and parents’ psychological state directly affects their children’s perception of the condition [6,8,9]. Some studies [10,11] have indicated that the perception of stigma experienced by the mother and children is consistent. Numerous studies [2,12,13] have shown that children with CL/P experience significant stigma, and limited engagement in social activities suggests that the parents of these children may experience high levels of stigma. Furthermore, Parents are troubled by their children’s conditions from birth to adulthood, while children often experience discrimination after their cognitive development has matured. Therefore, exploring ways to prevent these patients and their parents from feeling stigmatized is urgently necessary.

Currently, research on the perception of stigma among parents of children with CL/P is predominantly qualitative, emphasizing the exploration of factors contributing to parental stigma. However, there is limited reporting on assessments regarding the level and variation in the perception of stigma. In particular, there is no research on the perception of stigma in children with CL/P in China. Previous studies [11,14] have shown that superstition is the main reason for parents’ perception of stigma, and only 40% of parents believe that genetic problems cause CL/P. One study [11] found that 72% of mothers felt ashamed of having children with CL/P, and some even abandoned their babies. Therefore, it is crucial to examine the perception of stigma among parents of children with CL/P, pinpoint those experiencing heightened stigma levels, implement tailored nursing interventions based on sensitive factors, and mitigate the likelihood of public incidents. This study aims to investigate experiences of stigma in parents of children with CL/P and analyze the contributing factors.

Methods

Study Design and Participants

This cross-sectional study was conducted using a convenience sample of parents of children with CL/P, recruited from 2 hospitals in southern and western China (from the cities of Guizhou and Guangzhou) between June 2020 and January 2023. All parents of children who met the inclusion and exclusion criteria for surgical treatment in the Department of Stomatology were invited to complete a questionnaire. The inclusion criteria were as follows: parents of children (aged <15 years) with CL/P undergoing nasoalveolar molding therapy at the Department of Stomatology. These parents were invited to complete an anonymous questionnaire.

Exclusion criteria included parents of infants with additional birth defects or medical conditions, those with genetic diagnoses (eg, Down syndrome or Trisomy 21 syndrome), and individuals unable to complete the questionnaires due to critical illness or mental disorders.

Data Collection

After the doctors introduced the operational procedure or the nurses introduced the environment of the wards, the participants were invited to fill in the questionnaires. Uniform instructions were used to explain the study aims and their relevance to the participants. The participants were informed that the study was anonymous and voluntary and that they could quit anytime.

Variables and Instruments

The demographic data were collected via a questionnaire. Three questionnaires with good reliability and validity were used to collect the data on stigma, social anxiety, and depression.

Demographics Questionnaire

The demographic information questionnaire was designed by researchers after consulting the literature and mainly included parents’ age, role (father or mother), education level, and working status as well as children’s age, sex, type of CL/P, surgery status, and number of surgeries.

Disability Discrimination Perception Scale

Stigma was assessed using the Disability Discrimination Scale (DDPS), initially developed by Liu and Shen [15]. The questionnaire comprises 10 items (eg, “When participating in activities, I feel that people around me would not talk to me and avoid me”), designed to explore the perception of stigma among individuals with disabilities in their daily lives. It is also suitable for children aged 10 to 16 years. Respondents rated each item on a 5-point scale, ranging from 1 (very inconsistent) to 5 (completely consistent). Higher total scores indicate a greater perception of stigma, with scores ranging from 10 to 50. The scale demonstrates good internal consistency, as evidenced by a Cronbach’s reliability of 0.89. The criterion validity was 0.47, indicating good validity [15].

The Center for Epidemiological Studies Depression Scale

The level of depression was measured by the Center for Epidemiological Studies Depression Scale (CES-D) [16]. CES-D
consists of 20 items (eg, “I was bothered by things that usually don’t bother me”), and each item is scored from 0, indicating “rarely or none of the time (less than 1 day)” to 3, indicating “most or all of the time (5-7 days).” The total score of all items ranges from 12 to 60, with higher scores indicating a greater likelihood of depression; a total score of 15 points or less indicates no depression; 16 to 19 points indicate possible depression; and a score of 20 points or higher indicates definite depression [16]. The scale is suitable for screening people with depressive symptoms and can also be used to assess the severity of depressive symptoms. The Cronbach $\alpha$ of CES-D was 0.87, indicating good internal consistency. The split-half reliability was 0.85, the test-retest reliability was 0.70, and the criterion validity was 0.75. Therefore, CES-D had good reliability and validity.

**The Interaction Anxiousness Scale**

The Interaction Anxiousness Scale (IAS) was used to assess the subjective propensity to experience social anxiety independent of behavior [17]. The IAS contains 15 self-reported items (eg, “I want to be confident in social situations more”), which are answered on a 5-point scale, ranging from 1 (very inconsistent) to 5 (completely consistent). Total scores range from 15 to 75, with higher scores indicating higher levels of social concern. The Cronbach $\alpha$ reliability of the scale was 0.87, the test-retest reliability was 0.80, and the criterion validity was 0.48. In this study, according to the actual situation, 7 items related to sexual life were deleted, and 8 items were selected for evaluation. The reliability of the scale was retested, and Cronbach $\alpha$ reliability was 0.68, indicating acceptable reliability.

**Statistical Analysis**

IBM SPSS Statistics (version 25.0; IBM Corp) for Windows, was used for statistical analysis. Standard descriptive statistical values (means and SDs) were calculated. The independent samples 2-tailed $t$ test and ANOVA were used for the intergroup comparisons of parameter changes. Pearson analysis was used to examine the relationship between perception of stigma, social anxiety, and depression. Multiple linear regression was performed to assess the association between demographic factors, anxiety, depression, and perception of stigma. The significance level was set at 5%.

**Ethical Considerations**

The study was approved by the Ethics Committee for Clinical Studies at Guangzhou Women and Children's Medical Center, Guangzhou Medical University (NO.2022268A01). This study obtained informed consent from participants, who had the option to withdraw at any time. The research data were collected anonymously.

**Results**

In this study, a total of 110 questionnaires were distributed. Of the collected questionnaires, 104 were complete, resulting in a 94.6% response rate.

**Participant Characteristics**

Most participants were mothers aged 25-30 years and unemployed, with a high school diploma. Their children had CL/P, and surgery had not been performed. Unemployed parents constituted 71% (n=74) of the sample, with nearly half (n=14, 47%) of the employed parents being self-employed. Over half (n=61, 59%) of the respondents had completed high school. The children’s average age was 3.06 (SD 2.02) years. A total of 73 (72%) children had not undergone surgery, while most of those who had done the surgery (n=20, 65%) had undergone the procedure twice. A descriptive analysis of the general demographics, work-related characteristics, and disease-related information of the participants is shown in Table 1.
Table 1. Demographic characteristics of the participants (N=104).

Prevalence of Stigma, Social Anxiety, and Depression
The mean scores for the dimensions of perception of stigma, depression, and social anxiety were 22.97 (SD 9.21), 38.34 (SD 8.25), and 22.86 (SD 6.69), respectively. Additionally, 38% (n=40) of the participants exhibited a perception of stigma level beyond the moderate level, and every participant experienced evident depression, with 72% (n=75) displaying average levels of social anxiety.

Univariate Analyses of Factors Associated With Stigma
The demographic data, including parents’ age, role, education level, and working status as well as the children’s age, sex, CL/P type, surgery status, and the number of surgeries, were analyzed
using a one-way ANOVA and t tests. The results of the Kolmogorov-Smirnov test suggested that the continuous variables were reasonably and normally distributed. The t tests revealed that the parents whose children had undergone surgery experienced lower stigma levels compared to those whose children had not undergone surgery ($P=.01$). The perception of stigma scores differed significantly among parents having different educational backgrounds ($P<.001$) and between those whose children underwent different numbers of surgeries ($P=.04$). The specific results are detailed in Table 2.

Correlation Analysis With Perception of Stigma, Social Anxiety, and Depression

The results showed that the perception of stigma was related to social anxiety ($r=0.54; P<.001$) and depression ($r=0.39; P<.001$); there was also a correlation between depression and social anxiety ($r=0.30; P=.002$). The specific results are shown in Table 3.

Regression Analyses of Stigma

With the perception of stigma as the dependent variable, depression, social anxiety, and demographic data with differences between groups were included in the model as independent variables, and multiple linear regression analyses were performed. In the perception of stigma model, depression, social anxiety, educational background, and status of surgery were significant correlates explaining 40.4% of the total model variance ($F_8=9.726; P<.001$; $R^2=0.450$; adjusted $R^2=0.404$).

Discussion

This study found that parents of children with CL/P experienced a high level of perception of stigma and obvious social anxiety and depression. In addition, parents’ education level, children’s status of surgery, social anxiety, and depression affect parents’ levels of perceived stigma. This study complements the gap in the study of stigma perception in families of children with CL/P in China. Parents in our study exhibited a higher level of stigma perception. This could be attributed to the fact that most children underwent corrective surgery during infancy, making parents more attuned to discrimination, as they believe that visual impairments affect their children’s social lives. Thus, prevailing data suggest that Chinese clinical nurses should pay attention to the quality of life of parents of children with CL/P.

Our study showed that children’s sex and the type of CL/P could not affect parents’ discrimination perception. This is consistent with the findings of previous studies that reported no significant difference in the level of discrimination perception between patients of different sexes and CL/P types [10]. The results of our study showed no significant difference in the level of stigma perception between fathers and mothers. Fathers also had a high
level of stigma perception. However, previous studies [14,18] suggested that mothers of children with CL/P experienced severe stigma or discrimination while ignoring the possibility that fathers also experienced high levels of discrimination. Two other studies [19,20] pointed out that the main sources of stress among fathers were the treatment process, feeding, and social stigma. Therefore, in the care process of children with CL/P, we should not only focus on the mother’s psychological state but also consider the psychological state of the father. The importance of family nursing should also be emphasized.

Parents of children with CL/P experience obvious depression and anxiety. It is consistent with the findings of previous studies reporting that parents of newborns with CL/P had significantly higher levels of anxiety compared to control parents [20]. The study findings are consistent with the current literature, as depression or depressed mood in parents of children with CL/P is a common phenomenon [21,22]. Kumar [23] reported the highest incidence of depressive episodes, with 42% of parents of children with CL/P aged >10 years showing a strongly or very strongly elevated depressive disorders screening index. Sommer [24] has pointed out that mothers of children with CL/P believe their children have a negative impact on them. Their negative views and emotions are mainly derived from the long treatment times, the difficulty of treatment, the uncertainty of the infant’s future condition, and the fear of rejection. Family members of infants with CL/P experience stigma, anxiety, and worry, which may lead to individual negative emotions and coping styles, produce adverse intergroup relations, reduce subjective well-being and life satisfaction, and ultimately affect the quality of family life. Relieving the stigma perceived by parents of children with CL/P is the first step to relieving negative emotions like anxiety and depression in these parents. Therefore, we should pay attention to the physical rehabilitation of children as well as the mental health of children and their parents.

In this study, parents with junior high school education showed a high level of stigma perception, and the perception of stigma was lower among parents with a college education or higher. So far, no study has investigated the relationship between the education level of parents who have children with CL/P and their stigma perception. A previous study [6] showed that caregivers of children with attention deficit hyperactivity disorder, who have higher education levels, experience higher levels of stigma. However, the results of this study were inconsistent with a previous study, possibly because parents with a junior high school education have less knowledge of the condition and are more likely to focus on the appearance of their children. The difference could potentially be attributed to the fact that parents with higher education levels are more likely to access relevant information about the condition and feel more confident about the later recovery process. Hence, health care professionals should focus on parents with a high school education or lower, monitor variations in their perceived stigma levels, comprehend their psychological well-being across different stages of their children’s lives, and offer tailored psychological support.

Cleft surgery provides hope to those children and their parents, offering the possibility of re-enrollment in schools, employment opportunities, social acceptance, and improved prospects for marriage [6]. Undergoing surgery directly affects the level of the stigma perceived by parents. Parents of children without surgery perceive a higher level of stigma, which is consistent with previous studies [14] suggesting that parents of children with CL/P show obvious negative emotions in the first 3 months after the birth of their children without surgery. Therefore, the initial 3 months emerge as a pivotal phase for health care professionals to alleviate parental anxiety and deliver emotional and educational assistance to parents of infants with CL/P. Through comprehensive nursing and presurgical support, mothers can enhance their early feeding capabilities, expedite the bonding process with their infants, and facilitate the infants’ swift recovery. Familiarity with CL/P beforehand serves to diminish maternal stress during initial interactions, mitigating anxiety and perceptions of discrimination. Consequently, encouraging mothers to engage with CL/P-related charitable organizations or fostering interaction among children with CL/P in shared spaces can effectively reduce anxiety and perception of stigma levels.

This study has several limitations. All the participants in this study were family members of children who were willing to undergo surgery, and no family members of children who were unwilling to undergo treatment were included, which may have led to selective bias. Parents filled out the scale based on recall, which may introduce information bias. The sample size of this study was small, as it was limited to hospitals only from 2 provinces with a large gap in economic levels between the 2 places, and fewer fathers were included in the study. Future studies should increase the sample size and broaden the scope of the investigation.

Our findings highlight a concerning trend of diminished quality of life among parents of children with CL/P. Factors such as parents’ education level, the status of surgery in children, depression, and social anxiety are shown to influence the level of stigma experienced by these parents. Implementing comprehensive nursing care and providing presurgical support are effective strategies for alleviating parents’ social anxiety, reducing perceived stigma, and preventing depression.

Acknowledgments

The authors are sincerely grateful to all the participants who responded to the questionnaires and all the nurses and doctors for supporting this investigation.

Abstract

Background: While many factors, including social determinants of health, affect cancer mortality, one modifiable risk factor that may contribute to cancer disparities is obesity. The prevalence of obesity in the American Indian/Alaska Native population is 48.1% per the Centers for Disease Control and Prevention. The overall cancer mortality for the American Indian/Alaska Native population is 18% higher than the White population as reported by the American Cancer Society. Interventions tailored to American Indian/Alaska Native communities that promote healthy lifestyle behaviors after cancer diagnosis and prior to cancer surgery (prehab) might improve cancer outcomes for this population.

Objective: The aim of the study is to characterize the lifestyle behaviors of San Carlos Apache cancer survivors and identify preferences for the adaption of a prehab intervention.

Methods: Semistructured interviews and validated questionnaires were completed with San Carlos Apache cancer survivors (N=4), exploring their viewpoints on healthy lifestyle and cancer risk and preferences for program development. A thematic content analysis was conducted.

Results: Participants had an average BMI of 31 kg/m² and walked 53 minutes daily. The majority of participants reported a high willingness to change eating habits (n=3, 75%). All 4 reported willingness to participate in a diet and exercise program. Important themes and subthemes were identified: (1) cancer is perceived as a serious health condition in the community (N=4, 100%); (2) environmental exposures are perceived as cancer-causing threats (n=3, 75%); (3) healthy diet, exercise, and avoiding harmful substances are perceived as mitigating cancer risk (n=3, 75%); (4) barriers to healthy habits include distance to affordable groceries (n=3, 75%) and lack of transportation (n=2, 50%); (5) there is high interest in a prehab program geared toward patients with cancer (N=4, 100%); and (6) standard monitoring practiced in published prehab programs showed early acceptability with participants (N=4, 100%).

Conclusions: Collaboration with tribal partners provided important insight that can help inform the adaptation of a culturally appropriate prehab program for San Carlos Apache patients diagnosed with cancer.

Introduction

Cancer is the second leading cause of death for the American Indian/Alaska Native population with related disparities in cancer screening, incidence, stage at diagnosis, and timely treatment [1-8]. Consequences of colonialism such as geographic isolation, poverty, and social determinants of health have not only created steep disadvantages in the progression of cancer but also contributed to detrimental behaviors related to diet and exercise that place tribal members at higher risk for worse cancer outcomes [9]. There are 13 obesity-related cancer subtypes that account for 40% of all cancers diagnosed in the United States, which confers significant risk for the American Indian/Alaska Native population, given the 48.1% prevalence of obesity for this population [10,11]. Published data suggest that brief exercise interventions following diagnosis of solid tumor malignancies might lower cancer progression, specifically through the regulation of metabolism and the immune response [12-14]. Epidemiologic studies have suggested anti-inflammatory foods can improve cancer outcomes [15-18]. While anti-inflammatory diet and exercise trials are increasing for patients with cancer in the general population, few have involved patients from American Indian/Alaska Native populations [19].

The Partnership for Native American Cancer Prevention, established in 2002, is a program that strives to alleviate the unequal burden of cancer among Native Americans in the Southwest through research, training, and community outreach [20]. Through the Partnership for Native American Cancer Prevention, the investigators of this project partnered with the San Carlos Apache Healthcare Corporation (SCAHC) with approval from the Tribal Council. The San Carlos Apache reservation, established in 1871, spans 1.8 million acres of Sonoran Desert and alpine forests in Southeastern Arizona and is home to 10,815 people. The tribal government and SCAHC are committed to providing quality care that honors Apache traditions and promotes Apache values of well-being, goodness, balance, harmony, and beauty [21-23].

Lifestyle modifications in nutrition and exercise prior to oncologic treatment are key strategies of prehabilitation (prehab) and have been shown to optimize patients’ functional capacity and improve postoperative outcomes [24-26]. Results from this work are being used to propose the next evolution of this project, which is the adaptation of a culturally appropriate prehab program for San Carlos Apache patients diagnosed with cancer who are preparing for surgery. It was recognized that San Carlos Apache community members, specifically those who have experienced the cancer spectrum from diagnosis to survivorship would have the best insight for developing a program specifically tailored to the San Carlos Apache community. The purpose of this project was to conduct semistructured interviews and administer validated questionnaires to characterize lifestyle behaviors of San Carlos Apache cancer survivors and identify appropriate approaches for the adaption and delivery of a lifestyle intervention for San Carlos Apache patients diagnosed with cancer.

Methods

Study Design

The principles of community-based participatory research were followed throughout the study. SCAHC and Tribal Council members advised the project activities, which were conducted with their approval and collaboration. Qualitative semistructured interview questions were developed through an iterative process supervised by faculty experts in qualitative methods. The questions were then presented to tribal community members at SCAHC to ensure the content was appropriate. The questions reflected the content of published prehab programs and focused on understanding the most acceptable approach for program adaptation for San Carlos Apache patients. The questions were organized according to four areas: (1) knowledge of cancer and its causes and prevention, (2) perspectives on cancer and lifestyle, (3) diet and physical activity preferences, and (4) attitudes and beliefs regarding diet and physical activity interventions for survivors. In total, 32 semistructured interview questions were asked of participants, including potential subprompts. Interview data were complemented with facilitator administration of 2 validated questionnaires about nutrition and physical activity. These were the Rapid Eating Assessment for Participants-Shortened Version (REAPS) and the International Physical Activity Questionnaire (IPAQ), which were selected because of the validity, reliability, literacy, and low participant burden of these brief instruments [27-30].

Interviews were conducted by the principal investigator through password-protected Zoom (Zoom Video Communications). The participants accessed the platform through telephone dial-in. The camera feature was not used, names were avoided, and data were deidentified. The participants’ responses were audio-recorded with permission and transcribed. The interviewer took handwritten notes of the responses to cross-check the transcription and verify accurate audio recording. Minor errors were corrected on the final transcriptions.

An independent reviewer with expertise in qualitative methods and American Indian/Alaska Native health was consulted to perform a thematic content analysis of the deidentified transcripts using a matrix system grounded in a framework focused on determinants of health from an Indigenous perspective. This method has been used for analyzing qualitative data with other tribes and is described elsewhere [31]. Briefly, the matrix was used to organize the questions and responses into a coded summary chart, wherein similar responses were grouped together after an iterative process of grouping, regrouping, and refining. From this, the content was grouped into themes and subthemes. Direct quotes particularly illustrative of key themes were extracted. The reviewer summarized the principal findings for intervention planning.

Participants and Recruitment

Tribal members who are cancer survivors residing on the San Carlos Apache reservation, aged at least 18 years, and diagnosed with cancer within the previous 15 years were recruited for semistructured interviews. Recruitment efforts were centered on the recommendations of the social workers and physicians at SCAHC. The social workers at SCAHC engage all patients...
diagnosed with cancer, not only at diagnosis but also during survivorship, per their facility’s routine. This was recognized to position the social workers in contact with the highest volume of potential participants, who were approached on a rolling basis over the course of 3 months. Furthermore, social worker engagement was intended to minimize influence since the social workers are neither part of the university study team nor the clinical care team. The social workers introduced the study to the survivors, and for those who expressed interest in the study, the social workers verified that prospective participants gave permission to share their contact information. Each prospective participant underwent a brief screening by the study lead (JE) to verify eligibility following a telephone screening script. If individuals agreed to participate, they were consented and then scheduled for a semistructured interview on a separate day.

Ethical Considerations
This project was developed in collaboration with the San Carlos Apache Tribal Council and SCAHC. Human Subjects approval was obtained from the University of Arizona Institutional Review Board (study ID CR00001226), SCAHC Institutional Review Board, and San Carlos Apache Tribal Council Health Committee. All materials were approved by the Tribal Council and SCAHC. The tribal support letter was submitted to the University of Arizona. SCAHC Institutional Review Board and Tribal Council approved the content of this paper and its submission. Informed consent was obtained from all participants (verbal or written option, all participants chose verbal and were sent a hard copy of the written consent form). Upon completion, participants received a gift card as compensation for their time. Privacy and confidentiality were upheld in the data collection, and the data were deidentified.

Results

Demographics and Questionnaires on Physical Activity and Diet Behaviors
A total of 4 participants were interviewed from May to July 2022. SCAHC referred 12 potential participants; 8 were successfully contacted and 4 agreed to study participation (response rate of 4 of 12 potential participants or 33%). Interviews lasted 60-80 minutes. The average age of participants was 64 years, with 1 male patient and 3 female patients. The participants were diagnosed with cancer between 2015 and 2021. A family history of cancer was reported by 3 (75%) participants. All were overweight or obese with an average BMI of 31 kg/m². There were 2 (50%) participants who reported past smoking, and 1 (25%) who reported past moderate alcohol consumption. Based on the IPAQ, the participants reported an average of 158 minutes of vigorous activity daily, 90 minutes of moderate activity daily, and 225 minutes of sitting daily. All patients reported walking specifically as part of their physical activity routine and reported an average of 53 minutes of daily walking. Based on the REAPS, it was elicited that 2 (50%) participants ate 4 or more meals per week from restaurants or takeout, 3 (75%) ate 2 or more servings of fruit per day, 3 (75%) ate 2 or more servings of vegetables per day, 3 (75%) answered they usually or sometimes use processed meats, 2 (50%) regularly ate fried foods, 3 (75%) rarely ate sweets, and 2 (50%) reported drinking 16 ounces or more of nondiet soda or punch per day. On a scale of 1-5, for willingness to make changes in their eating habits where 1=very willing and 5=not at all willing, 3 (75%) participants answered positive willingness with a score of 1-2.

Semistructured Interviews: Qualitative Analysis
Overview
The following themes were revealed (Textbox 1): (1) cancer as a serious health condition in the community, (2) environmental exposure and contamination as a main cause of cancer, (3) personal choices as risk factors or prevention, (4) barriers, (5) acceptability of diet and physical activity programs, and (6) acceptability of monitoring and biospecimen collection.
Textbox 1. Qualitative semistructured interview themes and subthemes.

- Cancer as a serious health condition in the community
- Environmental contamination and exposure as a cause of cancer
  - Occupational exposure
  - Chemical in the community
  - Water contamination
- Personal choices as risk factors or prevention
  - The power of food, exercise, and lifestyle
- Barriers
  - Distance and transportation
  - The built environment
- Acceptability of diet and physical activity program
  - Considerations for program development
    - Support and encouragement
    - Central location
    - Education
- Acceptability of monitoring and biospecimen collection

Cancer as a Serious Health Condition in the Community
All participants affirmatively stated that cancer is a problem for the San Carlos Apache community. Participants defined cancer as a serious condition with the words “horrible,” “deadly,” and “life-threatening.” Based on this perception, all 4 participate in cancer screening and surveillance. Half of the participants endorsed the concept of cancer as potentially curable and the importance of health care in cancer prevention.

Environmental Exposure and Contamination as a Main Cause of Cancer
There were 3 (75%) participants who described an environmental issue as a main cause of cancer.

Occupational Exposure
Exposure to harmful chemicals through occupation was described by 2 (50%) participants as a main cause of cancer:

Some of it is asbestos for a lot of our workers who worked in these asbestos mines.

Another connected cancer to exposures in the workplace (workplace redacted for identity protection):

I used to be a [occupation redacted]. It was the environment we worked in. That’s why we’re doing an early retirement, [workplace redacted], because of our environment, what we ingested from the environment.

Chemicals in the Community
A history of chemicals in the community believed to be linked to cancer was vividly described by 1 (25%) participant:

I remember I was very young when they sprayed our area. I remember the planes hanging out in our area and how it killed a lot of our trees. I remember the one thing that really impacted me was the poppies. A lot of beautiful poppies that would grow all the way around our area where I lived, which was a mile at the time. We hardly have that any more ... There was a thing called agent orange ... I remember one time climbing there and I saw the planes. I remember them spraying something alongside the river.

Water Contamination
Water as a main cause of cancer was described by 2 (50%) participants with asbestos in the water and the pipelines themselves perceived as cancer-causing:

To me I think it’s drinking water from the faucet ... Way back in the years there were cancer causing pipelines that were installed. And this person told my Dad that you won’t be surprised when people from the reservation will be experiencing this cancer.

Asbestos was sprayed and caused contamination of our water. I’m sure, I mean those run right through the areas where they have mined and it seeps into our water system.

Personal Choices as Risk Factors or Prevention: The Power of Food, Exercise, and Lifestyle
The personal choices participants linked to cancer risk or prevention had a recurring connection to food, exercise, and lifestyle. Diet choices were believed to be a main cause of cancer by 2 (50%) participants, and 2 (50%) expressed that substance-free living is important to cancer risk reduction.
Nutrition is prevention.

Exercise regularly. Don’t smoke. Don’t drink. Keep down on your fatty foods.

I think it helps prevent it. Because a strong body kind of resists it, I believe.

Sugar and processed foods were specifically mentioned as impacting cancer:

I truly believe that the sugar we take in has a lot to do with it ... Processed food is a part of it. If we sit around and do nothing, that unhealthy food builds up in our body. However, if we exercise, it is burned off, then the food nourishes our body.

However, one participant did not believe food and physical activity impacted the risk of cancer based on her personal experience of self-perceived healthy diet and activity but a diagnosis of cancer:

I guess I have to say no from my own experience, because I did that, you know, I exercised like crazy. I ate well. I made sure everything—I grew up in a home where we had our own garden and made sure that we ate healthy food, and that’s how I grew up.

Barriers

Distance and Transportation

Distance and transportation were cited as barriers to healthy lifestyle behaviors. There were 2 (50%) participants who described how lack of transportation impacted their ability to eat healthier and potentially participate in programming. There were 3 (75%) participants who described the distance to a grocery store with affordable prices and fresh options as barriers to healthy eating.

Having the transportation probably because right now my ride is down and all of us have a hard time making our way there.

You know that this [name of grocery store redacted] could have more healthy food and not so much processed food. Prepackaged stuff. If they could make other things available out there. I hardly ever go to [redacted] except to get immediate things, you know ... Their stuff is very high compared to others but can’t make the distance to [other location] every day.

The Built Environment

Participants described how the hills on their reservation and the busy road add challenges to their ability to exercise outdoors.

It’s dangerous to even cross the street. When I do go out, I usually go up with someone early in the morning.

Having the time and a level place to walk ... it is hilly where I live.

Acceptability of Diet and Physical Activity Programs

Overview

The participants were asked about a theoretical diet and physical activity program in their community, and all stated they would participate. When asked if they would participate when first diagnosed with cancer, all said yes with half providing no stipulation and half expressing concern about it interfering with treatment or the side effects of treatment being prohibitive.

Oh, yes, I sure would. I would love that.

Yeah, as long as it did it not interfere with my treatment.

When asked if their participation would have been influenced if it were explained that participating during cancer treatment could potentially improve cancer outcomes, all responded with strong affirmation, including those who had initial apprehension about it interfering with treatment.

Considerations for Program Development

The participants were invited to brainstorm the type of diet and physical activity program (prehab) they would want for their community. There were recurring responses about the need for support and encouragement, a central location, and education. Participants emphasized the need for peer support and encouragement, particularly the importance of including a cancer survivor as part of the program team.

People who have experienced cancer might be someone to have there. They know their issues and what they went through and can share ... Like a group where people could learn what’s going on with them and know somebody is listening to them that knows what is going to happen ... I think I was lost when I was told about having cancer, and it was scary in ways, and nobody ever told me you’re not going to die from this one.

All participants referenced their community center as the preferred location for prehab. While there was consistency on the community center as the chosen central location, upon further probing, it became apparent that each district of the reservation has its own community center, and while the participants were uniform on the category of “community center,” they were referencing different candidate buildings. Reflective of the concern that lack of transportation is a barrier to a healthy lifestyle, one participant recommended that transportation to the central location be provided by the program. Participants also voiced interest in education, delivered either by peers or health professionals.

Somebody in oncology who can share what happens as nobody gets taught about these things. I was having to get on the computer to find out what this word means and the different services available. It’d be nice if someone had sat me down and kind of counseled me on it and what could happen.

First you have to educate them on the disease and what it does to their body. Then you have to cover the things that could be promoting it to happen. And lastly the things that could change that.

There was no clear consensus on how often the program should meet. One participant requested a daily program. The others recommended 1-3 sessions weekly. There was no consensus on how long each session should occur with a range of responses from 30 to 120 minutes, but 3 (75%) supported 1 hour as...
appropriate. Participants practiced a wide range of physical activities including treadmill, weights, biking, running, gardening, gathering acorns, and aerobics. All 4 mentioned walking as a favorable regular activity. There were 3 (75%) participants who described going to a fitness center as favorable. The participants were presented with a list of food items that have been included in other prehab programs and asked about their likelihood of consuming these if the food items were provided. On a scale of 1-5 with 1=absolutely would not eat and 5=absolutely would eat, the participants viewed fiber powder and flax seeds negatively, protein shakes neutrally, and walnuts as highly favorable, with all 4 giving a score of 4-5 likelihood of consuming walnuts as part of a prehab program.

Acceptability of Monitoring and Biospecimen Collection
All participants responded positively to the following forms of monitoring: measurement of heart rate, blood pressure, and weight; blood collection to measure glucose, cholesterol, and levels of inflammation; and biospecimen collection (ie, tumor tissue) to measure inflammation. Half brought up that this is a personal choice, and they were not sure if others would agree to monitoring.

I would. I don’t know about other people but I can. It’s a necessary part of what you do.

Yeah. It’s important to be monitored when you’ve got cancer.

The question about biospecimen collection generated more discussion. It was first explained that measuring inflammation in the cancer tissue before and after a prehab program is one way to see if the program is effective, and that it can be done without any extra procedures beyond those required for standard cancer treatment. Then the participants were asked, “Looking back, do you think you would be comfortable with your biopsy tissue and the tumor removed by the surgeon to be analyzed for inflammation to see if a diet and physical activity program can change cancer cells?” All said they would with 3 of the participants providing a yes without stipulation, and 1 person asking for further clarification. After repeating the explanation, the individual responded, “I definitely agree with that.”

Discussion
Principal Findings
To our knowledge, this is the first study to engage San Carlos Apache cancer survivors for their perspectives on lifestyle modifications in diet and physical activity and the cancer journey. It is the investigators’ long-term goal to work with the tribe and health facility to collaboratively develop a nutrition and physical activity prehab program that serves patients with cancer. Prior to programmatic development, the team recognized that it was critical to invite community members into the discussion early as a first phase of research to learn if such programming would be appealing and what background the community prioritizes. From these interviews, important themes and subthemes were highlighted: (1) cancer is perceived as a serious health condition in the community; (2) occupational exposures, chemical exposures, and water contamination on the reservation are perceived as cancer-causing threats; (3) healthy foods, regular exercise, and avoiding harmful substances are mostly perceived as measures an individual can use to try to prevent cancer, though there is recognition that it is not a guaranteed protection; (4) lack of transportation, distance to affordable groceries and recreational centers, and hilly and high-traffic roads are barriers to healthy habits for this community; (5) there is high interest in a prehab program geared toward patients with cancer that should include components of encouragement and education and take place at a central location; and (6) standard monitoring practiced in published prehab programs, which includes blood and tumor-tissue samples, is acceptable to the individual cancer survivors who participated in this study with the important point made that it is their personal view, and openly sharing a clear rationale may encourage wider acceptability.

Comparison to Prior Work
Lifestyle interventions for optimizing cancer outcomes are undergoing a paradigm shift in which earlier engagement (ie, prehab) holds promise for greater impact, including modulating inflammation. Obesity is considered a pro-inflammatory condition, and the synergy between obesity and inflammation is thought to influence cancer risk and progression. With an increased risk of obesity, American Indian/Alaska Native populations carry an increased risk of obesity-related cancers and worse outcomes [24-26]. Previous studies with participants from the general population have shown that prehab interventions have modulated inflammation in multiple cancer subtypes as measured by biomarkers in windows as brief as 3-5 weeks between diagnosis and operation [32-36]. The preoperative period is a unique window before treatment side effects have set in and might be more conducive to patient participation while additionally fostering healthy behaviors for treatment and survivorship ahead. Such studies have never been implemented for American Indian/Alaska Native populations. With a disproportionate burden of obesity and cancer mortality, prehab interventions during this diagnosis-to-surgery window of opportunity could provide gains in health equity for American Indian/Alaska Native populations, a group underrepresented in clinical research [37].

Leaders in the field have published their recommendation that well-designed interventions should include tumor-derived tissue from diagnostic biopsies and surgical resections to evaluate the effects of the intervention on the tumor microenvironment [12,38]. While this is an accepted measure with general populations, it is a delicate subject with American Indian/Alaska Native audiences, as some tribes have experienced breaches in the ethical conduct of research and misuse of their biospecimens [39]. Our team wanted to proactively address this component of prehab trials to understand whether this would be an acceptable method of measuring outcomes with San Carlos Apache participants. Prepared for apprehension, we were encouraged to learn that the participants saw the benefit of monitoring vitals, blood samples, and tissue samples. We hold this trust in the highest regard and comply with the University of Arizona’s rigorous process for tribal-related research (ABOR1-118 Tribal Consultation Policy), which recognizes the fundamental principles of tribal sovereignty and requires documented evidence of consultation and approval when...
conducting research with Native Nations [40]. These processes and special considerations are important to highlight for any team interested in research with a tribal partner, and prospective investigators should bear in mind that each individual tribe determines the process that must be followed at all steps of the investigation.

Dietary interventions rich in omega-fatty acids have been conducted outside the prehab context to alter inflammation in various disease conditions including cancer. These studies have featured omega-rich foods, like walnuts, which have a high content of polyunsaturated fatty acids and antioxidants that can improve blood lipid profiles, reduce oxidative stress, influence inflammatory biomarkers, and reduce tumor growth, offering a natural and tasty way of improving outcomes [41-54]. This single food intervention affords simplicity in delivery, has previously demonstrated high uptake and adherence, and was highly endorsed by the San Carlos Apache participants. One person commented that walnuts grow wild on the reservation and would be perceived as a more natural, traditional food option.

Strengths and Limitations
This study has limitations. With 4 participants, the findings may not be fully representative of all San Carlos Apache patients with cancer; however, the participants were consistent in most of their responses, which may have achieved saturation or sufficiency of themes. Qualitative researchers are recognizing that sufficiency depends on the rigor of the process and the richness of the data it generates, more than the absolute number of participants [55]. With the length of time these participants invested in the interviews and the candor of their responses, we believe this to be a strong and meaningful data set. Another limitation is that cancer survivors rather than patients who were newly diagnosed with cancer were interviewed. Survivors were selected because of their line of sight on the full spectrum of the cancer experience in their community, which had the advantage of providing reflections outside the acute exhaustion of a new diagnosis. This has the potential for recall bias and might not have rendered their real-time experience as accurately. Finally, a surprising result was the very high level of vigorous or moderate physical activity the participants reported, which is more active than average prehab patients and should be explored further.

Future Directions
Based on these qualitative data, San Carlos Apache members have demonstrated interest in a nutrition and exercise program delivered between diagnosis and oncologic surgery that includes encouragement, education, standard monitoring methods, and support in overcoming barriers to participation. The participants offered valuable insight on the specifics that would adapt published prehab models to their community. Such an intervention would attempt biochemical change using food as medicine and exercise as resilience, which is reflective of the wider momentum that American Indian/Alaska Native scholars are building in national discussions on the topics of Indigenous food sovereignty, decolonizing the diet, embracing traditional perspectives, and restoring balance [56-59].

Conclusions
American Indian/Alaska Native populations are known to be underrepresented in clinical trials and research, and even more importantly, they have never been included in the adaptation and participation of an intervention designed to modulate inflammation through diet and exercise prior to cancer surgery. San Carlos Apache would be the first tribal partner to conduct such a program and deliver the emerging science of prehab to a population that has yet to be included in this field of work. Future directions should include the findings from these interviews with continued tribal collaboration to develop a program specific to the San Carlos Apache community.

Acknowledgments
The authors acknowledge the cancer survivors of the San Carlos Apache community who participated in this study as well as the collaboration of the San Carlos Apache Healthcare Corporation and the Tribal Council. The authors would also like to thank Sherrie Harris and Marcy Langley for their support of the project through their roles at San Carlos Apache Healthcare Corporation. This research was supported by the National Cancer Institute of the National Institutes of Health (awards U54CA14392 and K08CA276137). Abstract

Background: An emerging focus on person-centered care has prompted the need to understand how shared decision-making (SDM) and health coaching could support self-management of diabetes and hypertension.

Objective: This study aims to explore preferences for the scope of involvement of health coaches and health care professionals (HCPs) in SDM and the factors that may influence optimal implementation of SDM from the perspectives of patients and HCPs.

Methods: We conducted focus group discussions with 39 patients with diabetes and hypertension and 45 HCPs involved in their care. The main topics discussed included the roles of health coaches and HCPs in self-management, views toward health coaching and SDM, and factors that should be considered for optimal implementation of SDM that involves health coaches. All focus group discussions were audio recorded, transcribed verbatim, and analyzed using thematic analysis.

Results: Participants agreed that the main responsibility of HCPs should be identifying the patient’s stage of change and medication education, while health coaches should focus on lifestyle education, monitoring, and motivational conversation. The health coach was seen to be more effective in engaging patients in lifestyle education and designing goal management plans as health coaches have more time available to spend with patients. The importance of a health coach’s personal attributes (eg, sufficient knowledge of both medical and psychosocial management of disease conditions) and credentials (eg, openness, patience, and empathy) was commonly emphasized. Participants viewed that addressing the following five elements would be necessary for the optimal implementation of SDM: (1) target population (newly diagnosed and less stable patients), (2) commitment of all stakeholders (discrepancy on targeted times and modality), (3) continuity of care (familiar faces), (4) philosophy of care (person-centered communication), and (5) faces of legitimacy (physician as the ultimate authority).

Conclusions: The findings shed light on the appropriate roles of health coaches vis-à-vis HCPs in SDM as perceived by patients and HCPs. Findings from this study also contribute to the understanding of SDM on self-management strategies for patients with diabetes and hypertension and highlight potential opportunities for integrating health coaches into the routine care process.

Introduction

Lifestyle factors, including engaging in adequate physical activity and consuming a healthy diet, are important in the management of diabetes and hypertension [1-3]. However, many patients with diabetes and hypertension do not achieve optimal lifestyle targets [4-6]. Effective interventions to help patients with diabetes and hypertension should be tailored for each patient, and this may be achieved through engaging in shared decision-making (SDM). In line with the growing emphasis on person-centered care, SDM is recognized as a way to empower patients with chronic diseases such as diabetes and hypertension. SDM involves patients and health care professionals (HCPs) collaboratively making a health care decision after discussing the treatment, management, and support packages and considering the patient’s preferences, priorities, and goals [7-9]. Although there is limited research on the effect of SDM on clinical outcomes for diabetes and hypertension [10], studies invariably suggest that SDM makes a positive difference to patients in their care. This includes better treatment adherence, increased patient coping, improved knowledge attainment, higher levels of patient satisfaction, and greater empowerment [10-12].

In addition to situations requiring treatment decisions, SDM may be useful in supporting healthy behavior change [13,14]. A feasibility study on decision tools in primary care to help initiate lifestyle change among patients with or at risk of coronary heart disease has shown the potential beneficial effects of paper-based tools for SDM in initiating behavior change [15]. Another feasibility study of an internet-based decision aid to encourage lifestyle change and adherence among people at moderate or high risk of coronary heart disease was found to increase participants’ ability to make clear decisions about making changes [16,17]. However, it was suggested that further impact may have been achieved if more comprehensive implementation strategies had been available for the interventions [16,17].

Despite the evidence supporting SDM, it is not widely practiced in clinical settings due to several reasons, such as low patient self-efficacy, a power imbalance between patients and physicians, and HCP’s limited time and knowledge [12,18-20]. To overcome these communication and resource barriers, several studies proposed the inclusion of health coaches to facilitate the SDM process in chronic care through continuous counseling dialogue with patients and exploration of patients’ situations and preferences in order to make informed decisions together on treatment and lifestyle [21,22]. Health coaches are individuals who aid patients in gaining the knowledge and confidence necessary to become engaged in their care and promote communication and collaborative decisions between patients and HCPs [23]. The practice of health coaching can differ in the type of coach, their training, and their level of involvement [24]. Nonetheless, randomized controlled trials have shown that health coaching can lead to enhanced self-management of diabetes and hypertension [25,26]. Furthermore, the experiences of patients and HCPs were found to be largely positive [27-29].

Although literature has documented the effectiveness and feasibility of SDM and health coaching, the evidence primarily comes from patients and HCPs who were willing to take part in or complete interventions [30-32]. There are fewer studies that have examined the viewpoints of potential end users’ perspectives regarding their preferences for and expectations of SDM [33,34], as well as the role and relationships of health coaches in patient care practice [35]. Obtaining the buy-in of patients and HCPs is crucial when developing a robust care model. To this end, we conducted a study to gather the viewpoints of patients and HCPs to gain insight on developing strategies for SDM programs that incorporate nurse-trained health coaches in primary care.

The aim of this formative study was to explore the perspectives and preferences of HCPs and patients with diabetes and hypertension concerning the respective professional roles of health coaches and HCPs in SDM, as well as the factors that should be considered for optimal implementation of a SDM model that involves patients, health coaches, and HCPs.

Methods

This was a qualitative study, reported following the Consolidated Criteria for Reporting Qualitative Research (COREQ) Guidelines [36].

Setting and Participants

This study was conducted in Singapore, a multiethnic city state where the majority of the population (80%) obtains health care from the public health care system [37]. Participants were mainly from SingHealth Cluster, which is the largest regional health care system in Singapore, offering a complete range of medical care for patients, including those with diabetes and hypertension. Eligible patient participants were those aged 40 years and older, diagnosed with diabetes and hypertension, and attending public primary care clinics. We identified eligible patients from a study cohort that investigates the clinical and cost-effectiveness of a behavioral intervention delivered through mobile health [38]. The participants were then approached through a phone call with the study aim and methods explained. On the other hand, eligible HCP participants were those responsible for managing patients with diabetes and hypertension in public primary care clinics, step-down care, and secondary or tertiary centers with at least 1 year of experience. We approached potential HCP participants through email and provided background information. Purposive sampling was adopted in terms of age (patients) and clinical experience (HCPs) to maximize diversity of perspectives.

Data Collection

We conducted focus group discussions (FGDs) with participants between February 2022 and May 2022. A semistructured topic guide was developed and subsequently pilot-tested to facilitate discussions on the roles of health coaches and HCPs in self-management, views toward health coaching and SDM, and factors that should be considered for optimal implementation of SDM that involves health coaches. All FGDs were carried out through web-based videoconferencing by facilitators (CMT and WBT) who were trained in social sciences and qualitative
research and did not have a personal relationship with the participants. Each FGD session lasted approximately 90 minutes for patient participants and 60 minutes for HCP participants. No repeat interviews were conducted, and transcripts were not returned to participants for further input. Data collection and analysis were an iterative process that continued until no new themes emerged. Field notes were taken to support the contextual interpretation of the data.

**Data Analysis**

All FGDs were audio-recorded and transcribed verbatim. Transcripts were checked for accuracy and thematically analyzed. A total of 2 coders (CMT and WBT) were assigned to code the patient FGDs, while 2 other coders (JKP and VXL) were assigned to code the HCP FGDs. The team adopted the 6 steps to thematic analysis suggested by Braun and Clarke [39], in which the coders first familiarize themselves with the data and generate initial codes independently before collating the codes into potential themes together. The themes were constantly reviewed, refined, and reclassified to ensure the best fit of themes to the data. Discrepancies between coders were resolved through consensus meetings involving all study team members. The FGDs were conducted until thematic saturation occurred at the 17th and 18th FGDs with patients and HCPs, respectively. Storing and managing data during data analysis was done using NVivo (version 12; QSR International).

**Ethical Considerations**

This study was approved by the SingHealth Centralized Institutional Review Board (2019/2468). Participants provided verbal informed consent before the study began. The study team maintained data confidentiality by redacting personally identifiable information from interview transcripts and generating unique study identifiers, which were linked to participant identifiable information only through a password-protected file. Participants were reimbursed SG $60 (US $44.70) to defray the cost of their participation in this research.

**Results**

**Participant Characteristics**

Out of 89 patients approached, 39 were recruited for the study, with the most frequent reasons for the decline being difficulties in participating in web-based interviews or schedule unavailability. The recruited patients participated in 17 FGDs. Their age ranged from 43 to 68 years, with 74% (29/39) being male candidates and 64% (25/39) being Chinese. Concurrently, we approached 52 HCPs and recruited 45 HCPs who participated in 18 FGDs, with schedule unavailability as the main reason for the decline. Approximately 65% (29/45) were clinicians, followed by 16% (7/45) being nurses. The range of clinical experience in managing chronic diseases of the HCPs was from 1 year to 28 years (Table 1).

\(^a\)HCP: health care professional.
\(^b\)FGD: focus group discussion.
\(^c\)N/A: not applicable.

Through our analysis, we identified three themes that represent (1) the participants’ perspectives concerning the professional roles of health coaches and HCPs in SDM, (2) the perceived importance of health coaches’ credentials and attributes, and (3) a total of 5 essential elements to be considered for optimal implementation of SDM. Figure 1 presents a visual summary that suggests how SDM involving health coaches could be applied in clinical settings to facilitate diabetes and hypertension self-management, based on the findings.
Perceived Preference for Professional Roles of HCP and Health Coach in SDM

While there were some commonalities in the roles of HCPs and health coaches in the SDM model of care, a distinction in the extent of their responsibilities was evident.

Patient Education

Many of the patient participants and HCP participants recognized the shared responsibilities of HCPs and health coaches in improving patients’ understanding of their conditions in order to decide on the self-management strategies that fit best according to their individual situations and capacities. However, their expectations of the specific roles that HCPs and health coaches would play in patient education differed. The health coach was seen to be more effective in engaging patients in lifestyle education and informing patients on healthy lifestyle choices, while the HCPs are expected to educate patients on medication and alternative treatment options for their conditions. The participants explained that the difference in expectations was based on the perceived amount of time availability the professionals have with the patients and the background of the professionals.

[The health coach] is a single point of contact that I can refer to, who is an expert in this area, and I can leverage on that to achieve the goals that I want. Knowing that there is somebody associated with you, and you can engage with it helps a lot. Whether it’s about physical activity, food intake, [or] the discipline you need to get in order to achieve the goals, if I know I can reach out to someone to talk about it, it will definitely make a difference. [Patient 37, Patient FGD #13]

I will tell her what the best option as a physician is, based on our guidelines. However, I will tell her other possible options if let’s say she doesn’t want the recommended option. As a physician, it’s our duty to tell patients the options they have and the pros and cons of each option. [HCP 36, HCP FGD #12]

Goal Setting

Both patient participants and HCP participants agreed that setting actionable goals would be crucial to improving clinical outcomes. However, the brief consultation sessions in primary care settings were inadequate for patients to develop personalized care plans with their HCPs. Thus, patient participants saw the value of involving the health coach to work with them to set actionable goals while taking into consideration their personal circumstances in order to devise an appropriate self-management plan that aligns with the expectations of the HCPs. At the same time, HCPs suggested that the health coach plays an important role in identifying any lapses and bridging the gaps between the treatment offered by HCPs and the health care preferences and goals of the patients.

A doctor’s goals may be different from a patient’s goals. Sometimes it’s hard for us to assess the ideas, values, and preferences during our short 10 to 15 minutes [consultations]. If the health coach informs us, that will be good so that the patient, doctor, and health coach can be on the same page to help the patient achieve his or her goals. [HCP 36, HCP FGD #12]

[A health coach should] connect with the patient to discover what the problems are and also be aware of the patient’s environment. Then align these with the expectations that HCPs might have of the patient. So, the health coach’s duty is basically to identify all of these, in order to make things easier. [Patient 25, Patient FGD #10]

Patient Empowerment

According to patients, “feeling empowered” entailed remaining motivated to engage in behaviors that promote their health. To
this end, they preferred to work with the health coaches and mutually establish achievable goals related to behaviors such as diet and exercise. The partnership that patients form with their health coach allows patients to feel supported throughout their self-management journey, which motivates them to be more engaged and adherent to the chosen care plan. Likewise, HCP participants recognized the significance of such a partnership, in which the patients are free to express their expectations and wishes for care while deciding on a care plan that would be tailored to their individual needs and preferences.

> It would be more of a motivating aspect because the health coach can help set specific Agendas, target them, and communicate with patients...In this way, we are more motivated to try hard to meet the targets. Because when seeing the doctor, you know, he/she will just tell you to lose weight but [the] health coach can motivate you for sure. [Patient 25, Patient FGD #10]

> In an ideal setting, [health coaches] need to understand what their targets are, and what the patient thinks of their health conditions. From there, see what the patient is willing and able to do and what their plans are going forward. [HCP 09, HCP FGD #1]

### Importance of Health Coach’s Credentials and Attributes

Both patient participants and HCP participants emphasized the importance of health coaches’ credentials and attributes that would influence their acceptance of health coaching as part of routine patient care. Most participants mentioned that a desirable health coach would need to possess sufficient knowledge of both medical and psychosocial management of diabetes and hypertension so that health coaches could offer appropriate guidance to patients.

> Health coach should be medically trained to give correct advice. I mean, apart from medication and disease management [which is the ambit of HCPs], the health coach should be able to provide psychosocial counseling. [HCP 38, HCP FGD #8]

A health coach’s personal attributes were equally stressed; most participants noted that a health coach should demonstrate positive personality traits such as openness, patience, and empathy to effectively improve a patient’s willingness to consider the recommended health practices as suggested by the health coach.

> How do I become open to the health coach? Firstly, I think the health coaches themselves must be very caring and full of empathy, to disarm all the unhappiness of the patient, maybe then patients will be willing to tell the coach about their story. [Patient 51, Patient FGD #17]

### 5 Essential Elements for Optimal Implementation of SDM

A total of 5 elements have been identified that participants believe should be considered for optimal implementation of the SDM model of care involving health coaches.

#### Target Population

Most participants (patients and HCPs) shared that SDM should target a certain segment of patients to maximize its benefits. They believed that individuals with newly diagnosed chronic conditions and those with poorly controlled diabetes and hypertension would benefit more from the proposed SDM model of care involving health coaches. This is because these patient groups may have inadequate knowledge or support to effectively manage their conditions. Thus, the education, guidance, and discussion provided by the health coach could prepare them with the necessary knowledge to begin their self-management journey effectively.

> Maybe this will help for those who just are diagnosed with diabetes, and you know, those at a loss or don’t know what to do. But if you’re working with a “seasoned” patient, they know what to do, what to expect and all. [Patient 17, Patient FGD #3]

#### Commitment of all Stakeholders

Participants asserted that in order to effectively facilitate SDM and achieve the mutually established goals of improving self-management, all stakeholders involved in this communication process should be equally committed. They expressed commitment to engaging in open dialogues and establishing partnerships among all 3 parties, including patients, HCPs, and health coaches, at targeted times and through preferred modalities. While patient participants expressed a preference for frequent check-ins with the health coach (eg, monthly), HCP participants felt that meetings between health coaches and HCPs should be arranged on a case-by-case basis, depending on the urgency and complexity of the patient’s conditions due to their high workload. Most participants were open to the varied modes of communication, including in-person and web-based means to facilitate the SDM to cater to different situational needs (eg, web-based call for a brief check-in and an in-person call for an in-depth dialogue).

> I think doctors need to focus on the very complex cases for communication with health coaches. We can’t put too much effort into handling every single chronic patient because the workload will be too high. [HCP 02, HCP FGD #2]

#### Continuity of Care

Care continuity was identified by participants as a critical factor in facilitating SDM. Both HCP participants and patient participants expressed a preference for having the same health coach for follow-up appointments to foster a sense of rapport, continuity of care, and motivate patients to carry out the plan of care. Additionally, patient participants felt that following up with the same health coach would help them build trust with their health coach and disclose their concerns, strengths, and limitations in their self-management journey.

> In a polyclinic setting, the doctor will change every appointment. If the same health coach can provide consistent support and counseling to the patient, and if the patient has someone who is checking on him,
he will want to take better care of his chronic conditions. [HCP 02, HCP FGD #2]

I think the health coach should be someone that at least I know and have some level of good relationship...so I can treat the coach like a friend and open up. [Patient 32, Patient FGD #9]

**Philosophy of Care**

Participants highlighted the importance of open communication and person-centered inquiry to facilitate mutual understanding among all parties involved in SDM. They valued strategies that could allow patients to set personal goals, negotiate, and discuss challenges. Thus, the philosophy of care was focused on supporting patients to make informed choices and engaging patients in discussion to develop a care plan that is tailored to individuals, as opposed to simply offering generic health advice that may not be as effective in motivating patients.

Ask the patient what they want first, because if it’s not something that they want, it’s not likely that they will cooperate with us [HCPs or health coaches] even though it is what we want from them. [HCP 49, HCP FGD #18]

**Faces of Legitimacy**

Notably, our interviews revealed that patients generally prioritized the advice given by their physicians because they perceived their physician’s advice to be more important and reliable than that of health coaches and other HCPs (eg, dieticians, nurses, and physiotherapists). This could pose a challenge to SDM when consensus cannot be built about the preferred self-management plan among all parties involved and patients are less receptive to exploring other treatment options and recommendations unless they are endorsed by a physician.

I’ll still take the final instructions from the doctor. Frankly speaking, the health coach might be knowledgeable in terms of some medical information, but they are still not reliable. [Patient 17, Patient FGD #3]

Sometimes it also depends on which healthcare provider is approaching the patient. A lot of times, our patients defer to what we intended so if the doctors don’t say like “Oh you need to do this” then they won’t really cooperate because doctor’s recommendations take precedence over whatever other professionals are seeking to help. [HCP 49, HCP FGD #18]

To mitigate this, some of our HCP participants, who are physicians, suggested that reinforcement and endorsing the advice from the health coaches and other HCPs during follow-up appointments would be important in increasing patients’ trust in other providers and promoting effective communication in SDM.

One thing that physicians like me could do is to reinforce what the health coach has taught the patients. Then the patient would realize that, Oh yes, that [advice given by health coach] is very important. [HCP 49, HCP FGD #18]

**Discussion**

**Principle Findings**

This study explored the preferences and perspectives of both patients and HCPs on how SDM involving health coaches could help patients make informed decisions about their health and improve self-management of their diabetes and hypertension. While some perspectives varied across patients and HCPs, we identified three unified themes, including (1) the perceived preference for and expectation of the roles of HCPs and health coaches in SDM, (2) the importance of health coaches’ credentials and attributes, and (3) the elements necessary for effective implementation of SDM. The findings gained from this study offered key insights to support efforts to optimally implement SDM involving health coaches for patients with chronic conditions.

The lack of patient education [40,41] and psychosocial support [42-45] can hinder patients’ ability to self-manage their diabetes and hypertension, which eventually results in suboptimal control and negative health outcomes. In this study, patient participants and HCP participants agreed that the primary responsibility of a health coach is to educate patients on healthy lifestyle choices and provide several self-management options before setting actionable goals that align with the patient’s needs and preferences, while an HCP is expected to provide medication education and offer alternative treatment options for their conditions. In this regard, SDM provides a platform for patients, health coaches, and HCPs to engage in conversations that enable information to be shared and address each party’s expectations for care [13]. In addition, the involvement of health coaches in SDM has been shown to improve self-management by fostering greater patient involvement in their care and designing care plans that take into account their unique treatment goals and preferences [46]. When patients have a better understanding of their options and have the autonomy to express their preferences and wishes for care, they are more likely to be satisfied with the eventual plan of care and adhere to it [47]. Moreover, our findings showed that the involvement of a health coach would offer patients a sense of support through their self-management journey and motivate them to take charge of their diabetes and hypertension self-care. This finding reflects previous studies that found integrative health coaching improved patients’ psychosocial outcomes, resulting in reduced perceived barriers to self-management, enhanced perceptions of social support, and ultimately improved clinical outcomes in patients with diabetes and hypertension [48-50]. The results of this study offer valuable insights into the distinct responsibilities of health coaches and HCPs in SDM and chronic disease management and highlight potential areas of emphasis in patient coaching, workflow, and collaborative efforts.

A common theme running through the FGDs was participants’ keen interest in the credentials and characteristics of health coaches. Participants stressed the importance of a health coach’s positive attitude and knowledge in both the medical and psychosocial aspects of disease management in order to engage in a partner relationship in SDM. Indeed, a health coach’s professional expertise and personal traits, such as openness and
empathy, can improve the therapeutic relationship and ultimately enhance self-management skills [30,51]. Therefore, it is essential for health coaches to receive appropriate clinical training and education as well as possess a strong capacity for empathy [52]. Beyond the credentials and characteristics of health coaches, studies on SDM also stressed the importance of a supportive and caring environment with adequate interaction time as key aspects of the patient-provider partnership in chronic care [53,54]. Many of the physicians interviewed in this study often mentioned that they are unable to cover all aspects of the patient’s self-care due to the brief consultation sessions they have with the patients. The time required for information sharing and clarifying patients’ values, needs, and preferences could impact the already-pressured clinical setting [13]. Therefore, it was suggested that the involvement of health coaches in SDM would help to prioritize discussions about specific aspects of diabetes and hypertension self-management (ie, medical and lifestyle) and allow patients to benefit from the enhanced support from their health coaches, who have more time to work with them on modifying their lifestyle and achieving better control of their conditions. Our findings underscore the significance of health coaches’ competencies to ensure that health coaches can fulfill their core responsibilities and the potential benefit of involving health coaches in SDM to support patients further in their self-management journey.

Lastly, our participants believed that newly diagnosed or less stable patients could benefit the most from SDM involving health coaches and emphasized the importance of continuity of care through the same coach. They also recognized that open communication and person-centered inquiry would be crucial for improving the quality of SDM. Indeed, previous studies demonstrated that open communication and consistent coaching improved decision quality, knowledge, and risk perception among patients with diabetes and hypertension [10,55]. Despite these findings supporting the use of SDM to support healthy behavior change among patients with chronic disease, patients in this study still held a strong belief in the traditional approach of “doctor knows best” (faces of legitimacy), with many patients relying disproportionately on physicians for decisions [56]. Patients’ reliance on physicians for decisions may pose a challenge to the SDM process involving health coaches since patients may prioritize the advice of their physicians over that of health coaches. For health care institutions that wish to implement SDM for chronic disease management, we suggest distinguishing the roles of HCPs and health coaches in chronic disease management to ensure successful implementation of SDM. Institutions can also consider educating patients about the unique and valuable contributions that health coaches can make in their care [57] to reinforce their trust in health coaches. As observed in this study, the health coaches’ involvement in SDM was important in offering personalized support to patients to modify their lifestyle and self-management in order to achieve behavioral change and gain better control of their diabetes and hypertension. Future research should aim to identify factors that affect patients’ engagement and trust with health coaches to enable successful implementation of this SDM model for chronic disease management.

Limitations
This study has a few limitations. The perspectives of health coaches were not included, which may limit the comprehensiveness of the results. Furthermore, participants’ preferences and expectations were not examined by subgroups such as HCP’s professional roles or patients’ confidence levels in self-management and cultural backgrounds. Further research focusing on these aspects may prove useful for a richer understanding of the SDM implementation. Despite these limitations, this study provided valuable insights into the SDM model of care, highlighting how patients, HCPs, and health coaches can collaborate and the factors needed to be considered for robust implementation of the SDM for patients with diabetes and hypertension.

Conclusions
Our findings examined the viewpoints of potential end users’ perspectives regarding their preferences for and expectations of SDM from patients and HCPs. Our analysis identified the appropriate roles of health coaches vis-à-vis HCPs in SDM and underscored the importance of a health coach’s credentials and personal attributes. At the same time, the five elements for optimal implementation of SDM can be used to guide future efforts to contextualize SDM and integrate health coaches into routine primary care to support diabetes and hypertension treatment.

Acknowledgments
The authors thank the participants who generously provided their time and shared their perspectives. We would also like to thank Cassandra and Valen from the Centre for Population Health Research and Implementation for their support for the study. This study is supported by the National Research Foundation, Singapore, under its AI Singapore Programme (AISG-GC-2019-001-2A). Abstract

Background: Adult obesity and overweight pose a substantial risk to global public health and are associated with various noncommunicable diseases. Although intermittent fasting (IF) is increasingly used as a relatively new dietary strategy for weight loss, the effectiveness of 2 days per week of dry fasting remains unknown.

Objective: This study aims to evaluate the effectiveness of a combined dry IF and healthy plate (IFHP) and healthy plate (HP) intervention in improving anthropometric outcomes and body composition.

Methods: This nonrandomized controlled trial involved 177 adults who were overweight and obese. Among them, 91 (51.4%) were allocated to the IFHP group and 86 (48.6%) were allocated to the HP group. The overall study duration was 6 months (October 2020 to March 2021). The intervention was divided into 2 phases: supervised (3 months) and unsupervised (3 months). The data were collected at baseline, after the supervised phase (month 3), and after the unsupervised phase (month 6). Anthropometric (weight, height, waist circumference, and hip circumference) and body composition (body fat percentage, body fat mass, skeletal muscle mass, and visceral fat area) data were measured at all 3 data collection points. Sociodemographic data were obtained using a questionnaire at baseline.

Results: Most participants were female (147/177, 83.1%) and Malay (141/177, 79.7%). After 3 months, there were significant reductions in weight (difference −1.68; P<.001), BMI (difference −0.62; P<.001), body fat percentage (difference −0.921; P<.001), body fat mass (difference −1.28; P<.001), and visceral fat area (difference −4.227; P=.008) in the IFHP group, whereas no significant changes were observed in the HP group. Compared to baseline, participants in the IFHP group showed a significant decrease in weight (difference −1.428; P=.003), BMI (difference −0.522; P=.005), body fat percentage (difference −1.591; P<.001), body fat mass (difference −1.501; P<.001), visceral fat area (difference −7.130; P<.001), waist circumference (difference −2.304; P=.001), and hip circumference (difference −1.908; P=.002) at month 6. During the unsupervised phase, waist (IFHP difference −3.206; P<.001, HP difference −2.675; P=.004) and hip (IFHP difference −2.443; P<.001, HP difference −2.896; P<.001) circumferences were significantly reduced in both groups (P<.01), whereas skeletal muscle mass (difference 0.208;
Introduction

Background

Obesity, defined as a disease by the American Medical Association in June 2013 [1], poses greater and long-lasting harm to the collective health of adults and children worldwide. Despite being prioritized in health policies for decades, the prevalence of obesity continues to rise across countries and socioeconomic statuses. Globally, the obesity rate has almost tripled since 1975 with 39% and 13% of adults being overweight and obese, respectively [2]. A similar pattern has been observed in Malaysia where the prevalence of overweight and obesity in adults had increased by 12.6% from 2011 to 2019 [3]. In 2019, the National Health and Morbidity Survey reported that half of the adult population in Malaysia was either overweight (30.4%) or obese (19.7%) compared with 29.4% and 15.1% in 2011, respectively [3].

Obesity is a leading health problem that increases the risk of multiple health conditions such as cardiovascular diseases, type 2 diabetes mellitus, dyslipidemia, asthma, infertility, and certain types of cancers. In addition, it has adverse effects on the economy and national productivity. In 2019, the economic impact of overweight and obesity across 161 countries was estimated to be an average of 2.19% of the gross domestic product. If the current trends continue, it is projected to rise to 3.29% of the gross domestic product by 2060 [4]. Obesity has other associated indirect costs and losses, such as lost workdays, economic burdens stemming from premature mortality, and reduced work productivity [4].

Dietary modification is a keystone of weight management. As the foundation of weight loss, a state of negative balance must be achieved. Over the decades, there has been much debate on how to attain and maintain this negative energy balance by researching the most practical and feasible methods for weight loss. Studies have demonstrated that different dietary regimes are not only effective in lowering weight but also in improving the risks of chronic diseases such as type 2 diabetes mellitus, hypertension, and nonalcoholic fatty liver disease [5-8]. Intermittent fasting (IF) is a form of calorie restriction that consists of various eating plans that cycle between fasting and nonfasting states over a defined period. The effectiveness of wet IF in reducing weight and improving cardiometabolic effects has been proven in recent studies [9,10]. However, the benefits of dry fasting (except for Ramadan fasting) are not well documented. Wet IF is a form of fasting that restricts the consumption of all types of food and drink except water [11], whereas dry IF is defined as a complete fast in which no food or fluid intake is allowed [12].

A practical and easy method for restricting calorie intake is by controlling the portion size of a meal. This method has been widely practiced worldwide and differs based on the culture and eating habits [13,14]. In Malaysia, the Malaysian Healthy Plate is a portion control method that was created to translate the messages in the Malaysian Dietary Guidelines 2010 and Malaysian Food Pyramid 2010 [15]. It is a single-meal guide that suggests food intake following the quarter-quarter-half concept, which divides the plate into a quarter plate of grains or grain products; a quarter plate of fish, poultry, meat, or egg; and a half plate of fruits and vegetables [16].

Objectives

Although numerous studies have proven the effectiveness of conventional IF in reducing body weight [17], the efficacy of 2 nonconservative days per week of dry IF remains unclear. Furthermore, the reported benefits of the Malaysian Healthy Plate on improving health are still lacking, despite being widely practiced in Malaysia since 2016. To date, no other study has reported the effects of combined IF and a healthy plate (HP) dietary protocol on health. Hence, this nonrandomized controlled trial aims to determine the effectiveness of combined IF and HP (IFHP) and HP interventions in improving anthropometric outcomes and body composition. We hypothesized that there would be a significant improvement in the outcomes in both groups, with more prominent changes observed in the IFHP group because of the added IF intervention.

Methods

Study Population and Design

This nonrandomized controlled study involved a total of 177 participants with overweight or obesity. The participants were divided into 2 intervention groups, the combined IFHP group and the HP group, based on their designated workplace (the National Institutes of Health in Setia Alam; the Institute for Medical Research, Jalan Pahang; and the Institute Kementerian Kesihatan Malaysia [Teknologi Makmal Perubatan], Jalan Pahang). The distance between Jalan Pahang and Setia Alam is approximately 40 km. The allocation was conducted in a manner that aimed to prevent contamination bias and was chosen based on the practicality of monitoring the participants. The study population exhibited a rather homogeneous set of sociodemographic characteristics, environmental conditions, facility settings, and job types.

P=.04) and visceral fat area (difference −2.903; P=.003) were significantly improved in the IFHP group only. No significant difference in the between-group comparison was detected throughout the intervention (all P>.05).

Conclusions: A combined IFHP intervention was effective in improving anthropometric outcomes and body composition in adults with overweight and obesity.

Introduction

Background

Obesity, defined as a disease by the American Medical Association in June 2013 [1], poses greater and long-lasting harm to the collective health of adults and children worldwide. Despite being prioritized in health policies for decades, the prevalence of obesity continues to rise across countries and socioeconomic statuses. Globally, the obesity rate has almost tripled since 1975 with 39% and 13% of adults being overweight and obese, respectively [2]. A similar pattern has been observed in Malaysia where the prevalence of overweight and obesity in adults had increased by 12.6% from 2011 to 2019 [3]. In 2019, the National Health and Morbidity Survey reported that half of the adult population in Malaysia was either overweight (30.4%) or obese (19.7%) compared with 29.4% and 15.1% in 2011, respectively [3].

Obesity is a leading health problem that increases the risk of multiple health conditions such as cardiovascular diseases, type 2 diabetes mellitus, dyslipidemia, asthma, infertility, and certain types of cancers. In addition, it has adverse effects on the economy and national productivity. In 2019, the economic impact of overweight and obesity across 161 countries was estimated to be an average of 2.19% of the gross domestic product. If the current trends continue, it is projected to rise to 3.29% of the gross domestic product by 2060 [4]. Obesity has other associated indirect costs and losses, such as lost workdays, economic burdens stemming from premature mortality, and reduced work productivity [4].

Dietary modification is a keystone of weight management. As the foundation of weight loss, a state of negative balance must be achieved. Over the decades, there has been much debate on how to attain and maintain this negative energy balance by researching the most practical and feasible methods for weight loss. Studies have demonstrated that different dietary regimes are not only effective in lowering weight but also in improving the risks of chronic diseases such as type 2 diabetes mellitus, hypertension, and nonalcoholic fatty liver disease [5-8]. Intermittent fasting (IF) is a form of calorie restriction that consists of various eating plans that cycle between fasting and nonfasting states over a defined period. The effectiveness of wet IF in reducing weight and improving cardiometabolic effects has been proven in recent studies [9,10]. However, the benefits of dry fasting (except for Ramadan fasting) are not well documented. Wet IF is a form of fasting that restricts the consumption of all types of food and drink except water [11], whereas dry IF is defined as a complete fast in which no food or fluid intake is allowed [12].

A practical and easy method for restricting calorie intake is by controlling the portion size of a meal. This method has been widely practiced worldwide and differs based on the culture and eating habits [13,14]. In Malaysia, the Malaysian Healthy Plate is a portion control method that was created to translate the messages in the Malaysian Dietary Guidelines 2010 and Malaysian Food Pyramid 2010 [15]. It is a single-meal guide that suggests food intake following the quarter-quarter-half concept, which divides the plate into a quarter plate of grains or grain products; a quarter plate of fish, poultry, meat, or egg; and a half plate of fruits and vegetables [16].

Objectives

Although numerous studies have proven the effectiveness of conventional IF in reducing body weight [17], the efficacy of 2 nonconservative days per week of dry IF remains unclear. Furthermore, the reported benefits of the Malaysian Healthy Plate on improving health are still lacking, despite being widely practiced in Malaysia since 2016. To date, no other study has reported the effects of combined IF and a healthy plate (HP) dietary protocol on health. Hence, this nonrandomized controlled trial aims to determine the effectiveness of combined IF and HP (IFHP) and HP interventions in improving anthropometric outcomes and body composition. We hypothesized that there would be a significant improvement in the outcomes in both groups, with more prominent changes observed in the IFHP group because of the added IF intervention.

Methods

Study Population and Design

This nonrandomized controlled study involved a total of 177 participants with overweight or obesity. The participants were divided into 2 intervention groups, the combined IFHP group and the HP group, based on their designated workplace (the National Institutes of Health in Setia Alam; the Institute for Medical Research, Jalan Pahang; and the Institute Kementerian Kesihatan Malaysia [Teknologi Makmal Perubatan], Jalan Pahang). The distance between Jalan Pahang and Setia Alam is approximately 40 km. The allocation was conducted in a manner that aimed to prevent contamination bias and was chosen based on the practicality of monitoring the participants. The study population exhibited a rather homogeneous set of sociodemographic characteristics, environmental conditions, facility settings, and job types.
This study enrolled participants aged 19 to 59 years with a BMI ≥23 kg/m² (overweight or obese) who were ready to participate in the intervention (assessed through readiness to participate in screening) and provided informed consent. The exclusion criteria included the following: (1) a recent involvement in weight loss programs (eg, IF, diet changes, physical activity changes, or activities that were performed constantly to reduce weight); (2) having any eating disorder; (3) diagnosed with diabetes and hypertension (on medication) or other metabolic health disturbance conditions; (4) taking any medication or supplements that can affect the study outcomes; (5) pregnancy; and (6) a lack of capacity or language skills to independently follow the protocol. A detailed description of the study design and methodology has been published elsewhere [18].

Sample Size Calculation
Sample size calculation was conducted using the PS: Power and Sample Size Calculation program (version 3.1.6; William D Dupont and Walton D Plummer, Jr). The sample size was calculated based on a between-group mean difference (δ) of 5% (SD 10%) in weight loss, 95% CI (±α= .05), and a power of study of 80% (1−β=.80). According to a review by Ryan and Yockey [19], a minimum weight loss of 5% is needed to improve cardiometabolic risk such as hypertension, diabetes mellitus, and hyperlipidemia. The minimum sample size required for this study was 64 participants for each arm. After considering 40% attrition, the calculated sample size for each arm was 90 participants, and a total of 180 participants were required for this study.

Dietary Protocol
Participants in the combined IFHP group were required to observe dry fasting from dawn to dusk for 2 days a week (Mondays and Thursdays) and practice HP for the rest of the week. During the fasting days, they were encouraged to have a meal before dawn, and no food or drink was allowed following that meal (approximately 13 hours) until sunset. Smoking and sexual activity were also forbidden during the fasting day, following the Islamic fasting obligation. For the remaining 5 days of the week, they were asked to apply the HP concept while consuming meals.

In the HP group, the participants were required to practice the HP concept daily, which entailed the division of plate portions into a quarter for protein, a quarter for complex carbohydrates, and a half for fruits and vegetables. Although they were advised to practice the HP concept for all 3 main meals per day, compliance with the dietary protocol was considered if they applied the concept to at least 1 main meal per day. The adherence to dietary protocols was monitored by trained research assistants through a daily record of food intake picture (1 meal per day) and a weekly fasting record.

Study Procedures
There were two stages of the recruitment phase: (1) health screening and (2) readiness to participate in screening. Those who were interested in joining the study were screened for the inclusion and exclusion criteria by the study team. Eligible volunteers were screened for their readiness to participate in the study, namely their motivation, enthusiasm, and willingness to commit to study protocols. Only participants who were ready to commit were included in the study.

The overall duration of the intervention was 6 months, which included 3 months of a supervised phase and another 3 months of an unsupervised phase. During the supervised phase, a reminder to fast was sent to their mobile phone on the eve of fasting days and compliance was recorded twice weekly. For HP, all participants were required to send at least 1 picture of their meal every day to the research assistants. On the contrary, no fasting reminder or meal pictures were exchanged during the unsupervised phase.

The data collection was conducted at 3 time points: baseline (before the intervention started), month 3 (at the end of the supervised phase), and month 6 (at the end of the unsupervised phase). During baseline data collection, the participants were asked to answer questions on sociodemographic factors. Anthropometric measurements were taken, including body composition analysis, at all 3 points of data collection.

Measurements of body weight and height were conducted using a Seca electronic column scale (Seca GmbH and Co KG) in kg and cm to the nearest 0.1 kg and 0.1 cm, respectively. Body weight was measured in light clothing and participants were required to remove their outer garments and shoes. BMI was calculated by dividing weight by height squared (kg/m²) and categorized into overweight (23.0-27.4 kg/m²), obese I (27.5-32.4 kg/m²), obese II (32.5-37.4 kg/m²), and obese III (≥37.5 kg/m²) based on the cutoff points for public health action in Malaysia [20]. Waist and hip circumferences were measured using a Seca measuring tape (Seca GmbH and Co KG) to the nearest 0.1 cm, with the participants standing. Waist circumference was measured at the midpoint between the top of the iliac crest and the lower margin of the last palpable rib, whereas hip circumference was measured at the widest diameter around the buttocks. To minimize measurement error, 2 measurements were taken for each parameter and the average was calculated. The waist-to-hip ratio was calculated by dividing the waist measurement by the hip measurement.

For body composition analysis, parameters such as body fat percentage, body fat mass, muscle mass, and visceral fat area were measured. These parameters were measured using a tetrapolar bioimpedance multifrequency InBody 770 analyzer (Biospace). Personal profiles (age, height, weight, and sex) were entered after reading the measurement. Before the measurement, the participants were asked to remove all metal items and stand barefoot on the device in a supine position. They then grasped the handles of the units with their thumbs and palms while maintaining direct contact with the electrode. In total, 8 polar tactile electrodes were used in the bioelectrical impedance analysis (BIA): 2 for each thumb, 2 for the palms, and 2 for the front and 2 for the back of each foot. The body composition results were computed using proprietary prediction algorithms that were built into the firmware of the device and applied only to the device being studied. The total time required for the measurement was approximately 2 minutes [21].

The International Physical Activity Questionnaire (IPAQ)–Short Form was used to assess the physical activity of the participants.
over the past week. The questionnaire has been validated for use among adults in 12 countries [22]. In this study, we used the Malay version of the IPAQ-Short Form, which was validated using the data from the 2011 National Health and Morbidity Survey [23]. The participants were asked to record the number of days in the previous week that they engaged in specific activities (vigorous and moderate activities and walking) for at least 10 minutes as well as the amount of time (in min) that they engaged in a particular activity on an average day. Energy expenditure or metabolic equivalent of task (MET) minutes per week was used to determine the physical activity based on the IPAQ scoring protocol. To calculate the MET scores for each activity, the total minutes spent on vigorous activity, moderate activity, and walking over the past week were multiplied by 8, 4, and 3.3, respectively. The total physical activity score was calculated as the sum of the MET scores for each of the 3 activity categories. All participants were asked to maintain their usual physical activity throughout the study period. The physical activity score was included as one of the controlled variables in the analysis.

The Food Frequency Questionnaire (FFQ) was used to measure the participants’ dietary intake over the previous month. The questionnaire consisted of questions covering the frequency of consuming cereals and cereal products, fast food, meat and meat products, fish and seafood, eggs, legumes and legume products, milk and milk products, vegetables, fruits, drinks, alcoholic drinks, confectionaries, bread spreads, and flavor intake. We used the validated Malay version of the FFQ, which consists of 165 items [24], and the participants required approximately 30 minutes to answer the questions at each point of data collection. We calculated the calorie intake using nutrient data that were extracted from the Nutritionist Pro nutrition analysis software (version 7.8.0; Axxya Systems). The calorie intake changes observed in this study confirmed the dietary protocol adherence.

**Statistical Analyses**

Statistical analysis was performed using the SPSS software (version 25; IBM Corp). For continuous variables, the normality of distribution was tested using the Kolmogorov-Smirnov test. Normally distributed data were presented as mean (SD), whereas the median (IQR) summarized the skewed data. For categorical variables, frequencies were calculated and presented as percentages. All variables were compared using the independent 2-tailed t test or Mann-Whitney U test for continuous variables and the chi-square or Fisher exact test (n ≤ 5 in any cell) for categorical variables. To determine the changes in outcome following the intervention, a generalized estimating equation (GEE) analysis was performed, which was adjusted for possible confounders such as age, ethnicity, sex, and physical activity. The GEE statistical analysis has been widely used owing to its robustness and ability to analyze correlated, nonnormally distributed data [25]. Compared with the repeated measures ANOVA, GEE provides more flexibility in handling missing data and accommodates unbalanced designs. The time effect was analyzed for all 3 comparisons: baseline versus month 3, baseline versus month 6, and month 3 versus month 6. To control for the overall type I error rate, we adjusted for multiple comparisons using the Bonferroni correction method in the GEE analysis. For the calorie intake analysis, we excluded participants with extreme calorie intake (<500 and >3500 kcal/day for women and <800 and >4000 kcal/day for men) [26]. All statistical tests were 2-sided, and the significance level was set at .05.

**Ethical Considerations**

This study was approved by the Medical Research and Ethics Committee, Ministry of Health Malaysia (NMRR-19-3261-51726) and was conducted in full conformity with the current revision of the Declaration of Helsinki and the International Council for Harmonisation Guidelines for Good Clinical Practice. Before recruitment, all participants were thoroughly briefed about the potential risks involved with participating in this study, and written informed consent was obtained from them. The participants had the autonomy to discontinue their involvement in the study at any point. The data were treated as strictly confidential, and each participant was assigned a unique anonymous identifier. Each participant received a reimbursement of RM30 (US $6) after each data collection, resulting in a total compensation of RM60 (US $13) per participant across the study period. This study was registered with ClinicalTrials.gov (NCT05034653).

**Results**

**Flow of Study Participants**

Overall, 302 volunteers were interested in joining the study, of which 99 (32.8%) were excluded because of the failure to meet the eligibility criteria during the first screening stage. Another 27 volunteers were excluded during the screening process in stage 2 for multiple reasons, such as pursuing further education, commitment issues, or relocating. Hence, a total of 177 participants were recruited in this study: 91 (51.4%) in the IFHP group and 86 (48.6%) in the HP group. During the supervised phase of the intervention, a total of 28 participants withdrew from the study (IFHP: 16/28, 57%; HP: 12/28, 43%), whereas 27 participants withdrew during the unsupervised phase (IFHP: 12/27, 44%; HP: 15/27, 56%). The reasons for dropout included the inability to commit to the study intervention (24/55, 44%); pregnancy (13/55, 24%); transfer to a different workplace (8/55, 15%); started medication for hypertension, diabetes, or hypercholesterolemia (5/55, 9%); and other reasons (5/55, 9%). Finally, 63 and 59 participants completed the study in the IFHP and HP groups, respectively (Figure 1).
Sociodemographic Characteristics

Table 1 summarizes the characteristics of the participants based on the intervention groups at baseline. A majority of the participants were female (147/177, 83.1%) and Malay (141/177, 79.6%) with a mean age of 34.47 (SD 7.40) years. Most participants (121/177, 68.4%) had a diploma or degree as the highest educational status. In terms of background illness history, 5.1% (9/177) and 1.1% (2/177) of the participants reported being diagnosed with hyperlipidemia and hypertension, respectively. However, none of the participants were taking any medication for the illnesses. Participants in the IFHP group had a higher mean weight (72.50, SD 18.55 kg) than those in the HP group (70.60, SD 16.28 kg); however, this difference was not statistically significant ($P=.13$). In addition, no significant differences in physical activity, daily calorie intake, other body composition, and anthropometric parameters were found between the participants from both intervention groups (Table 1). Detailed $t$ test results are presented in Multimedia Appendix 1.

Changes in Anthropometric and Body Composition

Baseline Versus Month 3

Within the IFHP group, there was a significant reduction in weight (estimated margin [EM] mean difference −1.680; \(P<.001\)), BMI (EM mean difference −0.620; \(P<.001\)), body fat percentage (EM mean difference −0.921; \(P<.001\)), body fat mass (EM mean difference −1.280; \(P<.001\)), and visceral fat area (EM mean difference −4.227; \(P=.008\)) at month 3 compared to baseline. Meanwhile, no significant changes were observed in skeletal muscle mass (\(P=.43\)), waist circumference (\(P=.45\)), and hip circumference (\(P=.80\); Table 2).

Table 2. Comparison of the anthropometric and body composition changes between the intermittent fasting healthy plate (IFHP) and healthy plate (HP) groups at baseline, month 3, and month 6.

</table>

P values <.05 are considered statistically significant. P values were derived from the GEE test adjusted for sex, age, ethnicity, and physical activity.
body fat mass (EM mean difference $-0.206; P=.78$), and visceral fat area (EM mean difference $-0.118; P>.99$). However, these changes were not statistically significant. The hip circumference significantly increased at month 3 compared to baseline (EM mean difference 1.861; $P<.001$).

There were no significant changes in other parameters (all $P>.05$; Table 2).

**Baseline Versus Month 6**

After 6 months, participants in the IFHP group showed significant reduction in weight (EM mean difference $-1.428; P=.003$), BMI (EM mean difference $-0.522; P=.005$), body fat percentage (EM mean difference $-1.591; P<.001$), body fat mass (EM mean difference $-1.501; P<.001$), body fat area (EM mean difference $-7.130; P<.001$), waist circumference (EM mean difference $-2.304; P<.001$), and hip circumference (EM mean difference $-1.908; P=.002$). However, there were no significant changes observed in skeletal muscle mass ($P>.99$; Table 2).

Moreover, hip circumference (EM mean difference $-1.034; P=.03$) showed a significant reduction among participants in the HP group after 6 months. Although there was a reduction in weight, BMI, body fat percentage, body fat mass, and visceral fat area, it was not statistically significant (all $P>.99$). The increase in skeletal muscle mass was also not statistically significant ($P>.99$; Table 2).

**Month 3 Versus Month 6**

Comparing month 6 to month 3, there were significant improvements in skeletal muscle mass (EM mean difference $0.208; P=.04$), visceral fat area (EM mean difference $-2.903; P=.003$), waist circumference (EM mean difference $-3.206; P<.001$), and hip circumference (EM mean difference $-2.443; P<.001$) in the IFHP group. Otherwise, there were no significant changes in other parameters (all $P>.05$; Table 2).

Furthermore, participants in the HP group showed a significant reduction in waist circumference (EM mean difference $-2.675; P=.004$) and hip circumference (EM mean difference $-2.896; P<.001$) at month 6 compared to month 3. However, no other significant changes were observed (all $P>.05$; Table 2).

In view of the between-group comparison, there were no significant differences between the IFHP and HP groups observed at all time points (all $P>.05$; Table 2).

**Calorie Intake Changes**

There was a significant reduction in calorie intake at month 3 and month 6 compared to baseline in both intervention groups (Table 3). Compared to baseline, participants in the IFHP group consumed an average of 325 kcal and 266 kcal fewer calories per day after 3 months (EM mean difference $-325.09; P=.002$) and 6 months (EM mean difference $-266.70; P=.006$), respectively. Similarly, there was a significant reduction in calorie intake at month 3 (EM mean difference $-320.11; P=.004$) and month 6 (EM mean difference $-437.79; P<.001$) compared to baseline in the HP group. However, there were no significant changes in calorie intake between month 3 and month 6 in both the IFHP ($P>.99$) and HP ($P=.73$) groups. There was also no significant difference in the between-group comparison throughout the intervention ($P=.94$; Table 3).

**Discussion**

**Principal Findings**

To our knowledge, this is the only study to investigate the effect of IFHP regimens on anthropometric outcomes and body composition worldwide. This study found that a combined IFHP diet had a notable effect on weight, BMI, body fat percentage, body fat mass, and visceral fat area after 3 and 6 months of intervention. Although there were no changes in weight and BMI in the IFHP group at month 6 compared to those at month 3, visceral fat area was greatly reduced, whereas skeletal muscle mass showed a substantial improvement. After 6 months, a notable reduction in hip and waist circumference was observed among participants in both groups. The improvement was seen during the unsupervised period as there were no notable changes...
in these parameters at month 3. This study showed mixed findings when comparing supervised and unsupervised phases. After completing the supervised phase at month 3, the IFHP group showed substantial reductions in weight, BMI, body fat percentage, body fat mass, and visceral fat area, but not in skeletal muscle mass, waist circumference, or hip circumference. Meanwhile, only skeletal muscle mass, waist circumference, hip circumference, and visceral fat area improved significantly during the unsupervised phase. Overall, there was no notable difference between groups throughout the study period.

Comparisons With Previous Works, Interpretations, and Implications

The short- and long-term effectiveness of the 2-day per week fasting in reducing weight has been reported in various studies [27-30]. Generally, the concept of a 5:2 IF diet is defined in most studies as restricting calorie intake to approximately 25% of the baseline energy intake twice a week, which makes it slightly different from our IF protocol. Furthermore, any zero-calorie beverages, such as plain water, were allowed during the fasting period. In 2013, a randomized controlled study was conducted to determine the efficacy of combined fasting (Islamic Sunnah Fasting for 2 days per week) and calorie restriction (reduction of 300-500 kcal/day from habitual energy intake) among older men for 3 months. The study reported a significant interaction effect in body weight, BMI, fat percentage, fat mass, and fat-free mass after 3 months [31].

Studies reported in a recent systematic review and meta-analysis showed a positive effect of a portion control diet on weight and body composition [32]. The concept of the plate model, which was first introduced by the Community Nutrition Group of the British Dietetic Association and the Swedish Diabetic Association, provides a simple and practical visual tool to demonstrate the healthy portion of a meal intake [33]. Although the division and type of food in a meal differ according to culture and eating habits, the foundation concepts of a “plate model” or HP are calorie restriction and healthy redistribution of macronutrients, such as carbohydrates, proteins, and fibers. Our study found that among those on the HP diet alone, there were reductions in weight, BMI, body fat percentage, body fat mass, and visceral fat area after 3 and 6 months, but the changes were not statistically significant. This suggests that the addition of the IF diet 2 days per week to the HP diet had a greater impact on weight loss and improvement in body composition.

Notably, there was >4 cm² and 7 cm² loss of visceral fat area among participants in the IFHP group after 3 and 6 months, respectively. Our findings are in agreement with those of previous studies [34,35]. In a study conducted among overweight older men, there was a significant reduction in the visceral fat area following a 6-week time-restricted feeding intervention [35]. The role of fasting in facilitating lipolysis has been studied extensively. Fasting stimulates intracellular lipolysis, which is triggered by several hormonal changes such as decreased levels of insulin and increased cortisol, catecholamines, and growth hormone levels. Lipolysis is also stimulated by the sympathetic innervation of the adipose tissue [36]. A classical study supported the role of these hormones in triggering the lipolysis of adipose tissue following fasting by reporting that hypophysectomy or adrenalectomy in rats caused a reduction in plasma nonesterified fatty acid levels [37].

Central adiposity, represented by abnormal waist circumference, waist-to-hip ratio, and waist-to-height ratio, is highly associated with a higher risk of noncommunicable diseases such as cardiovascular disease and cancer [38-40]. Although both intervention groups showed significant reductions in waist and hip circumference after 6 months, greater mean differences were observed among participants in the IFHP group. Previous studies reported a similar significant reduction in waist and hip circumference after IF [34,41,42]. The London Ramadan Study is an observational study conducted during Ramadan to explore the health consequences of Ramadan IF. Besides other findings, this study showed a significant decrease in waist (mean difference ~1.93 cm; *P*<.01) and hip circumference measurements (mean difference ~2.86 cm; *P*<.01) [41]. In the IFHP group, we observed a significant decrease in both parameters during the unsupervised phase of the intervention (from month 3 to month 6). Although there was an insignificant increase in weight and BMI during this period, body fat percentage and visceral fat area were significantly reduced, which may explain the improvement in waist and hip measurements.

Apart from the weekly fasting record and daily meal picture, the reduction in calorie intake served as one of the adherence monitoring methods for the dietary protocols used in our study. The significant reduction in calorie intake at months 3 and 6 explained the improvement observed in the anthropometric outcomes and body composition parameters, especially among participants in the IFHP group. The findings also confirmed the principle of calorie restriction in IF and HP without the need to properly count the calorie intake allowable to be consumed per day to cause weight loss. A recent study reported no significant difference between time-restricted feeding and calorie restriction interventions in calorie reduction and weight loss after 3 months [43]. This finding provides an advantage to both interventions as they are more practical and easier to comply with.

Improvements in clinical end points and cardiometabolic biomarkers following changes in body composition have been reported in various studies [44,45]. However, for weight changes, it has been suggested that different degrees of weight loss contribute to different biomarker responses [46]. On the basis of the findings of a randomized controlled trial conducted among obese Americans, a 5% weight loss significantly improved the plasma concentrations of some cardiometabolic risk factor parameters, such as insulin, triglyceride, glucose, leptin, and alanine transaminase, but did not have a significant effect on other parameters (low-density lipoprotein, high-density lipoprotein, free fatty acids, and adiponectin). Only after 16% weight loss, the plasma concentration of free fatty acids, C-reactive protein, and adiponectin improved significantly. Moreover, this study demonstrated that liver and adipose tissue sensitivity improved with a 5% weight reduction and remained stable, whereas muscle insulin sensitivity continued to improve with weight losses of 11% and 16%, respectively [46].

The main advantages of the BIA method in the assessment of body composition are its noninvasiveness, lack of the necessity...

JMIR Form Res 2024 | vol. 8 | e51542 | p.2191
for highly qualified personnel, short duration, and active involvement of the participants. Furthermore, the repeatability of the BIA test is crucial for observing changes in the body composition of an individual, either in a clinical setting or for research purposes [47]. However, this test also has its limitations. Several factors have been shown to influence the measurement parameters, including body structure, obesity status, body temperature, hydration status, water and electrolyte imbalance, physical activity, and errors while performing the procedure [47]. This study tried to reduce some of these limitations by properly preparing for the examination, such as instructing the participants to fast at least 6 hours before the procedure and ensuring compliance with the procedure during measurements. Apart from the abovementioned limitations, the literature has reported inconsistent results among ethnicities. On the basis of current data, BIA is still not recommended for African American individuals, but studies have shown that it provided valid results in other populations, including Asian populations, by using race-specific equations [48].

Strengths and Limitations

This study has several strengths. To our knowledge, this study is 1 of 2 studies that were conducted to investigate the health impact of dry IF twice per week. However, although the other study [31] was conducted among overweight older men, our study allowed for higher generalization of the findings as a broader range of age group (19 to 59 years) of participants and both sexes were involved. Two days of voluntary dry fasting per week (on Mondays and Thursdays) is commonly practiced in countries with a predominantly Muslim population, including Malaysia. The positive implications on health demonstrated in our study will encourage people to practice this IF protocol as a weight management method beyond religious obligation. Those who are interested in practicing but are not accustomed to the 13-hour dry fast, such as non-Muslims, must take special precautions to avoid dehydration, lethargy, and electrolyte imbalance. In addition, although the Malaysian Healthy Plate has been introduced since 2016, there is no study that investigates its effectiveness in improving health. Our findings have added new evidence to the body of knowledge and evaluated the outcome of the Malaysian Healthy Plate at the same time.

The main limitation of this study was the impact of the movement control order implemented during the COVID-19 pandemic on the findings of the study and the participants’ compliance with the intervention. As civil servants, many of our participants worked from home during most of the intervention period. Staying at home may limit their physical activity, influence their food intake control, reduce motivation toward weight loss, and expose them to unhealthy eating. The negative consequences of social lockdowns on weight management and weight-related behavior have been reported in several studies [49,50]. Furthermore, the use of FFQ to measure dietary consumption has several limitations. Despite the requirement for good memory and literacy among participants, the food-based FFQ used in our study may also have led to response errors if the participants did not prepare their food and were unaware of the ingredients. Moreover, the dietary intake tends to be underestimated because various seasonings and culinary oils that significantly contribute to energy and nutrient intakes are not considered when calculating dietary intakes [51].

Conclusions

To the best of our knowledge, this study is the first to introduce a protocol for healthy eating that combines 2-day per week dry IF with the Malaysian Healthy Plate. Our study found that a combined dry IF and HP diet was effective in reducing weight and improving body composition. Although practicing the HP protocol alone has been demonstrated to reduce weight and improve body composition to some extent, the inclusion of a dry IF component is necessary to further amplify these effects. The significant reduction in calorie consumption in both groups validates the efficacy of both dietary protocols as a feasible and practical method for calorie restriction.

Acknowledgments

The authors would like to thank the Director General Health of Malaysia for granting permission to publish this paper. The authors acknowledge the participants and are grateful to the study teams for their support and contribution to this study. This study was funded by the Ministry of Health Malaysia Research grant NMRR-19-3261-51726.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Authors’ Contributions

SRA, NHA, RMWMZ, NSS, NMK, RJMSMJ, MKNK, NAS, NAZA, AA, YZT, AO, ZS, and MFMN conceptualized the study and contributed to the design and implementation of the research. SRA drafted the first version of the manuscript. SRA, RMWMZ, ZS, and AY conducted data analyses. All authors reviewed and edited the subsequent drafts of the manuscript. All authors have read and approved the final version of the manuscript.

Abstract

Background: This study examined the effects of the COVID-19 pandemic on the gambling behavior of individuals who were already actively engaged in such pursuits. We aimed to uncover the intricate consequences of the pandemic on this specific demographic, emphasizing the importance of understanding the complex connection between public health concerns such as the COVID-19 pandemic and gambling behavior from a public health perspective. In addition to identifying immediate impacts, this study holds significance in assessing potential long-term public health implications for the broader gambling industry.

Objective: This study investigated how the COVID-19 pandemic has affected the gambling behavior of Mainland Chinese tourists in Macau from a public health perspective. We aimed to understand the changing patterns of gambling habits within this specific demographic by comparing their behavior before and during the pandemic, with a particular emphasis on the evolving dynamics of gambling and their public health consequences. This study provides a detailed exploration of the impact and implications of global health emergencies on this particular demographic’s gambling behaviors and preferences.

Methods: This study used a robust cross-sectional analysis involving a sample of 334 Mainland Chinese gamblers with prior experiences in casinos in Macau. The sample deliberately encompassed individuals involved in gambling before and during the COVID-19 pandemic. Data were collected through carefully designed questionnaires to gather information on gambling habits, preferences, and observed behavioral changes in the sample.

Results: This study unveiled a notable shift in Mainland Chinese gamblers’ behavior during the COVID-19 pandemic. A considerable number of participants opted for web-based platforms over traditional land-based casinos, resulting in reduced budgets, less time spent on gambling, and decreased participation in social gambling. Remarkably, there was a notable surge in online gambling, indicating a noteworthy adaptability of gamblers to changing circumstances. These findings emphasize the dynamic nature of gambling habits during global public health emergencies, revealing the resilient and evolving preferences of Mainland Chinese gamblers in response to the challenges posed by the pandemic.

Conclusions: This study highlights the negative impact of the COVID-19 pandemic on casino gambling, notably evident in a significant decline in Mainland Chinese tourists visiting Macau for gambling. There is a noticeable shift from traditional gambling to web-based alternatives, with individuals seeking options within the pandemic constraints. Furthermore, the findings point out an increase in gambling among the younger generation and behavioral changes in individuals with mood disorders. The findings of this study emphasize the critical need for proactive measures to address evolving gambling preferences and associated risks during public health crises; furthermore, these findings underscore the importance of adaptive strategies within the gambling industry, as well as the necessity for effective public health interventions and regulatory frameworks to respond to unprecedented challenges with efficacy and precision.

Introduction

Background
Gambling addiction is widely acknowledged as a significant public health concern [1,2]. Some common types of gambling-related harm include financial difficulties, mental health problems, relationship disruption, emotional distress, cultural harm, and also involvement in criminal activities [3]. In Macau, gambling plays a vital role in driving economic growth, tourism, and job creation. Since 2006, Macau has risen to prominence as the world’s largest gambling market, surpassing Las Vegas [4,5], with Mainland Chinese tourists constituting a substantial 93% of the city’s gambling clientele [6]. While this success has undoubtedly contributed significantly to tourism and economic development, it has also brought forth a concerning issue—the rise of gambling addiction among the influx of Chinese tourists. Despite their pivotal role in Macau’s prosperity, the substantial number of Chinese tourists engaging in gambling activities raises pressing concerns regarding the prevalence of problem gambling within this demographic.

The COVID-19 pandemic, caused by SARS-CoV-2, has been a global health crisis since late 2019 and continues to affect the world today [7]. Similar to many other regions, Macau has not been immune to the rapid spread of the virus. In response, the region implemented stringent measures to control the transmission, including a mandatory 14-day quarantine and a required nucleic acid test for entrants. This pandemic has evolved into a worldwide public health crisis, with profound economic repercussions on a global scale [8]. Macau’s gambling industry, in particular, faced significant challenges, experiencing a substantial decrease in gambling revenue [9]. This decline underscores the impact of the pandemic on gamblers’ behavior and the challenges faced by the sector due to public health measures. The highly contagious nature of the coronavirus prompted a crisis in environmental health for tourists and gamblers [10]. In response, public health authorities prioritized anti–COVID-19 measures, ranging from recommendations to enforceable mandates. In Macau, the local government adopted a stringent approach, implementing a zero-tolerance policy with mandatory quarantine and nucleic acid testing at entry and exit points. Furthermore, casino operators adopted measures to limit the concentration of gamblers and reduce the risk of virus transmission. Aligned with the Chinese government, the authorities in Macau implemented a health code system for public health and safety. The COVID-19 pandemic significantly impacted the casinos in Macau, leading to lasting negative effects on the gambling and tourism industries. Some casinos were forced to close due to the challenges posed by the pandemic [11].

The growing global prevalence of gambling and its potential impact on public health prompted us to analyze the evolving patterns of gambling. Chinese gamblers constitute the primary course of patronage for casinos across Asia [12]. While gambling is prohibited in Mainland China, Macau stands out as a legal gaming destination due to its Special Administrative Region (SAR) status under the “one country, two systems” principle. This study holds particular relevance in understanding the behavior of Chinese gamblers within regional and global public health environments. The COVID-19 pandemic has significantly influenced gambler behavior, including factors such as travel restrictions [13], risk assessment [14], alternative attractions, the impact of destination marketing strategies [15], and the rise of online gambling [16]. Macau’s distinctive position as a major gambling hub, heavily dependent on tourism, presents an intriguing case to investigate the public health implications of COVID-19 and gambling addiction. However, there is a notable research gap in understanding the changes in gambling behavior among Mainland Chinese gamblers in Macau during the pandemic. Examining these shifts is crucial to addressing the existing knowledge gap in this context and gaining a comprehensive understanding of the effects of the pandemic on gambling patterns and preferences. This knowledge will enable the implementation of evidence-based public health policies and practices that prioritize the well-being and safety of both local residents and tourists in the postpandemic era.

We aimed to investigate the gambling behaviors of Chinese gamblers during the COVID-19 pandemic, specifically by comparing their past and current behaviors through a cross-sectional analysis. Furthermore, this study explores the factors that influence these behaviors within the context of public health measures. The findings offer valuable insights and recommendations for industry executives and policy makers, facilitating a comprehensive understanding of the shifts in gambling patterns during public health crises. Considering the importance of public health, these insights could also serve as a crucial resource for guiding strategic adjustments in the gambling industry.

The Literature
COVID-19 Impact on Tourism: Historical Context and Consequences in Macau
Gambling is a recognized public health issue with wide-ranging implications. The recent COVID-19 pandemic has brought forth significant public health implications for the gambling industry worldwide [16]. In response to the pandemic, the Macau SAR government implemented various proactive measures to safeguard public health, including specific guidelines and regulations for casinos [17]. Following the confirmation of the first COVID-19 case on January 22, 2020, the local government temporarily suspended casino and entertainment businesses for half a month starting February 4, 2020. Furthermore, nonessential services were postponed, with entry bans for nonresidents implemented from March 18, 2020, except for individuals from Mainland China, Hong Kong, Taiwan, and nonresident workers. Effective from May 11, 2020, entry requirements included a negative COVID-19 test within 7 days or a Macau Guangdong Health Code [18]. Macau gradually resumed normal casino operations in August 2020, but foreign tourists were required to undergo nucleic acid testing within 7
days before arrival. Preventive measures within casinos included mask-wearing mandates, exclusion of individuals with fever or acute cough, health declarations, and health codes. Entry was denied to those with influenza-like symptoms, and visitors’ health conditions were closely monitored. Inside the casinos, efforts were made to prevent close contact, avoid overcrowding, suspend promotional activities, and limit the number of individuals to ≤50% of the venue’s capacity. A minimum distance of 1 m was maintained between gamblers.

The ongoing pandemic and the subsequent prevention strategies have contributed to the resurgence of travelers visiting Macau for gambling and leisure purposes. The rapid transmission of COVID-19 has led to a decline in consumer economic activity, directly impacting the gambling and tourism industry. The COVID-19 pandemic has had a devastating effect on the global tourism sector, as strict measures have been taken to contain the spread of SARS-CoV-2. Consequently, there has been a substantial decline in global tourist arrivals [19]. For instance, in Macau, total visitor spending (excluding gambling) in the first quarter of 2020 experienced a substantial year-on-year decline of 70.4%, reaching MOP 5.01 billion (MOP $1=US $0.12). Per capita expenditure also decreased by 4.8%, with each visitor spending approximately MOP 1555 during that period [20].

On the basis of the aforementioned information, it is evident that COVID-19 has had a significant impact on consumer behavior and public health, particularly in relation to the gambling industry and the broader tourism sector. The pandemic has resulted in negative effects on gambling spend and public health, such as a decrease in gambling revenue, changes in the consumption patterns of tourists, and a decline in the overall tourism industry [21]. Moreover, the public health implications of COVID-19 have not only affected the emotional and psychological well-being of gamblers but also led to changes in their behavioral patterns due to safety concerns [22]. The altered behavior and psychological needs resulting from the COVID-19 pandemic are likely to influence the perception of safety among tourists and subsequently affect their willingness to gamble and their gambling behavior from a public health perspective.

**Gambling Behavior**

Gambling is part of a gambler’s leisure activities and social relations [23]. Given the unique characteristics of gambling compared to other consumption behaviors, the gambling process carries the possibility of influencing income. Rational individuals who engage in gambling derive enjoyment from the overall journey of the activity, regardless of whether they win or lose money during the process. Gambling as a consumption item exhibits a distinct attribute wherein the potential for income fluctuation during consumption is observed [24]. Gambling is recognized as an activity through which individuals have the opportunity to pursue potential financial gains or explore avenues for earning income [25]. Furthermore, it is essential to consider gambling behavior as a continuous variable. The involvement of individuals in gambling displays inherent flexibility, indicating the potential for modifications influenced by various factors. Within this continuum, it is noteworthy that gamblers often demonstrate a propensity for frequent gambling [1] and engage in a wider variety of games [26,27].

Gambling behavior is associated with gambling experience, frequency, and morbidity [28-30]. More frequent gambling, participation in more types of gambling, and the cost of gambling are associated with pathological gambling behavior [26,27]. The South Oaks Gambling Screen, developed by Lesieur and Blume [31], was designed to measure and assess pathological gambling behavior, particularly focusing on gambling frequency. Raylu and Oei [32] developed the Gambling Urge Scale to measure pathological gambling behavior with gambling adventures. Hasking and Oei [33] tested the pressure measurement of pathological gambling behavior using COPE questionnaire.

Moreover, gambling behavior is influenced by several factors, including psychological activity and the psychological characteristics of participation in gambling [34]. In particular, the theory of adaptation is used as a supplement to the exposure hypothesis to study the impact of the environment on gambling behavior. Social adaptation will lead gamblers to gradually realize that their chances of winning money are negative in the long run. In response, gamblers adjust the amount of money they bet and even their gambling behavior (such as abandoning gambling). People’s prolonged lack of exposure to gambling facilities can lead to a gradual reduction in interest in gambling games or a modification of their behavior [35].

In addition, gambling is a limited rational economic behavior influenced by the environment and culture. Binde [36] noted that due to cultural and historical influences, gambling participation has not improved despite various restrictions. After analyzing the psychological characteristics of gambling participants, they found that gambling intention leads to attributes such as the concept of luck, the neglect of probability, the “illusion of success,” and “the illusion of control.” Participation will be influenced by personal psychological characteristics such as risk aversion, ambiguity aversion, risk tolerance, loss aversion, and optimism. However, the National Research Council found that approximately 98% of Americans had no clinical problems [37]. The association between gambling intention and the frequency of gambling, as well as problem gambling, has been consistently observed in research studies [38,39]. Despite the implementation of diverse restrictions, it is important to acknowledge that participation in gambling behavior has not witnessed significant improvement, which can be attributed to the influence of cultural and historical factors [40]. In the realm of gambling research, it is widely acknowledged that gambling behavior is intricately linked to both the experience and frequency of gambling [28,30]. These prior studies highlight the significance of individuals’ prior exposure to gambling activities as a key determinant influencing their subsequent gambling behavior. Consequently, researchers have introduced the variable of experience as an additional determinant to elucidate the intricate complexities underlying gambling behavior [41].

Chinese gamblers have unique gambling characteristics [42]. The Diagnostic and Statistical Manual of Mental Disorders (Fifth Edition), defines gambling disorder as a behavioral
addiction characterized by “persistent and recurrent problematic gambling behavior leading to clinically significant distress or impairment” [43]. Despite most forms of gambling being banned in Mainland China (except for state-run lotteries), the prevalence of gambling addiction in Mainland China is estimated to be higher than that in many Western countries, affecting approximately 2.5% to 4% of the adult population [44]. The participation rate in various forms of gambling in China is relatively high, which may be influenced by the cultural acceptance of gambling [24]. This cultural acceptance of gambling as a form of entertainment and social activity has contributed to its widespread practice among Chinese individuals [45-47]. However, it is important to acknowledge that the Chinese government has been making considerable efforts to combat illegal cross-border and online gambling activities, aiming to mitigate potential negative consequences such as financial strain and addiction [48,49].

Familiarity and recognition of gambling are the factors that attract Chinese individuals to casinos [30]. In contrast to tourists from various regions [6], the Chinese community stands out for its strong emphasis on gambling, as it is widely regarded as a preferred form of entertainment [45]. Furthermore, the Gambling Among Members of Ethnic Communities in Sydney Project found that Chinese participants thought gambling was a routine social activity rather than a way to escape the problems of everyday life [51]. A multisite study on older Chinese-Canadian gambling patterns and associated predictors showed that higher education levels and higher life satisfaction reduced the likelihood of gambling [52]. Some studies have found that Chinese (especially men) individuals have higher rates of gambling and problem gambling than the general population [53]. Chinese people who participate in gambling spend more money per week than the general community, and the participation rate of casino game consoles in the Chinese community is lower than that in other communities [54]. Galletti [55] reported that Chinese gamblers often gamble differently than the average North American gambler. Chinese gamblers often adjust their bets drastically based on their perception of luck, essentially outperforming the average North American gambler. Chinese gamblers often adjust their bets drastically based on their perception of luck, essentially outperforming the average North American gambler regarding the frequency of participation in various forms of gambling and gambling bets [32].

The COVID-19 pandemic has had several notable effects on gambling behavior from a public health standpoint. First, previous studies have reported significant reductions in the number of individuals engaging in gambling activities due to the pandemic and public health interventions [22,56]. In addition, the implementation of travel restrictions aligned with public health recommendations has influenced gambling behavior by imposing limitations on the gamblers’ ability to travel to their preferred destinations [13]. Furthermore, individuals have been more cautious in assessing the risks associated with traveling abroad [14], leading to considerations of alternative attractions or tourism products that notably increased during the pandemic [16]. In addition to the aforementioned impacts, there has been a notable increase in online gambling, particularly among the younger generation [22]. It is also important to note that during the COVID-19 pandemic, online gambling was associated with an elevated risk of problem gambling [57].

**Methods**

**Study Design**

This study used a quantitative design to investigate the gambling behavior of Mainland Chinese gamblers in Macau during the COVID-19 pandemic. Given the challenges of distributing questionnaires directly to individuals amidst the pandemic, a web-based data collection method was used. The survey team consisted of members from the marketing department of Macau casinos who actively engaged with customers through their social instant SMS text messaging platform (WeChat groups, Tencent Holdings Limited). This approach allowed the study team to effectively gather data on the gambling activities of these customers in Macau both before and after the pandemic.

**Data Collection**

Owing to the travel restrictions imposed during the COVID-19 pandemic, conducting on-site questionnaire distribution became challenging. Therefore, this study used web-based surveys through the social instant SMS text messaging platform “WeChat” to investigate gamblers who had visited Macau to gamble before the pandemic and whether they had visited Macau during the pandemic. The study used a carefully designed questionnaire using a closed-question format to gather data. To ensure a representative sample, a targeted sampling approach was adopted to reach out to individuals with relevant experiences and characteristics regarding the research topic. The survey was conducted from February 24 to March 2, 2021. A total of 350 questionnaires were distributed among the active groups on WeChat, a popular instant SMS text messaging and social media platform in Mainland China. Following a careful review of the responses received, 334 questionnaires were considered valid, representing a response rate of 95.4%.

**Measures**

We used the following measurement tools to assess gambling behavior in this study. The South Oaks Gambling Screen, developed by Lesieur and Blume [31] in 1987, was used to measure pathological gambling behavior based on gambling frequency. The Gambling Urge Scale [32] was used to measure pathological gambling behavior characterized by excessive risk-taking [58]. The COPE (Pressure Measurement of Pathological Gambling Behavior Scale) was used to assess the pressure associated with pathological gambling behavior [33]. In addition, the gambling experience scale is used to gauge various aspects of gambling behavior [28,29,59]. The gambling behavior scale encompassed the following 3 dimensions: gambling amount (3 items: “I often choose to bet large amounts when I gamble”; “I can control the amount of money I bet”; and “I can bet on budget when I gamble”); gambling mood (3 items: “when I am depressed”; “I will increase the number of times I engage in gambling when I feel stressed and nervous”; and “I will prolong my gambling time, I feel self-blame for my gambling behavior and consequences”); and social gambling (3 items: “I can give up or delay critical social activities because I turn to gambling”; “If someone invites me to gamble together,
I will not hesitate to get involved”; and “I will most likely participate in gambling-related activities if it is necessary for socializing”.

The basic sociodemographic variables included in this study were sex (female or male); marital status (married or unmarried); age (grouped into 3 categories: ≤25 years, 26-35 years, ≥36 years); monthly income (divided into 4 groups: monthly income of <RMB 10,000, RMB 10,001 to RMB 20,000, RMB 20,001 to RMB 30,000, and ≥RMB 30,001); education level (categorized as high school or below, junior college degree, and bachelor’s degree or above); and gambling before the age of 21 years (indicated as either yes or no).

In addition to the sociodemographic variables, the respondents were asked to provide information about their behavior during the COVID-19 pandemic. The questionnaire included the following items: participation in gambling activities during the pandemic (with options of yes or no); online gambling during the pandemic (with options of yes or no); pre-pandemic gambling frequency (once a week, once a month, once a day, or irregular); gambling budget for each prepandemic participation (<RMB 10,000, RMB 10,001 to RMB 20,000, RMB 20,001 to RMB 30,000, ≥RMB 30,001, or no budget); gambling budget for each gambling participation after the pandemic (<RMB 10,000, RMB 10,001 to RMB 20,000, RMB 20,001 to RMB 30,000, ≥RMB 30,001, or no budget); duration of stay at the casino (<6 hours, 6-12 hours, 1 day-2 days, 2-3 days, or >3 days); and habits (with options of smoking, drinking, not smoking, or not drinking).

Analysis

The methodological approach of this study involved the use of an web-based survey design to collect data on gambling behavior from Mainland Chinese gamblers. Specifically, this study focused on examining both online gambling and on-site gambling activities. The survey was developed and distributed through WeChat groups and consisted of 3 sections. The first section encompassed statements related to on-site and online gambling and other gambling activities. This section included questions about the frequency of gambling in the past year and the gambling budget both before and during the pandemic. The second section used 9 scales to measure various aspects of gamblers’ behavior. Respondents were asked to rate their responses on a 5-point scale. The last section of the survey was dedicated to collecting demographic data from the respondents and providing information about their characteristics.

Ethical Considerations

The methodology and survey questionnaire used in this study were approved by the institutional review board of the Center for Gaming and Tourism Studies, Macao Polytechnic University (ethics approval number: RP/CJT-02/2023/E01). All procedures complied with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards. The key aspects of the research ethics of human subjects are confidentiality, privacy, and consent. We obtained informed consent from all participants after fully informing them about the study. Privacy and confidentiality of participants’ personal information were strictly maintained throughout the research process, with data anonymization techniques used during reporting to protect their identities. Throughout the study, attention was given to addressing any potential conflicts of interest and upholding the highest ethical standards to protect the rights of the participants. No compensation was provided for participation in any aspect of the study.

Results

Sample Characteristics

The descriptive data for the sample is presented in Table 1. Among the 334 respondents, 49.1% (n=164) reported participating in gambling activities before the age of 21 years, while 50.9% (n=170) indicated that they did not engage in such activities. Of the 334 respondents, 48.8% (n=163) indicated their involvement in casino gambling activities during the pandemic, while 51.2% (n=171) reported abstaining from such activities. Furthermore, 52.4% (175/334) of the respondents reported participating in online gambling, whereas 47.6% (159/334) individuals reported nonparticipation in online gambling. Of the respondents, 64.4% (215/334) of individuals identified as male. Regarding educational attainment, 24.9% (83/334) of the respondents indicated that their education level was high school or below, 41.6% (139/334) respondents reported that they were enrolled in college, and 33.5% (112/334) respondents held bachelor’s degrees or higher qualifications. A substantial majority of participants, 77.5% (259/334) stated that they were married.

In terms of age distribution, the largest proportion of respondents (192/334, 57.5%) were aged 26 to 35 years, followed by those aged 36 to 50 years (96/334, 28.7%). Regarding monthly income, most respondents (177/334, 53%) earned <RMB 10,000; in addition, 95 (28.4%) of the 334 respondents reported a monthly income between RMB 10,001 and RMB 20,000, while 44 (13.2%) fell within the income range of RMB 20,001 to RMB 30,000.

Before the pandemic, the gambling frequency of the 334 respondents varied as follows: 126 (37.7%) individuals engaged in gambling once a month, 81 (24.3%) individuals gambled once a week, 23 (6.9%) individuals gambled once a day, and 104 (31.3%) individuals gambled irregularly. As for the allocation of the gambling budget, 202 (60.5%) respondents allocated <RMB 10,000, 76 (22.8%) respondents allocated between RMB 10,001 and RMB 20,000, 45 (13.5%) respondents allocated between RMB 20,001 and RMB 30,000, and 11 (3.3%) respondents allocated ≥RMB 30,001.

During the pandemic, the gambling budget distribution among the 334 respondents was as follows: 156 (46.7%) respondents allocated <RMB 10,000, 79 (23.7%) respondents allocated between RMB 10,001 and RMB 20,000, 37 (11.1%) respondents allocated between RMB 20,001 and RMB 30,000, 18 (5.4%) respondents allocated ≥RMB 30,001, and 44 (13.2%) respondents did not have any specific budget.

</table>
Regarding the duration spent in casinos, the following patterns were observed among the 334 respondents: 172 (51.5%) individuals spent <6 hours in casinos, 96 (28.7%) individuals dedicated 6 to 12 hours, 48 (14.4%) individuals engaged in gambling for 1 to 2 days, and 18 (5.4%) individuals extended their visits for >2 to 3 days in casinos. These findings elucidate the diverse levels of engagement and time commitment exhibited by the surveyed individuals during their casino experiences.

Measurement Model

First, we tested the questionnaire for its reliability. The measurement of gambling behavior had a Cronbach α coefficient of 0.824 for gambling amount, 0.824 for gambling mood, 0.804 for social gambling, and 0.858 for gambling involvement, indicating a high level of reliability. Next, the scale was further validated through an exploratory factor analysis. The Kaiser-Meyer-Olkin measure of sampling adequacy was found to be 0.940, indicating that the scale was suitable for factor analysis. The Bartlett Test of Sphericity yielded a chi-square value of 2105.821 ($P$ < .001), supporting the suitability of the scale for factor analysis. The dimensionality reduction analysis was performed using SPSS software (version 26.0; IBM Corp). The validity test demonstrated that each question factor had loadings ranging from 0.659 to 0.813, indicating a high level of conceptual validity for the scale. The total number of explanatory variables accounted for 72.65% of the variance, indicating that the measured indicators provided substantial explanatory power. Overall, the analysis revealed a high level of reliability of the measured indicators.

Variance Analysis

We conducted binary logistic regression analysis based on unweighted data to examine group comparisons of gambling behaviors. Chi-square tests were used to explore potential independent variables associated with the changes in gambling behavior, which served as the dependent variable. The results of the logistic regression analysis are presented as odds ratios with 95% CIs. All statistical analyses were performed using SPSS software.

First, we analyzed the samples based on whether respondents of different genders participated in Macau casinos during the pandemic and engaged in online gambling. The descriptive statistics of the sample are presented in Table 2. A total of 64.4% (215/334) male individuals and 35.6% (119/334) female individuals responded to the survey. Among the 334 participants, a total of 175 (52.4%) respondents were involved in online gambling, of which 136 (77.7%) were male individuals and 39 (22.3%) were female individuals. During the pandemic, 78.4% (116/334) of male individuals and 21.6% (32/334) of female individuals were involved in online gambling. In addition, 27 (8.1%) of the 334 respondents, comprising 20 (74.1%) male individuals and 7 (25.9%) female individuals, did not visit Macau; 15 (4.5%) respondents, comprising 10 (66.7%) male individuals and 5 (33.3%) female individuals, traveled to Macau for gambling. During the pandemic, 171 (51.2%) of the 334 respondents, with 89 (52%) male individuals and 82 (48%) female individuals, did not travel to Macau. This shows that the impact of the pandemic on gambling is enormous.
The basic statistics related to traveling to Macau and participating in online gambling are presented in Table 3. Gender differences were evident, with notable variations in gambling habits among individuals aged 21 years, frequency of gambling before the COVID-19 pandemic, monthly income, gambling budget (before the pandemic), gambling budget (during the pandemic), and the length of stay at casinos ($P < .01$). Furthermore, marital status exhibited significant differences in traveling to Macau for gambling ($P < .01$), whereas no notable differences were observed in online gambling. However, there were no significant differences in terms of education or age between those who traveled to Macau and those who engaged in online gambling.

An independent sample test was conducted to compare the gender of individuals who traveled to Macau for gambling (Table 4). The results revealed that there was a significant difference in the gambling amount for married individuals who traveled to Macau and participated in gambling during the pandemic ($P < .05$). However, no significant difference was observed in traveling to Macau for gambling during the pandemic. These findings suggest that the pandemic has had a significant impact on the gambling behavior of married gamblers. In addition, regardless of marital status, there were no significant differences in gambling amounts during the pandemic.

### Notes

- **GONLINE**: gambling online.
- **GINVOIVE**: gambling in casinos.

The basic statistics related to traveling to Macau and participating in online gambling are presented in Table 3. Gender differences were evident, with notable variations in gambling habits among individuals aged 21 years, frequency of gambling before the COVID-19 pandemic, monthly income, gambling budget (before the pandemic), gambling budget (during the pandemic), and the length of stay at casinos ($P < .01$). Furthermore, marital status exhibited significant differences in traveling to Macau for gambling ($P < .01$), whereas no notable differences were observed in online gambling. However, there were no significant differences in terms of education or age between those who traveled to Macau and those who engaged in online gambling.

An independent sample test was conducted to compare the gender of individuals who traveled to Macau for gambling (Table 4). The results revealed that there was a significant difference in the gambling amount for married individuals who traveled to Macau and participated in gambling during the pandemic ($P < .05$). However, no significant difference was observed in traveling to Macau for gambling during the pandemic. These findings suggest that the pandemic has had a significant impact on the gambling behavior of married gamblers. In addition, regardless of marital status, there were no significant differences in gambling amounts during the pandemic.

</table>
We conducted an ANOVA on the variables related to gambling in Macau (Table 5). The results indicated that individuals who traveled to Macau for gambling during the pandemic reported spending >2 days at casinos and gambling significantly higher amounts compared to those who stayed for 1 to 2 days. In addition, the social gambling behavior of those who stayed between 6 and 12 hours and those who stayed for >2 days was significantly higher than that of individuals who stayed for 1 day to 2 days.

The budget for each gambling session (before the pandemic) indicated notable differences among the different income groups. The group with a budget of ≥RMB 30,001 reported gambling significantly higher amounts compared to the group with a budget of RMB 20,001 to RMB 30,000 and the group with a budget of <10,000 or the group without a budget. There were significantly more gamblers aged <25 years and 26 to 35 years in Macau during the pandemic than those aged >36 years. Among gamblers who gambled more often than before the pandemic, the group that gambled once a day reported significantly higher rates of gambling than the other frequency groups.

Furthermore, an ANOVA was conducted on variables related to online gambling (Table 6). Regarding academic qualifications, the influence of gambling sentiment on gamblers with a college degree was considerably higher than that on gamblers with a high school education or below. In terms of the frequency of gambling before the pandemic, the group that gambled daily exhibited significantly higher rates compared to the other frequency groups. Among online gamblers, those aged 26 to 35 years accounted for a larger proportion of gambling compared to those aged >35 years; those aged <25 years and 26 to 35 years significantly engaged in more social gambling compared to those aged >35 years. Among non–online gamblers, those aged <25 years and those aged 26 to 35 years had a significantly larger presence than those in the 35-year age group.

Online gambling budgets vary during the COVID-19 pandemic. Nevertheless, the group with a gambling budget of >RMB 30,001 still maintained significantly higher gambling amounts compared to the group without a budget for online gambling. In terms of the duration spent at the casino participating in gambling, the group spending >2 days at the casino stayed more than twice as long as the group spending 1 day to 2 days.

**Discussion**

**Principal Findings**

Recognition is growing that gambling poses an increasing public health concern. Despite being beneficial for the economy and profitable for businesses, gambling causes personal and social harm to both individuals and communities. In particular, gambling presents a significant global public health challenge with the rise of online gambling [60]. The effects of gambling on public health are evident across various levels, including personal, interpersonal, and societal dimensions [61]. In this cross-sectional study, we investigated the changes in the gambling behavior of Mainland Chinese gamblers visiting Macau and participating in online gambling during the COVID-19 pandemic. In addition, we analyzed other factors that influenced gambling behavior during the pandemic, such as certain sociodemographic characteristics. We used data from a sample of 334 respondents to conduct a comparative analysis of gamblers’ gambling behaviors. The main findings of this study are presented subsequently.

First, the COVID-19 pandemic has had a significant and wide-ranging impact on gambling behavior. Among the 334 respondents in this study, a substantial proportion of 171 (51.2%) individuals reported not participating in gambling during the pandemic. This finding underscores the profound influence of the pandemic on individuals’ gambling behavior. Specifically, the willingness of gamblers to visit Macau for gambling tourism has been affected due to the various consequences of public health measures [56]. The effects of gambling on public health are evident across various levels, including personal, interpersonal, and societal dimensions [61]. In this cross-sectional study, we investigated the changes in the gambling behavior of Mainland Chinese gamblers visiting Macau and participating in online gambling during the COVID-19 pandemic. In addition, we analyzed other factors that influenced gambling behavior during the pandemic, such as certain sociodemographic characteristics. We used data from a sample of 334 respondents to conduct a comparative analysis of gamblers’ gambling behaviors. The main findings of this study are presented subsequently.

First, the COVID-19 pandemic has had a significant and wide-ranging impact on gambling behavior. Among the 334 respondents in this study, a substantial proportion of 171 (51.2%) individuals reported not participating in gambling during the pandemic. This finding underscores the profound influence of the pandemic on individuals’ gambling behavior. Specifically, the willingness of gamblers to visit Macau for gambling tourism has been affected due to the various consequences of public health measures [56]. Notably, 20 (74.2%) male individuals and 7 (26%) female individuals of the respondents refrained from gambling in Macau and instead opted for an alternative approach, which included online gambling. This finding aligns with the conclusions drawn by Sachdeva et al [16], indicating that individuals consider various factors that influence their ultimate gambling behavior in the face of changing circumstances, especially during a pandemic.

Second, it is noteworthy that, among the 334 respondents, 175 (52.4%) individuals engaged in online gambling, with 136 (77.7%) being male individuals and 39 (22.3%) being female individuals. This indicates the proportion of participants who turned to online gambling, particularly during the pandemic. Notably, 20 (74.2%) male individuals and 7 (26%) female individuals of the respondents refrained from gambling in Macau and instead opted for an alternative approach, which included online gambling. This finding aligns with the conclusions drawn by Sachdeva et al [16], indicating that individuals consider various factors that influence their ultimate gambling behavior in the face of changing circumstances, especially during a pandemic.

Third, the results revealed significant differences among Mainland Chinese gamblers who engaged in both travel to Macau and online gambling, with regard to gender, gambling habits, prepandemic frequency of play, monthly income, gambling budget (before and during the pandemic), and length of stay at the casino (P<.01). Notably, marital status demonstrated significant differences in terms of traveling to Macau for gambling (P<.05), whereas no significant differences in terms of marital status were observed in online gambling. However, we did not find any significant differences regarding the education and age of gamblers in this study. Despite the changes in participation methods and behaviors during the pandemic, this finding aligns with the conclusions drawn by...
Chan et al [50], suggesting that problem gambling may be prevalent among Chinese gamblers, regardless of whether they participate in gambling at land-based casinos or web-based platforms.

To examine the difference in gambling behavior among individuals who visited casinos, we found from this study that there was a significant difference in gambling amount among married individuals who traveled to Macau for gambling ($P<0.05$). However, there was no significant difference in the gambling budget of married gamblers before and during the pandemic. Moreover, regardless of marital status, there was no significant difference in gambling expenditure during the pandemic. Among the gamblers who visited Macau for gambling during the pandemic, those who stayed longer at the casino and participated in gambling exhibited higher levels of gambling expenditure compared to those who stayed for 1 day to 2 days. This suggests that high-value gamblers tended to extend their stay at the casinos before the pandemic and had a tendency toward problem gambling [57]. Regarding casino gambling, respondents who stayed at the casinos for 6 to 12 hours or >2 days demonstrated a significantly greater level of involvement than those who stayed for 1 day to 2 days. Before the pandemic, individuals with gambling budgets of >RMB 30,001 were considerably higher than those with other budgets, indicating that high-value gamblers had higher budgets allocated to gambling before the pandemic. In terms of age demographics, gamblers aged <25 years and those aged 26 to 35 years were considerably more prevalent than those aged >36 years during the pandemic, indicating that young gamblers were more prevalent than gamblers in other stages before the pandemic. Among the gamblers who gambled regularly before the pandemic, those who gambled once a day exhibited a significantly higher frequency compared to those who gambled once a week, once a month, or irregularly. Furthermore, in the context of social gambling, it was observed that those aged <25 years and those aged 26 to 35 years had significantly higher frequency of gambling compared to those aged 35 years. This indicates a greater inclination of gamblers in these age groups to participate in gambling for social purposes [22]. Consequently, the pandemic has shaped their behaviors within the casino environment during this period of public health crisis.

When examining the difference in gambling behavior of online gamblers, the results reveal a significant difference in the number of gamblers based on educational attainment, particularly between college-educated individuals and those with a high school education or below. This discrepancy suggests that the gambling sentiment and mindset of gamblers in this study may have been influenced by the pandemic, leading to changes in their behavior. Regarding the frequency of gambling participation before the COVID-19 pandemic, the number of gamblers who gambled once a day was considerably higher than that in the other groups, suggesting that gamblers who gambled frequently also placed more bets. Regarding age, among the gamblers participating in online gambling, those aged 26 to 35 years exhibited significantly higher gambling expenditure compared to those aged 35 to 45 years; those aged <25 years and 26 to 35 years demonstrated significantly higher gambling mood compared to those aged 35 to 35 years; furthermore, those aged <25 years or 26 to 35 years displayed considerably high involvement in social gambling, indicating the increased participation of the younger generation in online gambling and social gambling activities compared to older age groups [22]. The budget allocation for each gambling session during the pandemic revealed that the group with a budget >RMB 30,001 was significantly larger than the group with other budget allocations, reflecting the importance of online gambling as a prevalent form of gambling in the aftermath of the pandemic. Regarding the duration of gambling participation, the group that engaged in gambling for >2 days was significantly larger than the group that participated for 1 day to 2 days. This finding suggests that online gambling serves as a platform that fulfills the socialization needs of gamblers over a prolonged period.

Gambling has gained widespread popularity among adolescents worldwide [23,62]. Excessive or problematic gambling can give rise to various public health implications, including financial consequences, addiction, and mental health issues. A public health approach is essential to address and mitigate the harm associated with gambling [63,64]. The harm caused by gambling can manifest in various ways, affecting both individuals and communities. Considering the economic significance of the gaming industry, it is advisable to adopt a comprehensive and coordinated approach that engages policy makers, gaming operators, and the broader community to effectively prevent problem gambling among both local citizens and tourists. Public health initiatives are recommended to involve the implementation of player protection measures, public awareness and education, provision of support services, self-regulation within the industry, and promotion of responsible gambling practices to create safer environments. Addressing gambling addiction issues at both personal and societal levels can lead to the minimization of negative impacts associated with gambling, the safeguarding of vulnerable populations, and the fostering of overall well-being in individuals and communities.

**Limitations**

This study has several limitations that should be acknowledged. First, the data collected for this study were obtained from a survey conducted with gamblers on a social instant SMS text messaging platform (WeChat), which may introduce the possibility of selection bias and limit the generalizability of our findings. In addition, the relatively small sample size used in this study may restrict the generalizability of the results.

Second, the scale designed to measure gambling behavior in this study was simplified based on previous research. This simplification may have overlooked important dimensions of gambling behavior, potentially impacting the comprehensiveness of our findings. Furthermore, the study did not categorize the different types of gambling games, making it difficult to ascertain the specific preferences of gamblers, such as table games, slot machines, online gambling, and sports betting. Future research should consider using more comprehensive scales to capture the complexity of gambling behavior and incorporate the categorization of different types of gambling activities.
Third, while the cross-sectional design used in this study is useful for examining associations at a specific point in time, a time-series approach would provide a more accurate reflection of the dynamic changes in individuals’ gambling behavior. Future research should consider longitudinal designs to gain a better understanding of how gambling behaviors evolve and to capture the impact of various factors on these changes. Furthermore, it is important to recognize that the COVID-19 pandemic has significantly altered the macroenvironment, including work and income situations, which may have influenced changes in gambler behavior. Future research should include relevant control variables to account for these potential confounding factors and to obtain a more comprehensive understanding of the impact of the pandemic on gambling behavior.

Conclusions
The primary conclusion of this paper is that a high proportion of the original Mainland Chinese gamblers opted not to visit Macau for gambling purposes after the outbreak of the COVID-19 pandemic. While the reasons for this shift may vary, the public health crisis has resulted in a decreased reliance on land-based gambling and a greater inclination toward online gambling. Consequently, there has been a reduction in the amount of money spent at gambling establishments and a decrease in the duration of casino visits. Casinos have traditionally served as highly popular social venues for gamblers. However, the antipandemic measures implemented by governments and casino operators have, to some extent, affected the social gambling behavior of individuals, leading to a shift away from traditional casinos and a greater emphasis on online gambling platforms.

Additionally, the COVID-19 pandemic has led to a notable increase in online gambling activities among Mainland Chinese gamblers. Particularly, the younger generations have been significantly affected by this observed phenomenon. Online gambling has gained popularity during the pandemic, with a substantial increase in both the amount and frequency of gambling observed. The restrictions imposed by the pandemic have had an impact on gamblers’ behavior, affecting their mood while participating in gambling activities. Notably, individuals with a middle level of education have experienced a significant impact on their gambling behavior. The findings of this study indicate that the pandemic has led to a decrease in land-based gambling, creating an environment that is conducive to controlling problem gambling; however, there appears to be a shift in gambling behavior from traditional casinos toward online gambling platforms as a direct consequence of the pandemic. The impact of the COVID-19 pandemic on gambling behavior underscores the significance of implementing targeted public health strategies and interventions to address the changing dynamics of gambling during public health emergencies.

Abstract

Background: Since 2016, the government of Bangladesh has been piloting a health protection scheme known as Shasthyo Surokhsha Karmasuchi (SSK), which specifically targets households living below the poverty line. This noncontributory scheme provides enrolled households access to inpatient health care services for 78 disease groups. Understanding patients’ experiences with health care utilization from the pilot SSK scheme is important for enhancing the quality of health care service delivery during the national-level scale-up of the scheme.

Objective: We aimed to evaluate patient satisfaction with the health care services provided under the pilot health protection scheme in Bangladesh.

Methods: A cross-sectional survey was conducted with the users of the SSK scheme from August to November 2019. Patients who had spent a minimum of 2 nights at health care facilities were selected for face-to-face exit interviews. During these interviews, we collected information on patients’ socioeconomic characteristics, care-seeking experiences, and level of satisfaction with various aspects of health care service delivery. To measure satisfaction, we employed a 5-point Likert scale (very satisfied, 5; satisfied, 4; neither satisfied nor dissatisfied, 3; dissatisfied, 2; very dissatisfied, 1). Descriptive statistics, statistical inferential tests (t-test and 1-way ANOVA), and linear regression analyses were performed.

Results: We found that 55.1% (241/438) of users were either very satisfied or satisfied with the health care services of the SSK scheme. The most satisfactory indicators were related to privacy maintained during diagnostic tests (mean 3.91, SD 0.64), physicians’ behaviors (mean 3.86, SD 0.77), services provided at the registration booth (mean 3.86, SD 0.62), confidentiality maintained regarding diseases (mean 3.78, SD 0.72), and nurses’ behaviors (mean 3.60, SD 0.83). Poor satisfaction was identified in the interaction of patients with providers about illness-related information (mean 2.14, SD 1.40), availability of drinking water (mean 1.46, SD 0.76), cleanliness of toilets (mean 2.85, SD 1.04), and cleanliness of the waiting room (mean 2.92, SD 1.09). Patient satisfaction significantly decreased by 0.20 points for registration times of 16-30 minutes and by 0.32 points for registration times of >30 minutes compared with registration times of ≤15 minutes. Similarly, patient satisfaction significantly decreased with an increase in the waiting time to obtain services. However, the satisfaction of users significantly increased if they received a complete course of medicines and all prescribed diagnostic services.

Conclusions: More than half of the users were satisfied with the services provided under the SSK scheme. However, there is scope for improving user satisfaction. To improve the satisfaction level, the SSK scheme implementation authorities should pay attention to reducing the registration time and waiting time to obtain services and improving the availability of drugs and prescribed diagnostic services. The authorities should also ensure the supply of drinking water and enhance the cleanliness of the facility.

Introduction

Globally, more than half of the population encounters difficulties in accessing essential health care services, with the majority residing in low- and middle-income countries (LMICs) [1]. These nations experience substantial challenges in financing health care [2-5]. Consequently, health care financing in these countries heavily relies on out-of-pocket spending by households, leading to increased financial distress on families during their illness [2,3,6]. In many instances, the most affected are those in poverty, and they lack access to health care services when they are unwell [7]. Similar to other LMICs, out-of-pocket spending for health care in Bangladesh is notably high. Recent evidence indicates that 68.5% of the total health care expenditure is shouldered by households through out-of-pocket payments [8]. Another recent study reported that such high out-of-pocket payments resulted in 24.6% of households experiencing catastrophic health expenditure when estimated using the 10% threshold of the budget share method. Furthermore, in 2016, over 8.5 million people were pushed into poverty due to health care expenses [9]. Moreover, the incidence of catastrophic health expenditure is more concentrated among the poorest households (16.5%) compared to the richest (9.2%) [10]. To reduce the burden of health care among the population and progress toward universal health coverage, the Government of Bangladesh has developed the Health Care Financing Strategy 2012–2032, intending to provide financial protection for health care to all citizens by 2032 [11]. As a component of this strategy, the Health Economics Unit of the Ministry of Health and Family Welfare of the Government of Bangladesh has been implementing a social health protection scheme known as “Shasthyo Surokhsa Karmasuchi (SSK)” since 2016. Although there is a comprehensive plan to cover the entire population of the country within the financing scheme, the current implementation is limited to a noncontributory scheme focusing on the below-poverty-line population. The scheme is being piloted in 3 subdistricts: Kalihati, Madhupur, and Ghatail under Tangail District. The scheme has enrolled almost 1,00,000 households that have access to inpatient health care services from Upazila Health Complexes (UzHCs) of the respective Upazilas (subdistricts) and district hospitals. Participation in the scheme is mandatory for households identified as being below the poverty line, and their enrollment is noncontributory, meaning that these enrolled households are not required to pay any fees for services. Notably, the scheme does not offer purchasing services to the above-poverty-line population. The government established a pool fund, allocating BDT 1000 (US$12) per household per year as a premium (BDT 84.5 = US$ 1, August 2019, Bangladesh Bank). This measure ensures access to inpatient health care services for the enrolled below-poverty-line households, covering 78 different disease groups. The annual coverage limit for each household is BDT 50,000 (US $592). Under the scheme, inpatient health care is delivered through UzHCs, serving as the first access point for the insured beneficiaries to receive health care services. Through a structured referral system, the beneficiaries can also access services at the Tangail District Hospital. The scheme ensures that insured patients receive free diagnostic services and medicines through hospitals, contracted diagnostic centers, and pharmacies. The SSK management authority, scheme operator, hospitals, contracted diagnostic centers, and pharmacies play crucial roles in the implementation of the scheme [12].

Although the scheme provides free inpatient care services to the member households, the health care utilization under the SSK scheme is notably low. A study revealed that less than half of the beneficiary households used health care services under the SSK scheme [13]. Several factors may contribute to this low utilization rate. For instance, quality of care might be a significant factor among the various important determinants of health service utilization. Quality of service is recognized as one of the key components in achieving universal health coverage by its definition [14]. Traditionally, the quality of health care services was primarily assessed based on professional practice standards. However, in the recent decades, patients’ perceptions of health care have emerged as an important indicator for evaluating the quality of health care services. Various studies have demonstrated that health service utilization is closely linked with users’ perceptions of the quality of health care provided [15-17]. Consequently, patient satisfaction is considered as an important aspect of performance improvement of the delivered health care services, alongside clinical effectiveness. It is a multidimensional aspect where patients’ perceptions and attitudes shape their overall health care–seeking experience [18,19]. Several factors, including registration time and process, waiting time to obtain health care services, interpersonal communication, and availability of basic amenities within health care facilities, can influence patient satisfaction with health care services [20-23]. Increased utilization and satisfaction of any insurance scheme are associated with improved quality of health care services. However, the literature provides mixed evidence. For example, a study in India found no significant difference in satisfaction levels between insured and uninsured hospitalized patients [24]. Conversely, regarding the overall quality of care provided under the National Health Insurance Scheme of Ghana, a significant portion of insured patients reported higher satisfaction compared with uninsured patients [25]. Evidence from Nigeria indicated that most patients were satisfied with the service delivery of their national health insurance scheme [26-28]. In Ethiopia, a study revealed that approximately 55% of enrollees were satisfied with the community-based health insurance scheme [29], whereas another study from the same country indicated that over 90% of households were satisfied with the community-based health insurance scheme [30]. Different Vietnamese studies have reported poor satisfaction among beneficiaries regarding service coverage and quality of care.
under national health insurance [31,32]. A recent study conducted on a self-financed health insurance scheme in Bangladesh showed that, overall, members of the scheme were satisfied with the health care services; however, their satisfaction levels could be improved in several aspects of health care service delivery [33].

Despite the pilot implementation of the SSK scheme since 2016 and its low utilization, no research has been conducted on service users’ experiences and levels of satisfaction with the scheme. Gaining a better understanding of beneficiaries’ experiences and levels of satisfaction with the health care service provided under the pilot SSK scheme is crucial. This insight can help identify the gaps in the quality of health care services provided. Such evidence will be useful for the key stakeholders of the health protection scheme, allowing them to make necessary changes in the service delivery process and related aspects to enhance the quality of health care services provided under the scheme. As a result, this study was conducted to address 2 central research questions: (1) What is the level of satisfaction among the beneficiaries of the SSK scheme? and (2) What are the factors influencing their satisfaction level? In addressing these research questions, this study aimed to assess patients’ levels of satisfaction with the services offered by the SSK scheme in Bangladesh.

Methods

Study Design

A cross-sectional exit patient survey was designed to gain insights into the experiences of insured patients with various aspects of the service delivery process and the quality of services provided under the pilot SSK scheme. Every second patient who had been admitted for at least 2 nights at a scheme-designated facility was selected and interviewed at the time of discharge.

Study Setting and Sample

The study was conducted in the UzHCs of Kalihati, Madhupur, and Ghatail Upazilas (subdistricts), and Tangail District Hospital of Tangail District. Insured inpatients were interviewed after discharge from the health care facilities. The survey of the respondents took place between August 18 and November 16, 2019, on working days, from Saturday to Thursday. Every second discharged inpatient from the male and female wards was interviewed. To ensure the quality of the data, a maximum of 4 patients were interviewed each day at an SSK hospital. A total of 438 discharged inpatients aged 18 years or older were interviewed from 3 UzHCs (Kalihati, n=128; Madhupur, n=176; and Ghatail, n=134) and Tangail District Hospital (n=88).

Data Collection Process

A semistructured questionnaire was designed and pretested before data collection. Face-to-face interviews were conducted with the insured patients and, in certain cases, with attendants of patients at the time of discharge. An attendant was considered as a respondent when the patient was not involved with the various dimensions of the service delivery process during the inpatient episode owing to the physical condition.

The questionnaire covered demographic and socioeconomic details of the respondents and households, health care utilization, and various dimensions of satisfaction related to the SSK scheme. These dimensions included the registration process at the SSK booth, the dignity of patients during treatment, clear communication with health care providers, privacy during treatment, the quality of basic amenities, the availability of drugs and supplies, and the availability of prescribed diagnostic services.

Four experienced research assistants were employed for patient recruitment and conducting the interviews. Prior to the interviews, written informed consent was obtained from all participants, and their participation was entirely voluntary. Completed interviews were cross-checked among the interviewers and further reviewed by the supervisor to ensure data quality and to address any associated issues, if needed, during the data collection.

Study Variables

We collected information on various background characteristics of the patients, including age, sex, education level, current employment status, current marital status, and family size. For measuring satisfaction levels, we considered several dimensions of health care delivery under the SSK scheme.

The first dimension was hospitalization-related factors. It included self-reported illnesses and length of stay. Self-reported illnesses were categorized into 3 groups: communicable, noncommunicable, and others (ie, obstetrics and injury). Communicable diseases encompass illnesses caused by viruses or bacteria that spread through contact, bodily fluids, blood products, insect bites, or the air. Noncommunicable diseases, on the other hand, are those that do not transmit between individuals and often necessitate long-term treatment.

The second dimension was service utilization–related aspects. It included waiting time for registration, waiting time to obtain health care services, behavior of health care providers (including physicians, nurses, and other staff, such as ward boys and cleaners), interaction of health care providers with patients, privacy during diagnostic services, and confidentiality of the health care provided.

The third dimension was facility environment and basic amenity–related factors. It included cleanliness of health facilities, waiting rooms, and toilets, and availability of drinking water.

The satisfaction measurement items demonstrated a satisfactory level of internal consistency, as indicated by an overall Cronbach α coefficient of 0.77 out of 1.0 [34].

Satisfaction Measurements

Patient satisfaction was measured with a collective outcome of 14 different items. The selection of items for measurements was devised based on a literature review of patient satisfaction with the insurance scheme as well as previous systematic reviews [26,27,33,35-40]. The existing literature has examined various aspects of health service delivery from the patients’ viewpoints, encompassing domains such as patient-provider interactions, the physical environment, and internal management processes.
We selected items that revolved around these domains as they encompassed the most influential satisfaction constructs. The 14 items are presented in Textbox 1.

Each considered item was rated on a 5-point Likert scale (very satisfied, 5; satisfied, 4; neither satisfied nor dissatisfied, 3; dissatisfied, 2; very dissatisfied, 1). The total satisfaction score of respondents for all items ranged from a minimum of 14 to a maximum of 70. Furthermore, we included an item in the questionnaire to assess the overall satisfaction (on a scale of 5) with the services at the SSK facility.

Statistical Analysis

We analyzed the data using Stata version 16 (StataCorp) [41]. We performed both descriptive analysis and statistical inferential tests to measure the association between dependent and independent variables. In the descriptive analysis, background characteristics of the study participants and health care facility utilization–related characteristics were presented in terms of frequency (n) and percentage (%) with 95% CIs. Moreover, we performed a t-test for variables with 2 categories and 1-way ANOVA for variables with more than 2 categories to test the significant differences in average satisfaction levels across the demographic and socioeconomic characteristics related to the SSK scheme.

To identify factors associated with patients’ average scores for satisfaction with the services under the SSK scheme, a linear regression analysis was performed. We estimated the satisfaction level for each patient by taking the average of the reported satisfaction levels in the 14 items. In the univariate unadjusted regression model, the dependent variable was the mean satisfaction score and the independent variables were age, gender, education, employment status, marital status, family size, self-reported illness, length of hospitalization, registration time, waiting time to obtain services, status of receiving drugs and supplies, and status of receiving diagnostic services. However, in the multivariate regression model, we included independent variables that had a significant association with the satisfaction score (ie, P values ≤.05) in the univariate regression models. We considered P values of <.05 as statistically significant in our analysis.

Ethics Approval

This study was approved by the Research Review Committee and Ethical Review Committee of the icddr,b (protocol#: PR-17047). Participants in the study were recruited and interviewed after obtaining written informed consent, and their participation was voluntary.

Results

Descriptive Statistics

A total of 438 patients aged 18 years and above were interviewed at the studied facilities (Table 1), and 60.1% (263/438) of the patients were female. According to education level, 60.9% (267/438) of patients had no education, whereas 24.2% (106/438) and 14.8% (65/438) had primary and secondary levels of education, respectively. Moreover, 67.8% (297/438) of patients were not involved with income generation. In terms of marital status, 83.3% (365/438) of patients were married. Moreover, 54.1% (237/438) were from a household consisting of more than 4 members.

</table>
According to self-reported diseases, 62.6% (274/438) of patients reported the reason for hospitalization as noncommunicable disease, 30.8% (135/438) reported the reason as communicable disease, and 7.0% (29/438) reported the reason as other health problems (ie, obstetrics and injury). Regarding the length of hospitalization, 47.5% (208/438) of patients were admitted for 3-4 days, 34.5% (151/438) were admitted for 2 days, and 18.0% (79/438) were admitted for more than 4 days. Among the respondents, 66.2% (290/438) mentioned that they had completed their registration process within 15 minutes, and 58.9% (258/438) waited for 15 minutes or less to get services. The majority of patients (347/438, 79.2%) received all prescribed medicines and supplies free from the SSK pharmacy. Regarding laboratory services, 74.4% (326/438) of patients reported that they received diagnostic services as prescribed. More details of the descriptive statistics are shown in Table 1.

### Level of Satisfaction by Different Items

Patient satisfaction with the items considered while using the SSK scheme is shown in Table 2. A total of 14 satisfaction items were used to examine patient satisfaction. The highest average score on satisfaction was related to “privacy maintained during diagnostic tests” (mean 3.91, SD 0.64), followed by “physicians’ behaviors” (mean 3.86, SD 0.77), “services at the SSK registration booth” (mean 3.86, SD 0.62), “confidentiality maintained about diseases” (mean 3.78, SD 0.72), and “services from nurses” (mean 3.6, SD 0.83). Among service-related items, a lower level of satisfaction was reported for the interaction of service providers with patients (mean 2.14, SD 1.4). Among the items in the environment and basic amenities domain, comparatively higher satisfaction was found for the cleanliness of the health facility (mean 3.43, SD 0.76), followed by the cleanliness of the waiting room (mean 2.92, SD 1.09) and toilets (mean 2.85, SD 1.04). The lowest level of satisfaction was reported for the availability of drinking water (mean 1.46, SD 0.76).

^aSSK: Shasthya Suroksha Karmasuchi.
Overall Patient Satisfaction With Health Care Services at SSK Facilities

Considering the response to the overall patient satisfaction with the services at SSK facilities, 8.5% (37/438) reported being very satisfied and 46.6% (204/438) reported being satisfied with the services received under the SSK scheme. On the other hand, 31.3% (137/438) of respondents reported feeling neither satisfied nor dissatisfied. Moreover, 8.9% (39/438) were dissatisfied and 4.8% (21/438) were very dissatisfied (Multimedia Appendix 1).

Patient Satisfaction by Socioeconomic and Hospital Service Utilization Characteristics

Patient satisfaction levels significantly varied across different groups of age, sex, marital status, illness type, registration time, waiting time, status of receiving drugs, and status of getting diagnostic tests (Table 3). Patients aged between 45 and 64 years were comparatively more satisfied (mean 3.28, 95% CI 3.21-3.34) with services under the SSK scheme, and the difference in the satisfaction level across the age groups was statistically significant ($P<.001$). Male patients were significantly ($P=.01$) more satisfied (mean 3.24, 95% CI 3.17-3.31) than female patients. Married and widowed, divorced, or separated individuals were more satisfied than unmarried individuals, and the difference was statistically significant ($P<.001$). However, there was no significant difference in satisfaction by education level, employment status, or household size.

Patients with noncommunicable diseases had a higher satisfaction level (mean 3.22, 95% CI 3.17-3.28) than patients with other illnesses, and the difference in the satisfaction level was statistically significant ($P=.008$). Satisfaction scores decreased with increases in the length of hospitalization, registration time, and waiting time. The satisfaction level was significantly ($P=.006$) higher among patients who received all prescribed drugs from the scheme (mean 3.20, 95% CI 3.15-3.26). Similarly, the satisfaction level was higher among patients who received all prescribed diagnostic or laboratory services compared with other groups (mean 3.22, 95% CI 3.17-3.27), and the difference in the satisfaction level across the groups was statistically significant ($P<.001$).

aOne-way ANOVA.

Determinants of Patient Satisfaction With Services Provided Under the SSK Scheme

Our analysis demonstrated noteworthy associations between satisfaction scores and various factors (Table 4). The satisfaction score was significantly higher by 0.13 points in patients aged between 45 and 64 years than in patients aged between 18 and 44 years. Additionally, the satisfaction score was significantly higher by 0.34 points in married patients than in unmarried patients. Moreover, the satisfaction score was significantly higher by 0.15 points in patients seeking care for noncommunicable diseases than in patients seeking care for communicable diseases. We found a significant negative association of the satisfaction score with extended registration and waiting time for obtaining services. Conversely, a positive association was observed with the status of receiving all drugs, supplies, and diagnostic services. The satisfaction score was significantly lower by 0.18 points in patients with a registration time of 16-30 minutes and by 0.33 points in patients with a registration time of >30 minutes than in patients with a registration time of ≤15 minutes. Similarly, the satisfaction score was significantly lower by 0.30 points in patients who waited for 16-30 minutes to obtain services and by 0.36 points in patients who waited for >30 minutes to obtain services than in patients who waited for ≤15 minutes to obtain services. Moreover, the satisfaction score was significantly higher by 0.13 points in patients who received the complete course of prescribed medicines from the SSK pharmacy than in patients who received partial medicines and supplies. Likewise, the satisfaction score was significantly higher by 0.26 points in patients who received partial diagnostic services and by 0.28 points in patients who received full diagnostic services than in patients who were not prescribed diagnostic services.

The study showed that patient satisfaction was the highest regarding the privacy and confidentiality maintained by providers during diagnostic tests and the patients’ diseases. The finding is similar to that in a study conducted in Bangladesh [33] among the beneficiaries of a community-based health insurance scheme. Another study conducted among adult patients at a general hospital in Ethiopia also reported that patient privacy and confidentiality maintained by health care providers were significantly associated with higher satisfaction levels [47]. Our study found that patients were satisfied with providers’ behaviors, particularly physicians’ and nurses’ behaviors, which influenced the overall level of patient satisfaction. Although not directly comparable, the proportion of patients satisfied with the behavior of providers was higher than the proportion reported in a study conducted in rural Bangladesh (84% vs 69%) [45]. Previous studies have also reported that the behavior of health care providers toward patients is directly connected with patient satisfaction [33,43,48].

Regarding interactions with health care providers, our study found that two-thirds of patients were not satisfied. This might be the result of patients not knowing about their illnesses from physicians during their treatment episodes. It is evident from the literature that patients’ satisfaction levels are influenced by healthy interpersonal communication with health care providers as this maintains a better physician-patient relationship [43]. A previous study conducted in Bangladesh showed that more than half of the surveyed patients could not ask questions to their providers about their illness [49]. However, as all patients in our study were inpatients and stayed at the facility for at least 2 days, it is unlikely that patients could not ask their providers about their illness.

Patient experiences with the cleanliness of health facilities and toilets and the availability of drinking water were not positive. Previous studies revealed that the health facility environment and cleanliness were crucial aspects of patient satisfaction [33,50-52]. Moreover, evidence indicates that since environmental contamination is directly connected with nosocomial infection, the physical environment can lead to the dissatisfaction of patients at health facilities instead of increasing satisfaction [33,50-52].

We found that patient age was significantly associated with the level of satisfaction. Another study conducted in Bangladesh [44] reported significant variation in the average satisfaction score across patient age, which is similar to our findings. Two other studies conducted among beneficiaries of health insurance schemes also reported similar findings that age was significantly associated with the level of satisfaction [30,53]. Lower waiting times for registration and health care were significantly associated with patient satisfaction. The findings are consistent with the literature that patients’ satisfaction levels are influenced by healthy interpersonal communication with health care providers as this maintains a better physician-patient relationship [43].

### Discussion

#### Principal Results and Comparison With Prior Work

We found that 55.1% (241/438) of patients were either very satisfied or satisfied with the services provided by the SSK health protection scheme. The mean satisfaction score was 3.17 out of 5, which means that, on average, the satisfaction level among the patients was slightly above the level of neither satisfied nor dissatisfied. Regarding the 14 considered items for measuring satisfaction, most of the patients were either very satisfied or satisfied with services at the SSK center (368/438, 84.0%), physicians’ behaviors (366/438, 83.6%), and privacy maintained during diagnostic services (297/364, 81.6%). On the other hand, majority of the patients were either very dissatisfied or dissatisfied with the availability of drinking water (409/438, 93.4%) and interaction with health care providers (293/438, 66.9%) regarding the illness. In multiple regression analysis, we found that receiving prescribed drugs and diagnostic services, the waiting time for registration, and the waiting time for getting treatment were the strongest predictors of patient satisfaction.

Health financing schemes are becoming popular to maintain and improve the health of the population in LMICs [2,6,42]. The SSK health protection scheme has been introduced to increase the access of the poor population to inpatient health care services and ensure financial protection against expenditure to alleviate poverty or extreme poverty induced by out-of-pocket payments for health care in Bangladesh. Although several studies have been conducted on patient satisfaction with health care utilization in different settings in Bangladesh [33,43-46], patient satisfaction with services under the SSK health protection scheme has not been studied thus far. The mean satisfaction score in our study was higher than that in a study conducted to assess satisfaction with the service quality of UzHCs among the uninsured population (3.17 vs 2.75) [44]. The SSK scheme provides health care to members through selected UzHCs; however, compared with nonmembers, insured patients are supposed to receive all prescribed medicines and diagnostic services from private providers contracted by the scheme [13]. The situation is different for other UzHCs where the SSK scheme is not being implemented. The availability of medicines and diagnostic services under the SSK scheme might have increased the satisfaction level among the insured patients.

Our study showed that patient satisfaction was the highest regarding the privacy and confidentiality maintained by providers during diagnostic tests and the patients’ diseases. The number of observations was 438, R-square value was 0.319, and adjusted R-square value was 0.293. The dependent variable is the average satisfaction score of 14 items.

N/A: not applicable.
with the findings that prolonged waiting times for registration and services are associated with lower client satisfaction [54,55]. Patients who received care for noncommunicable diseases were significantly more satisfied than patients having communicable diseases. This might be because people having noncommunicable diseases require regular medications, which are common and available through the contracted pharmacy. Such availability of medicines might have increased patient satisfaction. Similarly, SSK beneficiaries who received all prescribed medicines and diagnostic services were significantly more satisfied. According to the benefits package of the SSK scheme, patients should receive all prescribed medicines and diagnostic services for 78 disease groups. However, 20.8% (91/438) of patients reported that they received partial medicines and 8.7% (38/438) reported that they received partial diagnostic services. It might have happened that some of the prescribed medicines or diagnostic tests were not correlated with the 78 disease categories and therefore were not provided under the scheme. However, evidence indicates that medicines and diagnostic tests are associated with higher out-of-pocket expenditure and lead to falling into poverty [9,56,57]. Scheme beneficiaries are provided free essential medicines and free diagnostic services, and they have a low chance of incurring treatment costs and experience low risks of catastrophic health expenditure, impoverishment, and further impoverishment [9], thus increasing their satisfaction with the services under the scheme. However, other variables, such as education level, employment status, family size, and length of hospitalization, were not significantly associated with satisfaction levels. This might be because the SSK scheme targets the below-poverty-line population having relatively similar socioeconomic characteristics; thus, their perceptions of satisfaction do not vary across these factors. These findings are consistent with the findings of other studies conducted in India [24] and Turkey [37].

This is the first study to explore patient satisfaction with the pilot SSK scheme in Bangladesh. Furthermore, we included patients from all 4 facilities under the SSK scheme rather than selecting them purposively. The findings of this study will help SSK implementation authorities to understand the patient experience of the service delivery process and the quality of health care provided under the SSK scheme.

Limitations
The design of this study was observational in nature, which did not allow us to establish any causal inference with satisfaction and other characteristics under the SSK scheme without a control group. The study only focused on the point of view of the beneficiaries, and we did not explore the providers’ views in this context. The survey collected self-reported satisfaction information from patients, which is highly susceptible to social desirability bias as patients might give responses that please health care providers instead of truly reflecting their satisfaction. However, we interviewed patients at hospital premises in the absence of any providers to minimize such bias.

Conclusions
Our findings demonstrate that more than half of the patients were overall satisfied with the services provided under the SSK scheme. However, there is room for improvement in several dimensions, such as the cleanliness of the waiting room and toilets and the availability of drinking water. Furthermore, attention should be paid to minimizing the waiting time for registration and accessing health care services, and improving providers’ skills on interaction with patients. The results of this study could help stakeholders make necessary changes in the identified determinants of satisfaction related to health service delivery of the SSK scheme. Such changes will enhance the quality of services as well as increase utilization of the scheme in the target population, ultimately advancing progress toward achieving universal health coverage.

Abstract

Background: Health organizations face the critical task of executing and overseeing comprehensive health care. To address the challenges associated with this task, evidence-based dashboards have emerged as valuable tools. Since 2016, the regional health organizations of Quebec, Canada, have been responsible for ensuring implementation of the Quebec Alzheimer Plan (QAP), a provincial plan that aims to reinforce the capacity of primary care services to detect, diagnose, and treat persons with dementia. Despite the provincial scope of the QAP, the diverse material and human resources across regions introduce variability in the interest, utility, and specific needs associated with these dashboards.

Objective: The aim of this study was to assess the interest and utility of dashboards to support the QAP implementation, as well as to determine the needs for improving these aspects according to the perspectives of various types of professionals involved across regions.

Methods: An evaluative study using qualitative methods was conducted within a collaborative research approach involving different stakeholders, including the ministerial advisor and the four project managers responsible for supporting the implementation of the QAP, as well as researchers/scientific advisors. To support these organizations, we developed tailored, 2-page paper dashboards, detailing quantitative data on the prevalence of dementia, the use of health services by persons with dementia, and achievements and challenges of the QAP implementation in each organization’s jurisdiction. We then conducted 23 focus groups with the managers and leading clinicians involved in the implementation of the QAP of each regional health organization. Real-time notes were taken using a structured observation grid. Content analysis was conducted according to different regions (organizations...
Introduction

Health organizations worldwide are encouraged to continually improve their performance by identifying areas in need of enhancement and implementing interventions to address them [1-3]. The learning health system approach posits that a system “learns” through a reflective or cyclical process that engages a community in an empirical analysis of data related to a problem, leading to the discovery of new knowledge and practices [1-4]. Dashboards are an important tool to support a learning health system as they allow tracking the performance of an organization or a specific process and identifying areas in need of improvement [5]. These visual and interactive tools are used to monitor, measure, control, and analyze the performance and outcomes of an organization or a specific process [6,7] and can assist decision-makers in making changes based on the obtained results [8,9]. Dashboards may include alerts, customization options, and contextual information [7,10].

Dashboards can serve decision-makers as well as health managers and professionals in focusing on the most critical activities, monitoring trends, analyzing and identifying areas in need of improvement, and making data-driven decisions [7]. They can foster reflection on the causes explaining results and adjusting actions to better achieve the intended goals [11]. In this sense, their use can be beneficial for improving the quality of care, reducing costs, and increasing efficiency in health care [12]. Additionally, dashboards reduce cognitive load, task completion time, and errors, and enhance situational awareness and adherence to evidence-based practice guidelines [12]. However, the diverse needs of different users (decision-makers, managers, or clinicians) can make it challenging to choose indicators in a dashboard that must be concise to fulfill its function [13,14]. These needs vary and depend on the clinical or managerial context, population characteristics, and the role of professionals [10], which can create information overload [6]. Indeed, health care managers in Canada often report the presence of too many indicators in dashboards, leading to confusion [13,15]. It is necessary to adapt the dashboards to professional contexts and consider the multiplicity of uses in their development and evaluation [16].

The use of a dashboard in national programs such as an Alzheimer Plan further increases the need for considering the multiplicity of uses, as these dashboards need to take into consideration regional differences, especially with respect to resources and populations. Dashboards have been used in the implementation of national programs for health improvement in many countries, including the United States, Canada, and Australia [17-19], for evaluating major neurocognitive disorders [20,21] or for improving care for these individuals [22]. To our knowledge, no study has reported the use of dashboards in the context of implementing an Alzheimer Plan.

Quebec is one of the first Canadian provinces to have developed and implemented an Alzheimer Plan [23]. The Quebec Alzheimer Plan (QAP; Plan ministériel sur les troubles neurocognitifs majeurs) gives interdisciplinary primary care clinic clinicians the responsibility to identify, assess, diagnose, treat, and follow individuals with dementia and their care partners [24,25]. The person-centered approach of the QAP is anchored in primary care, with specialized services supporting more complex clinical situations [24,25]. The QAP includes an implementation strategy supported by the development of professional and organizational capacities, the deployment of partnership governance, ambitious change management, and an independent evaluation by our research team [24,25]. For the generalization of the QAP to the entire province in 2016, the Ministry of Health and Social Services assigned the responsibility for implementing the QAP to the regional health organizations [23,25,26]. This involves training and mentoring doctors and health care professionals in each interdisciplinary primary care clinic in their territory and supporting implementation of the QAP. Four QAP project managers, one for each integrated university health and social services network overseeing regional health organizations [27], served as an interface between the Ministry of Health and Social Services and the health organizations in their territory. These four project managers support organizations to promote change and the sharing of experiences among organizations in their territory.
Health care needs and resources vary significantly from one organization to another based on regional factors such as geographic distribution and demographic characteristics of the population [1,28-30], as well as the availability of local health and social services [1,29,31,32]. For example, the higher population density [1] in urban regions can increase both health and social services needs and resources [1,32]. Although these regions benefit from more resources, access to emergency services, psychosocial services, services for older adults, and mental health services remains suboptimal in almost all regions [29]. Health organizations in more remote areas generally cover very large territories [33]. These organizations face challenges such as geographic accessibility issues [31,34], a lack of local resources across the care continuum [35-37], and an aging population with complex health needs [28,38]. It is important to consider these regional differences in the development of dashboards supporting the implementation of a large-scale Alzheimer Plan [39,40]. Thus, in 2020, the ministry entrusted our research team with the development of dashboards to support regional health organizations in their implementation activities. The objective of this study was to evaluate the interest and utility of these dashboards and to assess the needs for improving them according to various types of health professionals in different regions.

Methods

Design

We conducted an evaluative study based on descriptive qualitative methods [41].

Context Surrounding the Development of Dashboards

For dashboard development, we used a collaborative approach [42] at the core of learning health system approaches. Such an approach can lead to more relevant, efficient, and sustainable results than a more traditional approach in terms of development and problem-solving in the relevant communities and organizations [43].

In collaboration with the ministerial advisor and the four project managers of the QAP, we selected a format and relevant indicators for this exercise. These choices of format and indicators were then validated with members of the QAP advisory committee, composed of managers, leading clinicians, and anyone involved in the QAP implementation from regional organizations in the province.

A format of a maximum 2-sided sheet was selected (see Multimedia Appendix 1). The choice of a paper rather than digital format was made owing to its simplicity, accessibility (easily accessible to all without depending on technology or connectivity), and instantaneous visibility (without requiring complex navigation). These advantages were prioritized despite the knowledge of disadvantages such as the need for manual updates and space limitations. This support is particularly useful experimentally, even though we acknowledge that it will need to evolve into a digital modality during potential routinization in regular managerial processes.

On the first page, nine indicators were selected from provincial clinical-administrative data from the Quebec Integrated Chronic Disease Surveillance System developed by the Institut national de santé publique du Québec [44]. Indicator selection was based on a conceptual framework on the quality of care for dementia, covering a continuum of care from primary care to emergency use and hospitalizations [45]. Eight of these indicators (type of physician most regularly visited, percentage of people with at least one visit to a family doctor, average number of visits to a family doctor per person, percentage of people with at least one emergency room visit, percentage of people with at least one hospitalization, average number of days hospitalized per person, percentage of people with at least one hospitalization with an alternative care level—representing patients who are hospitalized but no longer requiring acute care and waiting for long-term placement—and average number of days in care level) were measured in 2019-2020 in the population of individuals with dementia 65 years and older, and one indicator (prevalence) was measured between 2000-2001 and 2019-2020 in the population of individuals with dementia 40 years and older. While these surveillance data are highly useful for tracking diseases, they are sometimes underused by local actors due to their excessive quantity and the lack of means for rapid analysis [44]. Data visualization, facilitated by dashboards, makes these data more accessible, facilitating decision-making.

On the second page, we presented findings of a thematic analysis of two sources: annual reports to the Ministry of Health and Social Services produced by the managers involved in the QAP between 2017 and 2019, as well as notes of meetings between the ministerial advisor and the four QAP project managers with the managers involved in the QAP in 2020. While quantitative data highlight high-level trends, qualitative data served to enrich the dashboards by providing context to the figures, offering a more comprehensive and engaging perspective [46].

Finally, we chose to present specific results for the population of each health organization and for the entire province. This choice was made to contextualize the results of each organization to those of the entire province.

Data Collection

In spring 2022 (April to June), the ministerial advisor and the four QAP project managers (EM, CF, JD, and CM) organized 90-minute virtual meetings with the managers and leading clinicians involved in the QAP implementation as well as other persons involved in the QAP (eg, research personnel) in each of the 24 regional health organizations. These meetings aimed to share the new directions of the QAP and explore the progress and challenges of the pandemic with each organization. The last 30 minutes of these meetings were devoted to presenting regional dashboards and facilitating group interviews by the research team. The research team had approximately 10 minutes to present the dashboards (5 minutes for quantitative aspects and 5 minutes for qualitative aspects) and approximately 20 minutes to conduct a group interview with the participants in the meetings to assess the interest and utility of the dashboards as well as to assess the needs for improvement of these dashboards. The interview guide included four open-ended questions and prompts: “Are these results surprising to you?” “How will this dashboard be useful to you?” “Are there any
results missing that you would have wanted in this dashboard?” and “Do you have any questions?”

Four members of the research team alternatively facilitated the group interviews (GAL, MG, YC, and IV). One member (GAL) was present in 20 group interviews, ensuring consistency, reinforcing study fidelity and credibility [47]. Two members were always present: one to present the quantitative part of the dashboards (GAL or IV) and the other to present the qualitative part (MG or YC). In addition, one member was designated the main note-taker, while the second member supported the main note-taker and had to read and complete the notes or suggest modifications on a document shared live and online by the main note-taker.

The note-takers were instructed to note dynamics between the participants and to indicate the participant who put forth each observation noted. Thus, a code was assigned to the interlocutor: manager (ie, director, deputy director, coordinator, unit or service head), leading clinician (ie, territorial nurse, physician, or social worker), other participant (ie, research agent or research coordinator), or an unidentified person (when note-takers had not identified the interlocutor).

Consent was obtained verbally at the onset of meetings, and no audio or video recordings were conducted to streamline the analyses to protect confidentiality, especially given the involvement of project managers in organizing the meetings.

Ethical Considerations

This study received ethical approval from the ethics committee of the Centre intégré universitaire de santé et de services sociaux de l’Estrie - Centre hospitalier universitaire de Sherbrooke (MP-31-2021-3701) to ensure that all research activities involving human participants adhered to ethical standards and guidelines. The participants provided informed consent before participating in the study, emphasizing their voluntary participation, the purpose of the research, and the confidentiality of their information. All procedures involving human subjects were conducted in accordance with the ethical standards of the ethics committee and the principles outlined in the Declaration of Helsinki. The research team prioritized participant well-being, privacy, and the responsible handling of data throughout the study.

Analysis

Overview

Content analysis was performed on the observation notes [48]. First, a research team member (GAL) read all the notes several times to become familiar with the content. Subsequently, a preliminary version of the coding manual was generated by analyzing the observation notes. Each segment of the notes taken in the observation grid, deemed relevant and related to the research question, was coded and then grouped under conceptual categories. Once the preliminary coding manual was developed, all conceptual categories were defined. A second research team member (MG), who participated in the majority of group interviews, reviewed the manual to ensure its accuracy and consistency. The coding manual was then iteratively revised during the analysis [49] until consensus was reached among all research team members (GAL, MG, YC, and IV).

Categorization by Region

Each regional health organization involved in the QAP was categorized into one of three groups using a method used by the Ministry of Health and Social Services [50].

Thus, 13 organizations were categorized in a “university/peripheral regions” group, referring to regions located in a university city where there is a medical school or on the outskirts of such cities. Four organizations were categorized in a “mixed regions” group, where a lack of resources applies to only one part of the territory or where only a part of the territory is considered rural or remote. Seven organizations were categorized in a “remote or isolated regions” group, including organizations not falling into any of the above categories and for which the entire territory is considered remote from urban centers or even isolated. A list of organizations grouped by region is presented in Multimedia Appendix 2.

Similarities and differences were then noted between different types of regions (university/peripheral, mixed, and remote/isolated).

Categorization by Type of Participants

As interest, perceived utility, and needs in terms of dashboards could vary among different types of participants (managers, leading clinicians, or other participants), and their degree of participation also varied greatly between group interviews, a specific analysis for each type of participant was conducted.

Similarities and differences were then noted between different types of professionals (managers, leading clinicians, and other participants).

Results

Participants

Overall, 23 group interviews were conducted. One organization from a university/peripheral region could not participate due to a significant change in the local governance of the QAP, and two organizations from remote/isolated regions participated in the same group interview. Eighty-two individuals participated in the group interviews: 44 were managers, 32 were leading clinicians, and 7 were other participants (mainly research coordinators).

Similarities Across Regions

Interest

Dashboards received positive reactions from participants in all regions. Some indicators sparked more discussion than others. These discussions focused on whether the results were surprising or not and on participants providing justifications for these results. Participants from all regions were particularly interested in the following indicators: alternative care level, prevalence, emergency room visits, and the type of physician most regularly visited. Participants from all regions were also highly interested in qualitative results, but the varied nature of these results does
not allow for a more specific analysis of these discussions (Table 1).

\[f\] Despite the fact that no indicators of references were presented, the discussions revolved around references to emergency or hospitalizations.

### Utility

Participants from all regions offered several reflections on the utility of the dashboards. Primarily, participants believed that their tailored dashboard would be useful for identifying successes and challenges specific to their territory. Moreover, the participants thought the dashboards could mobilize different stakeholders, including the top management of regional health organizations or clinicians from interdisciplinary primary care clinics in their region. In all cases, the reception of dashboards suggested a desire for broader processes of critical thinking, self-examination, and learning on the part of participants (Table 2).

**Specific Needs**

**Comparisons**

Participants from all regions made proposals or asked clarifying questions suggesting specific needs. The participants appreciated the element of comparisons presented, but many suggested for the dashboard to also present the temporal trend of indicators. Other types of comparisons were also proposed depending on the organizations, without unanimity among regions. For example, participants from a mixed organization would have liked to have a comparison to the metropolis of the province (Montreal), while participants from another mixed organization would prefer to have a comparison to a territory that is geographically or demographically similar or, conversely, to be compared to a territory that is completely different (Table 3).

**Targeted Populations and Other Indicators**

Participants from all regions expressed the need to produce results concerning patients not registered in interdisciplinary primary care clinics or without a family doctor (orphan patient), and to produce results on services received by individuals with dementia from health care professionals other than fee-for-service physicians (Table 3). Proposals particularly concerned visits with nurses, social workers, pharmacists, and occupational therapists, without a real consensus on the type of professional (Table 4).

Divergences Between Regions

Interest
Participants from university/peripheral regions were particularly interested in results on hospitalizations and continuity of care (visits to family physicians). These same results were less emphasized by participants from other regions (mixed or remote/isolated) (Table 1).

Utility
Participants from university/peripheral regions were the first to propose that these dashboards could serve as a planning tool for their local QAP steering committees as well as for training clinicians. Following this observation, participants in subsequent focus groups were all invited to directly address this point. Not all responded enthusiastically to this opportunity, and responses varied among participants within the same region, whether peripheral/university, mixed, or remote/isolated. This indicates that perceived utility varies among participants, even among those from university/peripheral regions. Participants from university/peripheral regions also mentioned that these dashboards could be useful for research purposes. This difference likely reflects the level of engagement of regional teams with the QAP (Table 2).

Specific Needs
Stratifications
Participants from remote/isolated or mixed organizations proposed stratifying data based on smaller territories. They suggested that presenting data for their vast territory did not allow for detecting variations they perceived between different subregions (Table 3).

Targeted Populations and Other Indicators
Participants from university/peripheral and mixed regions made several suggestions targeting vulnerable patients or other diverse indicators. For example, they proposed stratifying dashboards or having specific data for patients known in home support or support for elderly autonomy, patients of solo-practicing physicians, and patients with mental health disorders not identified before being diagnosed with dementia (Table 3). Several specific indicators were proposed, but these proposals varied widely between different organizations, whether from university/peripheral or mixed regions. These propositions included: reasons or complexity of hospitalization or consultation, follow-up in interdisciplinary primary care, trajectory indicators, customer satisfaction, home care follow-up, number of clinicians trained under the QAP, timely diagnosis, and projections for the next 10 years (Table 4).

Participants from remote/isolated organizations expressed a need for more information and culturally adapted training for their region. In particular, they expressed the need for diagnostic tools and training adapted to their population, which includes many people from Indigenous communities.

Similarities and Differences According to Type of Professionals
Leading clinicians who participated in the focus groups mainly came from university/peripheral or mixed organizations. Additionally, university/peripheral organizations were the only ones in which other types of participants (research agents or coordinators) took part in the focus group.

In general, managers and leading clinicians shared the same interest in the prevalence indicator. However, leading clinicians expressed needs that managers and other participants did not express, particularly on follow-up indicators in Family Medicine Groups (interdisciplinary primary care teams), reasons for consultations/visits in primary care or emergencies, and patient satisfaction.

Some managers and research agents or coordinators would have appreciated more information on how individuals with dementia were identified for quantitative indicators. Finally, only one leading clinician and the research agents or coordinators suggested using these dashboards for research purposes.

Discussion

Principal Findings
This study determined that dashboards are of interest to those responsible for implementing an Alzheimer Plan in regional health organizations, and their format and content were appreciated regardless of the region or profession of the participants [51]. The study also highlighted specific needs regarding these dashboards that transcend all regions. Participants from all regional health organizations expressed a need for data on orphan patients or those not registered in interdisciplinary primary care clinics, as well as data on indicators related to services offered by other health care and social professionals (ie, nurses, social workers, pharmacists, and occupational therapists). These needs seem to express a desire to better delineate the challenges posed by orphan patients.
in the organization of health care across the province and to better monitor how interprofessional collaboration takes shape in interdisciplinary primary care clinics (Family Medicine Groups in Quebec).

We also identified interests and specific needs among participants from different regions and different types of professionals. The interest in hospitalization and continuity of care expressed by participants from university/peripheral regions (more urban) can be explained by the higher population density and a diversity of health resources in these regions [31]. Additionally, urban regions often have a greater diversity of health care and social professionals, specialists, and medical technologies available to meet the population’s needs [52]. In contrast, in remote or isolated regions, resources and the number of professionals may be more limited [36,38]. This higher resource availability in urban settings could explain higher interest in continuity of care in urban settings.

Another significant specific need that varied between regions is the need for diagnostic tools and adapted training expressed by participants from remote and isolated regions. The geographical, demographic, and socioeconomic characteristics of these regions make them unique and require different approaches to meet their health needs [1]. Health care professionals in these regions often face different challenges in providing health care for people with dementia [35,36]. This specific need may arise from the observation that both in Quebec and Canada, there is a higher proportion of Indigenous communities in rural areas [53,54], requiring cultural adaptation of care delivery and supporting tools. This is especially important considering the data availability in these regions [55].

Two regions only received qualitative dashboards. Quantitative surveillance data were not available for these organizations either due to their small populations posing risks to data dissemination or due to the fee-for-service mode of physician payment, on which surveillance data rely, but which is less frequent in these regions [56]. The inclusion of qualitative data has proven to be a significant asset in addressing these limitations.

Finally, organizations that span a larger territory (often from remote/isolated or mixed regions) expressed the need for a more granular analysis [42]. Several participants wanted more precise data for smaller territories. However, an ethical constraint prevented us from producing dashboards for smaller territories. Producing a single dashboard for all 24 regional health organizations remains a challenge to explore in future work.

The collaborative approach among researchers, scientific advisors from the National Institute of Public Health of Quebec, QAP project managers, and the QAP ministerial advisor is a major strength of the study [42]. This approach ensured a good understanding of the QAP implementation and formed an alliance between different stakeholders. The research and scientific advisor team could identify the most relevant data, while project managers—as the true points of contact with leading clinicians and managers of different regional health organizations—ensured that the messages were meaningful and well understood by all. The ministerial advisor and the four project managers responsible of the QAP also ensured that the collected and presented data allowed all stakeholders to align with the QAP orientations.

**Limitations**

The study also has limitations, particularly in terms of participant acquiescence biases during focus groups. Although the meetings were organized for guidance purposes, managers and leading clinicians from regional health organizations may have felt the need to demonstrate their progress to the ministerial advisor and project managers, as well as to researchers, due to their apparent proximity to the decision-makers and in front of their colleagues. To counter this acquiescence bias, we reiterated the independence of the research team from decision-makers at the beginning of each meeting. Another limitation is the categorization of different regions. Such categorizations are often arbitrary and inconsistent and do not consider the diversity of each region, especially for larger territories, which are often more remote [57]. However, this categorization aligns with that of the Ministry of Health and Social Services and reflects the organization of resources across the different regions of Quebec [50]. Finally, the relatively short time for conducting focus groups (30 minutes) could be considered a limitation. However, in addition to achieving data saturation during focus groups, we conducted these focus groups across all health organizations involved in the QAP and involved several stakeholders (at least one manager was always present, leading clinicians participated in several focus groups, and even research professionals participated in a few), ensuring good representativity of the results.

**Future Work and Recommendations**

Considering that the use of dashboards for an Alzheimer Plan is not documented in the scientific literature, future research should focus on the adoption of this tool in different regional health organizations in Quebec and at the governmental level. Studies on the use of dashboards exist for the evaluation of major neurocognitive disorders and the improvement of care offered to these individuals [20-22], but no study specifically mentions the use of a dashboard for an Alzheimer Plan. This will facilitate the transition from an experimental dashboard to a regular tool for managing or monitoring the implementation of an Alzheimer Plan. The composition of focus group participants was different for each region, which may have influenced the results and conclusions. The presence of more leading clinicians in university/peripheral regions may have led to discussions more focused on clinical aspects, while the predominance of managers in mixed or remote/isolated regions may have led to discussions more focused on logistical and organizational challenges related to service delivery in these regions. Other demographic characteristics of participants, such as gender and sex, could have influenced discussions and analyses. It would be interesting for future studies to analyze these differences. Furthermore, no patient or caregiver was part of the focus group, a major element of a learning health system. With increasing incentives to include citizens in health innovations, it will be a great opportunity to study the impact of their perspectives on developing and using dashboards.
Conclusion
In conclusion, dashboards are part of a learning health system and are a very useful tool for reporting on the challenges and issues related to the implementation of an Alzheimer Plan. However, it is important to consider the differences in the utility and information needs of various regions and types of professionals when developing dashboards to enable an adapted, efficient, and equitable implementation of an Alzheimer Plan that extends to a diverse set of organizations with varied resources. Taking these differences into account in the development of dashboards supporting the implementation of an Alzheimer Plan allows for better meeting the needs of all individuals with major neurocognitive disorders and providing optimal and equitable care, regardless of their region of residence.

Acknowledgments
We would like to thank Laura Rojas-Rozo, Mary Henein, Juliette Champoux-Pellegrin, and Sylvie Muller for formatting the dashboards; Louis Rochette from the Institut national de santé publique du Québec for extracting quantitative data and enthusiastically responding to related questions; and the managers, clinicians, and other participants who provided many insights to better support them in the implementation of the Quebec Alzheimer Plan. This work was supported by the Canadian Consortium on Neurodegeneration in Aging (CNA-163902). The Consortium is funded by a grant from the Canadian Institutes of Health Research (CIHR) and by funding from several partners.

Data Availability
All data generated or analyzed during this study are included in this published article and its appendix files. The comprehensive data set, including anonymized participant information and research materials, is available upon reasonable request. Researchers seeking access to the data for academic, noncommercial purposes can contact the corresponding author to facilitate the sharing of relevant materials. The aim is to promote transparency, reproducibility, and collaboration within the scientific community while respecting the privacy and confidentiality of the participants.

Authors’ Contributions
GAL and IV designed the study. All authors participated in the development of regional dashboards. GAL, MG, YC, IV, EM, CF, JD, and CM contributed to data collection and interpretation of results. GAL and ALC drafted the initial manuscript. All authors read and approved the final manuscript.

Conflicts of Interest
None declared.

Abstract

Background: The incidence of major adverse cardiovascular events (MACEs) remains high in patients with acute myocardial infarction (AMI) who undergo percutaneous coronary intervention (PCI), and early prediction models to guide their clinical management are lacking.

Objective: This study aimed to develop machine learning–based early prediction models for MACEs in patients with newly diagnosed AMI who underwent PCI.

Methods: A total of 1531 patients with AMI who underwent PCI from January 2018 to December 2019 were enrolled in this consecutive cohort. The data comprised demographic characteristics, clinical investigations, laboratory tests, and disease-related events. Four machine learning models—artificial neural network (ANN), k-nearest neighbors, support vector machine, and random forest—were developed and compared with the logistic regression model. Our primary outcome was the model performance that predicted the MACEs, which was determined by accuracy, area under the receiver operating characteristic curve, and F1-score.

Results: In total, 1362 patients were successfully followed up. With a median follow-up of 25.9 months, the incidence of MACEs was 18.5% (252/1362). The area under the receiver operating characteristic curve of the ANN, random forest, k-nearest neighbors, support vector machine, and logistic regression models were 80.49%, 72.67%, 79.80%, 77.20%, and 71.77%, respectively. The top 5 predictors in the ANN model were left ventricular ejection fraction, the number of implanted stents, age, diabetes, and the number of vessels with coronary artery disease.

Conclusions: The ANN model showed good MACE prediction after PCI for patients with AMI. The use of machine learning–based prediction models may improve patient management and outcomes in clinical practice.

KEYWORDS
acute myocardial infarction; percutaneous coronary intervention; machine learning; early prediction; cardiovascular event
**Introduction**

Acute myocardial infarction (AMI) is a common clinical acute and severe disease with rapid onset, rapid progression, and high mortality [1-3]. In 2017, there were approximately 695,000 new cases of AMI in the United States, and it is estimated that 325,000 people will have recurrent events [4]. There are approximately 500,000 new cases of AMI in China every year, and 2.5 million patients have a history of myocardial infarction [5]. As technology has advanced, percutaneous coronary intervention (PCI) has become the primary approach for treating AMI. Although PCI can significantly reduce the fatality rate of AMI, the rate of major adverse cardiovascular events (MACEs) among patients after PCI is still very high, which seriously affects the clinical outcomes of patients [6-10]. A study by Copeland-Halperin et al [11] showed that the incidence of MACEs in patients with AMI one year after PCI was 17.8% [11].

Identifying patients with AMI undergoing PCI who are at high risk of MACEs may help clinical decision-making incorporate timely measures to improve clinical outcomes. Some studies, such as Global Registry of Acute Coronary Event [12], Thrombolysis in Myocardial Infarction Risk [13,14], and Acute Catheterization and Urgent Intervention Triage StrategY-PCI [15], as well as studies that generated the Mayo Clinic PCI Risk and the China Acute Myocardial Infarction scoring systems, have explored the risks after PCI [16]. Despite these advances, individualized prediction of MACEs remains challenging with low specificity and positive predictive accuracy, and most of the methods rely on traditional parameter models, such as logistic regression, to screen for variables and build a series of risk-scoring models.

In recent years, machine learning methods that rely on a strong self-learning capability, such as random forest (RF), k-nearest neighbors (KNN), support vector machine (SVM), and artificial neural network (ANN) have become increasingly prevalent in prognostic prediction [1,13,17,18]. By calling various functions, these models can extract and integrate information from all kinds of complex data to make better predictions. A study of a consecutive cohort of patients with hypertrophic cardiomyopathy (HCM) presented a machine learning–based model to identify individual patients with HCM at high risk of developing advanced heart failure symptoms. The results showed that the 5-year risk prediction of progressive heart failure in patients with HCM can be estimated [19].

We found that machine learning models, such as RF, ANN, SVM, and KNN, perform well in clinical prognosis prediction research. Thus, this study sought to develop a machine learning–based model, integrating clinical, anatomical, and laboratory features, to predict MACEs in patients who have recently been diagnosed with AMI after their first PCI and improve overall patient outcomes by implementing earlier management.

**Methods**

**Study Design, Setting and Participant Selection**

This retrospective cohort study was conducted at the Department of Cardiovascular Medicine, the Second Affiliated Hospital of Nanchang University (a teaching tertiary hospital), in Jiangxi Province, China. We collected electronic medical records of patients with AMI who underwent PCI for the first time from January 2018 to December 2019. These patients were followed up through December 2021.

The inclusion criteria of the participants were as follows:

- The patient was ≥18 years of age.
- This was the patient’s first clinically diagnosed AMI (clinical evidence of AMI as evident from the detection of a rise or fall of cardiac troponin values and at least one of the following symptoms of myocardial ischemia: symptoms of acute myocardial ischemia, new ischemic electrocardiogram (ECG) changes, and development of pathological Q waves).
- PCI was performed for the first time at this hospital.
- Among the left main artery, left circumflex branch, left anterior descending branch, and right coronary artery, at least one had stenosis ≥50%.
- Complete medical records and follow-up data were available.

The following exclusion criteria were applied:

- History of PCI and coronary artery bypass grafting treatment
- Complications from other heart diseases requiring surgical procedures, such as heart bypass
- Recent active bleeding
- An intracerebral mass or an aneurysm

We adopted the “Guidelines for Developing and Reporting Machine Learning Predictive Models in Biomedical Research” to guide the reporting of our study [20].

**Data Collection, Definition of Outcomes, and Predictor Variables**

Data were collected from electronic health records, including demographic characteristics, clinical investigations, the first laboratory tests, and disease-related events. MACEs were defined as cardiomyopathies (excluding infectious, familial, alcohol, and drug-related cardiomyopathies), hypertensive heart disease, recurrent myocardial infarction, heart failure, sudden cardiac death, revascularization, malignant arrhythmia, and stent thrombosis [21]. Abnormal Q waves were identified by the clinician based on ECG results. Left ventricular ejection fraction (LVEF) was defined as normal (more than 50%), mildly abnormal (40% to 50%), moderately abnormal (30% to 40%), and severely abnormal (less than 30%) [22]. According to the number of diseased coronary vessels and implanted stents, they were classified as I, II, III, and IV.
Ethics Approval
This study was reviewed and approved by the Second Affiliated Hospital of Nanchang University Medical Ethics Committee (No. Review 2017 No. (098)).

Data Preprocessing for Machine Learning Model Development
All analyses were performed with R software (version 4.0.1; R Core Team). The patients were randomly assigned to training (n=953, 70%) and testing (n=409, 30%) data sets by calling the createDataPartition function using the random number method, and chi-square tests showed that there was no statistical difference between them ($\chi^2_1=2.169; P=.14$). We developed machine learning models using the training data set. We analyzed the missing and out-of-range values with imputation methods. We used multiple imputation with chained equations to assign any missing predictor values [23]. The imputation processes were performed separately in the training and testing sets after the data were split. To improve the accuracy of the machine learning models and increase the speed of finding the optimal solution by gradient descent, we standardized and normalized all input variables before the model was built. To alleviate the problem of imbalanced classification samples, we adopted the random oversampling method. We used the ROSE package in R to generate new balanced training data. After random oversampling, the number of patients with MACE in the training data sets changed from 186 to 471.

Predictor Selection for Model Development
The model was built using demographic information (age and sex), personal comorbidities (diabetes and peripheral arterial disease), preoperative PCI (LVEF, the number of diseased vessels, and abnormal Q waves), serological examination (beta 2 microglobulin, B-type brain natriuretic peptide, glucose, serum creatinine clearance, and estimated glomerular filtration rate), and the characteristics of PCI (the number of implanted stents; n=65; Table S1 in Multimedia Appendix 1). A total of 12 variables with significant differences in the univariate analysis were included in the model development (Table 1).

**Model Testing and Performance Evaluation**

Based on a previous application of the model [24], the parameter range of the model was preset, and the GridSearchCV function was used to select the optimal parameters of each machine learning model.

To minimize potential overfitting in the above machine learning models, we called the trainControl function in the caret package of R language for 7-fold cross-validation during the development process. The model performance was assessed for accuracy, recall, precision, area under the receiver operating characteristic curve (AUC), and \(F_1\)-score in the testing data set. We identified
the important predictors through importance analysis of the variables. Logistic regression analysis was used to compare the absolute value of the coefficients of variables; RF was used to measure the importance of features by calculating information gain through entropy; and the ANN method was used to calculate the relative importance of variables based on the generalized weight method.

**Statistical Analysis**

The following R packages for machine learning approaches were used: caret, randomForest, and neuralnet. Baseline characteristics were compared with the Wilcoxon rank sum test for continuous variables and the chi-square test for categorical variables. We considered $P<.05$ (2-sided) to be statistically significant.

**Results**

A total of 1531 patients were screened; 140 patients who did not undergo PCI for the first time were excluded; 19 patients were lost to follow-up; and 1362 patients who were successfully followed up were included in this analysis (Figure 1). The mean follow-up time was 28.0 (SD 11.0) months (median 29.9 months). A total of 252 MACEs were observed, including 128 cases of recurrent myocardial ischemia and 117 cases of myocardial infarction and reinfarction. The positive rates of MACEs were 4.63%, 11.38%, 14.54%, and 18.50% at 30 days, 6 months, 1 year, and 3 years after PCI, respectively. MACEs occurred in 203 (18.7%) male patients and 49 (17.8%) female patients. As shown in Figure 2, the survival rate of the sample population decreased rapidly in the first 3 months after PCI, especially 30 days after PCI, and there was no difference in the log-rank test of the survival curve between male and female patients.

Table 1 shows the baseline characteristics of the MACE group and the non-MACE group. Age, diabetes, peripheral and cerebrovascular history, LVEF, abnormal Q wave, the number of vessels with coronary artery disease, the number of implanted stents, brain natriuretic peptide, serum creatinine, estimated glomerular filtration rate, beta 2 microglobulin, and glucose were significantly different between the 2 groups ($P<.001$). The nonsignificant differences in variables between the 2 groups are shown in Table S1-S6 in Multimedia Appendix 1.

Table 2 shows the performance of the 3 models with 7-fold cross-validation. ANN, KNN, SVM, RF, and logistic regression exhibited the best to worst performance in terms of their AUC, accuracy, recall, and $F_1$-score. However, KNN performed best in terms of precision. The average accuracy, recall, precision, AUC, and $F_1$-score of the ANN model were 80.52%, 81.33%, 69.94%, 83.68%, and 79.47%, respectively.

In the testing data set, the ANN model showed a higher AUC than RF and logistic regression. Figure 3 shows that the AUCs of the ANN, RF, KNN, SVM, and logistic regression models were 0.805, 0.798, 0.772, 0.727, and 0.718, respectively; the average accuracy for the above 3 models was 0.821, 0.741, and 0.729, respectively, and the average $F_1$-scores were 0.804, 0.722, and 0.709, respectively.

The 10 most important predictors in the ANN model are shown in Table 3. These were LVEF (0.27), the number of implanted stents (0.14), age (0.13), diabetes (0.10), the number of vessels with coronary artery disease (0.09), vascular disease (0.08), brain natriuretic peptide (0.05), glucose (0.05), beta 2 microglobulin (0.04), and abnormal Q wave (0.02).

Discussion

Principal Findings

In this study, we developed a machine learning–based model integrating clinical, anatomical, and laboratory test features to predict MACEs in patients with newly diagnosed AMI after their first PCI. The major findings suggest that the ANN model had higher predictive accuracy (accuracy of 87.99%, AUC of 0.81, and F1-score of 0.71), compared to RF, KNN, SVM, and logistic regression.

Among the patients with AMI in this study, the rates of MACEs at 30 days, 6 months, 1 year, and 3 years after PCI were 4.63%, 11.38%, 14.54%, and 18.50%, respectively, and the incidence of MACEs at 30 days after PCI was slightly less than the 5.5% reported in the Harmonizing Outcomes with RevascularIZatiON and Stents in Acute Myocardial Infarction study (HORIZONS-AMI) [25]. The incidence of MACEs at half a year was higher than the 6.67% reported by Chow et al [26], consistent with the 2-year rate of MACEs reported by Sanmenxia City (18.06%). The survival condition of patients with AMI in this study, the rates of MACEs at 30 days, 6 months, 1 year, and 3 years after PCI were 4.63%, 11.38%, 14.54%, and 18.50%, respectively, and the incidence of MACEs at 30 days after PCI was slightly less than the 5.5% reported in the Harmonizing Outcomes with RevascularIZatiON and Stents in Acute Myocardial Infarction study (HORIZONS-AMI) [25]. The incidence of MACEs at half a year was higher than the 6.67% reported by Chow et al [26], consistent with the 2-year rate of MACEs reported by Sanmenxia City (18.06%). The survival condition of patients with AMI in this study, the rates of MACEs at 30 days, 6 months, 1 year, and 3 years after PCI were 4.63%, 11.38%, 14.54%, and 18.50%, respectively, and the incidence of MACEs at 30 days after PCI was slightly less than the 5.5% reported in the Harmonizing Outcomes with RevascularIZatiON and Stents in Acute Myocardial Infarction study (HORIZONS-AMI) [25]. The incidence of MACEs at half a year was higher than the 6.67% reported by Chow et al [26], consistent with the 2-year rate of MACEs reported by Sanmenxia City (18.06%).

Our results indicated that the 3-year prognostic risk among patients with AMI undergoing their first PCI was mainly related to age, ECG characteristics, ventricular ejection ability, coronary artery lesions, stent implantation after PCI, and some serological variables. Yang et al [32] found that the risk ratio of hospital deaths after PCI was 3.723 (95% CI 2.86-4.84) for South Korean patients aged >65 years relative to those aged ≤65 years. A Korean multicenter AMI National Institutes of Health–registered project found that the MACE rate, 3 years after PCI, among patients with AMI with an LVEF <40% was 3.34 times that of the control group [33]. Fam et al [34] conducted a retrospective study on patients with clinical AMI in Asian multiethnic groups and found that the risk of MACEs among patients with diabetes, 2 years after PCI, was 1.84 times higher than that among patients without diabetes [34]. Diabetes is a chronic metabolic disease, and long-term diabetes is often accompanied by bleeding disorders, vascular endothelial dysfunction, small artery lesions, high blood sugar [35], hemostatic disorders [36], endothelial dysfunction, and a series of other changes [37]. These characteristics will accelerate the process of atherosclerotic disease deterioration. The number of coronary artery lesions

and the number of stents implanted in a patient are also positively correlated with the risk of postoperative MACEs to a certain extent. This may be because a higher number of vessels with coronary artery disease and the number of implanted stents tend to indicate a more serious condition, leading to a worse prognosis for the patients. Hongbo et al [38] found that the probability of a poor prognosis in patients with multiple coronary artery lesions was 20.0%, compared with 6.98% in patients with single coronary artery lesions [38].

The results of the machine learning model showed that predictors like LVEF, number of implanted stents, and age were more important to the model. LVEF is a common variable that reflects left ventricular function, and patients with a low LVEF have a significantly higher MACE rate [39]. An increase in age can lead to the aggravation of atherosclerosis [40]. The number of implanted stents may be related to the severity of the disease and the extent of the infarction [41]. This reminds us that we should pay special attention to the prognosis of patients with AMI who have a low LVEF value, older age, and more implanted stents in clinical practice.

Study Limitations
This study has some limitations. First, there may have been an issue of survival bias in the study, as patients with missing follow-up data were excluded. Second, the data have missing values. We have filled missing values with multiple imputation; however, imputation with these techniques could synthetically reduce the variance in these variables and may have affected the accuracy of the constructed model. Finally, although the models were internally validated with data from the same hospital, further work should include validation with external data from other hospitals or centers.

Conclusions
This study revealed that the ANN model showed good MACE prediction performance for patients with AMI after PCI, and it identified the most important predictors, which may aid in clinical decision-making and improve outcomes. This model needs to be externally validated in larger populations and multicenter settings.

Abstract

Background: Psychological inflexibility is a core concept of acceptance and commitment therapy (ACT), which is a comprehensive, transdiagnostic interpretation of mental health symptoms. Erectile dysfunction (ED) is a condition that affects male sexual performance, involving the inability to achieve and maintain a penile erection sufficient for satisfactory sexual activity. Psychosocial factors primarily influence ED in men younger than 40 years, whereas biological factors are more likely to be the underlying cause in older men.

Objective: This web-based cross-sectional study examined differences in depression, anxiety, and psychological inflexibility among men with ED younger and older than 40 years in a Japanese population.

Methods: We used a web-based survey to gather data from various community samples. ED was assessed by the International Index of Erectile Function - 5 (IIEF-5) questionnaire, while depression, anxiety, and psychological inflexibility were evaluated by the Patient Health Questionnaire-9 (PHQ-9), General Anxiety Disorder-7 (GAD-7), Acceptance and Action Questionnaire-II (AAQ-II), Cognitive Fusion Questionnaire (CFQ), and Valuing Questionnaire–Obstacle Subscale (VQ-OB) questionnaires. The chi-square test estimated the scores of PHQ-9 and GAD-7 among men with ED, comparing those younger than 40 years and those older than 40 years. Additionally, a two-way ANOVA was conducted with ED severity and age group as independent variables, assessing psychological inflexibility.

Results: Valid responses from 643 individuals (mean age 36.19, SD 7.54 years) were obtained. Of these, 422 were younger than 40 years (mean age 31.76, SD 5.00 years), and 221 were older than 40 years (mean age 44.67, SD 2.88 years). There was a statistical difference in the prevalence of depression as judged by PHQ≥10 between men with ED younger and older than 40 years (P<.001). On the other hand, there was no difference in the prevalence of anxiety as judged by GAD≥10 (P=.12). The two-way ANOVA revealed that the interactions for CFQ (P=.04) and VQ-OB (P=.01) were significant. The simple main effect was that men with ED younger than 40 years had significantly higher CFQ (P=.01; d=0.62) and VQ-OB (P<.001; d=0.87) scores compared to those older than 40 years in moderate ED and severe ED. Additionally, it was found that men younger than 40 years with moderate to severe ED had significantly higher CFQ (P=.01; d=0.42) and VQ-OB (P=.02; d=0.38) scores compared to men younger than 40 years without ED. On the other hand, no interaction was found for AAQ-II (P=.16) scores.

Conclusions: To the best of our knowledge, this web-based cross-sectional study is the first to examine the relationship between psychological inflexibility and ED. We conclude that men with moderate and severe ED younger than 40 years have higher psychological inflexibility and might be eligible for ACT.

**Introduction**

The efficacy of acceptance and commitment therapy (ACT) has been evaluated in numerous randomized controlled studies exploring various targeted conditions [1]. There is supporting evidence for ACT across various physical illnesses (eg, chronic pain [2], diabetes [3], epilepsy [4], cancer [5], and irritable bowel syndrome [6]). Many of these studies use a transdiagnostic method to analyze psychological issues within individual health conditions. Psychological inflexibility is a core concept of ACT, which is a comprehensive, transdiagnostic interpretation of mental health symptoms [7]. Psychological inflexibility highlights two interrelated processes: cognitive fusion and experiential avoidance. Cognitive fusion represents the phenomenon by which individuals are influenced by the literal meaning of their thoughts instead of viewing them as transient internal states [8]. Experiential avoidance represents an attempt or desire to suppress unwanted internal experiences, such as emotions, thoughts, memories, and bodily sensations [9]. These processes are obstacles to one’s valued living activities, decreasing well-being [10].

Erectile dysfunction (ED) is a condition that affects male sexual performance, involving the inability to achieve and maintain a penile erection sufficient for satisfactory sexual activity [11]. Several reviews and clinical guidelines are available for ED. However, many of these approaches to assessing and treating ED purely from a medical perspective seldom address the psychosocial components of ED [12]. Pharmacological treatment alone does not respond to all the concurrent factors of ED, including anxiety, loss of self-confidence, depressed mood, difficulties in a couple’s communication, relationship disputes, or a partner’s sexual problems [13]. Recent systematic reviews have shown that combining phosphodiesterase-5 inhibitors with psychological treatment exhibits significant potential for treating ED [14].

There is a widespread assumption that psychosocial factors primarily influence ED in men younger than 40 years, whereas biological factors are more likely to be the underlying cause of ED in older men. Moore et al [15] showed different symptom patterns among patients with ED according to age groups. They reported that younger men had comparatively more significant depressive symptoms, with lower relationship satisfaction, more negative reactions from partners, and lower job satisfaction. Given these findings, it is possible that people younger than 40 years are more psychologically inflexible than those older than 40 years and that ACT is more effective for them. However, studies on ACT for ED remain limited, with only a few identified. Therefore, this cross-sectional study used assessments to evaluate depression, anxiety, and psychological inflexibility in men younger and older than 40 years. However, it is well known that ED prevalence varies across geographical groups [16,17]; therefore, it is essential to research ED etiology according to different racial, cultural, religious, and socioeconomic backgrounds. There might be many potential patients with ED in Japan, so we conducted a web-based survey for this study.

**Methods**

**Participants**

To gather data from a wide range of community samples, we used a web-based survey, conducted with the assistance of a marketing research service provider (Rakuten Insight, Inc) in Japan. Based on the International Index of Erectile Function – 5 (IIEF-5) cutoff point [18], participants of all severities were recruited to include a certain percentage of patients of all ages. All enrolled participants followed the following criteria: (1) male; (2) aged 20 to 50 years; and (3) married or living with a fixed sexual partner for more than 6 months. The exclusion criteria were as follows: (1) sexual dysfunction caused by Peyronie disease or other organic lesions of the external genitalia; (2) prostate cancer, hypertensive disease, cardiac disease, cerebrovascular disease, chronic kidney disease, and diabetes; and (3) a history of sertraline or other medicines that may influence erection and psychological symptoms.

Participants were first instructed that this survey would be administered anonymously, and their responses were not compulsory. Then, those participants who agreed to participate in this research responded to the surveys. Participants were given points to exchange for items within the survey company’s system as a reward.

**Ethical Considerations**

This study was approved by the Waseda University Academic Research Ethical Review Committee (2019-363). The study protocol followed the guidelines for epidemiological studies in accordance with the Declaration of Helsinki.

**Measurements**

**International Index of Erectile Function-5 (IIEF-5)**

The Japanese version of IIEF-5 is a 5-item self-report questionnaire designed to measure erectile function [18]. Items are rated on a 5-point Likert-type scale, ranging from 1 to 5. The total score can range from 5 to 25, with high scores meaning high erectile function. Based on the original validation studies, the total score can then be interpreted as suggesting “no ED” (22-25), “mild ED” (17-21), “mild-to-moderate ED” (12-16), “moderate ED” (8-11), and “severe ED” (5-7).

**Patient Health Questionnaire-9 (PHQ-9)**

The Japanese version of the Patient Health Questionnaire-9 (PHQ-9) is a 9-item self-report questionnaire designed to measure depression [19]. Items are rated on a 4-point Likert-type scale, ranging from 0 to 3. The total score can range from 0 to 27, with high scores meaning high depression. Based on the original validation studies, the total score can then be interpreted as suggesting no depression (0-4), mild depression (5-9), moderate depression (10-14), moderately severe depression (15-19), severe depression (20-27), or major depression (28-30).
or severe depression (20-27). A cutoff score of 10 is suggested as indicating a possible diagnosis of depressive disorder.

**Generalized Anxiety Disorder-7 (GAD-7)**

The Japanese version of the Generalized Anxiety Disorder-7 (GAD-7) questionnaire is a 7-item self-report questionnaire designed to measure generalized anxiety disorder [20]. Items are rated on a 4-point Likert-type scale, ranging from 0 to 3. The total score can range from 0 to 21, with high scores meaning high anxiety. Based on the original validation studies, the total score can then be interpreted as suggesting no anxiety (0-4), mild anxiety (5-9), moderate anxiety (10-14), or severe anxiety (14-21). A cutoff score of 10 is suggested as indicating a possible diagnosis of generalized anxiety disorder.

**Acceptance and Action Questionnaire-II (AAQ-II)**

The Japanese version of the Acceptance and Action Questionnaire-II (AAQ-II) is a 7-item self-report questionnaire designed to measure experiential avoidance [21]. Items are rated on a 7-point Likert-type scale, ranging from 1 to 7. The total score can range from 7 to 49, with high scores meaning high experiential avoidance.

**Cognitive Fusion Questionnaire (CFQ)**

The Japanese version of the Cognitive Fusion Questionnaire (CFQ) is a 7-item self-report questionnaire designed to measure cognitive fusion [22]. Items are rated on a 7-point Likert-type scale, ranging from 1 to 7. The total score can range from 7 to 49, with high scores meaning high cognitive fusion.

**Valuing Questionnaire–Obstacle Subscale (VQ-OB)**

The Japanese version of the Valuing Questionnaire–Obstacle Subscale (VQ-OB) is a 5-item self-report questionnaire designed to measure obstruction of valued living [23]. Items are rated on a 7-point Likert-type scale, ranging from 0 to 6. The total score can range from 0 to 30, with high scores meaning high obstruction of valued living.

**Statistical Analysis**

We used mean (SD) values to describe numerical data and counts and percentages to describe categorical data. The chi-square tests estimated categorical data, and numerical data were estimated by t tests. A two-way ANOVA test was used to assess the differences in men with ED aged younger and older than 40 years regarding psychological inflexibility and the interaction between them. Post hoc tests were conducted using the Holm method to control for type I errors. Cohen d index was calculated as effect sizes, serving as standardized indicators unaffected by sample sizes. All tests were 2-tailed, and a statistical difference was assumed when the P value was <.05. All statistical analyses were conducted through IBM SPSS Statistics (version 25.0; IBM Corp).

**Results**

We obtained valid responses from 643 individuals (mean age 36.19, SD 7.54 years). Of these, 422 were younger than 40 years (mean age 31.76, SD 5.00 years), and 221 were older than 40 years (mean age 44.67, SD 2.88 years). Table 1 shows the demographic characteristics of participants by age difference. No statistical difference was found in ED severity, phosphodiesterase-5 inhibitors use, and marriage status between men with ED younger and older than 40 years.

aIIEF-5: International Index of Erectile Function-5.
bPDE-5: phosphodiesterase-5 inhibitor.

The prevalence of depression as judged by PHQ≥10 among men younger than 40 years was 39.81% (168/422), and it was 24.89% (55/221) among those older than 40 years. There was a statistical difference in the prevalence of depression between the two groups (P<.001). In addition, the prevalence of anxiety, as judged by GAD≥10, was 27.25% (115/422) among men.
younger than 40 years, and it was 21.72% (48/221) among those older than 40 years. There was no difference in the prevalence of anxiety between men with ED in the two age groups (\(P=.12\)). Table 2 illustrates these results.

aPHQ-9: Patient Health Questionnaire-9.
bGAD-7: Generalized Anxiety Disorder-7.

The two-way ANOVA was performed with ED severity and age (<40 or >40 years) as independent variables and the scores of AAQ, CFQ, and VQ-OB as dependent variables. The results showed no significant differences in AAQ-II (\(P=.14\)), CFQ (\(P=.08\)), and VQ-OB (\(P=.30\)) scores attributed to ED severity. Moreover, no difference in ED severity or psychological inflexibility depending on the duration of the marriage was found. On the other hand, there were significant differences in the scores of CFQ (\(P=.04\)) and VQ-OB (\(P=.004\)) attributed to age. As the interactions were significant for CFQ (\(P=.04\)) and VQ-OB (\(P=.01\)) scores, the simple main effect was examined. It was found that men with ED younger than 40 years had significantly higher CFQ (\(P=.01; d=0.62\)) and VQ-OB (\(P<.001; d=0.87\)) scores compared to those older than 40 years, in cases of moderate and severe ED. Additionally, it was found that men with moderate to severe ED younger than 40 years had significantly higher CFQ (\(P=.01; d=0.42\)) and VQ-OB (\(P=.02; d=0.38\)) scores compared to men with no ED younger than 40 years. These results are illustrated in Table 3 and Figures 1 and 2.

Discussion

Principal Findings

This cross-sectional study evaluated depression, anxiety, and psychological inflexibility in men younger and older than 40 years with ED. There was no statistical difference in demographic characteristics between the two groups. The average age of the participants was 31.76 (SD 5.00) years in men younger than 40 years; the population was assumed to have mainly mild-to-moderate psychogenic ED. On the other hand, the average age of the participants was 44.67 (SD 2.88) years in men older than 40 years; the population was assumed to have mostly mild-to-moderate organic ED.

Depression was found in both groups. The results of our study were consistent with a previous study [15], which found that younger men had comparatively greater depressive symptoms. In contrast, the prevalence of anxiety was not different between the two age groups. One possible reason is that the anxiety in men with ED is not general anxiety but specific anxiety about sexual situations. Masters and Johnson [24] highlighted the
central role of sexual performance anxiety in couples presenting with sexual dysfunction [24]. In treating sexual dysfunctions, Kaplan [25] emphasizes the importance of addressing specific sources of sexual anxiety, such as fear of failure and not pleasing one’s partner [25]. Although a Japanese version does not exist now, it may be necessary to use a questionnaire like the Erectile Performance Anxiety Index [26].

Men with ED younger than 40 years had significantly higher CFQ and VQ-OB scores than those older than 40 years in cases of moderate and severe ED. Furthermore, men with moderate-to-severe ED younger than 40 years had significantly higher CFQ and VQ-OB scores compared to men without ED. These results partly support our hypothesis that men younger than 40 years are more psychologically inflexible than those older than 40 years. Cognitive fusion might be the critical component of ACT for ED. For example, the fusion with sexual performance anxiety, such as “I might fail again,” makes it impossible to pay attention to the sexual partner, which results in erectile failure. It is also consistent with Barlow’s theory [27]. Barlow [27] proposed a model for the interaction of anxiety and cognitive interference. This model examines how anxiety and cognitive interference interact, particularly in a sexual context, where a lack of control over one’s arousal diverts attention from erotic arousal to physical arousal and the negative consequences associated with failure to attain an erection.

On the other hand, there were no significant differences in the scores of the AAQ-II, which might be related to psychometric issues with AAQ-II. To date, the most used self-report measure of psychological inflexibility, especially experience avoidance, has been the AAQ-II. There was no significant difference in ED severity and psychological inflexibility depending on the duration of the marriage. However, various issues regarding the AAQ-II have emerged from the existing literature [28]. The authors found that the AAQ-II faced challenges in distinguishing distress (like negative affect and neuroticism) from experiential avoidance. For clinical application, researchers have expanded the range of measures for psychological inflexibility. They have developed specific versions of the AAQ-II tailored to different populations or disorders, with currently over 20 available versions (examples include those for the workplace, tinnitus, irritable bowel syndrome, exercise, and epilepsy). The disorder-specific AAQ-II variants indicate greater incremental validity in their targeted areas than the general AAQ-II [29]. Thus, developing a questionnaire on ED-related psychological inflexibility might be necessary.

There are some limitations to this study. First, this study used a cross-sectional approach, indicating merely “associations” rather than “causality” between psychological inflexibility and ED. Further controlled experimental and longitudinal studies are essential to delve deeper into the impact of psychological inflexibility on ED. Second, in this study, no responses were obtained from the partners of men with ED. Including the partners in the assessment and treatment of ED is recommended. It is desirable to obtain responses from partners in future studies. Finally, the specific racial or ethnic and socioeconomic profiles of the participants may restrict the broader applicability of the findings. The study was also conducted during the COVID-19 epidemic, which may have influenced the results.

Conclusions
To the best of our knowledge, this web-based cross-sectional study was the first to examine the relationship between psychological inflexibility and ED. We conclude that men with moderate and severe ED younger than 40 years have higher psychological inflexibility and might be eligible for the ACT. In addition, developing a Japanese version of the questionnaire is necessary to measure ED-related anxiety and psychological inflexibility.

Abstract

Background: Prior suicide attempts are a relatively strong risk factor for future suicide attempts. There is growing interest in using longitudinal electronic health record (EHR) data to derive statistical risk prediction models for future suicide attempts and other suicidal behavior outcomes. However, model performance may be inflated by a largely unrecognized form of “data leakage” during model training: diagnostic codes for suicide attempt outcomes may refer to prior attempts that are also included in the model as predictors.

Objective: We aimed to develop an automated rule for determining when documented suicide attempt diagnostic codes identify distinct suicide attempt events.

Methods: From a large health care system’s EHR, we randomly sampled suicide attempt codes for 300 patients with at least one pair of suicide attempt codes documented at least one but no more than 90 days apart. Supervised chart reviewers assigned the clinical settings (ie, emergency department [ED] versus non-ED), methods of suicide attempt, and intercode interval (number of days). The probability (or positive predictive value) that the second suicide attempt code in a given pair of codes referred to a distinct suicide attempt event from its preceding suicide attempt code was calculated by clinical setting, method, and intercode interval.

Results: Of 1015 code pairs reviewed, 835 (82.3%) were nonindependent (ie, the 2 codes referred to the same suicide attempt event). When the second code in a pair was documented in a clinical setting other than the ED, it represented a distinct suicide attempt 3.3% of the time. The more time elapsed between codes, the more likely the second code in a pair referred to a distinct suicide attempt event from its preceding code. Code pairs in which the second suicide attempt code was assigned in an ED setting at least 5 days after its preceding suicide attempt code had a positive predictive value of 0.90.

Conclusions: EHR-based suicide risk prediction models that include International Classification of Diseases codes for prior suicide attempts as a predictor may be highly susceptible to bias due to data leakage in model training. We derived a simple rule to distinguish codes that reflect new, independent suicide attempts: suicide attempt codes documented in an ED setting at least 5 days after a preceding suicide attempt code can be confidently treated as new events in EHR-based suicide risk prediction models. This rule has the potential to minimize upward bias in model performance when prior suicide attempts are included as predictors in EHR-based suicide risk prediction models.
Introduction

Suicide is the tenth leading cause of death in the United States, with more than 48,000 suicide deaths annually [1]. Over the past 20 years, the suicide rate has increased by over 35% [2]. Most people who die by suicide have recently interacted with the health care system, with over half having a health care visit in the month prior to death [3,4]. Health care systems thus offer a key opportunity to identify people at high risk for suicide. Unfortunately, clinicians are poor at predicting who will make a suicide attempt [5] and traditionally studied risk factors perform no better than chance at predicting future suicidal behavior [6].

Recent work has focused on developing and validating machine learning models that use routinely collected electronic health record (EHR) data to predict future suicidal behavior [7]. Such models have demonstrated high levels of accuracy, exceeding that seen with clinician prediction and usual clinical risk factors [6,8-10]. EHR-based suicide risk prediction models, however, face one significant challenge that to date has not been adequately addressed. Suicide attempt is generally the outcome of interest in these models and is typically defined by International Classification of Diseases (ICD) diagnostic codes [11,12]. Within a given patient’s EHR, a suicide attempt code may be given multiple times across distinct health care encounters, often over very short periods of time (eg, days and weeks). Such “recurrent” codes may represent either distinct, new events (ie, multiple suicide attempts) or refer to the same event (ie, a single suicide attempt). The latter may occur when, for example, after making a suicide attempt, a patient has an emergency department (ED) visit followed by an inpatient hospitalization or outpatient follow-up encounters, with one (or multiple) suicide attempt codes assigned at each. In the absence of manual reviews of the narrative notes within patients’ EHRs, which cannot be performed at scale, it can be challenging to determine whether such recurrent suicide attempt codes, especially when documented over short time periods, refer to independent, distinct suicide attempts. Failure to make this important distinction can result in a form of “data leakage” in which the outcome to be predicted is included among features used for the prediction. This can result in substantial inflation of model performance [13].

To address this issue, some researchers have restricted model development to predict only the first occurrence of a suicide attempt code in a patient’s EHR [14-16]. This approach has a major limitation, however, in that a past suicide attempt is among the strongest known predictors of future suicidal behavior [17]. Thus, models that predict only the first documented suicide attempt ignore the subset of patients who may be at highest risk and thus of greatest clinical concern: those with a prior suicide attempt. Another approach is to include any previous suicide attempt codes as predictors of a subsequent suicide attempt code [18-21] thus including potential “repeat attempters” in these models. This approach, however, poses a significant risk of artificially inflating model performance if subsequent codes do not in fact refer to new suicide attempts. In other words, if a suicide attempt code instance used as an outcome actually indexes an attempt that was included a predictor, model performance will be inflated.

To minimize the risk of data leakage while retaining the option of including prior attempts as predictors, we aimed to develop an automated rule for determining whether recurrent suicide attempt codes in the EHR refer to distinct events. Such a rule might be based on relevant variables including clinical setting (eg, a suicide attempt code documented in the ED may be more likely to refer to a new suicide attempt event than one given in a non-ED setting), method (eg, suicide attempt codes that specify different methods may be more likely to refer to distinct events than codes specifying the same method), and time (eg, the more time elapsed between 2 suicide attempt codes, the less likely it may be that the codes refer to the same event). Here, we conducted a comprehensive manual EHR chart review to derive an automated rule that could identify criteria for selecting distinct suicide attempts with high confidence.

Methods

Data Source

The data source for this study was the Mass General Brigham (MGB) Research Patient Data Registry [22]. This registry covers 6.7 million patients treated in MGB-affiliated hospitals including the Massachusetts General Hospital and Brigham and Women’s Hospital in Boston.

Ethics Approval

This research was approved by the MGB institutional review board, which granted a waiver of informed consent (protocol #2018P001508).

Case Definition and Inclusion Criteria

Details of the development of our EHR-based case definitions for suicide attempt in the MGB health care system are reported elsewhere [14,15]. In brief, we first identified candidate ICD, Ninth Revision (ICD-9) and ICD, Tenth Revision (ICD-10) codes that are likely to capture suicide attempts. Next, expert clinicians conducted manual chart reviews of 670 patients (over 3000 narrative notes) to determine a final set of codes that capture suicide attempts with a positive predictive value (PPV) of >0.70: for ICD-9, E95*, 965*, 967*, 969*, and 881*, and for ICD-10, X71*-X83*, T14.91*, T36*-T50*, T56.9, T57.9, T58.0, T58.1, T58.9, T59.9, T60.9, T61.0, T61.1,
T61.9, T62.9, T63.9, T64.0, T64.8, and T65.9, where the fifth is 2).

For this study, we randomly selected a sample of 300 patients with 2 suicide attempt codes documented at least one but no more than 90 days apart (the “narrow sample”). This interval was chosen to capture codes that were given within a narrow time frame and thus potentially enriched for being “leaked” codes. In a sensitivity analysis, we randomly selected a second, smaller sample of 100 patients with 2 suicide attempt codes documented at least 1 day apart but with no other restrictions on intercode interval (the “broad sample”). A total of 31 patients appeared in both narrow and broad samples. Patients for whom we were unable to confidently locate the narrative notes corresponding to documented suicide attempt codes (eg, no narrative notes available within 30 days of the suicide attempt code date, narrative notes recorded on paper and never migrated to the EHR) were excluded after the sampling process.

Results

Descriptive Statistics

The mean number of suicide attempt codes per patient in the narrow sample was 3.38 (SD 4.62; range 1–47). A total of 225 (75%) patients had <4 codes and 281 (93.7%) had <10 codes. A total of 210 (20.7%) code pairs had a second code reflecting a subsequent encounter for a condition for which the patient had received active treatment (indicated by a seventh “D” character).

Regarding how often the codes in a pair referred to distinct suicide attempts, of the 300 patients in the narrow sample, only 81 (27%) had more than one confirmed (by manual chart review) suicide attempt captured by the reviewed code pairs. Of the 1015 code pairs, only 180 (17.7%) referred to 2 distinct suicide attempt events. Table S1 in Multimedia Appendix 1 presents an example of sampled codes (and the variables assigned to each code and code pair) for a deidentified patient.

For clinical setting, the most common code pair types were non-ED/non-ED (n=542, 53.4%) followed by ED/ED (n=274, 27%). Regarding the 749 total non-ED codes, the most commonly represented clinical setting was inpatient (n=411, 54.9% of all non-ED codes), followed by other or unclear setting (n=149, 19.9% codes), intensive or critical care units (n=134, 17.9% codes), and outpatient (n=55, 7.3% codes). For suicide attempt method, the majority of code pairs (n=766, 75.5%) comprised 2 codes that referred to the same method. The median interval between codes in each code pair, across all codes, was 1 day. Among code pairs that referred to distinct suicide attempt events, the median interval was 35 days.

PPVs

Clinical Setting

Non-ED/ED code pairs (23 total code pairs) had the highest PPVs (0.96, 95% CI 0.87-1.04) for distinct suicide attempt events (Table 1). ED/ED pairs (274 total code pairs) had the second-highest PPVs (0.49, 95% CI 0.43-0.55). When the second code in a pair was assigned in a non-ED setting, PPVs were low (below 0.10).

In a sensitivity analysis, we excluded codes or encounters documented in inpatient settings with a prior code on the previous day from an inpatient or critical or intensive care setting in which each code in the pair was documented to 2 distinct suicide attempts (dichotomous variable indicating distinct or not distinct suicide attempts), (2) clinical setting in which each code in the pair was documented (dichotomous variable indicating ED or non-ED [eg, outpatient and inpatient setting], (3) suicide attempt method of each code in the pair (categorical variable with 6 categories derived from previous literature: poisoning, cutting or piercing, hanging or strangulation or suffocation, jumping, firearm, and other [which included codes with no specified method]), and (4) time elapsed (in days) between codes in each pair [23]. When there were multiple encounters with suicide attempt codes on the same day, these variables were assigned to codes at the day level; see Table S1 in Multimedia Appendix 1 for an example of how we combined multiple same-day encounters.

Data Analysis

We defined PPV as the probability that the second code in a pair referred to a new suicide attempt independent of the first code in the pair. To mimic the approach that would likely be taken in building predictive models, each code pair was treated independently (ie, we did not account for the nested nature of code pairs within patients). First, for the narrow sample, we calculated (in Excel [Microsoft]) PPVs and 95% CIs by clinical setting, suicide attempt method, and intercode interval, respectively. For clinical setting, we calculated the PPVs for 4 possible code pair types: (1) both codes documented in the ED (ED/ED), (2) first code ED and second code non-ED (ED/non-ED), (3) first code non-ED and second code ED (non-ED/ED), and (4) neither code ED (non-ED/non-ED). For suicide attempt method, we calculated the PPVs of 2 possible code pair types: (1) same suicide attempt method for codes in a pair and (2) different suicide attempt methods for codes in a pair. For intercode interval, we first calculated PPVs for all 7-day intervals from 1 to 91 days, followed by collapsing across intervals from 92 days on. We then calculated the PPVs for time intervals within each of the 6 (4 clinical settings and 2 suicide attempt methods) code pair types. To derive our proposed rule, we set our benchmark PPV to 0.90. For each of the 6 code pair types, we determined the minimum time elapsed between codes (ie, interval floor) at which the PPV was at least 0.90. For a sensitivity analysis, we computed the same series of PPVs for the broad sample.

Procedure

Under the supervision of JWS (a senior clinician with expertise in the treatment of suicidal behavior), 2 study team members (EMM and ES) manually reviewed the EHR clinical encounter data (including narrative notes) relevant to each pair of suicide attempt codes (“code pair”) per sampled patient (1015 in the narrow sample and 300 in the broad sample; 1253 unique codes across the 2 samples). Each code pair comprised a given suicide attempt code and the immediately (temporally) preceding code in a patient’s EHR. All applicable code pairs per patient were examined (including other code pairs with >90-day intervals for patients in the narrow sample). Chart reviewers assigned the following variables to each code pair: (1) whether the code pair referred to 2 distinct suicide attempts (dichotomous variable indicating distinct or not distinct suicide attempts), (2) clinical setting in which each code in the pair was documented (dichotomous variable indicating ED or non-ED [eg, outpatient and inpatient setting], (3) suicide attempt method of each code in the pair (categorical variable with 6 categories derived from previous literature: poisoning, cutting or piercing, hanging or strangulation or suffocation, jumping, firearm, and other [which included codes with no specified method]), and (4) time elapsed (in days) between codes in each pair [23]. When there were multiple encounters with suicide attempt codes on the same day, these variables were assigned to codes at the day level; see Table S1 in Multimedia Appendix 1 for an example of how we combined multiple same-day encounters.

For this study, we randomly selected a sample of 300 patients with 2 suicide attempt codes documented at least one but no more than 90 days apart (the “narrow sample”). This interval was chosen to capture codes that were given within a narrow time frame and thus potentially enriched for being “leaked” codes. In a sensitivity analysis, we randomly selected a second, smaller sample of 100 patients with 2 suicide attempt codes documented at least 1 day apart but with no other restrictions on intercode interval (the “broad sample”). A total of 31 patients appeared in both narrow and broad samples. Patients for whom we were unable to confidently locate the narrative notes corresponding to documented suicide attempt codes (eg, no narrative notes available within 30 days of the suicide attempt code date, narrative notes recorded on paper and never migrated to the EHR) were excluded after the sampling process.
setting. For example, if a patient was given suicide attempt codes on three consecutive days in an inpatient setting, we only used the day 1 code. This resulted in 792 (versus 1015) analyzed code pairs. The results were overall very similar to when we did not exclude contiguous inpatient codes (Multimedia Appendix 2).

**Intercode Interval**

Table 3 presents PPVs for code pairs broken down by 7-day (week-long) intervals; the majority (n=797, 78.5%) of code pairs had an intercode interval of 7 days or less. The more days elapsed between 2 codes, the larger the PPV (and, fewer code pairs per strata). Table S7 in Multimedia Appendix 4 presents PPVs for code pairs broken down by interval and clinical setting (non-ED/non-ED, ED/non-ED, non-ED/ED, ED/ED), and Table S8 in Multimedia Appendix 5 presents PPVs for code pairs broken down by interval and suicide attempt method (same versus different). In another sensitivity analysis, given that ICD-9 is no longer used, we also computed all PPVs reported in Tables 1-3 when excluding code pairs with at least one ICD-9 coded event. The same pattern of findings held, with 95% CIs for all PPVs overlapping with those in Tables 1-3.

<sup>a</sup>PPV: positive predictive value.

As shown in Figure 1, across all code pairs, pairs with an interval of at least 53 days had a PPV of 0.90 (range 0.88-0.93). The interval floors meeting our benchmark PPV (at least 0.90) within each of the 6 code pair types are also labeled in Figure 1 (clinical setting) and Figure 2 (suicide attempt method). For non-ED/ED code pairs (23 code pairs), an interval floor of 1 day had a PPV of 0.96. When both codes were assigned in the ED (271 code pairs), PPV reached 0.90 when the intercode interval was at least 5 days. When the second code in a pair was documented in an ED (regardless of the setting in which the first code was documented), PPV was 0.91 when the intercode interval was 5 days (the PPV was 0.89 for 4 days). Thus, whenever the second code in a pair was documented in an ED at least 5 days after the previous code, the probability that the second code referred to an independent suicide attempt was at least 90%.

Figure 1. PPVs for interval floors by code pair types defined by clinical setting. The labeled data points indicate the interval floor at which the PPV was at least 0.90 (or the maximum PPV). Gray lines reflect PPVs for interval floors across all code pair types. Red lines refer to code pairs documented in ED (first code) and ED (second code) settings (ED/ED). Blue lines are non-ED/ED code pairs; purple lines ED/non-ED; and green lines non-ED/non-ED. ED: emergency department; PPV: positive predictive value.
Sensitivity Analysis: Broad Sample

Results from the same series of analyses in the broad sample are presented in Multimedia Appendix 6. Of the 100 patients, 45 (45%) had more than 1 confirmed suicide attempt. Of the 300 code pairs, 86 (28.7%) referred to 2 distinct suicide attempts. The median interval between codes in each pair was also 1 day. Among code pairs that referred to distinct suicide attempts, the median interval was 133 days. Overall, we found a similar pattern of PPVs (in almost all cases overlapping 95% CIs) to those from the narrow sample. Across all code pairs in the broad sample, those with an interval of at least 37 days had a PPV of 0.90 (range 0.87-0.93). When both codes were given in the ED (86 pairs), PPV reached 0.90 when the interval was at least 2 days.

Discussion

Primary Findings

Machine learning suicide risk prediction models that leverage routinely collected EHR data can outperform clinician assessment [8] and have the potential to improve how patients at risk for suicide are identified and treated. These models are typically trained using ICD codes to label suicide attempts. An under-appreciated challenge when building these models, however, is that ICD codes indexing a single suicide attempt are often used repeatedly across multiple encounters. This could create a substantial problem for models that incorporate prior suicide attempts, an established risk factor, in predicting subsequent attempts or suicidal behavior.

Some investigators side-step this issue by restricting model predictions to only the first occurrence of a suicide attempt code. This approach, however, limits the utility of prediction models by ignoring prior attempts, the best-known risk factor for suicidal behavior, and limiting their application to a subset of those at risk; prior studies indicate that nearly one-quarter of those who engage in deliberate self-harm have recurrent episodes within 3 years [24]. Here we aimed to develop a portable, automated rule for determining when recurrent suicide attempt codes refer to distinct suicide attempt events in a patient’s history. Based on chart review of clinical encounters corresponding to 1015 unique ICD code pairs, we found that, for patients with more than 1 documented suicide attempt code, repeat codes most often (>80% of the time) reflected nonindependent events, underscoring the high frequency of “leaked” suicide attempt codes. When collapsing across all clinical settings, repeat codes needed to be documented at least 53 days after the preceding code in order to refer (with probability >90%) to a new, distinct suicide attempt. However, repeat codes documented in an ED at least 5 days after the preceding suicide attempt code were likely (probability >90%) to refer to a new, distinct suicide attempt.

The most informative variables for determining whether recurrent suicide attempt codes referred to distinct suicide attempts were the clinical setting in which the codes were documented and the time elapsed between codes. First, regarding clinical setting, when a suicide attempt code was documented in an ED after the preceding code, it referred to a new suicide attempt more than half the time. Suicide attempt codes documented in non-ED settings, accounting for most of the second codes among all code pairs, however, were highly unlikely to refer to a new suicide attempt (probability <5%). This may be due to the fact that the vast majority (nearly three-quarters) of non-ED codes occurred in inpatient or intensive or critical care units, where patients may be treated over the course of several days or longer, potentially accumulating multiple suicide attempt codes that all refer to the same index event that may have prompted inpatient or intensive treatment. This pattern of findings, for one, highlights the considerable risk of treating all recurrent suicide attempt codes (especially those from non-ED settings) as distinct events, and the potential importance of using a simple rule, such as that proposed here, to identify probable distinct suicide attempt events.
Along these lines, the more time elapsed between 2 suicide attempt codes, the more likely it was the codes referred to distinct events. Combining these 2 variables—clinical setting and time elapsed—provided a simple rule for determining whether recurrent suicide attempt codes refer to distinct events with at least 90% probability. Although the accuracy of our proposed rule (at least 5 days elapsed between a code given in the ED and the preceding code) may differ in other health care systems, we recommend that others consider taking into account these 2 variables when incorporating recurrent suicide attempt codes in EHR-based suicide risk prediction models.

Perhaps surprisingly, whether the coded suicide attempt method for 2 codes in a pair was the same or different did not provide value in identifying distinct suicide attempt events. However, in the relatively small proportion of code pairs (24.5%) that referred to different methods, the most common “profile” was 1 code with a specific method (eg, poisoning and cutting or piercing) and the other code with method categorized as “other” (not a different specific method); notably, the “other” category included codes lacking any specified method. Thus, the fact that method did not help identify distinct events may largely reflect inconsistencies in how or whether the suicide attempt method is coded by providers. In contrast, neither of the other 2 variables examined (clinical setting nor intercode interval) should be impacted by irregular coding practices, and thus may also be more scalable and reliable for other health care systems planning to use this or a similar rule.

Our derived rule (at least 5 days elapsed between a code from the ED and the preceding code) may have more impact on certain suicide-related prediction tasks than others. For example, it may be especially relevant when estimating patients’ risk of repeat suicidal behavior, for example after an ED visit for suicidal behavior, which could influence clinical decision-making at the point of care (eg, about discharge home or to outpatient care versus hospitalization). This rule may have less impact for other related prediction tasks, such as estimating patients’ risk of suicidal behavior after nonsuicide-related outpatient visits or broader population-based prediction efforts [25]. These results may also be less relevant for models that solely predict fatal self-harm or suicide deaths [26,27]. Future work should systematically evaluate the performance and clinical utility of models that do and do not incorporate the proposed rule for incorporating recurrent suicide attempt codes across a range of prediction goals and clinical contexts.

Our results must be considered in the context of a few key limitations. First, some of the sampled patients may have presented to hospitals outside of the MGB system for suicide attempts. In these cases, the corresponding diagnostic codes and contextual information were either unavailable or only sporadically recorded in narrative notes at subsequent clinical encounters within MGB. We also excluded sampled patients for whom chart reviewers could not confidently match data pulled from the MGB Research Patient Data Registry to the narrative notes.

Conclusions
This analysis indicates that EHR-based suicide attempt prediction models that include ICD codes for prior attempts as a predictor may be highly susceptible to bias due to data leakage in model training. Our proposed rule for circumventing this issue should minimize this bias and its inflationary effect on model performance metrics. The key variables included in our rule (clinical setting and time elapsed between codes) are widely available in health system data warehouses and should be easily integrated into EHR-based models. It is also possible that the approach taken in this study may be relevant for developing and refining machine learning models aimed to predict other episodic events of interest that can be repeatedly documented in the health record, such as unintentional overdose, domestic abuse, or episodes of violence. If effectively implemented into existing and future suicide risk prediction models, this rule could increase the robustness and validity of machine-learning based approaches to identifying the individuals at highest risk for suicide, and ultimately advance suicide prevention efforts in health care contexts on a large scale.

Acknowledgments
The authors thank the Enterprise Research Infrastructure and Services at MGB for their in-depth support and for the provision of the research patient data registry and the ERISOne Linux cluster. This work was supported by grants (NIMH R01 MH117599; JWS) and (K23MH120436; KHB) from the National Institute of Mental Health, and a gift from the Tommy Fuss Fund (JWS). Abstract

Background: There is a need for physical activity promotion interventions in adolescents and young adults with intellectual disabilities. Current interventions have shown limited effectiveness, which may be attributed to the absence of theory and a population-specific development. Combining a planning model (including theory) and cocreation with the target audience during intervention development could potentially address this gap.

Objective: This study aimed to report the systematic development of the Move it, Move ID! intervention by describing how the 8 different steps of the Behavior Change Wheel (BCW) were applied and present the results that emerged from those steps. In doing so, the (theoretical) content of the intervention is described in detail.

Methods: A total of 23 adolescents and young adults (aged 14-22 years) with mild to moderate intellectual disabilities were designated as cocreators of the intervention. Across 2 groups, 6 similar cocreation sessions were organized in each. The content and sequence of the sessions were structured to align with the 8 steps of the BCW. All sessions were recorded and transcribed verbatim. Both a deductive (ie, steps of the BCW) and inductive (ie, resonating the voice of the participants) analysis approach were applied specifically focusing on identifying and describing the findings within each of the BCW steps.

Results: After behavioral analysis (steps 1-4), 10 intervention goals were chosen and linked to Capability, Opportunity, and Motivation–Behavior components (theory within the BCW) that needed to be addressed. Psychological capability, social opportunity, and reflective motivation were emphasized as the first targets to focus on. A key finding was the urge for real-life social connectedness and social integration, which makes the social component as part of physical activity a central theme to focus on within intervention development. Judgments on the most suitable intervention functions (step 5) and behavior change techniques (step 7) were explained. When discussing the mode of delivery of the intervention (step 8), it was underscored that solely relying on a mobile health app would not fulfill participants’ social needs. Hence, the chosen intervention adopts a dyadic approach in which young individuals with intellectual disabilities are matched with peers without intellectual disabilities to engage in physical activities together, with a mobile app playing a supportive role in this partnership.

Conclusions: The transparent description of the development process highlights why certain intervention components and behavior change techniques were chosen and how they are intertwined by means of the selected intervention design. This paper provides a detailed blueprint for practitioners wanting to integrate the BCW and its associated behavior change techniques, in combination with actively involving the target group, into their intervention development for people with intellectual disabilities.

(JMIR Form Res 2024;8:e51693) doi:10.2196/51693
Both reviews concluded that only a small number of individuals meet the PA guidelines, indicating that they are less active than the general population [18,19].

**Current PA Interventions and Their Effectiveness**

Although PA research in people with IDs has been growing over the last decade, this field has been underresearched. A PA Series in *The Lancet* (2021) stated that, between 1999 and 2019, <5% of all articles in the 5 highest-impact medical journals focused on people with disabilities (not limited to IDs) and <7% of these addressed PA or health [2]. A systematic review from 2019 on the effectiveness of PA interventions among participants with IDs of all ages identified only three effective randomized controlled trials out of 9 [20]: (1) a 10-week progressive resistance training program in adolescents and young adults (aged 14-22 years) with Down syndrome in Australia [21], (2) a 12- to 16-month multicomponent diet and PA program in adults (aged 20-66 years) with mild to moderate IDs in Sweden [22], and (3) an 8-month PA and fitness program in “fast-walking” older adults with mild to moderate IDs (aged >40 years) in the Netherlands [23]. The success of these randomized controlled trials was mainly attributed to the following factors: (1) practical support from others (eg, a mentor) in guiding and helping participants with IDs through the intervention and for increasing motivation, (2) establishing a routine that involves regular PA as well as the adaptability of an intervention to the specific routines of both carers and participants, (3) the simplicity of an intervention by adapting interventions to the specific needs of the participants, and (4) familiarity with the intervention [20]. None of the 9 interventions in the systematic review by Hassan et al [20] included a technological component (ie, eHealth or mobile health [mHealth]). However, there seems to be no reason why digital interventions would not be feasible in this target group [24]. In the study by Ptomey et al [25], 95% of the participants, aged 14.9 (SD 2.2) years on average, reported that using a tablet computer was easy and enjoyable. It is then no surprise that, in recent years, there has been a growing interest in the development of digital interventions for individuals with IDs [26-30].

The number of effective PA interventions for people with IDs remains limited. A potential reason for the limited effectiveness is currently attributed to the lack of a theoretical framework for intervention development and the difficulty in concretizing behavior change techniques (BCTs) in an understandable way for this population [10,20,31,32]. A 2017 systematic review on the use of BCTs in lifestyle change interventions for people with IDs, for example, concluded that 73% of the studies aiming to improve PA in the target group did not use any theoretical framework [31]. Nevertheless, the use of a theoretical framework is an important prerequisite for intervention effectiveness [2,20,33-36]. Furthermore, when examining theory-based interventions for people with IDs, concerns have been raised regarding the suitability of the theories used (eg, social cognitive theory, theory of planned behavior, and self-determination theory) as a starting point for designing interventions for this specific target group. These theories may...
not sufficiently address the specific challenges faced by people with IDs. More specifically, these theories tend to be specific and detailed, yet they may not encompass the complete spectrum of potential influences on behavior within this particular target group and often concentrate on individual-level factors [20,31,32].

Applying the Behavior Change Wheel and a Cocreative Approach to Build Theory-Based PA Interventions

The Behavior Change Wheel (BCW) is a planning model aimed at guiding a scientific and systematic intervention development process [33,37]. The BCW contains a behavioral theory at its heart, the Capability, Opportunity, and Motivation–Behavior (COM-B) model, which encompasses the full range of influences contributing to the behavior of interest [33,38]. A total of 3 behavioral components are summarized in the COM-B model, which states that, for each behavior to occur, individuals need capability (physical and psychological), opportunity (physical and social), and motivation (reflective and automatic) [33,37,39]. The COM-B model is in turn linked to the Theoretical Domains Framework (TDF) [33,40], which subdivides the COM-B model into 14 domains. The BCW further formulates 9 intervention functions linked to 93 BCTs [41] and 7 policy types with the aim of modifying each of the 3 COM-B components and, thus, changing behavior. The COM-B model describes the minimal factors that behavioral scientists agree on to achieve behavior change and has been developed with interdisciplinary research in mind [37]. It is an open model and relatively easy to communicate, especially with vulnerable groups. In recent years, this model has demonstrated applicability in the context of PA among people with IDs and their carers [32,42]. This study chose the BCW as a planning model for intervention development because of its practical use and feasibility in combination with a cocreative approach. Current lifestyle modification approaches for this target group lack a robust foundation addressing their unique needs [10,32,43]. Therefore, deeply engaging with this group and customizing approaches to promote their PA is vital. Unfortunately, individuals with IDs are seldom heard in research, and interviews with caregivers often take precedence, potentially overshadowing their authentic experiences [43]. Neglecting the perspectives of individuals with IDs can undermine intervention acceptability, comprehensibility, and feasibility [10,44-48]. To clarify, previous intervention studies have reported that some BCTs may be too complex for the target group (eg, self-monitoring through the use of pedometers) [31,49]. The cocreative approach (in combination with the BCW planning model) in this study will aid in determining which BCTs might be most appropriate for people with IDs or adapting them if necessary through collaboration.

Aims

This paper aimed to (1) report the systematic development of the Move it, Move ID! intervention by describing how the different steps of the BCW were applied and (2) present the results that emerged from those steps. In doing so, we described the (theoretical) content of the Move it, Move ID! intervention in detail.

Methods

Participants and Recruitment

It was prioritized to focus on young people with IDs as cocreators rather than their parents or teachers because of the historical pattern of marginalization in previous research on intervention development [43]. Through purpose sampling, 2 class groups of adolescents or young adults with mild to moderate IDs aged between 13 and 22 years (ie, age of special needs secondary education in Flanders, Belgium) were recruited to participate in the cocreation sessions. In February 2021 and March 2021, a total of 2 physical education (PE) teachers from different special needs schools in Flanders were contacted to explain the purpose and design of the project via email and phone. They were asked whether they were interested in involving one of their classes in cocreating a PA promotion intervention. Each PE teacher subsequently suggested 1 class group to take part. All adolescents from the selected classes (classes A and B) were invited to participate during the first visit, in which written informed consent from all participants and passive consent from their parents were obtained (Table 1). Class A comprised 14 adolescents aged between 17 and 22 years with a mild to moderate level of ID (mean age 20.33, SD 1.94 years; 3/14, 21% female). Class B comprised 9 adolescents aged between 14 and 15 years with mild IDs (mean age 14.22, SD 0.44 years; 6/9, 67% girls). This aligned with cocreation guidelines, which recommend groups of 10 to 12 cocreators [45,50]. A detailed description of (the recruitment of) participants, as well as the ethical process (next subsection), can be found in the study by Maenhout et al [51].

**Ethical Considerations**

All participants and their parents or legal guardians received detailed and accessible information regarding the study design and purpose as well as data handling. To ensure privacy, the data were pseudonymized and only accessible to the researchers or their appointed representatives. Data confidentiality was always maintained. In consultation with the data protection officer of Ghent University (Belgium), the legal basis was changed from “active informed consent” of parents or legal guardians to “public interest,” although this did not exempt researchers from informing participants. This meant that parents or legal guardians needed to contact the researchers only if they disagreed with their child’s participation and, thus, researchers did not require active consent from parents or guardians to commence. The participants with IDs themselves were required to provide their active consent, which is why the first session involved a thorough, step-by-step review of the information and consent process with time for discussion. Young people with IDs participated voluntarily and could withdraw at any time. In appreciation of their participation, all participants received 2 cinema tickets, about which they were informed when they decided to participate. This study received approval from the Ethical Committee of the Faculty of Psychology and Educational Sciences at Ghent University, Belgium (2021/056 LM).

**Combining the BCW Development Process and a Cocreational Approach**

**Overview**

From April 2021 to June 2021, the 8 steps of the BCW were systematically followed for intervention development (Figure 1) [33]. In parallel, input was gathered from adolescents and young adults with IDs through 6 cocreation sessions (Table 1). The entire process was a mix of theoretical underpinnings (ie, COM-B), the domain expertise of the researcher, and the lived experiences of the target group (ie, cocreation sessions). The 6 sessions took place in their classrooms, each during 2 consecutive class hours. For a comprehensive explanation of the cocreation process, the methods used, and the participants’ experiences, we refer interested readers to our previously published paper [51].
Stage 1: Understand the Behavior

In step 1, the literature was reviewed by the principal investigator (PI; LM) to articulate the (health) problem in behavioral terms, this being “insufficient PA in people with IDs.” The next steps were then to select (step 2) and specify (step 3) the target behavior of the intervention, this being “increasing PA levels in adolescents and young adults with IDs,” by defining who needs to do it, what needs to be done differently to achieve change, where and when they need to do it, and how often and with whom they need to do it. This was done by generating a nonexhaustive list of possible barriers to and facilitators of PA for adolescents and young adults with IDs based on both the literature and information gathered in the second cocreation session (Table 1). Owing to the cocreative approach, insights from the literature (brought in by the PI) and input from the target group were intertwined (eg, visual cards of barriers and facilitators were developed by the PI inspired by the literature, which were brought up when the participants themselves could not come up with barriers and facilitators [anymore] [51]). In cocreation session 3, these barriers and facilitators were ranked according to importance by the target group. The most important barriers and facilitators were described as what needed to be targeted in the intervention and, consequently, formulated as the intervention goals. In step 4, these intervention goals were then assigned by the PI to the specific components of the COM-B model and theoretical domains of the TDF. No direct cocreation session was organized within this step as their input (from step 3) only needed to be linked to the theoretical components of the COM-B and TDF. However, this does not deviate from the essence of cocreation as the PI established these connections based on all the input provided by the participants.

Stage 2: Identify Intervention Options

In step 5, the BCW guide links COM-B components and TDF domains to 9 intervention functions [33]. Consequently, the broader research group of the PI (ie, the Physical Activity and Health research group) held expert meetings to decide which intervention functions were most suitable to work with based on the Affordability, Practicability, Effectiveness or Cost-Effectiveness, Acceptability, Side Effects or Safety, and Equity criteria [33]. These criteria are recommended by the BCW guide to make strategic judgments on the most appropriate intervention functions. No direct input from the cocreators was sought in this case, either. However, we approached this step with an open-minded perspective and only removed the intervention functions that were deemed not feasible by the project team. All other intervention functions were retained, allowing the cocreators to continue shaping the direction of development. The sixth step was to consider which policies would support the delivery of the intervention functions identified in step 5 [33]. However, as the researchers within this project did not have access to policy levers, step 6 was not applied. This is also described in the BCW guide by stating that “designers limited to a specific policy lever are directed to step 7 to identify BCTs” [33].

Stage 3: Identify Content and Implementation Options

In step 7, the BCW guide proposes the most appropriate BCTs for each intervention function (selected in step 5) [33]. In each of these, a distinction is made between “BCTs used most frequently and less frequently” [33]. For feasibility reasons, we focused primarily on the most frequently used BCTs during the development process. However, for the fourth cocreation session on BCTs, we also explored the less frequently used BCTs and selected relevant ones based on our expertise with the target group. The aim of this cocreation session was to find out which BCTs were understandable and feasible for adolescents and young adults with IDs and how BCTs could be adapted to meet these criteria. On the basis of the Affordability, Practicability, Effectiveness or Cost-Effectiveness, Acceptability, Side Effects or Safety, and Equity criteria and on input from the cocreators with IDs, a decision was made on which BCTs to include in the
Move it, Move ID! intervention. Finally, the eighth step was to identify the best way to deliver the intervention (ie, mode of delivery). As research has shown that the use of technology (ie, mHealth) is feasible and has high potential in adolescents and young adults with IDs [24,25,52], the target group was asked in the fifth cocreation session about their preferences and barriers to and facilitators of mHealth use.

Analysis

All the cocreation sessions were recorded and transcribed verbatim. A combination of a deductive (ie, 8 steps of the BCW) and inductive (ie, resonating the voice of the participants) analysis approach was applied specifically focusing on identifying and describing the findings from each of the steps of the BCW.

Results

Stage 1: Understand the Behavior

**Step 1: Define the Health Problem in Behavioral Terms**
Few people with IDs are sufficiently physically active [18,19].

**Step 2: Select the Target Behavior**
An increase in the total volume of PA should be targeted rather than aiming to meet the WHO guidelines regarding MVPA as even small positive changes in PA levels are associated with health benefits among people with IDs [53].

**Step 3: Specify the Target Behavior and Formulate Intervention Goals**

Multimedia Appendix 1 [32,54-63] provides an overview of 72 barriers to and 66 facilitators of PA for adolescents and young adults with IDs based on (1) a review of the literature by the PI in preparation for the cocreation sessions and (2) input from cocreators with IDs during these sessions. The appendix is divided into intrapersonal, interpersonal, and contextual factors, reflecting the multifaceted and complex nature of the influences on PA in this population. In the third cocreation session, participants ranked the barriers and facilitators according to their importance, providing guidance on which ones to address in the intervention. The 10 most important barriers (in the opposite direction, these would be facilitators) were identified: (1) the need for social connectedness, (2) the lack of practical support within the PA context, (3) the absence of a role model, (4) the need for others around them who also engage in PA, (5) the lack of confidence in their own abilities and body image, (6) the need for knowledge about the (health) benefits of PA, (7) the lack of knowledge about the different PA options available, (8) the low motivation to engage in PA, (9) the difficulty in setting goals, and (10) the need for help to incorporate PA into their existing schedules (ie, goal conflict) as they often depend on others for this. Evidently, this top list does not mean that the other barriers and facilitators were not relevant for some individuals at particular times, but in view of feasibility, it was decided to prioritize and primarily address those that were identified as the most important.

Previous studies have proposed schools as the ideal setting for PA promotion [8,32,64]. Participants with IDs in this study indicated that they are sufficiently encouraged at school to engage in PA via compulsory PE classes. However, they expressed difficulties in being physically active during leisure time. In the cocreation sessions, they expressed a preference for an intervention during their leisure time (ie, at home or in the community setting) rather than a school-based intervention:

> I think it’s best to go somewhere else. Then you have something separate from school. That you are really away. When you come back to school, that you can start again with a fresh head. [Cocreator 1; cocreation session 3; group A]

> [...] that you just keep your activities outside school and that you don’t keep it here between these four walls. [Cocreator 2; cocreation session 3; group A]

Textbox 1 summarizes the specifics of the target behavior gathered during the first 3 steps: who will perform the behavior; what needs to be done differently; and when, where, how often, and with whom it needs to be done.

Finally, the PI formulated 10 intervention goals targeting the most important barriers chosen by the cocreators (Table 2).
**Textbox 1.** Specify the target behavior (step 3 of the Behavior Change Wheel).

\(^{a}\)PA: physical activity.  
\(^{b}\)ID: intellectual disability.

**Step 4: Link Intervention Goals to COM-B Components and TDF Domains**

In step 4, the PI assigned the 10 intervention goals to the specific COM-B and TDF components of the BCW (Table 2). From this behavioral analysis, it can be inferred that psychological capability, social opportunity, and reflective motivation would be the first targets to focus on for increasing PA levels in adolescents and young adults with IDs.

**Stage 2: Identify Intervention Options and Steps 5 and 6 (Identify Intervention Functions and Policy Categories)**

Linking the selected COM-B components and TDF domains from step 4 to the intervention functions proposed by the BCW guide, all 9 intervention functions could be applied. In total, 7 intervention functions were chosen to further focus on: education, persuasion, incentivization, training, environmental restructuring, modeling, and enablement (see the detailed argumentation in Multimedia Appendix 2). The 2 other intervention functions were not selected as they were deemed (1) less practicable to apply as a research team (ie, restriction).
and (2) less acceptable or unlikely to have an impact on adolescents or young adults with IDs (ie, coercion).

Stage 3: Identify Content and Implementation Options

Step 7: Identify BCTs

Overview

A total of 12 BCTs were selected to proceed with. We have outlined our selection and reasoning for each selected BCT within the specific intervention function in the following sections. Multimedia Appendix 3 provides a detailed explanation of all the BCTs that were considered for the 7 intervention functions that came out of step 5, along with the accompanying rationale for why they were chosen and others were not.

Education

Participants with IDs expressed a lack of knowledge about PA options (eg, what is out there, what suits the person best, and where can it be done). For this reason, it was considered valuable to provide information on various PA options. However, the only BCTs formulated within the taxonomy by Michie et al [41] related to providing information are pertaining to consequences (ie, social, emotional, environmental, and health). Although participants mentioned the value of information about the health benefits of PA in previous stages, we collectively decided not to place a direct emphasis on information provision within our intervention. Participants do not desire an intervention centered on “learning” or “teaching” (see also their preference for an intervention outside the school context). According to them, the focus should be on enjoyment. Nonetheless, we anticipate that the target audience may indirectly experience positive effects through the intervention. In this regard, the BCT “salience of consequences” (under the persuasion intervention function) seemed more applicable as it focuses on using methods to specifically emphasize the consequences of performing a behavior, making them more memorable, which goes beyond mere information provision about these consequences. “Feedback on behavior” was also selected as participants indicated that they would like to receive feedback on how well they are performing the behavior.

Persuasion

The BCT “credible source” was valued by participants, but opinions varied on its presentation. Some preferred health professionals using fun visual communication, whereas others liked animated movies. In this target group, experts or influencers explaining PA benefits in an engaging way were considered more appealing than scientific videos. Furthermore, the significance of “verbal persuasion about capability” was strongly emphasized. Given the low self-efficacy within this population, offering verbal persuasion to counteract self-doubt was deemed highly valuable for adolescents/young adults with IDs.

Incentivization

Owing to the prominent role of social factors, we observed that the BCT “social reward” would be highly motivating for this target group.

Environmental Restructuring

Cocreators highlighted the importance of social connectedness and support in encouraging PA. As a result, we expect the greatest impact from recognizing and meeting their social needs, which entails a “restructuring of their social environment.”

Modeling

Participants expressed that it would be motivating to witness others engaging in PA around them, whether in person or indirectly through influencers such as on TikTok (serving as role models). The cocreators showed enthusiasm for involving influencers they admired to encourage PA. Considering budget limitations, it would not be feasible for us to incorporate a well-known influencer into the intervention. However, this does indicate that “demonstration of the behavior” might be an interesting BCT to include.

Enablement

The entire development process highlighted a strong emphasis on the importance of social support and social connections, whether from friends or individuals with expertise in PA (ie, social support BCT—practical, emotional, and unspecified). Participants expressed increased confidence when they could openly discuss their goals and challenges with friends, and their motivation to engage in PA was significantly higher when they could do it with others rather than exercising alone. Peer support was generally preferred, although younger adolescents with IDs (aged 14 years) also mentioned the potential for support from family members. Furthermore, participants agreed that having a list of goals to choose from would make it easier for them rather than having to come up with their own goals (ie, goal setting BCT). Most participants recognized the importance of “action planning” as a valuable BCT. However, insights from teachers revealed that adolescents and young adults with IDs often struggle with tasks such as maintaining a personal agenda or planner, which is typically managed by parents or carers. Therefore, it would be crucial to offer guidance during action planning. Creating a detailed action plan independently, including specifics such as what, when, where, and with whom, seemed challenging and burdensome for this group. Simplicity and minimizing cognitive effort were emphasized as essential factors. Similarly, the collaborative review and adjustment of the behavioral goal with individuals with IDs based on their progress was seen as advantageous. It was considered feasible to engage in close negotiation with them to either retain the same goal, make minor adjustments, or establish a new goal if necessary (referred to as “reviewing behavior goals”). The primary focus in this case is on shared decision-making and active involvement.

Training

The only BCT that we considered including under the “training” intervention function is “demonstration of the behavior.” However, we view this as more related to modeling behavior rather than as actual behavior demonstration within a training context. In the course of our intervention development, it became evident that the primary focus should be on addressing social needs and creating enjoyable experiences rather than on formal training in activities. Therefore, the “training” intervention function was omitted from this phase onward.
Step 8: Identify Mode of Delivery

On the basis of the literature, an mHealth app appeared to be a good and feasible approach for adolescents and young adults with IDs and, therefore, was verified during the fifth cocreation session. The cocreators indicated that they preferred an mHealth app with a straightforward design that clearly indicated its purpose and functionality (eg, through an introductory video). They suggested that the app should be visually appealing, with minimal text, bright colors, and no foreign-language words. They also suggested that a game component or chat feature would be of added value. Cocreators would not use an app that they had to pay for, was childish, or looked rather old-fashioned. They mentioned preferring not to receive too many notifications (ie, no more than 1 notification per day). Finally, this is a group that often faces negative comments and experiences of failure. When talking about mHealth, this also emerged as an aspect to be considered (eg, by keeping the reactions that can be given to each other in an app controlled).

At the end of the fifth cocreation session, cocreators indicated that an app alone would not be sufficient to encourage them to engage in (more) PA. They suggested that an app could be integrated into a broader intervention but not be a stand-alone intervention. More specifically, the desire for social connection with peers and social integration in real life was found to be a more important theme in intervention development. Therefore, the decision was made to focus on a buddy system as many people with IDs reported a lack of friendships with peers outside school, resulting in decreased opportunities to engage in PA during leisure time. To facilitate this buddy partnership, we chose to work with a buddy without IDs who could offer practical support during the intervention period, which reduced the reliance on context alone (ie, parents or carers) to guide the intervention implementation.

Move It, Move ID! Intervention

On the basis of the systematic steps of the BCW combined with a cocreational approach, the Move it, Move ID! intervention ultimately consists of a buddy partnership with a supporting app (ie, dyadic intervention). Figure 2 illustrates the development process, showing how COM-B components, intervention functions, and behavior change techniques (BCTs) are intertwined with the selected intervention design. A more in-depth description can also be found in Multimedia Appendix 3.

Figure 2. Visualization of the development process showing how Capability, Opportunity, and Motivation–Behavior (COM-B) components; intervention functions; and behavior change techniques (BCTs) are intertwined with the selected intervention design. PA: physical activity; TDF: Theoretical Domains Framework.

During an intervention period of 3 months, adolescents and young adults with IDs will be paired with a buddy without IDs of the same age range and encouraged to try out weekly PAs in Ghent (Flanders, Belgium). Buddies without IDs will be students (aged 17-23 years) of the coauthors of this paper and will receive 3 short training sessions (ie, maximum of 1 hour per session) on their role and responsibilities as a buddy.

Although the buddy partnership forms the core of the intervention, a supporting app will also be provided in which buddies and participants with IDs will be in direct contact with each other (an explanation of the scope and screenshots of the supporting app can be found in Multimedia Appendix 4). The app is considered a private space between participants with IDs and their buddies without adding parents or carers to the app. The PI will add a range of activities (eg, walking a shelter dog, dancing, playing Kubb, and undertaking an altitude trail) to the app at the start of the intervention. Participants will have the autonomy to choose whether they want to try an activity by agreeing (swiping right) or disagreeing (swiping left) with a proposed activity. When both the participant with IDs and the
buddy agree with a certain proposed activity, they will receive a pop-up to a chat function to make arrangements and schedule this activity on their shared agenda. The buddy will take the lead in this process. During an activity, the buddy can provide feedback such as how well they perform the behavior or words of encouragement. On the app pinboard, pairs can share photos of the activity they performed together, give comments, and also rate the activity afterward. This allows them to keep track of successful activities and identify less enjoyable ones.

Discussion

Principal Findings

This paper describes the systematic, theory-driven development of a lifestyle intervention to promote PA in adolescents and young adults with IDs using the BCW planning model combined with cocreation sessions involving the target group. The purpose of this transparent and detailed description was 2-fold. First, it aimed to develop a PA promotion intervention by identifying intervention components and BCTs that address the specific needs of this target group. Second, it aimed to encourage future researchers and intervention developers interested in PA among adolescents and young adults with IDs to apply a theoretical planning model in combination with cocreation when designing similar interventions or take the insights described into account in their own intervention development. By transparently describing the theory and BCTs that underpin the intervention, researchers are facilitated in broader evaluations to explore their driving mechanisms. In doing so, we adhered to the Medical Research Council guidelines, which emphasize the importance of theorizing how an intervention works and what works in which setting and identifying its other impacts [65]. This discussion will first delve deeper into the key findings regarding the development of the Move it, Move ID! intervention followed by a reflection on the experience of the development process by combining the BCW and cocreation.

The development process underscored the essential importance of collaborating with the target group as the intervention looks different from what the research team had envisioned in the project proposal (ie, developing an mHealth app). Active collaboration with young people with IDs highlighted the urge for real-life social connectedness and social integration, which makes the social component as part of PA a cornerstone within our intervention development [54-58]. Although the importance of social interaction has emerged in qualitative studies with the target group [66,67], this correlate has surprisingly not been included in studies examining the correlates and determinants of PA levels among young people with IDs [16,68]. However, a study from 2004 conducted within the context of the Special Olympics has already articulated that social support may be particularly crucial for individuals with IDs as they likely have a more limited friendship network compared with individuals without IDs [67]. In total, 3 intervention goals within this development process were consequently directed toward emphasizing the importance of “social opportunity” within the COM-B model. In addition, “psychological capability” and “reflective motivation” emerged as important areas for PA interventions as young people with IDs indicated a lack of knowledge about their PA options, a need for assistance in setting and planning goals, a requirement to enhance their confidence in their own capabilities, and the need to experience genuine enjoyment during PA before they would be motivated to engage in it. Throughout the remainder of the development process, the appropriate intervention functions and BCTs were then linked to these 3 COM-B components. At the end of the process, the cocreators underscored that solely relying on an mHealth app would not meet their social connectedness needs. They preferred face-to-face interaction over distant delivery modes. In addition, they expressed a preference for an intervention targeting their leisure time rather than one connected to their school context. For these reasons, a dyadic intervention was chosen in which young individuals with IDs will be paired with a peer without IDs to explore various PAs together outside the school context. A dyadic intervention refers to an approach or program that involves 2 individuals, typically with a focus on the interaction, relationship, or dynamic between them. Dyadic behavior change has been proven to be a promising approach in previous research [69-71].

As such, by incorporating an extensive and collaborative development process within a project application, one could re-evaluate the initial project proposal (ie, develop an mHealth app for young people with IDs targeted at promoting PA) with a thorough argument that adaptations are necessary from the perspective of the target group itself. In that regard, the combination of actively involving the target audience and applying a clear and scientific planning model was crucial. The most prominent planning models that are currently proposed to guide the development of effective interventions are Intervention Mapping [72] and the BCW [33]. Intervention Mapping includes 6 different steps to rigorously select determinants, performance, and change objectives using appropriate methods and strategies [72]. Although Intervention Mapping is comprehensive, its level of detail makes it more complex and, thus, less feasible, especially in combination with cocreation [73]. The BCW, in contrast, is more open, practical, and flexible as it was developed with interdisciplinary application in mind [37]. However, in applying the BCW within this project, it was noticed that its openness and flexibility could also lead to variable interpretations, with judgments from the researchers often required throughout the development process (eg, step 5). The variations in intervention development mainly depended on the resources available to the project team (eg, affordability and practicability). Moreover, even within this small research team of the Move it, Move ID! intervention, different steps within the BCW were sometimes interpreted differently. Some researchers saw the formulation of barriers to and facilitators of PA as belonging to steps 2 and 3 (as it was described in this paper), whereas others ascribed this to step 4 [74]. In our opinion, assigning these aspects to a certain step will not differ much from the behavioral diagnosis one will eventually arrive at. We consider it more important to discuss the different steps thoroughly within the research team so that the decisions made are well informed and can be argued for. By going through the different steps of the BCW, we learned that interventions can look different depending on the choices made without necessarily making one intervention better than the other. Further research should subsequently indicate which
interventions prove to be effective and why (ie, identifying driving mechanisms [65]). This could potentially lead to the formulation of guidelines outlining the best possible choices that could be made during intervention development within a specific target group and setting.

Nevertheless, by applying the theoretical planning model, the PI had a clear goal in mind in setting up the structure and flow of the cocreation sessions. In doing so, the BCW was instrumental in identifying an informed behavioral diagnosis and choosing which BCTs would be most applicable to have an impact on PA behavior change within this target group and setting. Although the literature suggests that the use of theory in intervention development is key [2,20,33-36], a 2019 meta-analysis formulated that the effectiveness of interventions would be less influenced by whether they are theoretically developed than by the specific BCTs used [75]. In contrast, we believe that both (ie, theory and choice of BCTs) are intertwined. A 2017 systematic review found that lifestyle change interventions for people with IDs aimed at improving PA levels typically used 5.9 BCTs, with “provide information on consequences of behavior in general,” “plan social support/social change,” “provide instruction on how to perform the behavior,” and “goal setting (behavior)” being the most frequently used BCTs [31]. However, 73% of the studies did not use any theoretical framework for intervention development [31]. After completing the full behavioral diagnosis based on the BCW, we included 12 BCTs in our intervention. This is not to say that the inclusion of more BCTs would be better but, rather, that the transparent description of the BCW steps made more evident why these specific BCTs were chosen and how they are intertwined by means of the intervention design. This demonstrates why we believe that the use of theory and the selection of BCTs are strongly connected.

Linking cocreation to the BCW, our goal was to create an intervention that starts with the experiences of the target group. This approach was intended to enhance the effectiveness and sustainability of the intervention by making it more suitable and acceptable for the target audience [10,44-48]. Cocreation with the target audience extended well beyond the described cocreation sessions for intervention development in this project. As the project progressed toward the effect study, ongoing collaboration continued with 2 coresearchers with IDs (ie, inclusive research [48]). These coresearchers maintained regular meetings (every 2 weeks) with the PI (LM) at the Department of Movement and Sports Sciences (Ghent University), actively engaging in various facets of the project. Their responsibilities included assessing prototypes of the app; offering feedback on the training of buddies; testing measurement instruments (comprising questionnaires, interviews, and accelerometers); providing insights into the recruitment strategy; contributing to the development of promotional materials such as flyers, information letters, and informed consent forms; and participating in efforts to enhance the project’s visibility among their peers, classmates, and other stakeholders. This ongoing collaboration with the coresearchers was purposefully designed to ensure the continued accessibility of the project even beyond the initial phase of intervention blueprinting. To conclude, the described intervention development addresses an important and often overlooked population that experiences health disparities and is at higher risk of physical inactivity and related health issues. This study highlights the importance of considering the unique requirements of people with IDs to develop tailored interventions that effectively meet their needs.

Limitations and Strengths

This study has some limitations. First, a wide age range of adolescents and young adults with IDs was included, which might make us question whether this intervention is applicable to both an individual aged 13 years and one aged 22 years. Indeed, younger adolescents with IDs (ie, aged 14 and 15 years) did indicate that they would be open to involvement with parents as buddies within an intervention, whereas this was not the case for young adults (ie, aged 17-22 years old). Choosing a tighter age limit (eg, ages of 13-16 years or 17-22 years) is recommended in future intervention development. Second, of the 23 cocreators, 5 (22%) had a comorbidity with autism spectrum disorder, and 1 (4%) adolescent had attention-deficit/hyperactivity disorder. This is considered a limitation as previous research has found different effects on PA among youth who have IDs and youth who have other developmental disabilities in addition to IDs [8], suggesting that further comparison of PA experiences between these groups is warranted. Within the further intervention development, little weight was given to these comorbidities. In contrast, we can also conclude that their perspective was included from the start of intervention development as they also acted as cocreators and this was not an exclusion criterion. Third, following the prioritization of young people with IDs as cocreators in the initial stages of blueprinting an intervention idea, we were unable to gather input from buddies (peers intended to be matched with the participants with IDs) and consider the broader context of individuals with IDs in the actual development phase of the intervention. This constraint was due to the project’s timeline. In light of this constraint, we recommend that future intervention developers consider including these stakeholders in subsequent phases of intervention development. Their perspectives and insights are invaluable in creating interventions that are comprehensive, inclusive, and truly reflective of the needs and dynamics of the entire participant group. The greatest strength of this study was the fact that a theoretical planning model was used in combination with cocreation to develop a PA promotion intervention for this target group. In this way, it addressed the two main reasons why current interventions often prove to be ineffective: (1) a lack of use of theory and (2) a lack of population-specific research. To the best of our knowledge, this is the first study that describes the collaborative development of a PA promotion intervention for and with adolescents and young adults with IDs. Within the Move it, Move ID! project, the decision was made to work only with participants with mild to moderate IDs; consequently, the findings cannot be extended to the target group of severe or profound IDs. Although future research should focus on the representation of all people with IDs in health research, the fact that a specific group was chosen to truly tailor an intervention to their needs can also be seen as a strength.
Conclusions

The Move it, Move ID! intervention was developed based on the BCW in combination with cocreation. Going through this process was seen as an added value by the research team, which makes it highly recommended to allocate adequate time, budget, and experienced scientific staff for intervention development. By systematically identifying the needs of young people with IDs and linking them to theoretical concepts step by step, cocreators with IDs emphasized the importance of face-to-face interactions and social components in PA promotion interventions. They indicated that relying solely on an mHealth app would not fulfill their social needs. The intervention will consist of a dyadic approach in which young individuals with IDs are paired with a peer without IDs to engage in PAs together, with an app solely providing support within this partnership. The detailed and transparent development process described is a valuable blueprint for practitioners wanting to integrate the BCW and its associated BCTs, in combination with actively involving the target group, into their intervention development for people with IDs.

Acknowledgments

The authors wish to thank the adolescents or young adults and teachers who expressed their opinions during intervention development for this project. This work was supported by the Research Foundation–Flanders under grant 11F3621N (2020-2024).

Data Availability

The data sets generated and analyzed during this study are not publicly available to protect participants’ privacy and confidentiality because of the small number of participants but are available from the corresponding author upon reasonable request. In addition, the upcoming effect study has been preregistered at the Open Science Framework, where all other materials concerning this project can be found.

Authors’ Contributions

LM, SC, G Cardon, G Crombez, and GVH conceptualized the study. LM collected the data (ie, organized the cocreation sessions) and wrote the original draft. JL assisted in combining the Behavior Change Wheel planning model and a cocreational approach. SC, JL, G Cardon, G Crombez, and GVH edited the manuscript and provided feedback. All authors have read and approved the final manuscript.

Assessing and Improving Data Integrity in Web-Based Surveys: Comparison of Fraud Detection Systems in a COVID-19 Study

Abstract

Background: Web-based surveys increase access to study participation and improve opportunities to reach diverse populations. However, web-based surveys are vulnerable to data quality threats, including fraudulent entries from automated bots and duplicative submissions. Widely used proprietary tools to identify fraud offer little transparency about the methods used, effectiveness, or representativeness of resulting data sets. Robust, reproducible, and context-specific methods of accurately detecting fraudulent responses are needed to ensure integrity and maximize the value of web-based survey research.

Objective: This study aims to describe a multilayered fraud detection system implemented in a large web-based survey about COVID-19 attitudes, beliefs, and behaviors; examine the agreement between this fraud detection system and a proprietary fraud detection system; and compare the resulting study samples from each of the 2 fraud detection methods.

Methods: The PhillyCEAL Common Survey is a cross-sectional web-based survey that remotely enrolled residents ages 13 years and older to assess how the COVID-19 pandemic impacted individuals, neighborhoods, and communities in Philadelphia, Pennsylvania. Two fraud detection methods are described and compared: (1) a multilayer fraud detection strategy developed by the research team that combined automated validation of response data and real-time verification of study entries by study personnel and (2) the proprietary fraud detection system used by the Qualtrics (Qualtrics) survey platform. Descriptive statistics were computed for the full sample and for responses classified as valid by 2 different fraud detection methods, and classification tables were created to assess agreement between the methods. The impact of fraud detection methods on the distribution of vaccine confidence by racial or ethnic group was assessed.

Results: Of 7950 completed surveys, our multilayer fraud detection system identified 3228 (40.60%) cases as valid, while the Qualtrics fraud detection system identified 4389 (55.21%) cases as valid. The 2 methods showed only “fair” or “minimal” agreement in their classifications (κ=0.25; 95% CI 0.23-0.27). The choice of fraud detection method impacted the distribution of vaccine confidence by racial or ethnic group.

Conclusions: The selection of a fraud detection method can affect the study’s sample composition. The findings of this study, while not conclusive, suggest that a multilayered approach to fraud detection that includes conservative use of automated fraud detection and integration of human review of entries tailored to the study’s specific context and its participants may be warranted for future survey research.

Introduction

Web-based survey research has become increasingly common in recent years, particularly because of its ability to reach broad populations efficiently and economically [1]. Web-based surveys involve inviting potential respondents to complete questionnaires through digital platforms that manage how questions are presented and how data are collected and stored [2,3]. These research methods have been used in response to the difficulties faced in traditional survey methods (i.e., recruiting participants using flyers, newspaper or radio or television advertisements or spreading by word of mouth and collecting data in person using computer-assisted survey instruments or over the phone), especially in reaching underrepresented populations [4,5]. The advantages of web-based surveys include eliminating the requirement for face-to-face interaction, offering flexible access to surveys, removing transportation and logistical barriers, and preserving anonymity. In recent years, COVID-19 pandemic restrictions limited opportunities for in-person research and provided additional justification for researchers to adopt web-based study designs while leveraging social media recruitment methods to reach diverse populations [6-9].

As web-based recruitment and survey methods in health research have become more ubiquitous and refined, so too have methods of web-based research fraud [10,11]. Fraud can manifest in multiple ways. For example, individuals may misrepresent themselves in order to appear eligible for a study or may submit duplicate surveys in order to receive multiple incentive payments. Additionally, fraudulent data may also come from automated operations enacting fraud at a large scale, often referred to as “bots” [11,12]. These methods are often used to target surveys offering participation compensation payments and can be lucrative when aimed at large web-based surveys, even those offering small payments [9,13]. Such fraud poses risks not only to research resources but also, importantly, to the integrity of research findings, as fraudulent data can distort results and undermine data quality. Specifically, fraudulent responses can introduce additional random noise or potentially add systematic bias to the data [14-16].

In response, researchers, companies operating in the digital research space (e.g., Qualtrics) [17], and organizations interested in digital data integrity (e.g., Google) [18] have developed methods to address fraudulent activity. The research community has crafted recommendations for fraudulent data identification and participant identity verification protocols [13,19,20]. Platforms specializing in web-based survey research such as Qualtrics [17] and Amazon Mechanical Turk [21] have also developed fraud detection features that accompany their services. While these proprietary systems for fraud detection offer a simple, automated approach to improving data quality, little information is available about the mechanisms they use [22]. Fraud detection systems often obscure details about how their validation process functions as an important strategy to protect the integrity of the fraud detection system, making it more difficult for fraudulent participants to circumvent protections. However, obfuscation also introduces questions about how fraud detection algorithms alter study samples and whether they introduce bias into analyses [20].

Little research has compared how fraud detection strategies impact study sample composition or examined their comparative effectiveness in correctly identifying fraud [22-25]. By accurately identifying and removing fraudulent responses to web-based surveys, research can improve data quality and strengthen the overall rigor of their methods. Robust, reproducible, and context-specific methods of accurately detecting fraudulent responses are needed to ensure integrity and maximize the value of web-based survey research. This paper aims to (1) describe the multilayer fraud detection techniques we developed and implemented in a large web-based survey collecting data about attitudes, beliefs, and behaviors related to COVID-19; (2) examine the degree of agreement between our multilayer fraud detection strategy and the proprietary fraud detection system used by Qualtrics; and (3) compare the study samples that resulted when using each of the 2 fraud detection methods.

Methods

Study Design

We collected data from November 2021 through February 2022 for the PhillyCEAL Common Survey, a cross-sectional study using a web-based survey to assess how the COVID-19 pandemic and response have impacted individuals, neighborhoods, and communities across the city of Philadelphia, Pennsylvania. The Checklist for Reporting Results on Internet E-Surveys was used to guide the reporting of our methods and results (Multimedia Appendix 1) [26]. The Qualtrics web-based survey platform was used to design the survey and automatically capture responses in a database. The usability and technical functionality of the survey were tested by the study team before launching the survey. Individuals were eligible to participate if they (1) resided within Philadelphia County (coterminous with the city limits) and (2) were at least 13 years of age. We recruited participants through advertisements on social media platforms (i.e., Facebook, Instagram, Twitter, and Reddit) and referrals from community partners (including one partner that provided study recruitment materials to individuals via door-to-door canvassing). The recruitment process directed individuals to a voluntary, open web-based survey, where they completed a screener consent form and answered a series of questions to determine eligibility and record basic demographic information. We did not allow participants to change their answers through a back button feature.

Eligible participants were automatically directed to the full study consent form. Following consent, participants were asked to complete a 20-minute questionnaire about their experiences, behaviors, and beliefs about COVID-19, risk of infection, testing, vaccination, treatment, and knowledge and beliefs about COVID-19 clinical trials. Participants completed 1 of 3 slight variations of the survey (i.e., the adult survey, the parent survey, and the youth survey), where additional questions or slight changes to wording were used on the parent and youth surveys. Participants completed only 1 of these 3 potential variations (i.e., survey groups were mutually exclusive), with participants of any age who reported having minor children completing the parent survey (103 questions), participants ages 25 years or
younger and not having minor children completing the youth survey (126 questions), and all other participants completing the adult survey (92 questions). To reduce participant burden, we used adaptive questioning to reduce the number of questions displayed based on their answers. Participants saw an average of 6 questions per page.

Participants were excluded if they did not complete the entire survey (n=2930) or did not provide a residential zip code matching 1 of the 48 zip codes of Philadelphia County (n=647). Participants confirmed eligible and marked as complete by both Qualtrics automation and our manual review of the data were compensated with a US $15 electronic gift card. To protect participant data, the web survey data were downloaded to a secure university server, deidentified by replacing contact information with unique IDs, and stored in a restricted folder with password protection.

Ethical Considerations

All participants completed an informed consent process before proceeding to the survey. Ethics approval was obtained from the institutional review board at the University of Pennsylvania (protocol 848650).

Preliminary Fraud Protection

Given the prevalence of fraud and duplicate responses in web-based survey research, we used several strategies to prevent fraudulent participants from accessing and completing the survey, serving as a baseline level of fraud protection for both our multilayer and the Qualtrics detection methods. Our preliminary line of defense against fraud was targeted toward nonhuman interferences such asbots. To proceed with the survey, all respondents had to pass a built-in Turing test provided by Qualtrics using Google’s reCAPTCHA (version 2) antifraud technology [27]. Depending on the respondent’s on-device saved data such as browser cookies, they either had to click a checkbox or solve a simple image challenge to pass the reCAPTCHA (version 2) test.

Since sophisticated bots can trick the reCAPTCHA (version 2) test [28], we added a honeypot question as a second line of defense against bots. Honeypots are survey questions hidden from rendering on the screen using custom JavaScript code [11]. They are, therefore, invisible to human respondents but accessible to bots that do not rely on what is rendered on screen. Since the honeypot is not visible to human respondents, any responses to the honeypot would immediately disqualify the entire survey response and end the survey.

We also created unique URLs for each recruitment source and advertisement campaign for the study. The unique URLs enabled us to identify the origin (recruitment source and ad campaign) of each survey response. This allowed us to individually monitor and suspend links that became the target of fraudulent survey responses.

Multilayer Fraud Detection Methods

Real-Time Exclusion of Fraudulent Responses

We implemented a suite near real-time data verification procedures to assess the veracity of data as they were collected, including techniques based on recommendations from prior research as well as several manual checks that were developed specifically for this study. A research team member would individually inspect submitted responses and label responses as fraudulent using the following criteria: (1) participants were asked to provide their residential address and the colloquial name of their neighborhood. Responses were marked as fraud if the neighborhood name provided did not match a standard Philadelphia neighborhood name corresponding to the residential address provided or any adjacent neighborhood; (2) the residential address provided did not match an existing address in Philadelphia County [20,23,29]; (3) the survey had the same start times and stop times plus or minus 1 minute as 2 or more other submitted surveys (rapid survey submission) [11,29]; (4) the respondent’s email address matched a previously enrolled participant’s email address [11,20]; (5) the zip code provided as part of the residential address was nonstandard (ie, a post office box code or a unique code) [20,23]; (6) the residential address had already been reported by at least 2 other respondents [20,23]; or (7) the URL from which the response was referred did not match any of the URL links distributed by the study team during recruitment. Responses labeled as fraud during real-time validation were not eligible to receive survey compensation.

Automated Post Hoc Identification of Fraudulent Responses

We developed a set of automated post hoc techniques designed to detect fraud that our real-time procedures may not have captured. Three criteria were developed for this post hoc fraud identification based on recommendations from prior research [11,20,22,23,29-32]. Since these criteria only identify suspicious entries and do not definitively prove that an entry is fraudulent, responses were labeled as fraud only if they satisfied 2 or more criteria. We settled on using a threshold of 2 criteria (rather than 1 or 3) in order to balance concerns about the potential of each of our 3 criteria to incorrectly label a participant as fraud with the necessity to exclude causes that showed strong evidence of fraud. The criteria were as follows:

1. In response to a free text item at the end of the survey soliciting additional comments or questions from the participant, the submitted survey included text that was identical to text submitted by other respondents. We considered a free text response an identical match if it was among free text entries of 1 word or greater that were repeated 100 or more times, free text entries of 2 words or greater that were repeated 10 or more times, or free text entries of 3 words or greater that were repeated 3 or more times (see Table S1 in Multimedia Appendix 2 for list of unique text strings excluded and their frequency in the full set of responses).
2. The IP address of a response belonged to a virtual private network or data center originated from outside the United States, as determined by using a security service for proxy and virtual private network detection and IP location information [33]; and
3. Responses provided in the main survey were inconsistent with responses to the same items in the screener for one or more key items that would not be expected to be variable
(ie, age, zip code, number of adults living at home with the participant, number of minors living at home with the participant, Hispanic or Latinx ethnicity, “Have you ever been tested for COVID-19?,” and “Have you received at least 1 dose of the COVID-19 vaccine?”).

Qualtrics Fraud Detection Methods

Qualtrics is a widely used web-based survey platform that allows users to create surveys with complex flow logic and customizable visual design. Qualtrics surveys are easily optimized for use on mobile devices and can display a wide variety of question types on both computer and mobile phone interfaces. Another key strength of the Qualtrics platform is its integration of 1-click translation, allowing users to quickly switch between various languages. This was crucial for our study, which recruited participants from diverse populations across Philadelphia and was available in English, Spanish, and Mandarin. In addition to these valuable features, Qualtrics also offers tools for detecting fraudulent survey responses. This automated and user-friendly system for fraud detection has the potential to help researchers improve data quality in their web-based surveys. Given the lack of research exploring how these consumer tools compare to existing published protocols for fraud detection, we sought to compare our multilayer fraud detection methods to the system used by Qualtrics.

The Qualtrics fraud detection system relies on Google’s reCAPTCHA (version 3) and Imperium’s RelevantID antifraud technologies. Both tools rely on proprietary machine learning models that analyze passive and behavioral data, browser interactions, and respondent metadata to identify abuse and fraud [18,34,35]. Unlike the reCAPTCHA (version 2) test respondents had to solve at the start of the survey, but detection using reCAPTCHA (version 3) does not present respondents with an image challenge nor block respondents and bots from proceeding with the survey. Instead, it returns a score (Q_RecaptchaScore) between 0.0 and 1.0 that Qualtrics records as part of the survey response. We used the recommended 0.5 score as the threshold for fraud, where a score under 0.5 is deemed likely to be a bot [17,18].

Like reCAPTCHA (version 3), RelevantID does not prevent bots from completing the survey. Instead, it attaches a score (Q_RelevantIDFraudScore) between 0 and 130 to each survey response. We followed Qualtrics’ recommendation in interpreting a score ≥30 as fraudulent and likely a bot [17]. In addition to bot detection, RelevantID identifies duplicate responses through digital fingerprinting and proprietary detection algorithms [34]. Qualtrics then attaches another score (Q_RelevantIDDuplicateScore) between 0 and 100 to the survey response. We followed the suggested score threshold where any score ≥75 is considered a duplicate [17].

Statistical Analysis

Agreement and Comparative Performance

The classification tables were created to display the degree of agreement between the 2 fraud detection methods for the full sample and for each of the 3 survey-type categories (ie, adult, parent, and youth).

Impact of Fraud Detection Method on Sample Characteristics

Descriptive statistics were computed for the full sample of responses, the subset classified as valid by our multilayer fraud detection method, and the subset classified as valid by the Qualtrics fraud detection method. As these 3 sets of responses are not mutually exclusive, we did not directly compare them statistically.

To test for differences between fraudulent and valid responses as classified by each fraud detection method, statistical comparisons were conducted for key study variables between the mutually exclusive sets of responses classified as fraudulent or valid within each method. Specifically, we used chi-square tests for categorical variables, 2-tailed t tests for normally distributed continuous variables, and Mann-Whitney U tests for continuous variables that were not normally distributed. The results of these analyses are presented in Table S2 in Multimedia Appendix 2 for the multilayer method and Table S3 in Multimedia Appendix 2 for Qualtrics.

To assess the degree to which the 2 fraud detection methods would impact the distribution of a key study variable, the point estimate and 95% CI were calculated for vaccine confidence by racial or ethnic group for each fraud detection method and for the entire sample without any fraud mitigation.

Variations in Survey Responses During Study Period

A time-series plot was created to show the cumulative responses to the study survey over time and their fraud classification by each of the 2 fraud detection methods. This plot highlights the periods in which social media recruitment campaigns are active and can also shed light on how the 2 fraud detection methods diverge in their classification of responses during different periods of high survey response. Additionally, we present a time-series plot showing the proportion of responses classified as fraud across the study period, including smooth locally weighted smoothing lines to visualize the trends over time. All analyses were performed with R (version 4.1.0; R Foundation for Statistical Computing).

Results

Multilayer Fraud Detection Methods

A total of 7950 completed survey responses were received. See Figures 1 and 2 for an overview of fraud detection results from our multilayer fraud detection methods. Using the real-time exclusion criteria of the multilayer fraud detection method, 4207 (52.92%) entries were classified as fraud. Of those classified as fraud, 1242 (29.52%) reported a neighborhood name that did not match their residential address, 648 (15.4%) provided an invalid residential address, 1397 (33.21%) displayed rapid survey submission, 42 (1%) used a repeated email address, 77 (1.83%) reported a nonstandard zip code, 398 (9.46%) reported a residential address that was used more than twice, and 403 (9.58%) did not have a valid recruitment URL. After the real-time exclusion, 3743 (47.08%) cases remained classified as valid.
Our automated post hoc fraud detection criteria identified additional cases as fraud. Of the remaining 3743 initially valid cases, 1561 (41.70%) cases had a duplicate response in the free text entry item, 394 (10.53%) cases had an IP address from outside the United States or from a virtual private network, and 619 (16.54%) had inconsistencies between the screener and main survey on at least 1 key item. Using our “2-strike” rule, we classified an additional 515 (13.76%) responses as fraud for meeting at least 2 of the above criteria. Thus, our multilayer fraud detection strategy classified a total of 4722 (59.40%) entries as fraud and 3228 (40.60%) entries as valid.

### Qualtrics Fraud Detection Methods

The Qualtrics fraud detection methods identified 498 (6.26%) cases as fraud by the RelevantID FraudScore, and 938 (11.80%) cases as duplicates by the RelevantID DuplicateScore. The Qualtrics fraud detection strategy classified a total of 3561 (44.79%) entries as fraud (ie, meeting one or more of the 3 criteria above) and 4389 (55.21%) entries as valid.

### Agreement and Comparative Performance

Table 1 presents confusion matrices showing the degree of agreement between our multilayer fraud detection method and the Qualtrics fraud detection method for the full sample and each survey-type category. The interrater reliability indicated “fair” or “minimal” agreement between the 2 methods for the full sample ($\kappa=0.25$; 95% CI 0.23-0.27), “moderate” or “weak” agreement for the adult ($\kappa=0.48$; 95% CI 0.43-0.53) and youth ($\kappa=0.50$; 95% CI 0.43-0.58) surveys, and “slight” or “none” agreement for the parent survey ($\kappa=0.13$; 95% CI 0.10-0.15) [36,37].
Table 1. Confusion matrix and interrater reliability ($\kappa$) between our multilayer fraud detection system and the Qualtrics fraud detection system for the full sample, only adult surveys, only parent surveys, and only youth surveys.

$^a$$\kappa$=0.25; 95% CI 0.23-0.27.

$^b$Values in italics represent agreement between the 2 methods.

$^c$Values represent disagreement between the 2 methods.

$^d$$\kappa$=0.48; 95% CI 0.43-0.53.

$^e$$\kappa$=0.13; 95% CI 0.10-0.15.

$^f$$\kappa$=0.50; 95% CI 0.43-0.58.

We conducted sensitivity analyses to assess the impact of choosing a “2-strike rule” for our post hoc fraud detection rather than a “1-strike rule” or a “3-strike rule.” Compared to the “2-strike rule,” which resulted in 515 additional cases being classified as fraud during the post hoc phase of fraud detection, the “1-strike rule” would have classified 2047 additional cases as fraud, and the “3-strike rule” would have classified 12 additional cases as fraud. In terms of agreement with Qualtrics’ fraud detection methods, the “1-strike rule” would have resulted in a $\kappa$ of 0.20 (95% CI 0.19-0.22) for the full sample, and the “3-strike rule” would have resulted in a $\kappa$ of 0.24 (95% CI 0.22-0.26) for the full sample.

Additionally, we explored how the 2 fraud detection strategies compared in their ability to classify cases with validated email addresses as valid entries. Validated email addresses were defined as email addresses ending in “.edu” or “.gov,” indicating an institutional affiliation. Of the 168 cases with validated emails, the multilayer fraud detection system correctly classified 166 (98.81%) as valid, while the Qualtrics fraud detection system correctly classified only 126 (75%) as valid.

**Impact of Fraud Detection Method on Sample Characteristics**

Decisions about which fraud detection strategies to use can impact the results of web-based survey research. Table 2 presents the descriptive statistics for sociodemographic variables, survey metric variables, and key study outcome variables on 3 versions of the data set: the full data set with no fraud detection (n=7950), the cases identified as valid by our multilayer fraud detection methods (n=3228), and the cases identified as valid by the Qualtrics fraud detection methods (n=4389). As these sets are not mutually exclusive, we cannot compare them directly; however, there are clear differences in the distributions of many study variables between the 3 sets. When comparing entries classified as fraud to those classified as valid for each of the 2 fraud detection methods (ie, mutually exclusive sets), all study variables, except for lifetime COVID-19 testing for the multilayer fraud detection, were found to be significantly different for both methods (Tables S2 and S3 in Multimedia Appendix 2).

Table 3 showcases in detail how a key variable of interest to researchers may be affected by using different fraud detection methods. In this data set, vaccine confidence among White respondents was greater when using our multilayer fraud detection ($\mu$=0.867; 95% CI 0.851-0.882) when compared to Qualtrics fraud detection ($\mu$=0.782; 95% CI 0.766-0.798). A similar pattern is seen for Hispanic or Latinx respondents and Black or African American respondents.

Variations in Survey Responses During Study Period

The response rate varied throughout the study and was correlated to several social media advertising campaigns and an extended holiday break where no responses were accepted. Figure 3 shows the cumulative number of responses over time, differentiated by fraud detection method and fraud classification. Time periods when social media advertising campaigns were active are highlighted on these plots. Responses tend to increase during social media campaigns. Notably, between January 13 and February 7, 2022, no social media campaign was active, yet a significant number of responses were received (n=766). These responses were largely classified as fraud by our multilayer fraud detection method (n=716, 93.47% classified as fraud) but were often classified as valid by the Qualtrics fraud detection method (n=296, 38.64% classified as fraud). Figure 4 shows the proportion of responses classified as fraud across the study period. The comparative fraud detection between the 2 methods was similar during the first half of the study period (November to December 2021), while the multilayer fraud detection method consistently identified a higher proportion of responses as fraud during the later portion of the study period (January to February 2022).
Figure 3. Fraud detection by multilayer fraud detection system and Qualtrics fraud detection system during the study period (November 2021 to February 2022). Highlighted regions indicate periods when social media campaigns were active (November 3-18, 2021; November 29-December 22, 2021; and February 7-10, 2022). Data collection was paused during an extended winter break from December 23, 2021, until January 12, 2022. The dotted vertical line represents January 12, 2022, when data collection was resumed.

Figure 4. Proportion of responses classified as fraud by multilayer fraud detection system and Qualtrics fraud detection system during the study period (November 2021 to February 2022). Smooth locally weighted smoothing lines are included to help visualize the trends over time.

Discussion

Principal Findings

Our multilayer fraud detection methods identified a substantial number of fraudulent cases. However, when comparing our fraud detection methods to proprietary fraud detection systems provided by web-based survey software, we saw low levels of agreement between the 2 methods. Our results highlight how the choice of fraud detection method can alter the distribution of key study variables.

Both our multilayer fraud detection methods and the Qualtrics fraud detection system identified significant levels of fraud; however, the 2 methods differed in which cases they identified as fraudulent and in which they identified as valid. Notably, these differences were most pronounced for participants who administered the survey specifically for parents. It is possible that fraudulent participants made assumptions about eligibility or compensation (e.g., parents are a more specific demographic that may be of interest to researchers, and thus, fraudulent entries that claim to be parents may be more likely to screen as eligible and receive compensation) and responded to eligibility questions in ways that guided them to the parent survey. With a greater
number, and perhaps a greater variety, of fraudulent participants, we then may have seen greater variability in the 2 methods’ ability to consistently identify the fraud.

The disagreement between our multilayer fraud detection and the Qualtrics fraud detection suggests that there are important differences in the methodologies being used by the 2 systems, which resulted in differences in classification. To fully understand and compare the relative performance of the 2 systems, detailed information is needed about the methods used by the Qualtrics fraud detection system. It is likely that the features of the RelevantID proprietary fraud detection method used by Qualtrics are intentionally obfuscated to prevent fraudulent participants from undermining its effectiveness. The trade-off for this black box tactic is that researchers who use the Qualtrics platform cannot ascertain how Qualtrics’ fraud detection algorithms function and how these methods compare to alternative fraud detection strategies. There is an inherent tension between transparency (ie, publishing the features of a fraud detection method improves scientific rigor) and defending against fraud (ie, making comprehensive information about a fraud detection method available may enable fraudulent participants to avoid detection) [22]. Additional research is needed to evaluate the effectiveness of proprietary fraud detection systems and compare them to published techniques used by researchers.

For both fraud detection methods, the cases identified as fraud differed in nonrandom ways from the cases classified as valid on key study variables. These differences could have implications for the interpretation of study results; if legitimate survey participants are classified as fraudulent, critical data are lost, and potential bias could be introduced. In addition, many automated fraud detection tools turn to proprietary machine learning data and predictive modeling for fraud detection [22,38]. This could disproportionately affect those with low literacy or barriers to internet access, as fraud detection tools may be more likely to flag them as fraudulent [19]. Given the existing digital divide across racial or ethnic groups [39,40], this may result in the further exclusion of racial or ethnic minorities in research if they are more likely to use older technologies and shared devices at home or in public spaces, such as computers at libraries or community centers (which may trigger the threshold for fraud due to user behavior that is atypical of a single-user device). One approach to overcoming this challenge is to integrate manual inspection of survey entries in place of or in addition to automatic processes that could result in bias [41,42]. However, human inspection of each survey entry can be time-consuming, more variable than automated processes, and could also result in bias. Future work should aim to better characterize subgroups that may be disproportionately flagged by fraud detection systems and develop ensemble approaches that integrate manual and automatic fraud detection while balancing fraud detection accuracy with protections against excluding valid participants.

While overly sensitive fraud detection could result in bias, fraud detection methods that are not sensitive enough to detect fraudulent entries could also add random noise or systematic bias to the data and threaten the integrity of the research [14-16]. It is important to note that we do not have insight into fraudulent participants’ techniques for responding to survey questions. Fraudulent participants may deliberately select specific demographic options (characteristics they believe will be more likely to result in their entry into the study), randomly select their responses, or use some combination of those techniques [9]. Additionally, rapid developments in machine learning and artificial intelligence have increasingly allowed bots to mimic human behavior [11,22], which could contribute to the seemingly human selection of responses on these surveys, including entries into free text fields [43]. Regardless, this analysis demonstrated the importance of developing study-specific fraud detection methods to supplant or supplement the proprietary fraud detection methods of web-based survey platforms.

Another point of note is the decreased effectiveness of fraud detection tools in determining user legitimacy, as major technology companies take increasing measures to protect user privacy. For example, it is common for fraud detection tools to rely on device fingerprinting and browser cookies to help determine the legitimacy of an individual [44]. While these 2 methods are regularly used by advertisers and marketers to track individuals and deliver targeted advertisements, they also provide a way for fraud detection tools to flag known bad actors and differentiate between legitimate and fraudulent responses. However, the invasive and comprehensive nature of device and browser fingerprinting has raised privacy concerns from users and privacy advocates alike [45,46]. Technology companies, such as Apple, Mozilla, and Brave, have in turn introduced measures to hide users’ identities and activity in a bid to protect user privacy. For instance, Apple’s Safari browser on the macOS desktop operating system now strips all unique identifiers from a user’s device profile, so they appear no different from millions of other Safari users [47]. These privacy-protecting measures, while helpful in safeguarding an individual’s digital presence, make it more difficult for fraud detection tools to differentiate between a legitimate human and a bot. This could partially explain the discrepancy we found between the fraud detection by Qualtrics using reCAPTCHA and RelevantID and our multilayer fraud detection.

Without a method to make a conclusive determination regarding which entries are truly fraudulent and which entries are genuinely valid, it is difficult to compare the relative performance of our multilayer fraud detection methods with the Qualtrics fraud detection methods. However, several pieces of evidence suggest that our fraud detection methods have advantages over Qualtrics in this study context. First, we saw that for email addresses that had an institutional affiliation (ie, “.edu” or “.gov,” which require identity confirmation and cannot be generated en masse) and thus were presumed to be valid, our fraud detection methods correctly validated 98% (n=166) of cases. In comparison, Qualtrics only validated 75% (n=126) of cases. Second, we saw an unusually large discrepancy between the 2 fraud detection methods during a period when the survey link was open, but no advertising or recruitment had recently been active. During this time when we did not expect to receive legitimate responses, we received hundreds of responses that were largely classified as fraud by our fraud detection methods but were generally classified as valid by the Qualtrics system.
While it is possible that valid participants were still able to find and access this survey in the absence of active recruiting, we believe this pattern is evidence of noneligible actors using automated systems in an attempt to gain additional compensation payments from the survey. Taken together, these 2 observations are indirect evidence that our multilayer fraud detection method may have better specificity (ie, can correctly identify valid entries) as well as better sensitivity (ie, can accurately detect fraudulent entries) when compared to the Qualtrics system in this study. While we are unable to conclude that the approach we developed for this study is more or less accurate in identifying fraud when compared to the system used by Qualtrics, we believe these pieces of indirect evidence suggest that using an automated system, such as the one available through Qualtrics, alone may be suboptimal. A multilayered approach was recommended to fraud detection that includes conservative use of automated fraud detection and integration of human review of entries that is tailored to the study’s specific context and its participants.

Limitations
This study is subject to several limitations. First, our comparison of fraud detection methods is limited by the fact that we are unable to definitively determine which entries are valid and which are fraudulent. We selected fraud detection criteria specifically intended to identify repeat respondents (eg, multiple responses providing identical information), fraudulent submissions from outside the Philadelphia region (eg, location verification using IP addresses), and submissions from bots or bot-assisted fraudulent participants (eg, requiring responses that would be difficult to generate via algorithm such as local, colloquial neighborhood names). Applying these criteria may still have resulted in the inclusion of illegitimate responses and the exclusion of legitimate ones. Second, because we cannot know for certain the true fraud status of participants, we are unable to calculate metrics like precision and recall for the fraud detection methods. Future research should aim to establish gold-standard indicators for fraud that could then be used to directly compare the efficacy of the different methods for fraud detection. Third, without knowing how Qualtrics detects fraud, we are unable to determine which components of our strategy may overlap with the Qualtrics strategy. This limits the conclusions we can draw about the comparative effectiveness of these fraud detection methods. Fourth, while we choose to compare our fraud detection methods with the automated systems used by the Qualtrics platform, we believe that similar comparisons and research are also needed with other proprietary fraud detection systems.

Recommendations
The following recommendations are offered for improving data integrity in web-based survey research based on the findings from this study:

- Use a multilayered approach to fraud detection that combines different techniques like bot detection, location verification, consistency checks, and manual review. Relying solely on one method may miss certain types of fraud.
- Carefully evaluate proprietary fraud detection systems and request details on their methodology if possible. Black box methods make it difficult to fully assess their impact on sample composition.
- Avoid overly strict fraud detection rules that may disproportionately exclude valid respondents from vulnerable groups. Balance rigor with inclusion.
- Continuously monitor survey responses over time to identify changes in fraud patterns that may require adjustments to detection methods.

Conclusions
Web-based research and recruitment through social media platforms offer powerful flexibility for researchers to collect large, diverse samples. Web-based surveys, however, are vulnerable to low-quality data from fraud and duplicate entries. Researchers must actively design their web-based studies with this vulnerability in mind and adopt active and adaptable methods of detecting and responding to fraudulent survey responses. Automated, proprietary fraud detection systems offered by web-based survey software may be an important tool in combating fraud, but additional research is needed to evaluate their effectiveness. Human verification of survey entries, while time-consuming, can add another layer of protection and enhance the rigor of web-based survey research. We believe a multilayered strategy that includes a combination of automated fraud detection tools, data enrichment, and human intelligence is the best approach for combating fraud.

Acknowledgments
The authors would like to recognize the contributions of the community partners who helped to distribute the survey as well as the research participants who shared their experiences and insights as part of this research. The authors would also like to thank Gared Harbison for his contributions to validating survey responses and cleaning and managing the data. This work was supported by funding from the National Institutes of Health Agreement OT2HL16156 as part of the Community Engagement Alliance Against COVID-19 Disparities, PhillyCEAL.

Abstract

Background: Interprofessional education (IPE) facilitates interprofessional collaborative practice (IPCP) to encourage teamwork among dental care professionals and is increasingly becoming a part of training programs for dental and dental technology students. However, the focus of previous IPE and IPCP studies has largely been on subjective student and instructor perceptions without including objective assessments of collaborative practice as an outcome measure.

Objective: The purposes of this study were to develop the framework for a novel virtual and interprofessional objective structured clinical examination (viOSCE) applicable to dental and dental technology students, to assess the effectiveness of the framework as a tool for measuring the outcomes of IPE, and to promote IPCP among dental and dental technology students.

Methods: The framework of the proposed novel viOSCE was developed using the modified Delphi method and then piloted. The lead researcher and a group of experts determined the content and scoring system. Subjective data were collected using the Readiness for Interprofessional Learning Scale and a self-made scale, and objective data were collected using examiner ratings. Data were analyzed using nonparametric tests.

Results: We successfully developed a viOSCE framework applicable to dental and dental technology students. Of 50 students, 32 (64%) participated in the pilot study and completed the questionnaires. On the basis of the Readiness for Interprofessional Learning Scale, the subjective evaluation indicated that teamwork skills were improved, and the only statistically significant difference in participant motivation between the 2 professional groups was in the mutual evaluation scale ($P=0.004$). For the viOSCE evaluation scale, the difference between the professional groups in removable prosthodontics was statistically significant, and a trend for negative correlation between subjective and objective scores was noted, but it was not statistically significant.

Conclusions: The results confirm that viOSCE can be used as an objective evaluation tool to assess the outcomes of IPE and IPCP. This study also revealed an interesting relationship between mutual evaluation and IPCP results, further demonstrating that the IPE and IPCP results urgently need to be supplemented with objective evaluation tools. Therefore, the implementation of viOSCE as part of a large and more complete objective structured clinical examination to test the ability of students to meet undergraduate graduation requirements will be the focus of our future studies.
Introduction

Interprofessional Collaboration Between Dentists and Dental Technicians

Conflicts are part of the life of any organization, and the dental professions are not spared. Jurisdictional battles and supremacy struggles are not alien to dentistry [1]. Unfortunately, despite the obvious reported benefits of interprofessional education (IPE) for interprofessional collaborative practice (IPCP) [2], there is a paucity of data about IPE to promote IPCP among dental professionals. Dentists and dental technicians need to communicate effectively and contribute their professional skills to ensure that they make decisions that are in the best interests of their patients [3]. A clear understanding of the interactions of the dental care team can promote teamwork [4], establish cooperative goals [5], encourage mutual respect [6], and promote IPCP between dental students and dental technology students [7].

IPE encourages teamwork among dental care professionals [8-11] and is increasingly becoming a part of the training programs for dental and dental technology students [12-17]; however, gaps still remain. Perhaps, the largest gaps are owing to the predominant focus of previous studies regarding IPE and IPCP on student and instructor perceptions and a lack of objective assessment of collaborative practice as an outcome measure [18,19]. This marked gap has necessitated the development of a conceptual framework to evaluate the impact of IPE on IPCP to strengthen the evidence for IPE as a tool to improve IPCP between dental and dental technology students [20].

The Objective Structured Clinical Examination

The objective structured clinical examination (OSCE) is an assessment tool based on the principles of objectivity and standardization, in which individual students move through a series of time-limited stations in a circuit for the purpose of assessment of professional performance in a simulated environment. At each station, the student is assessed and marked against standardized scoring rubrics by trained assessors [21]. OSCE has been widely adopted as a summative assessment in the medical undergraduate curriculum and is universally accepted as the gold standard for assessing clinical competence in dental education [22,23]; furthermore, its effectiveness has been confirmed by several studies [24-26]. On the basis of the extensive application of OSCE, the interprofessional OSCE (iOSCE) was initially developed to simulate IPCP [27]. Unlike conventional OSCE, iOSCE involves students from different professions, encourages students to work as a team, and requires the entire team to participate in all tasks [28]. This is performed to objectively evaluate the results of IPE. Within this framework, several variations of iOSCE have been developed to accommodate the training needs of health care teams built to address different disease categories (team OSCE [29,30], group OSCE [31,32], interprofessional team OSCE [28,33], etc). These iOSCE variants can be roughly divided into synchronous [33-36] and asynchronous [29,37] task-based variants. A team working in an operating room typically works synchronously, whereas health care teams of dentists and dental technicians typically work asynchronously. Although the use of iOSCE in medical education has been extensively reported [27-30,38-42], to the best of our knowledge, the use of iOSCE for asynchronous work, especially within dentistry and dental technology cross-professional education, has not been reported.

Although iOSCE may provide an ideal solution for dental and dental technology students to perform IPCP simulation based on real patient cases, the COVID-19 pandemic [43] highlighted the limitations of this traditional approach. For example, a plaster model generated from a clinical case and passed multiple times among students and examiners may pose a risk of infection. In addition, diagnostic stations are usually set up to facilitate OSCE. A station is typically equipped with a trained, standardized patient, and the students complete the diagnosis by asking questions and examining this standardized patient. The risk of infection at this type of station was heightened during the pandemic. Nevertheless, compared with the traditional OSCE, iOSCEs are more time consuming and resource intensive [44,45], especially in dental education; hence, a virtual approach, as developed and piloted in this study, is justified [46,47]. Notably, the conventional virtual OSCE (vOSCE) has been described as a method of performing OSCE using internet technology in medicine [47-49]. The major reason for this technological approach was the scattered nature of the locations of students requiring assessment. However, this approach does not fully leverage virtual technology in dentistry. The integration of digital dental technologies and cloud-based dental laboratory workflows could be practiced within the vOSCE framework [50], which now also forms a professional core course in dental technology education [51-53]. The development of iOSCE based on virtual technology could facilitate the inclusion of digital dental technology in the blueprint design of examination stations. This combination could simulate the critical needs of present-day dental laboratories and promote students’ improved perception about the current demands of the profession.

Objective

To address these research gaps, this study presented a new virtual iOSCE (viOSCE) to objectively assess the effectiveness of IPE as a tool to promote IPCP among dental and dental technology students. We have described the development and piloting of a viOSCE framework and its virtual techniques to validate the user-friendliness of IPE and document its effect on IPCP among dental and dental technology students. Data from both subjective and objective evaluations were collected, and their correlation was assessed.
Methods

Development of viOSCE

The principal investigator (PI) first limited the viOSCE knowledge to content related to the prosthodontics course. Content related to implantology and orthodontics was excluded because it is not part of the core undergraduate coursework for dental or dental technology students. On the basis of the Association for Medical Education in Europe guide [54], a modified Delphi method was used to generate content for viOSCE. The Delphi method is a decision-making process that uses expert opinion, gathered in the form of a survey, under the guidance and direction of the PI to reach group consensus through collaboration, independent analysis, and iteration [55]; this process is the most frequently used method to generate content for OSCEs [54]. The panel of experts in this study consisted of 9 instructors (including the PI) from the College of Stomatology, Chongqing Medical University. All 9 instructors had prosthodontics teaching experience and digital technology practical teaching experience with undergraduate dental and dental technology students. They had also participated in the design and examiner training for traditional OSCE, but only the PI had experience in IPE and vOSCE design.

In this study, there were 4 iterations (rounds) before the viOSCE station design was finalized. In the first round, the PI identified 10 potential topics for viOSCE based on the syllabus of the prosthodontics course for dentistry and dental technology students, gave initial suggestions for the station design, and created a manuscript that was emailed to the panel of experts. Each expert independently gave their opinion and selected 5 topics that they considered as the most important in the syllabus and the most suitable for assessment using viOSCE. In the second round, the PI identified 3 topics with the highest selection rate based on the expert feedback and designed draft blueprints for 20 stations based on the top 3 selected topics using existing virtual technology support. These were sent to the expert panel via email. The expert panel commented about the potential effectiveness of interprofessional collaboration at the stations, made necessary corrections, and returned the design drafts to the PI. In the third round, the PI summarized all the changes made by the expert panel and, finally, decided on 7 stations based on the availability of virtual technology and the time to be spent on the stations within the allotted time frame of the examination. Stations consuming a lot of time, requiring multiple devices for support, or requiring very large spaces were rejected. Next, the selected viOSCE station blueprint design was completed, the virtual technical support was finalized, and the PI sent the final viOSCE station blueprint to the expert panel via email. The expert panel created the scoring rubrics based on the final viOSCE station blueprint, and these were returned to the PI for finalization. In the final round, the PI compiled all the information and met with the group to get a consensus regarding the viOSCE station blueprint and scoring rubrics. Once all the experts approved the viOSCE test station blueprint and scoring rubrics, the PI declared the viOSCE design as complete and declared the panel of experts the viOSCE examiner panel (Figure 1).
**The viOSCE Framework**

The developed viOSCE framework consisted of 3 topics, namely, fixed prosthodontics, removable prosthodontics, and clinical diagnostics. There were 7 collaborative examination stations consisting of 4 asynchronous and 3 synchronous stations. All these stations were designed and developed using the Delphi method (Figure 2).
Figure 2. The framework of the viOSCE. CAD: computer-aided design; RPD: removable partial denture; viOSCE: virtual and interprofessional objective structured clinical examination.

At the fixed prosthodontic stations, the dental student prepared tooth 8 (maxillary right central incisor) on the simulator (Nissan Dental Products) and then worked with the dental technology student to scan the preparations using an intraoral scanner (Panda P2; Freqty Technology). The dental and dental technology students at the intraoral scanning station worked collaboratively. The dental student performed an intraoral scan task, and the dental technology student observed the scan results to determine whether they could be used for the computer-aided design (CAD) wax pattern station. After obtaining a digital model, the dental technology student used a CAD system (Dental system; 3shape) to design a single crown on the digital model of the preparation. Individual scoring rubrics were designed for tooth preparation, intraoral scan, and CAD wax pattern. The 3 examiners scored each of the 3 stations (Figure 3 and Tables 1-3).
Figure 3. The fixed prosthodontics stations of the viOSCE. (A) A dental student prepared tooth 8 on the simulator. (B) Dental and dental technology students scanned the preparation using an intraoral scanner. (C) A dental technology student created a digital wax pattern using the computer-aided design system. (D) A viOSCE examiner scored the preparation process and results. (E) A viOSCE examiner scored the intraoral scanning process and results. (F) A viOSCE examiner scored the digital wax patterns. viOSCE: virtual and interprofessional objective structured clinical examination.

At the removable prosthodontics station, real patient cases and intraoral digital models were selected and prepared by the PI, followed by approval by the expert panel. The intraoral digital model was a clinical plaster model scanned using Lab Scanner (E4; 3shape). Each dental student used our previously developed Objective Manipulative Skill Examination of Dental Technicians (OMEDT) system [56] to observe the intraoral digital model and to design a removable partial denture (RPD) framework. At the end of the design task, the dental student submitted the design and then discussed the design with the dental technology student; the dental student could make modifications if they wanted to. Next, each dental technology student used a CAD system (Dental system; 3shape) to design the framework of an RPD on the intraoral digital model based on the final design. A viOSCE examiner scored the first RPD design using the OMEDT system. Next, the viOSCE examiner scored the final RPD design and the digital framework of the RPD. The design discussion station was not scored by a separate examiner (Figure 4 and Tables 4 and 5).

The clinical diagnostics station used a virtual standardized patient (VSP) with the haptic device (UniDental, Unidraw). The VSP hardware does not have an anthropomorphic shape, but it interacts through vocal, visual, and haptic devices. On the basis of the novel oral knowledge graph and the coupled, pretrained Bert models, the VSP can accurately interact with a dentist’s underlying intention and express the symptom characteristics in a natural style [57]. On the basis of this algorithm, the PI adjusted and entered the real patient case details, allowing the dental technology student to work with the dental student as a chairside dental technician to make a diagnosis based on the information obtained from the interactions with the VSP. In this study, the clinical case designed on the VSP was a patient who required root canal treatment and full crown restoration. At the end of the dental student’s diagnosis and simulation, the dental technology student was required to assist the dental student in designing the restoration plan and help the patient in choosing the materials for crown restoration (this often determines the price of the treatment). Thus, dental and dental technology students finalized the prostodontic treatment plan collaboratively. The visual device built a virtual dental clinic environment and VSP model, allowing the students to view the VSP from global, extraoral, and intraoral perspectives. The haptic device allows dental students to perform intraoral and extraoral examinations using essential tools to explore the diagnostic evidence.

Owing to the complexity of collaborative diagnosis, the station was manually scored by 2 examiners independently based on the previously developed scoring rubrics, whereas the UniDental output machine provided an additional score according to the previously developed scoring rubrics. The average of the 3 scores formed the final score for the station. To ensure the relative independence and internal consistency of all scores, the examiners were not informed about the existence of the machine score. The PI exported the machine score data from the VSP at the end of the experiment (Figure 5 and Table 6).

**Performance Evaluation of viOSCE**

In this study, fourth-year undergraduate dental students and third-year undergraduate dental technology students participated in viOSCE because students at this stage of education had completed preclinical professional training. Overall, 50 students who met these requirements, including 25 (50%) dental students and 25 (50%) dental technology students, were recruited into the viOSCE user evaluation experiment and were divided into groups of 2 comprising 1 dental student and 1 dental technology student. The PI and examiner teams did not influence or determine the team-formation process. All participating students were informed that as this viOSCE was in the experimental phase, it was conducted as a small extracurricular skills competition, thus allowing for self-evaluation without a final examination situation, as previously reported [58]. This approach allowed for the simulation of an examination situation without affecting the final examination grade of the students. A month before commencing the experiment, the PI led an web meeting for students to explain the viOSCE, the relevant knowledge points, and the need to practice fully during the upcoming month. At the end of the meeting, the students completed the Readiness for Interprofessional Learning Scale (RIPLS) pretest questionnaire, which is a 19-item 5-point Likert-scale questionnaire; this type of questionnaire is the most frequently used method for the subjective evaluation of IPE and IPCP [18].

viOSCE was piloted after the 1-month preparation period. The panel of examiners marked points according to the previously prepared scoring rubrics, whereas some of the points were automatically scored by a machine. After this step, the participating students completed the posttest self-made questionnaire, to which a mutual evaluation scale and a viOSCE evaluation scale were added. The mutual evaluation scale asked the students to score the performance of their partner, whereas the viOSCE evaluation scale asked the students to score viOSCE. In total, 6 items were included in the mutual evaluation scale, and 7 items were included in the viOSCE evaluation scale (Textboxes 1 and 2). All items in both questionnaires were set to a maximum score of 100. Before issuing the questionnaire, the panel first reviewed all the questions, clarified ambiguities, and removed any double-barreled questions [59,60]. At the end of the experiment, one-on-one interviews were conducted with all the students to determine their perceptions about viOSCE.

**Textbox 1.** The mutual evaluation scale administered to dental and dental technology student groups who participated in the virtual and interprofessional objective structured clinical examination (viOSCE).
The virtual and interprofessional objective structured clinical examination (viOSCE) evaluation scale administered to dental and dental technology student groups who participated in viOSCE.

**Items**

- Evaluation of viOSCE effectiveness
- Evaluation of equipment, network operation and maintenance
- Evaluation of viOSCE examiners
- Evaluation of viOSCE staff
- Rationality of the clinical diagnostic design
- Rationality of the fixed prosthodontics design
- Rationality of the removable prosthodontics design

**Statistical Analysis**

Data were tabulated in a Microsoft Excel spreadsheet and imported into IBM SPSS Statistics for Windows (version 26.0; IBM Corp) for descriptive analysis. GraphPad PRISM 8.0 software (GraphPad Software) was used to create the graphs. Responses were summarized, and comparisons were made. Output data were presented as percentages and in graphical format. The Shapiro-Wilk test was used to test for normal distribution. Specific data analysis tests performed included descriptive statistics, 2-tailed paired t tests, and correlation analyses.

**Ethical Considerations**

The research ethics committee of the Affiliated Hospital of Stomatology, Chongqing Medical University, approved this study protocol (COHS-REC-2022; LS number: 096). All participants provided written informed consent before participation in the study.

**Results**

Of the 50 students, 32 (64%) completed the experiment. Interviews were conducted with the students who dropped out of further participation in the study. The main reasons for dropping out included the students’ belief that they or their collaborating partners had not practiced sufficiently to perform well in the experiment. A group had a verbal confrontation approximately an hour before the experiment began. The main reason for the conflict was that the dental technology student accused the dental student of not practicing sufficiently before the experiment. According to the study protocol, at the end of the experiment, the conflict was resolved by the PI. Both parties were counseled, mediated by the PI, and the 2 parties reconciled.

Data from the RIPLS, mutual evaluation scale, and viOSCE evaluation scale were first analyzed to determine the impact of viOSCE on the subjective evaluation of IPCP. All students (32/32, 100%) who completed the experiment were administered the RIPLS questionnaire before and after the experiment. The Cronbach $\alpha$ values were .835 for the pretest data and .731 for the posttest data, suggesting that the reliability and internal consistency were acceptable. The results failed the Shapiro-Wilk test for normality; therefore, the data were analyzed using the Wilcoxon signed rank test. The teamwork and collaboration subscale scores were significantly increased after the experiment ($P=.004$). In addition, there was a nonsignificant decrease in the negative professional identity subscale scores ($P=.21$). There was also an insignificant increase in the scores on the positive identity subscale and on the roles and responsibilities subscale ($P=.13$ and $P=.96$, respectively). Figure 6 depicts the RIPLS data before and after the viOSCE pilot.
After the experiment, the mutual evaluation scale was administered to all participating students (32/32, 100%) who completed the experiment. The Cronbach $\alpha$ value was .873, suggesting good reliability and internal consistency. Comparison of the results of the dental and dental technology students revealed that only the mutual evaluation scores for competition motivation were significantly different between the 2 groups ($P=.04$). The dentistry and dental technology students evaluated each other’s motivation to participate in the competition (competition motivation), and the dental students had higher scores than the dental technology students. Figure 7 depicts the mutual evaluation scale scores of the dental and dental technology students.
Similarly, after the experiment, the viOSCE evaluation scale was administered to all students (32/32, 100%). The Cronbach \( \alpha \) value was .706, suggesting acceptable reliability and internal consistency. Comparison of the viOSCE evaluation scale results of the dental and dental technology students with the Wilcoxon signed rank test results revealed that only the evaluation scores for the removable prosthodontics design were statistically significant \((P=.01)\) among the 7 items. Figure 8 depicts the viOSCE evaluation scale scores of the dental and dental technology students.

**Figure 8.** viOSCE evaluation scale data for dental and dental technology students. viOSCE: virtual and interprofessional objective structured clinical examination.
To explore the validity of the examiner panel scores in viOSCE, correlation analysis was conducted on the scores of each station under the 3 topics. Using Spearman correlation coefficient, for the fixed prosthodontics topic, a strong positive correlation between the scores of the tooth preparation station and the CAD wax pattern station was noted, and it was statistically significant ($r=0.67; P=.005$). Positive correlations between the scores of the intraoral scan station and the CAD wax pattern station and between the intraoral scan station and the tooth preparation station were not statistically significant ($r=0.179; P=.51$ and $r=0.387; P=.14$, respectively). For the removable prosthodontics topic, 11 (69%) of the 16 student groups finally decided to modify the RPD design initially made by the dental students. A negative but statistically insignificant correlation between the scores of the RPD design station and the CAD wax pattern station was noted ($r=-0.111; P=.68$). For the clinical diagnostics topic, the correlation analysis was conducted primarily for the machine scores and the examiner scores to determine the usability of the VSP in viOSCE and the consistency of machine scoring and examiner scoring. The results revealed a significant positive correlation between the scores of the 2 examiners, and the positive correlation between the machine scores and the 2 examiners’ scores was also significant. The results are shown in Table 7 and Figure 9.

To explore the relationship between the objective and subjective evaluations, correlation analysis was conducted between the viOSCE scores and the RIPLS scores as well as between the viOSCE scores and the mutual evaluation scale scores. Insignificant negative correlations were noted between the subjective evaluation scores presented by RIPLS and viOSCE. Similarly, the correlation of the mutual evaluation scale score with the viOSCE scores was not significant. The SD of the scores on the mutual evaluation scale showed a decreasing trend among students with higher viOSCE scores and those with lower scores, but an increasing trend was observed among those with median scores (Table 8 and Figure 10).

<sup>a</sup>viOSCE: virtual and interprofessional objective structured clinical examination.

Figure 10. Correlation analysis of the viOSCE scores and the mutual evaluation scale. (A) Correlation analysis of the viOSCE scores and the SD of the scores for each item on the mutual evaluation scale. (B) Correlation analysis of the viOSCE scores and the SD of the mean scores on the mutual evaluation scale. viOSCE: virtual and interprofessional objective structured clinical examination.

In the one-on-one interviews, 29 (91%) of the 32 students approved of the effectiveness of viOSCE and wanted to use it to assess their IPCP ability in the graduation examination. At the fixed prosthodontics station, 56% (9/16) of the dental technology students complained about the lack of lingual space prepared by their partners at the tooth preparation station, which made it difficult to design crown wax patterns, and the corresponding dental students reported not being aware of the condition before viOSCE. At the removable prosthodontics station, almost all the dental students (15/16, 94%) reported that the advice given by the dental technology students was effective in helping them complete the RPD design and considered their
design practice to be insufficient. In contrast, the dental technology students reported that helping the dental students complete the RPD design made them feel satisfied with their professional competence and felt that they were truly part of the team during the collaboration. At the clinical diagnosis station, the dental students felt that their clinical practice experience was not sufficient, especially when the dental technology students could provide a diagnostic plan faster than themselves.

In terms of positive feedback, the students believed that viOSCE promoted the friendship between themselves and their partners, helped them realize the continuity and relevance between their own work and the work of their partners, and enabled them to acquire a deep understanding of IPCP. The negative feedback mainly focused on their lack of clinical knowledge, inadequate preparation, and long waiting time at some stations.

**Discussion**

**Principal Findings**

The IPCP results of dentists and dental technicians reflect the quality of their IPE, skill training, and clinical experience. The results contribute to the much-needed IPE assessment literature and suggest that teamwork skills can be improved by IPCP and effectively assessed using this new evaluation scale. We used a modified Delphi process in this study. This is in accordance with Simmons et al [27], who found that the modified Delphi process is an effective tool to obtain consensus among professionals for the foundational work required. In addition, our study demonstrated the effectiveness of viOSCE in asynchronous and synchronous collaboration scenarios, while providing a methodological reference for developing a new iOSCE for dental health care professionals. As the collaboration scenario between the dentist and the dental technician may be both asynchronously applied through prescriptions and synchronously conducted in chairside discussions [61-63], it was deemed appropriate for the viOSCE framework to consider both synchronous and asynchronous scenarios.

The viOSCE scores in this study also reflect the effectiveness of the framework design. From the viOSCE examiner scores in the fixed prosthodontics section, a significant positive correlation between the scores of the tooth preparation station and the CAD wax pattern station was evident. This finding is consistent with the actual clinical asynchronous delivery scenario, where the dentist’s preparation largely determines the quality of the dental technician’s crown wax pattern. Qualitative evaluations extracted from the one-on-one interviews also supported this result. For the removable prosthodontics section, the negative correlation between the scores of the RPD design station and the CAD wax pattern station was not statistically significant, which might be owing to the fact that more than half of the groups (15/16, 94%) worked collaboratively to modify the RPD design to possibly compensate for the lack of training, which is consistent with the findings about dentists’ inadequate competence in RPD design reported in other studies [64,65].

As OSCE is essentially a simulated scenario-based examination, the use of virtual technology to build simulated scenarios has become an important direction for OSCE-related studies, especially in the field of dental education [43]. The COVID-19 pandemic has further contributed to dental educators’ interest in this area, as dental clinical practice typically occurs in a virus-laden aerosolized environment [66]. Therefore, providing a safe and robust learning environment in the simulation clinic is also critical to help students compensate for lost educational time. The virtual technologies used to construct the simulated clinical environment in this study include VSP and CAD. Previously, Janda et al [67] developed a virtual patient as a supplement to standard instruction in the diagnosis and treatment planning of periodontal disease. However, it could not fully understand complex or ambiguous questions, and the students felt frustrated during the practice [67].

Tanzawa et al [68] developed a robot patient that could reproduce an authentic clinical situation and introduced it into OSCE. However, the dialogue recognition of the robot patients was prespecified; the robot was unable to identify subjective patient descriptions or the dentist’s interrogation intention and could not support intraoral or extraoral examinations to obtain diagnostic evidence [68]. To fill these gaps, our study used VSP with intention recognition and haptic feedback to construct virtual dental clinical practice and diagnosis scenarios more realistically. As the diagnostic evidence collected by students through interrogation, inspection, and palpation was automatically summarized for the final differential diagnosis, and omissions in the examination process eventually led to a misdiagnosis, the system simulated a high-fidelity clinical environment. In addition, the results showed that 1 (6%) of the 16 student groups misdiagnosed their VSP because of incomplete interrogation and palpation. The correlations between the scores of the 2 examiners and the machine scores were statistically significant, thus confirming the robustness of the high-fidelity simulation scenarios constructed by the VSP and the machine scores. On the basis of these results, the use of VSP should be expanded and integrated into daily teaching to give students more opportunities for clinical practice training.

Consistent with the results of previous OMEDE studies [56], the use of CAD technology in viOSCE significantly reduced the time spent at each station for the dental technology students. Some dental technology students complained about the slowness of the CAD program. Upon further investigation, it was found that they imported both impressions at the same time. In dental laboratory practice, dental technicians usually import the impressions separately to prevent computational issues. This finding exposes the lack of virtual dental laboratory practice skills in teaching, which needs to be addressed.

The results showed that the teamwork and collaboration subscale scores were significantly increased at the end of the study (P<.004), suggesting that viOSCE can improve students’ teamwork skills. The increase in the other 3 subscale scores, although not statistically significant, can be explained by the choice of timing of viOSCE. The optimal time to expose medical students to IPE is still subject to debate [18]. viOSCE, as a clinical IPCP intervention introduced during the clinical year, had no significant effect on the promotion of negative or positive
identity or roles and responsibilities. This finding may be due to the fact that the students’ professional cognition had been stereotyped at this time, making it difficult to affect significant changes through IPE or IPCP intervention. This conclusion is supported by a previous study [69].

The results of the mutual evaluation scale showed statistically significant difference in participant motivation between the 2 professional groups, which could be explained by the results of the roles and responsibilities subscale. Of the 16 dental technology students, 4 (25%) expressed that they would not practice as dental technicians in the future because they wanted to choose other careers. Differences in the scores of the other items were not statistically significant, thus showing the effectiveness of viOSCE in the development of teamwork spirit. This result confirms that the OSCE design is well suited as a final evaluation of IPE and IPCP. In addition, the average score of each item of viOSCE was >60, indicating that the students were satisfied with the design and operation of viOSCE. The differences in scores between the 2 types of professionals were not statistically significant, except at the removable prosthodontics station, which was probably caused by the dental technology students’ unfamiliarity with the CAD program.

Overall, the internal consistency of all subjective evaluations was acceptable, and the results met expectations. Interesting observations were also made regarding the correlation between the subjective and objective evaluations. The SD of the scores on the mutual evaluation scale showed a decreasing trend among the dental and dental technology students with higher viOSCE scores and those with lower scores, but an increasing trend in the median score was observed. Although this trend was not statistically significant due to sample size limitations, this early finding provides data support for a summary of clinical experience published previously by Preston [70], who reported that the intensity of the relationship between dentists and dental technicians is determined by the difference in their professional skills. If the professional skills of both parties are high, there will be few problems in their cooperative relationship. The more discriminating and demanding the technician or dentist becomes, the more the relationship is strained when either fails to perform up to the other’s standards. This result suggests that in the study of IPE and IPCP for dentists and dental technicians, it is not sufficient to explore the improvement of the traditional assessment dimensions such as team collaboration skills and identity. The final quality of the output must be included in the assessment dimension. This also reaffirms the effectiveness of viOSCE as an objective, quantitative evaluation tool for IPE and IPCP.

Limitations and Future Studies
The main limitation of our study is the small convenience sample of participating students, which could have led to self-selection bias. The sample size should be expanded in the future to obtain more data and to further verify the robustness of the viOSCE framework. In addition, whether viOSCE should be made a part of the large and more complete OSCE to test the ability of students to meet undergraduate graduation requirements will also be the focus of our next study. Moreover, the independent application of the novel VSP in the education of dental students is an interesting topic that will be explored in the next step of this study.

Recommendations
On the basis of our results, we provide the following recommendations:

1. All dental health professionals should be educated to deliver patient-centered care as members of an interdisciplinary team [16].
2. IPE intervention–related skills should be introduced as preclinical skills.
3. The cooperation of the dental care team is complex, and the training for improving the cooperation ability of the dental care team should include both subjective and objective assessments.
4. viOSCE and scale assessment should be introduced for the assessment of IPE and IPCP at the clinical stage of training.

Conclusions
In this study, a novel viOSCE framework was developed and piloted. Data based on subjective evaluation scales and objective examiner scores were collected and analyzed, confirming the effectiveness of viOSCE as an objective evaluation tool for IPE and IPCP. The experimental design should be expanded to include more randomly selected students with a scientifically determined sample size to further develop studies focused on IPE and IPCP in dentistry and dental technology, ultimately promoting quality in dental clinical practice.

Acknowledgments
This study was funded by a major project of Chongqing Higher Education and Teaching Reform of the People’s Republic of China (reference number 201019 to JS and reference number 193070 to MP) and the Teaching Reformation Fund of the College of Stomatology, Chongqing Medical University (KQJ202105 to YD and KQJ202003 to MP). Abstract

Background: From 2016 to 2021, the volume of peer-reviewed publications related to tobacco has experienced a significant increase. This presents a considerable challenge in efficiently summarizing, synthesizing, and disseminating research findings, especially when it comes to addressing specific target populations, such as the LGBTQ+ (lesbian, gay, bisexual, transgender, queer, intersex, asexual, Two Spirit, and other persons who identify as part of this community) populations.

Objective: In order to expedite evidence synthesis and research gap discoveries, this pilot study has the following three aims: (1) to compile a specialized semantic database for tobacco policy research to extract information from journal article abstracts, (2) to develop natural language processing (NLP) algorithms that comprehend the literature on nicotine and tobacco product use among sexual and gender diverse populations, and (3) to compare the discoveries of the NLP algorithms with an ongoing systematic review of tobacco policy research among LGBTQ+ populations.

Methods: We built a tobacco research domain–specific semantic database using data from 2993 paper abstracts from 4 leading tobacco-specific journals, with enrichment from other publicly available sources. We then trained an NLP model to extract named entities after learning patterns and relationships between words and their context in text, which further enriched the semantic database. Using this iterative process, we extracted and assessed studies relevant to LGBTQ+ tobacco control issues, further comparing our findings with an ongoing systematic review that also focuses on evidence synthesis for this demographic group.

Results: In total, 33 studies were identified as relevant to sexual and gender diverse individuals’ nicotine and tobacco product use. Consistent with the ongoing systematic review, the NLP results showed that there is a scarcity of studies assessing policy impact on this demographic using causal inference methods. In addition, the literature is dominated by US data. We found that the product drawing the most attention in the body of existing research is cigarettes or cigarette smoking and that the number of studies of various age groups is almost evenly distributed between youth or young adults and adults, consistent with the research needs identified by the US health agencies.

Conclusions: Our pilot study serves as a compelling demonstration of the capabilities of NLP tools in expediting the processes of evidence synthesis and the identification of research gaps. While future research is needed to statistically test the NLP tool’s performance, there is potential for NLP tools to fundamentally transform the approach to evidence synthesis.

KEYWORDS

machine learning; natural language processing; tobacco control; sexual and gender diverse populations; lesbian; gay; bisexual; transgender; queer; LGBTQ+; evidence synthesis

Introduction

The use of nicotine or tobacco products is a leading preventable cause of cancer, heart diseases, and lung diseases in the United States [1], with cigarette smoking alone responsible for the death of half a million Americans each year [2]. Notably, sexual and gender diverse individuals, often referred to as the LGBTQ+ (lesbian, gay, bisexual, transgender, queer, intersex, asexual, Two Spirit, and other persons who identify as part of this community) populations, are particularly vulnerable to nicotine and tobacco product use [3]. Both the National Cancer Institute and the Centers for Disease Control and Prevention have recognized the LGBTQ+ populations as a critical target in their efforts to combat tobacco use disparities [4–10].

In response to the pressing need for tobacco control and the rapidly evolving landscape of the tobacco market, the National Institutes of Health (NIH) and other health foundations, including the American Cancer Society, have made substantial investments in tobacco control research and tobacco regulatory science [11,12]. According to our calculations using data from the NIH era reporter, funding for tobacco research has shown a remarkable increase, growing from US $7.7 billion in 2016 to US $11.2 billion in 2021 (Multimedia Appendix 1 [13]). Consequently, the volume of peer-reviewed publications related to tobacco has experienced a significant increase. This presents a considerable challenge in efficiently summarizing, synthesizing, and disseminating research findings, especially when it comes to addressing specific target populations, such as the LGBTQ+ populations.

One promising pathway to rapidly assessing the expanding body of literature is the use of natural language processing (NLP) models. NLP is dedicated to deciphering and comprehending how computers interpret human language, equipping them to analyze extensive data sets of natural language [14–16]. While NLP tools have garnered considerable recognition in biomedical research [4–10], aiding in tasks such as disease surveillance (eg, COVID-19) and diagnosing using medical records [17–23], their potential to expedite near real-time synthesis of evidence in tobacco control research remains untapped [24].

Another gap in existing NLP tools is the lack of applications in synthesizing social science research and modeling. A noteworthy example in the domain of tobacco research is the evaluation of the effectiveness of tobacco control policies, which are often assessed using complex statistical modelling and large-scale survey data. These methods demand a specialized semantic database for labelling studies and interpreting results. However, to the best of knowledge, such a semantic database has not been developed yet. Considering that policy interventions at federal, state, and local levels are designed to reach a large number of populations, the lack of a database to facilitate NLP applications may significantly undermine evidence synthesis and thereby the timely adoption of effective policies [25].

Furthermore, in light of the calls from entities such as the NIH and other health agencies to address tobacco use disparities within priority populations, including LGBTQ+ populations, the development NLP tools to aid in the discovery of effective policies tailored to these special populations remains uncharted territory [26–31]. There is an urgent demand for the development of NLP tools (eg, semantic database, NLP algorithms) in tobacco research that have the abilities to synthesize evidence in social science and assist in research gap discovery for priority populations.

In this pilot study, we aimed to achieve the following goals to address the identified research and application gaps: (1) compile a specialized semantic database for tobacco policy research to extract information from journal article abstracts, (2) develop NLP algorithms that comprehend the literature on nicotine and tobacco product use among sexual and gender diverse populations, and (3) compare the discoveries of the NLP algorithms with an ongoing systematic review of tobacco policy research among LGBTQ+ populations [32]. While this pilot study does not fully address the gaps by developing a comprehensive evidence synthesis or discovery tool for tobacco research, the outcomes may pave the road for future tools that can achieve this goal. Our vision is that NLP tools may be able to assist academic scholars and policy makers in prescribing public health policies, such as tobacco control policies, and addressing public health needs, such as reducing health disparities.

Methods

Development of a Tobacco Research Domain–Specific Semantic Database

Overview

To generate a tobacco research domain-specific semantic database, we used an iterative process that combines expert opinions and the reading of tobacco research papers in 4 leading tobacco journals (Tobacco Control, Nicotine and Tobacco Research, Tobacco Induced Diseases, and Tobacco Prevention and Cessation). The main categories of keywords were the followings: (1) tobacco use behaviors, prevalence, and outcomes; (2) population characteristics; (3) geographic locations; (4) method and inference; (5) policy; (6) tobacco products; (7) relation statement; and (8) tobacco characteristics. Under each main category, there were one or more subcategories, and each subcategory contained a list of named entities. Table 1 presents the categories of named entities in a domain-specific semantic database that were used for training and improving a language model for tobacco research on sexual and gender diverse populations. These categories are based on journal articles’ keywords, further guided by existing literature on how to use NLP methods to synthesize public health evidence [25,33]. These categories are important components of a study, encompassing measures, methods, results, conclusions, and hypothesis testing.

### Journal Selection

We chose 4 peer-reviewed tobacco-specific multidisciplinary journals, namely, *Tobacco Control*, *Nicotine and Tobacco Research*, *Tobacco Induced Diseases*, and *Tobacco Prevention and Cessation*, to extract articles and compile keywords at the initial stage. The first 2 are among the journals that have the highest impact factors in addiction research; in 2022, *Tobacco Control* had an impact factor of 5.2 and a 5-year impact factor of 5.7 [34], and *Nicotine and Tobacco Research* had an impact factor of 4.7 and a 5-year impact factor of 4.2 [35]. *Tobacco Induced Diseases* [36] and *Tobacco Prevention and Cessation* [37] are 2 other peer-reviewed journals that specifically publish research on nicotine and tobacco products but are not as highly ranked as the other 2 journals. The textual data from the 4 peer-reviewed journal articles contained a total of 2993 abstracts from published papers from 2015 to early 2021.

While the 2993 articles extracted from these journals do not represent the full body of tobacco research, they cover a significant share of tobacco studies and integrate evidence across the 5 translational research stages: basic research, preclinical research, clinical research, clinical implementation, and public health. These journals also ask authors to specify how the research reported contributes to tobacco control objectives, which have policy implications. Alternatively, a random sampling from PubMed searches using tobacco related terms may not yield studies that are necessarily translational in nature. Therefore, we focused on the articles published in the 4 journals in our study.

### Iterative Process to Expand Terms (Named Entities) in the Database

The general process included the following iterative steps: (1) to generate initial annotation data, we first compiled key terms from extracted articles and allocated key terms to categories using group discussions; (2) we enriched the database using various sources and group discussions (more specific descriptions below); (3) we fine-tuned the spaCy en_core_web_lg model with the initial annotation and following iterative versions of data (the en_core_web_lg model is a pretrained large language model that can extract multiple general named entities); (4) we expanded the list of named entities to include more keywords of similar meanings using SeedNER [38,39], that is, a small set of initial labeled examples or patterns that was used as a starting point for training a model; (5) we searched the occurrence of each keyword in the 2993 paper abstracts and kept those with high frequency; (6) during this process, named entities that were too generic to yield meaningful relations were removed from the database; and (7) we repeated steps 3 to 6 until the set of entities reached our satisfaction during group discussions.
Specific approaches were used for conducting step 2. For categories including “tobacco use behavioral outcomes,” “tobacco products,” and “tobacco characteristics,” the iterative process involved four steps: (1) discussions to determine whether to include newly identified key terms and how to allocate them into additional subcategories (Table 1); (2) using a named entity recognition (NER) model to extract named entities from 2993 paper abstracts from the 4 specific journals; (3) randomly sampling and reviewing the output of the NER model, correcting identified errors, and adding missed NERs; and (4) repeating steps 1 to 3 until we were satisfied with the model output.

The categories “population characteristics,” “geographic locations,” and “relation terms” are commonly used concepts in real life and not specific to tobacco control. We used Google searches, Wikipedia, and WordNet to enrich the key terms. In addition, for the “method and inference” category, we used the glossary of an econometrics methodology textbook by Cameron and Trividi to enrich the terms [40]. This textbook is widely used in economics and social science and its glossary should provide sufficient terms for this category.

For the “policy” category, we drew named entities from 2 sources that comprehensively summarize available tobacco control policies in the regulatory space. The first source was a peer-reviewed journal article by McDaniel et al [41] that conducted an intensive policy scan of all possible regulations that can contribute to tobacco endgame. The second source was the World Health Organization’s report on the global progress in implementing tobacco control policies, as recommended by the World Health Organization’s Framework Convention on Tobacco Control [42], which is the largest public health treaty signed by 182 countries and prescribes a comprehensive set of tobacco control policies. These policies are classified into 5 groups: M (monitor tobacco use and prevention policies), P (protect people from tobacco smoke), O (offer help to quit tobacco use), W (warn about the dangers of tobacco), E (enforce bans on tobacco advertising, promotion, and sponsorship), and R (raise taxes on tobacco) [42]. These sources cover policy key terms related to both national and international contexts and together create the most comprehensive policy terms to our knowledge.

Development of NLP Algorithms That Comprehend the Literature on Nicotine and Tobacco Product Use Among Sexual and Gender Diverse Populations

We used RoBERTa, an optimized BERT (bidirectional encoder representations from transformers)-based language model [43], to perform NER tasks. BERT is a state-of-the-art language model that excels at tasks such as sentiment analysis and text summarization. By learning patterns and relationships between words and their context in text, BERT can extract named entities that it has learned during training and potentially discover new ones.

We developed an NER model based on RoBERTa using the Python (Python Software Foundation) programming language and the spaCy library [44]. We began by defining 36 labels of categories (main and subcategories; Table 1) and extracting 1582 named entities using the existing NER model RoBERTa. Next, those named entities were used to tag abstracts and create a training set, using the annotation tool Prodigy [45]. A subset of the abstracts with labeled named entities was reviewed by 2 domain experts to identify key terms that were missing in our semantic database, which were added to the lists of named entities.

The RoBERTa model was then updated based on the richer database and further trained for a maximum of 20,000 steps, with early stopping implemented if no improvement was observed for 1600 consecutive steps. With a series of iterations, we used the updated RoBERTa model to assess the 2993 abstracts and labeled them with the categories.

When identifying studies related to LGBTQ+ populations, it is important to understand that this community is heterogeneous [46,47]. Given that LGBTQ+ key terms are included in the “population characteristics” categories, we were able to identify LGBTQ+ populations based on categorization. There were 111 LGBTQ+-related named entities in our database.

Comparison of the Discoveries of the NLP Algorithms With an Ongoing Systematic Review of Tobacco Policy Research Among LGBTQ+ Populations

Ideally, we would like to compare the results from our tools with those from systematic reviews and meta-analyses of studies related to tobacco control issues among LGBTQ+ populations. Systematic reviews and meta-analyses are state-of-the-art evidence synthesis methods that can provide the ground truth [48-50]. While we are currently conducting a separate systematic review of the effectiveness of tobacco control policies among LGBTQ+ populations, this review has not been finalized yet [32]. Nonetheless, the ongoing systematic review does provide some data points for comparisons, including the number of studies extracted from the 4 journals and presence of policy assessment. Therefore, we conducted comparisons of these 2 domains.

Ethical Considerations

This study does not involve human subjects, as it synthesizes data from research articles published at peer-reviewed journals. The Ohio State University Institutional Review Board has determined that it contains no human subjects and thus no further review is needed (study number: 2021E0776).

Results

In total, we identified 33 articles relevant to sexual and gender diverse populations from the 2993 abstracts. Our trained model successfully extracted 773 named entities (181 unique named entities) from the 33 paper abstracts to describe the themes of these articles. Among the 773 extracted named entities, 688 were already learned by the model during training, while 70 were new time- or age-related words (eg, 18 years, 2013), 9 were new statistical terms (eg, N=20), and 6 were newly discovered and labeled within other categories. We did not observe any newly discovered policy-related terms.

In Figures 1-3, we present the hierarchy of named entities extracted from abstracts in published papers that studied nicotine...
or tobacco product use among sexual and gender diverse individuals. Each number on the right is the frequency of the corresponding named entity by paper abstract. Named entities with the same color belong to the same main category.

Figure 1. Hierarchy and frequency counts of named entities extracted from published research in tobacco-specific journals from 2015 to early 2021 in 4 main categories: tobacco use, products, characteristics, and relation statement. Numbers represent the frequency of the corresponding named entity by paper abstract.
Figure 2. Hierarchy and frequency counts of named entities extracted from published research in tobacco-specific journals from 2015 to early 2021 in the main category of population characteristics. Numbers represent the frequency of the corresponding named entity by paper abstract.
According to our tool, among the 33 tobacco studies related to LGBTQ+ populations, the most frequent use outcomes were “cigarette smoking” (n=17), “substance use” (n=16), “prevalence” (n=16), and “risk” perception (n=14). Also, for these populations, “cigarettes” (n=15) were the most frequently mentioned combustible tobacco product and “e-cigarettes are” (n=8) was the most frequently mentioned noncombustible tobacco product. In addition, for tobacco characteristics, “alcohol” (n=7) and “nicotine” (n=5) were the most mentioned attributes among LGBTQ+ tobacco research papers.

The relation statement findings suggest that a majority of the studies examined “comparison” (n=26), “association” (n=23), and “correlation” (n=6). We found no studies that explicitly used the term “causal” or “causality” in the studies.
The population characteristics mentioned in the studies illustrated that among socioeconomic status terms, the most frequently included were “demographics” (n=8) and “SES factors” (n=8). Among sex and sexual and gender minority terms, the most frequent ones were “bisexual” (n=21), “lesbian” (n=19), and “gay” (n=19). Among racial and ethnic minority group terms, the most frequent ones were “minority groups” (n=8) and “Race/ethnicity” (n=6). For age group terms, the terms included “adult” (n=14), “young adult” (n=11), “adolescent” (n=5), “students” (n=3), and “adolescents and young adults” (n=2).

The policy category showed that in these studies, the most mentioned term was “intervention” (n=16). In addition, while the general term “tobacco control” was mentioned in 6 studies, only 1 study contained any specific policy term (“smoke free air law”). As such, there was a significant gap in policy research among the published articles in the 4 leading tobacco journals between 2015 and early 2021, since only 1 study mentions specific policies when it comes to tobacco research among the LGBTQ+ populations. The statistics and methodology terms further indicated that the most used terms included “survey” (n=18) and “logistic regression” (n=10), and relatively fewer studies mentioned terms related to causal inferences, such as “experimental research” (n=4), “randomization” (n=3), and “clinical trial” (n=1). The studies mentioning “US” also dominated in the numbers, with 12 studies in total. Several studies that assessed countries with multilevel governing levels, such as Canada and the United States, also appeared to have mentioned “state,” “city,” and “province,” suggesting that attention was paid to these defined areas.

We next compared our results using the NLP tools with our ongoing systematic review. Similar to the conclusions of the ongoing systematic review, we found very few studies that yielded specific policy recommendations. This finding was further corroborated by the lack of causal inference methods labeled by the NLP tool. While our NLP tool cannot replace systematic reviews just yet, it does show potential to complement the existing methods and requires less human supervision (systematic reviews usually require at least 2 human coders).

**Discussion**

This pilot study builds a semantic database dedicated to tobacco research and developed NLP algorithms to automatically identify, extract, and summarize textual data from published tobacco studies. We further demonstrated a user case wherein we assessed LGBTQ+ tobacco research by labeling key components of a tobacco study: tobacco use outcomes, tobacco characteristics, population characteristics, geographic locations, method and inference, and policy relevance.

It is worth noting that the components we categorized, such as “method and inference,” align with the typical sections found in scientific articles in social science, including measures, methods, results, conclusions, and hypothesis testing. As a result, our tool extracts text segments that are frequently assessed in evidence synthesis, thereby showing the potential of using NLP tools to enhance systematic reviews and facilitate meta-analyses.

Additionally, we leveraged the NLP algorithms we created to identify gaps in tobacco research concerning the LGBTQ+ populations and concluded that there is a scarcity of studies assessing impact policies on this demographic using causal inference methods. This finding is consistent with our ongoing systematic review, highlighting how NLPs have the capacity to aid in both evidence synthesis and research gap discoveries. This, in turn, has the potential to streamline research efforts, reduce labor costs, and influence the trajectories of future research directions.

Using the NLP tool, we further found some interesting patterns in tobacco research involving LGBTQ+ populations. It appears that the product drawing the most attention in the field is cigarettes or cigarette smoking and that the number of studies of various age groups is almost evenly distributed between youth or young adults and adults. Moreover, the existing evidence body is dominated by studies coming from the United States. These patterns are consistent with the research needs to reduce cigarette smoking among LGBTQ+ populations in the United States, where 16.1% of LGBTQ+ adults and 17.4% of LGBTQ+ high schooler students smoke cigarettes—this is 4% to 6% higher than their heterosexual counterparts. Therefore, our findings align with the ongoing research needs and the financial investments made by the US health agencies like the NIH, thereby bolstering the confidence in the NLP tool we developed.

Finally, while the semantic database and language model in this pilot study are designed to extract and summarize key components of tobacco research, many of the terms and labeling categories are broad and applicable to public health and social science research in general, such as “methods and inference” and “relation terms.” Therefore, our tool has the potential to transform the evidence synthesis paradigm in tobacco control and public health at large by enabling more efficient and effective analyses of large volumes of textual data. Future tool development may extend its reach to other public health domains, fostering the real-time translation of research findings into evidence-based policymaking, thereby contributing significantly to the advancement of public health initiatives.

Our study has several limitations. First, for the development of keywords and the application of the NLP, we focused on 4 peer-reviewed tobacco-specific research journals, which were not representative of the entire tobacco control literature. However, considering the prominence and extensive content covered by these journals, we believe that this selection is unlikely to introduce significant selection bias or result in the omission of crucial keywords. Second, although we used our ongoing systematic review as a benchmark for the qualitative assessment of the results obtained in this pilot study, we did not perform a quantitative comparison of our findings with the ground truth derived from the systematic review. This quantitative evaluation, which might include measures like Cohen kappa, was not conducted because the systematic review has not yet been finalized. Consequently, future research endeavors are required to undertake a thorough quantitative evaluation.
comparison between the training data and the established ground truth using statistical testing for a more comprehensive assessment of the NLP tool’s performance.

Despite the limitations, our pilot study serves as a compelling demonstration of the capabilities of NLP tools in expediting the processes of evidence synthesis and the identification of research gaps. Expanding the scope of this pilot research to encompass other public health disciplines, extending beyond the realm of tobacco control, holds the promise of fundamentally transforming the approach to evidence synthesis. Such expansion has the potential to play a pivotal role in shaping policy development across a wide spectrum of public health domains.

Abstract

**Background:** e-Learning has rapidly become a popular alternative to in-person learning due to its flexibility, convenience, and wide reach. Using a systematic and partnered process to transfer in-person training to an e-learning platform helps to ensure the training will be effective and acceptable to learners.

**Objective:** This study aimed to develop an e-learning platform for Small Steps for Big Changes (SSBC) type 2 diabetes prevention program coaches to improve the viability of coach training.

**Methods:** An integrated knowledge translation approach was used in the first 3 stages of the technology-enhanced learning (TEL) evaluation framework to address the study objective. This included three steps: (1) conducting a needs analysis based on focus groups with previously trained SSBC coaches, meetings with the SSBC research team, and a review of research results on the effectiveness of the previous in-person version of the training; (2) documenting processes and decisions in the design and development of the e-learning training platform; and (3) performing usability testing. Previously trained SSBC coaches and the SSBC research team were included in all stages of this study.

**Results:** Step 1 identified components from the in-person training that should be maintained in the e-learning training (ie, a focus on motivational interviewing), additional components to be added to the e-learning training (ie, how to deliver culturally safe and inclusive care), and mode of delivery (videos and opportunities to synchronously practice skills). Step 2 documented the processes and decisions made in the design and development of the e-learning training, including the resources (ie, time and finances) used, the content of the training modules, and how coaches would flow through the training process. The design and development process consisted of creating a blueprint of the training. The training included 7 e-learning modules, the learning modalities of which included narrated demonstration videos and user-engaging activities, a mock session with feedback from the research team, and a final knowledge test. Step 3, usability testing, demonstrated high levels of learnability, efficiency, memorability, and satisfaction, with minor bugs documented and resolved.

**Conclusions:** Using an integrated knowledge translation approach to the technology-enhanced learning evaluation framework was successful in developing an e-learning training platform for SSBC coaches. Incorporating end users in this process can increase the chances that the e-learning training platform is usable, engaging, and acceptable. Future research will include examining the satisfaction of coaches using the SSBC coach e-learning training platform, assessing coach learning outcomes (ie, knowledge and behavior), and estimating the cost and viability of implementing this training.

**Introduction**

e-Learning has emerged as a popular alternative to traditional in-person education in recent years, particularly with the advancement of technology and widespread availability of internet connectivity. e-Learning has revolutionized the way people learn by providing flexible, wide-reaching, and convenient access to educational resources, as well as personalized learning experiences that cater to individual needs and preferences. e-Learning has been adopted across various fields, including health care, and is effective in enhancing learning outcomes and improving overall learner engagement [1-3].

There is a paucity of research on how e-learning platforms are designed and developed. Partnering with end users can help guide e-learning platform development. An integrated knowledge translation (IKT) approach meaningfully engages the right research users at the right time throughout the research process and can increase the chances that the e-learning platform is usable, engaging, and acceptable [4-7]. Such approaches require in-depth qualitative methods to understand the perspectives of end users throughout the entire research process.

Frameworks can help guide the process of platform conception, design, development, implementation, and evaluation. This study was guided by the technology-enhanced learning (TEL) evaluation framework [8]. The TEL evaluation framework was informed by commonly used learning models, including the Kirkpatrick model [9]. The seven TEL evaluation framework stages are (1) conduct needs analysis and environmental scan; (2) document processes, decisions, and final product (3) test usability; (4) document key events during implementation and final product; (5) assess participant experience and satisfaction; (6) assess learning outcomes; and (7) estimate cost, reusability, and sustainability. The TEL lacks specific guidelines, which can be seen as both a strength and a limitation, as it permits flexibility for different users and contexts, but it can also be used haphazardly and may result in a product that has not considered end user needs.

This paper offers a guide for including an IKT approach to the needs analysis, design, development, and usability testing of an e-learning platform using the first 3 stages of the TEL evaluation framework. The proposed partnered stages of the TEL evaluation framework are described using the example of developing an e-learning platform for type 2 diabetes (T2D) prevention program coaches.

**Methods**

**Context**

Small Steps for Big Changes (SSBC) is a community-based T2D prevention program that aims to empower individuals with prediabetes to increase physical activity and improve their diet to reduce their risk of developing T2D. SSBC is delivered in and by staff and volunteers of the YMCA of Southern Interior British Columbia. Trained SSBC coaches (YMCA staff and volunteers) deliver 6 one-on-one sessions to clients over 4 weeks using a motivational interviewing (MI)-informed approach.

In-person 3-day workshops were previously used to train coaches to deliver SSBC. After completing the in-person training, coaches delivered the SSBC program with good levels of fidelity [10,11]. However, in-person coach training is not a viable format for future coach training due to difficulty in scheduling training time and the inability to revisit training components. Additionally, the in-person training was not developed using an IKT approach. To ensure usability and acceptability, the development of the SSBC coach e-learning platform used an IKT approach (ie, partnering with current SSBC coaches).

**Needs Analysis**

**Overview**

The information was gathered on the program needs and capacities (eg, the specific knowledge and skills required to become an SSBC coach) and individual needs of SSBC coaches (eg, preference for specific content and instructional approach). The various components of the needs analysis stage were assessed through meetings with the SSBC research team, focus groups with previously trained SSBC coaches, and analysis of previous research.

**Previous Research**

Dineen et al [10] evaluated the effectiveness of the SSBC in-person training. Data from this study helped determine coaches’ baseline levels of knowledge and skills prior to any training.

**SSBC Research Team Meetings**

The SSBC research team included the founder and director of SSBC (the last author) and the 2 in-person training facilitators (first and third author). The first meeting was held to determine whether the in-person training was a feasible and viable mode to continue to train SSBC coaches. The main reasons discussed for transitioning to e-learning were difficulties scheduling a 3-day in-person SSBC coach training for YMCA staff and volunteers, and concerns for practicality in the future expansion of SSBC to other Canadian and global facilities. Additional meetings with the research team were used to determine what knowledge and skills would be required of new SSBC coaches, what content from the in-person training would be included and excluded, and what new concepts could be added. Finally, SSBC research team meetings included discussions on measures to determine the effectiveness of the e-learning platform. In-depth meeting notes and minutes were recorded during meetings for later analysis.

**Focus Groups With SSBC Coaches**

Incorporating end users into the development of the e-learning platform (a main tenet of IKT) was done throughout the needs analysis, design, and development of the SSBC coach e-learning platform. Within the need analysis, focus groups with previously trained SSBC coaches were conducted. SSBC coaches who were trained through the in-person workshop were recruited via email to participate in a 2-hour focus group. Focus group questions centered on what content should or should not be included in the e-learning platform. Coaches also answered questions about motivation to learn, learning preferences (ie,
synchronicity, length of time, interactivity, and choice), and potential barriers for new coaches. Focus group data were analyzed using conventional content analysis [12].

**Design and Development**

To facilitate the design and development phase of this project, the research team hired a third-party digital health solutions company (3C Institute) that specializes in developing e-learning platforms. The first and last author had meetings with 3C Institute every 2 weeks to discuss project progress and make decisions. Throughout this time, the research team created a blueprint and storyboard of the detailed topics to be taught, discussed options for teaching formats (ie, a variety of didactic and user-engaging methods), and defined the learning objectives. The research team wrote the content for the module scripts, which were edited by 3C Institute to ensure they were clear and succinct. Modules were filmed by the research team, and 3C Institute developed graphics and compiled the modules.

SSBC coaches from the needs analysis phase were invited to participate in the design and development phase, specifically to review the overview of modules and methods of instruction and provide feedback.

All processes and decisions were documented in detailed meeting notes (eg, attendees, discussion points, and decisions). Calendar events and contracts captured the resources (eg, financial and time) required to develop the e-learning platform.

**Test Usability**

Usability evaluation helps to ensure that a product is usable, efficient, effective, and satisfying to its end users. Nielsen [13] identified five key components of usability: (1) learnability—how easily end users can accomplish basic tasks the first time they enter the e-learning platform; (2) efficiency—how well end users can perform tasks on the e-learning platform; (3) memorability—how easily end users can reestablish proficiency when they return to the e-learning platform after a period of not using it; (4) errors—how many errors the end users make, the severity of the errors, and their ease of recovery from the errors; and (5) satisfaction—how pleasant it is to use the e-learning platform.

Initial usability testing was conducted by the SSBC research team and the SSBC coaches involved in the e-learning platform design and development. Users were asked to navigate through the modules and learning activities and complete various tasks (eg, log in to the training platform, move through modules, and access the resource center). Written and verbal feedback on issues and errors were collected. A summary of concerns and usability issues was documented and sent to 3C Institute to be addressed. The level of usability was deemed acceptable by the first and last authors once all errors were resolved. In the true spirit of IKT, further usability testing will be examined through qualitative and quantitative methods upon release and implementation of the e-learning platform to ensure that the platform is usable by the end users.

**Ethical Considerations**

This study was approved by the behavioral research ethics board of the University of British Columbia (H21-01800). The participants provided informed consent for the focus groups and were involved in the further design and development of the e-learning platform. All data were deidentified upon data collection. Individuals were renumerated for their participation via e-transfer. Participants each received $50 CAD (US $36.83) for their participation in a focus group, and participants were given $25 CAD (US $18.42) for each module storyboard that they reviewed.

**Results**

**Needs Analysis**

**Previous Research**

Dineen et al [10] demonstrated that coaches had little knowledge about MI and SSBC program content prior to taking the in-person training. Coaches also reported high levels of satisfaction with the in-person training topics.

**SSBC Research Team Meetings**

The SSBC research team made the following decisions based on 3 meetings. SSBC coaches needed to have basic knowledge about T2D prevention, specific SSBC session content (ie, Canada’s physical activity guidelines, daily added sugar limits, carbohydrates, and the talk test), what MI is, the spirit of MI, MI skills (ie, open-ended questions, affirmations, reflections, summaries and ask-tell-ask), the 4 processes of MI, how to deliver SSBC content using MI, and how to deliver culturally safe and inclusive care. Coaches would need to demonstrate skills associated with delivering the SSBC program to clients, which includes appropriately delivering the correct information using an MI-informed approach.

Once a coach completed the e-learning modules, the coach would demonstrate their skills through a mock session, providing an opportunity for assessment and provision of feedback. Sufficient knowledge would be determined by scoring a minimum of 70% on a knowledge test on T2D prevention, SSBC-specific content, and MI at the end of the training. The research team would develop the knowledge tests, drawing from content directly covered in the SSBC coach e-learning training. Finally, the coaches’ skills would be monitored and assessed by coding a random selection of audio recordings from sessions with clients using session-content checklists and the Motivational Interviewing Competency Assessment tool [14].

**Focus Groups With SSBC Coaches**

Invitation emails were sent to 15 SSBC coaches to participate in a focus group, including information about the purpose of the focus group and remuneration of time. A total of 9 SSBC coaches volunteered to take part in a focus group, and they were split into 3 equal-numbered focus groups based on their availability. See Table 1 for focus group participants’ demographics and experience as a coach. On average, each focus group was 62 minutes.

The results from the conventional content analysis showed that coaches wanted more information on the evoking process of MI, on transitioning from sustain talk to change talk, and an understanding of the effectiveness of MI. The coaches spoke about the importance of knowledge checks throughout the
e-learning training, a collection of resources and commonly used documents (ie, a resource center), role-play videos demonstrating the skills being taught, and live sessions with a workshop facilitator to practice skills and receive feedback. The coaches suggested that modules be short in duration and for training to span over 2 weeks. The coaches’ recommendations also included the integration of a variety of learning methods through the use of didactic and user-engaging components. Additional resources suggested by coaches included video examples of delivering SSBC content using MI and various SSBC program delivery styles and scenarios. The participants desired a blended approach of asynchronous and synchronous learning, with an opportunity for practice and feedback.
